User and Group Permissions portlet
Create and delete role blocks for all roles, except for Administrator and Security Administrator.

Resource Permissions portlet
Create and delete role blocks for all roles, except for Administrator and Security Administrator.

For example, a user named Mary has the Administrator role on the Market News page (`Administrator@Market News Page`). The Market News page is the parent of the USA News Page. Mary automatically has the Administrator role on the USA Market News Page (`Administrator@USA Market News Page`) if you do not create a role block with the XML Configuration Interface.

All roles, including Administrator and Security Administrator, are automatically blocked for the following:

- Private pages
- Externalized resources that have an internal parent resource
- Internal resources that have an externalized parent resource

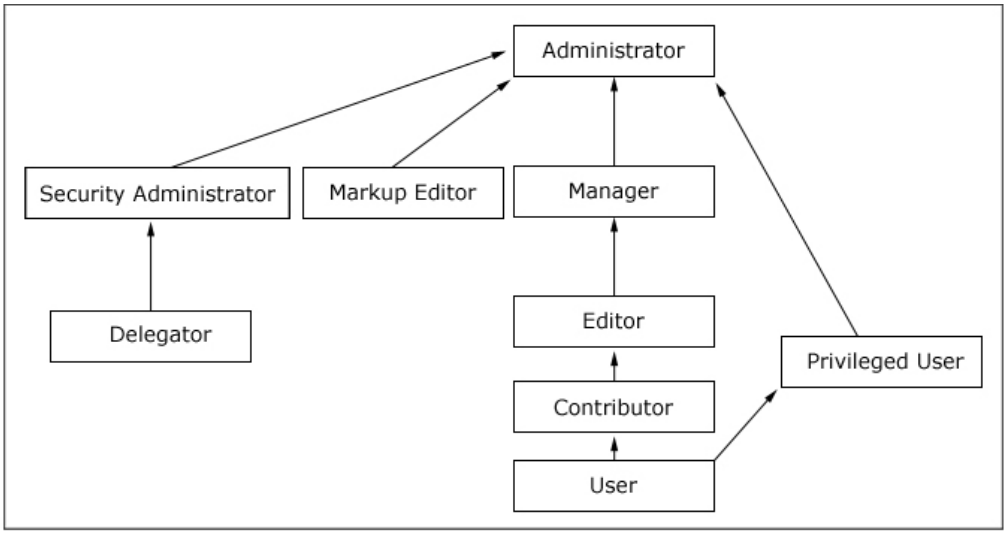
For example, WebSphere Portal Express controls access to the Market News page. IBM Security Access Manager controls access to the USA Market News page. This scenario is one in which an externalized resource, the USA Market News page, has an internal parent resource, the Market News page. In this scenario, the USA Market News Page, the child, does not inherit roles from the Market News Page, the parent. For this reason, if a user named Mary has the Editor role on the Market News Page (`Editor@Market News Page`), she does not automatically get the Editor role on the USA Market News page (`Editor@USA Market News Page`).

Roles

Roles provide task permissions for users on resources. For example, Editor is a role that allows users to view, modify, and create resources. Roles are denoted as `Role@`*`Resource`*; for example, `Editor@`*`Portal Page`*.

Roles are organized in a hierarchy. Roles are organized in a hierarchy. Roles that are higher in the hierarchy generally inherit the permissions of child roles. For example, to install web modules the Editor role on the virtual resource `Web Modules`, `Editor@Web Modules`, is the minimum role assignment for this operation. The Manager role is higher in the hierarchy than the Editor role. For this reason,

the Manager role includes the permissions of the Editor role. The `Manager@Web Modules` role also allows users to install web modules.



The following table describes the different allowed actions for roles:

Table 192. Allowed actions for roles

Role	Allowed Actions
Administrator	Unrestricted access on resources, which includes creating, configuring, and deleting resources. Administrators can also change the access control settings on resource; in other words grant other people access to those resources.
Security Administrator	Creating and deleting role assignments on resources. The Security Administrator role allows the user to act as a delegated administrator for that resource. The Security Administrator can delegate a subset of their privileges to other people according to the Delegated Administration Policy topic. For example, a user with Security Administrator and Editor roles can assign the Editor role to other people. The Security Administrator role on a resource does not give view or edit access to the resource.
Delegator	Assigning the Delegator role to principals (users and groups) allows roles to be granted to them. Having the Delegator role on other resources, such as specific portlets, is not useful. The set of roles that can be granted to those principals is defined through the Security Administrator and Administrator roles. For example, a user has a Delegator role on the SalesTeam user group but no Delegator role on the Managers user group. Therefore, this user can grant roles only to the SalesTeam or individual members of the SalesTeam user group but not to the Managers user group. The Delegator role on a resource does not give direct access to the resource. The purpose of the Delegator role is to allow the granting of roles to users or groups. Therefore, assigning the Delegator role on resources or resource types that are not users or user groups does not grant those users more privileges.

Table 192. Allowed actions for roles (continued)

Role	Allowed Actions
Can run as User (user impersonation)	After you enable the Impersonation feature, you can assign a user the Can run as User role. It allows them to view pages, portlets, and other portal components as another user. Support specialists can use this role to troubleshoot.
Manager	Creating new resources and configuring and deleting existing resources that are used by multiple users.
Editor	Creating new resources and configuring existing resources that are used by multiple users.
Markup Editor	Changing the HTML source for static portal pages.
Contributor	Viewing portal content and creating new resources. The Contributor role does not include the permission to edit resources. You can create only new resources. For example, a user is granted the Contributor role on the Template Category Teamspace. The user cannot modify the category itself but can create new templates in this category. **Note:** This role is only available for the following resources: • Application Templates • Application Template Categories • Application Template Root • Policies • All IBM Web Content Manager related documents
Privileged user	Viewing portal content, customizing portlets and pages, and creating new private pages.
User	Viewing portal content. For example, viewing a specific page.
No role that is assigned	Cannot interact with resource.

Application Roles

There is a higher level concept of roles called application roles. Application roles are identified by a unique name and can contain an arbitrary set of other roles (an example is `Editor@Market News page` and `Editor@Market News portlet`). It is possible to use application roles to bundle cohesive allowed actions, simplifying access control administration. Application roles with the same name in different database domains are correlated. It is possible to aggregate roles from different database domains within one application role.

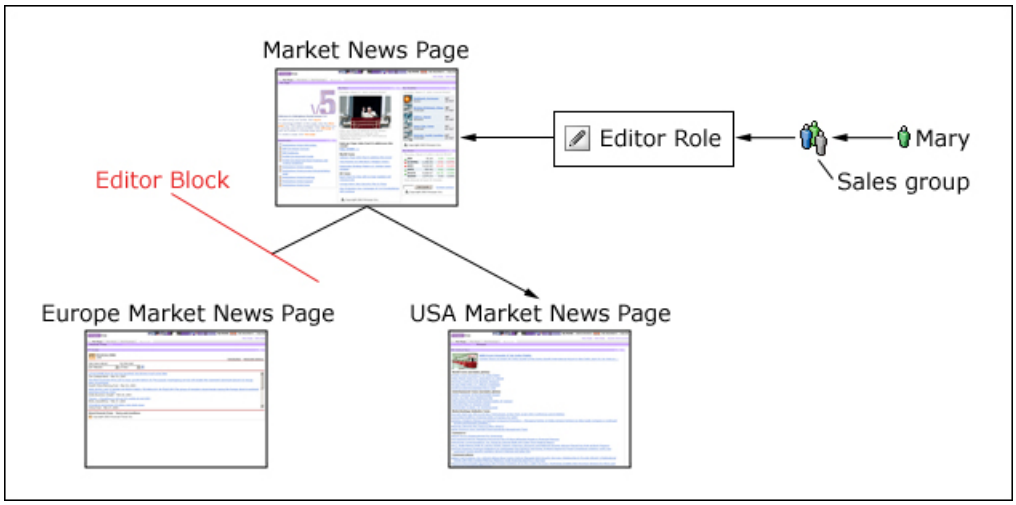
Inheritance

Resources are part of a hierarchy. By default, each resource in the hierarchy inherits the role assignments of its parent resource. This inheritance reduces the administration work. When you assign a group to a role on a parent resource, the group automatically acquires that same set of allowed actions for all child resources.

For example, suppose that a user, Mary, is a member of the Sales group. You can give Mary Editor access to the Market News page and all child pages by granting

the Editor@*Market News Page* role to the Sales group. All members of the Sales group implicitly acquire the Editor@*Market News Page* role. All members of the Sales group also inherit the Editor role on all child pages of the Market News page in the resource hierarchy. So, members of the Sales group automatically inherit the role Editor@*USA Market News Page*.

Inheritance through the resource hierarchy can be blocked at any level to provide more granular access control.



Role Assignments

Roles are assigned to users and groups that are contained in the user registry. Roles can be assigned by someone with the necessary authorization, such as the portal administrator, in any of three ways:

- Explicitly assigned to an individual user
- Implicitly assigned through group membership. If a group has a role, all members of the group automatically acquire the role. Nested groups (groups that are members of another group) inherit role assignments from their parent groups.
- Inherited through a role assignment on a parent resource. By default, roles on a resource automatically apply to all child resource unless role blocks are used.

Users and groups can have multiple roles on the same resource. For example, a user might have both the Editor and Manager roles on a particular page. One of these roles might be inherited through the resource hierarchy and the other might be explicitly assigned. If two roles in the same hierarchy are assigned for a user for the same resource, the higher role takes precedence. For example, if a user has the Manager and Editor role on a resource, the Manager role takes precedence over the Editor role.

Assign roles to individual users only in exceptional cases. Add or remove users from groups to reduce the number of role mappings and simplify maintenance.

Ownership

Each resource can have a dedicated owner. The resource owner can be a single user or a single user group. When a user creates a resource, such as a page, the user automatically becomes the initial owner of that resource. For non-private

resources, ownership provides the same set of allowed actions as the Manager role. For private resources, ownership provides the same set of allowed actions as the Privileged User role. This user can also delete the resource. For both non-private and private resources, these actions include the ability to delete the resource. Private resources can be owned only by users, not by user groups. It is not possible to define roles on private resources, and resource ownership cannot be inherited.

You can use the XML configuration interface or the Resource Permissions portlet to change the owner of a resource.

Private pages

A private page can be accessed only by its owner. Privileged Users (users assigned the `Privileged User` role) can explicitly create new private pages that are accessible only by themselves. Additionally, a Privileged User on a non-private page can personalize the page and create new private pages underneath it. Customizing a non-private page usually creates a private copy of the corresponding non-private page. Any changes that a Privileged User makes to a non-private page are not accessible by other users.

Note: Private pages cannot be controlled by an external security manager. Access control for private pages is always internally controlled by WebSphere Portal Express.

Traversal support

Users with role assignments on the resources `Page` or `URL Mapping` get the implicit permission to go to those resources. These users can go through all parent resources of those resources. Users see only the title of those resources. The corresponding resource content remains inaccessible unless those users have further role assignments that grant them normal access to those resources.

Related tasks:

"Automatically grant page access to community members" on page 759
If you want community members to automatically be able to access the page, without explicitly configuring access, you must enable that feature. Community membership must be integrated with portal security before you can enable this feature.

Related reference:

"Delegated Access Control Administration" on page 1569
IBM WebSphere Portal Express supports delegated access control administration.

Access permissions

Learn about sensitive operations for resources and the roles that are required to perform those operations. Sensitive operations include common tasks such as viewing portlets on specific pages and complex, high-risk tasks like running XML configuration interface scripts.

Roles provide permissions for user to perform specific operations on resources. The following tables denote roles as follows: `Role@`*`Resource`*.

Notes about the following tables:

- The following tables list minimum role assignments that are necessary to perform sensitive operations. Roles are organized in a hierarchy. Roles that are higher in the hierarchy generally include the permissions of roles that are lower

in the role hierarchy. For example, to install web modules the editor role on the virtual resource `Web Modules`, `Editor@Web Modules`, is the minimum role assignment for this operation. The manager role is higher in the hierarchy than the editor role. For this reason, the manager role includes the permissions of the editor role. `Manager@Web Modules` also allows users to install web modules.

- When access permissions are granted to any listed resource, it inherently requires access to the resource Access Control Administration.
- Use the Access Control Administration to change the owner of a resource.
- The resources that are listed can be different depending on other products that might be installed with the product. Some roles are required on virtual resources; other roles must be on resource instances.
- Users might also have access permissions for some operations through ownership of resources.
- Definition of terms:

  private
  Accessible only by the owner of the resource.

  Note: Creators of private resources automatically gain rights that are similar to the rights of a Manager. For example, if you create a private page, you have rights similar to manager for that page. You can also perform certain actions such as changing the page theme or deleting the page.

  non-private
  Accessible by those people who were granted access to the resource.

  public Accessible without authentication.

Table 193. Access permissions for Access Control Administration

Sensitive operation and description	Required role assignment
Viewing the access control configuration of a resource *R*	If *R* is under internal PORTAL protection: `Security Administrator@`*`R`* or `Security Administrator@`*`PORTAL`*. If *R* is under external protection: `Security Administrator@`*`R`* or `Security Administrator@`*`PORTAL`* + `Security Administrator@`*`EXTERNAL_ACCESS_CONTROL`* **Notes:** • *PORTAL* and *EXTERNAL_ACCESS_CONTROL* are virtual resources. • The `Security Administrator@`*`EXTERNAL_ACCESS_CONTROL`* role is created and managed in the External Security Manager. It must be modified with the external security management tools. For example, use the IBM Security Access Manager `pdadmin>` command line or the Computer Associates eTrust SiteMinder administrative console.

Table 193. Access permissions for Access Control Administration (continued)

Sensitive operation and description	Required role assignment
Creating a role *RT* on resource *R*	If *R* is under PORTAL protection: `Security Administrator@`*`R`* + *`RT@R`* or `Security Administrator@`*`PORTAL`* If *R* is under external protection: `Security Administrator@`*`R`* + *`RT@R`* or `Security Administrator@PORTAL` + `Security Administrator@`*`EXTERNAL_ACCESS_CONTROL`* **Notes:** • *PORTAL* and *EXTERNAL_ACCESS_CONTROL* are virtual resources. • The `Security Administrator@`*`EXTERNAL_ACCESS_CONTROL`* role is created and managed in the External Security Manager. It must be modified with the external security management tools. For example, use the Security Access Manager `pdadmin>` command line or the eTrust SiteMinder administrative console.
Deleting a role that is created from role *RT* on resource *R*. All corresponding role mappings are also deleted.	If *R* is under internal PORTAL protection: `Security Administrator@`*`R`* + *`RT`*`@R` + Delegator role on all assigned principals or `Security Administrator@PORTAL` If *R* is under external protection: `Security Administrator@`*`R`* + *`RT@R`* + Delegator role on all assigned principals or `Security Administrator@`*`PORTAL`* + `Security Administrator@`*`EXTERNAL_ACCESS_CONTROL`* **Notes:** • *PORTAL* and *EXTERNAL_ACCESS_CONTROL* are virtual resources. • The `Security Administrator@`*`EXTERNAL_ACCESS_CONTROL`* role is created and managed in the External Security Manager. It must be modified with the external security management tools. For example, use the Security Access Manager `pdadmin>` command line or the eTrust SiteMinder administrative console.
Creating or deleting a role assignment for user or group *U* created from role *RT* on resource *R*	If *R* is under internal PORTAL protection: `Security Administrator@`*`R`* + *`RT@R`* + `Delegator@`*`U`* or `Security Administrator@`*`PORTAL`* If *R* is under external protection: `Security Administrator@`*`R`* + *`RT@R`* + `Delegator@`*`U`* or `Security Administrator@`*`PORTAL`* + `Security Administrator@`*`EXTERNAL_ACCESS_CONTROL`* **Notes:** • *PORTAL* and *EXTERNAL_ACCESS_CONTROL* are virtual resources. • The `Security Administrator@`*`EXTERNAL_ACCESS_CONTROL`* role is created and managed in the External Security Manager. It must be modified with the external security management tools. For example, use the Security Access Manager `pdadmin>` command line or the eTrust SiteMinder administrative console.

Table 193. Access permissions for Access Control Administration (continued)

Sensitive operation and description	Required role assignment
Creating or deleting a role block for all roles that are created from role *RT* on resource *R*	If *R* is under internal PORTAL protection: `Security Administrator@R + RT@R` or `Security Administrator@PORTAL` If *R* is under external protection: `Security Administrator@R + RT@R` or `Security Administrator@PORTAL + Security Administrator@EXTERNAL_ACCESS_CONTROL` **Note:** A Security Administrator on this resource is always implicitly a Delegator on this resource. For all other roles, the `Security Administrator@R` plus the previous assignments are required. **Notes:** • *PORTAL* and *EXTERNAL_ACCESS_CONTROL* are virtual resources. • The `Security Administrator@EXTERNAL_ACCESS_CONTROL` role is created and managed in the External Security Manager. It must be modified with the external security management tools. For example, use the Security Access Manager `pdadmin>` command line or the eTrust SiteMinder administrative console.
Externalizing or internalizing resources:Moving a resource *R* back and forth from internal to external control. All non-private child resources of *R* move with it. Private resources cannot be externalized.	`Security Administrator@R + Security Administrator@EXTERNAL_ACCESS_CONTROL` or `Security Administrator@Portal + Security Administrator@EXTERNAL_ACCESS_CONTROL` **Notes:** • *Portal* and *EXTERNAL_ACCESS_CONTROL* are virtual resources. • The `Security Administrator@EXTERNAL_ACCESS_CONTROL` role is created and managed in the External Security Manager. It must be modified with the external security management tools. For example, use the Security Access Manager `pdadmin>` command line or the eTrust SiteMinder administrative console.
Modifying the owner of a resource:Setting a user or group *U1* as new owner of the non-private resource *R*, where the old owner was *U2*	`Delegator@U1`, `Delegator@U2`, `Manager@R`, and `Security_Administrator@R`

Table 194. Access permissions for Business Rules

Sensitive operation and description	Required role assignment
Viewing a Business Rule	`User@Business Rules Workspace` Set this permission on the Business Rules workspace in the Personalization navigator by selecting the root node and then choosing **Extra Action** > **Edit Access** from the menu.
Creating a Business Rule	`Contributor@Business Rules Workspace` **Important:** `Contributor@Business Rules Workspace` is the minimum required access permission to create a Business Rule. However, you must use `Editor@Business Rules Workspace` to create and maintain business rules and use the Portal administration facilities.
Deleting a Business Rule	`Manager@Business Rules Workspace`
Assigning a Business rule to a page *P*	For non-private pages: `Editor@P` and `User@Business Rules Workspace` For private pages: `Priviliged User@P` and `User@Business Rules Workspace`

Table 194. Access permissions for Business Rules (continued)

Sensitive operation and description	Required role assignment
Assigning a Business rule to a portlet *PO* on page *P*	For non-private pages: `Editor@P`, `User@PO`, and `User@Business Rules Workspace` For private pages: `Privileged User@P`, `User@PO`, and `User@Business Rules Workspace`
Additional actions	Use the **Set Access** icon in Personalization to add a user or a group to a role on the root of the workspace. The same role is given to that user or group for all Web Content Manager libraries, policies, and templates.

Table 195. Access permissions for Content Nodes such as pages, labels, and URLs

Sensitive operation and description **Note:** The operations in this column specifically refer to pages only, but also applies to labels and URLs in some cases.	**Required role assignment**
Traversing a page:Viewing the navigation of a page *P*	`User@P` or @ some child resource of *P*
Viewing the content of a page *P*, including page decoration and potentially the portlets on that page. The portlets on a page are protected separately. See the portlets on pages row of this table for information.	`User@P`
Modifying page properties includes the following actions: Adding or removing markup Adding or removing a locale Adding or removing parameters to or from a page *P*	`Editor@P`
Modifying page properties includes Set page layout properties of a static page.*P*	`Markup editor role`. If the resources are in secure locations of layout templates, use `Manager role`. For more information, see *Adapt the list of required runtime configuration changes for your theme* in the related links.
Changing the theme of a page *P*	`Editor@P`
Modifying the layout of a page *P* includes the following actions: Adding or removing wires Managing actions	For non-private pages: `Editor@P` For private pages: `Privileged User@P` For managing receiving actions of a portlet on a target page: `Editor@P` and `Editor@PO`
Customizing the layout of a non-private page: Creating a private, implicitly derived copy of a non-private page *P*	`Privileged User@P`
Adding a root page:Creating and adding a new top-level page *P*	For non-private pages: `Editor@Pages` For private pages: `Privileged User@PagesPages` is a virtual resource.
Adding a page:Creating a page under any Page *P*	For non-private pages: `Editor@P` For private pages: `Privileged User@P`
Creating a derived page:Creating a page underneath *P1* that is explicitly derived from page *P2*	New page is private: `Privileged User@P1` + `Editor@P2` New page is non-private: `Editor@P1` + `Editor@P2`
Deleting a page *P* and all descendant pages, including further subpages and the portlets on those pages	`Manager@P`
Moving page *P1* to a new parent page *P2*	For non-private pages: `Manager@P1` + `Editor@P2` For private pages: `Manager@P1` + `Privileged User@P2`
Locking or unlocking the contents of a non-private page *P*	`Editor@P` + `User@portlet` (Page Locks) + `User@page` (Locks)
Edit page associations for a non-private page *P*	`Editor@P`
Edit page associations for a private page *P*	`Privileged User@P`

Table 195. Access permissions for Content Nodes such as pages, labels, and URLs (continued)

Sensitive operation and description **Note:** The operations in this column specifically refer to pages only, but also applies to labels and URLs in some cases.	**Required role assignment**
Enabling membership-based access control delegation for a Community Page *P* associated to an IBM Connections Community *C* represented by the virtual user groups *G*. It is activated through the **Limit access to this page to only community members** Page Associations check mark.	`Editor@P + Security Administrator@P + Delegator@G + View Privileges@C(in IBM Connections)`
Activating Portal Page Security for a web content page *P* that is associated with site area *SA* in web content library *L*. This security is activated through the **Use Portal Page Security** check mark in the Page Associations window.	`Editor@P + User@SA + Administrator@L` and `Editor@P + User@SA + Administrator@L + Manager@VirtualResource CONTENT MAPPINGS`

Table 196. Access permissions related to Template Page instantiation

Sensitive operation	**Required role assignment**
Adding a root page Creating and adding a new top-level page *Pages* based on page template *T*	For non-private pages: `Editor@Pages` and `User@T` For private pages: `Privileged User@Pages` and `User@T` Additional roles can be required based on instantiation features associated to page template *T*: • *T* is associated to site area *SA1* in Web Content Manager, and the **wps.content.root** label is associated with site area *SA2*, with default content associations on each site area. Web Content Manager view permissions on *SA1* and Web Content Manager create content permissions on *SA2*. • *T* is associated to an IBM Connections community *C*. Grant the following privileges to the user in IBM Connections: – View *C* – Create new communities • *T* is configured to create a community during instantiation with the **ibm.portal.instantiation.community.create.new page** parameter. Grant the following privileges to the user in IBM Connections: Create new communities • *T* is enabled for Membership-based access control delegation: `Delegator@USER_GROUPS` *USER_GROUPS* is a virtual resource.
Adding a page Creating a page from Template *T* under any Page *P*	For private pages: `Privileged User@P` and `User@T` Additional roles can be required based on instantiation features associated to page template *T*: • *T* is associated to site area *SA1* in Web Content Manager, and the **wps.content.root** label is associated with site area *SA2*, with default content associations on each site area. Web Content Manager view permissions on *SA1* and Web Content Manager create content permissions on *SA2*. • *T* is associated to an IBM Connections community *C*. Grant the following privileges to the user in IBM Connections: – View *C* – Create new communities • *T* is configured to create a community during instantiation with the **ibm.portal.instantiation.community.create.new page** parameter. Grant the following privileges to the user in IBM Connections: Create new communities • *T* is enabled for Membership-based access control delegation: `Delegator@USER_GROUPS` *USER_GROUPS* is a virtual resource.

Table 197. Access permissions for the Credential Vault portlet

Sensitive operation and description	Required role assignment
Sensitive operation and description	Required role assignment
Adding, viewing, or deleting a vault segment	Management of the Credential Vault through the Credential Vault portlet requires access to an instance of the Credential Vault portlet.
Adding a shared administrative credential vault slot (containing a system credential)	Management of the Credential Vault through the Credential Vault portlet requires access to an instance of the Credential Vault portlet.
Retrieving the credential from a shared administrative credential vault slot (containing a system credential)	`User@slot` or `User@ADMIN_SLOTS`
Modifying a shared administrative credential vault slot (containing a system credential)	`Editor@slot` or `Editor@ADMIN_SLOTS`
Deleting a shared administrative credential vault slot (containing a system credential)	`Manager@slot` or `Manager@ADMIN_SLOTS`
Adding, viewing, deleting, or editing a non-shared vault slot	Management of the Credential Vault through the Credential Vault portlet requires access to an instance of the Credential Vault portlet.

Note: `Virtual resource: ADMIN_SLOTS` is a virtual resource. The permission on this node is propagated to all slots, if it is not blocked by an inheritance or propagation block.

Table 198. Access permissions for the **Enable Tracing** *portlet*

Sensitive operation and description	Required role assignment
Adding or deleting portal trace settings	Adding or deleting portal trace setting through the **Enable Tracing** portlet requires access to an instance of the **Enable Tracing** portlet.

Table 199. Access permissions for Event Handlers

Sensitive operation and description	Required role assignment
Managing event handlers:Creating, modifying, and deleting event handlers	`Security Administrator@Event Handlers` **Virtual resource:** *Event Handlers* is a virtual resource.

Table 200. Access permissions for the Manage Clients portlet

Sensitive operation and description	Required role assignment
Managing clients:Viewing the portlet; deleting, modifying, and adding clients in the `Manage Clients` portlet	`User@Manage Clients`

Table 201. Access permissions for Manage Search

Sensitive operation and description	Required role assignment
Creating a search index	`Editor@PSE_Sources` **Virtual resource:** *PSE_Sources* is a virtual resource.
Associating keywords with content items through the Search Center portlet, so that they are promoted to users who search for those keywords.	`Administrator@` for `Search Center Portlet` **Virtual resource:** *Search Center Portlet* is a virtual resource.
Modifying keywords that are associated with content items that exist in the Suggested Links portlet already.	`Administrator@` for `Suggested Links Portlet` **Virtual resource:** *Suggested Links Portlet* is a virtual resource.

Table 202. Access permissions for Manage Search

Sensitive operation and description	Required role assignment
Creating the New Virtual Portal	`Security Administrator@Portal` **Virtual resource:** *Portal* is a virtual resource.

Table 202. Access permissions for Manage Search (continued)

Sensitive operation and description	Required role assignment
Viewing the Virtual Portal	`Security Administrator@Portal` **Virtual resource:** *Portal* is a virtual resource.
Deleting the Virtual Portal	`Security Administrator@Portal` **Virtual resource:** *Portal* is a virtual resource.
Editing the Virtual Portal	`Security Administrator@Portal` **Virtual resource:** *Portal* is a virtual resource.

Table 203. Access permissions for Markups

Sensitive operation and description	Required role assignment
Managing Markups:Creating, deleting, or modifying a Markup	`Editor@Markups` **Virtual resource:** *Markups* is a virtual resource

Table 204. Access permissions for Policies

Sensitive operation and description	Required role assignment
Creating a Policy under any Policy	`Editor@Policy` and `User@Business Rules Workspace` **Notes:** • `Contributor@Policy` is the minimum required access permission to create a Policy under any Policy, though it is not recommended. `Editor@Policy` is recommended to create and maintain policies and use the Portal administration utilities. • If a rule must be created or edited during the creation of a Policy, then `Editor@Business Rules Workspace` and `Editor@Policy` is also required. • Business Rules workspace is the root node in the Personalization navigator for Business Rules resources. Set permissions on this node by selecting the workspace node and then choosing **Extra Action** > **Edit Access** from the menu.
Assigning a Business rule to a Policy	`User@Business Rules` and `Editor@Policy`
Editing a Policy	`Editor@Policy` and `User@Business Rules` **Note:** If a rule must be created or edited during the creation of a Policy, then `Editor@Business Rules` is also required.
Viewing a Policy	`User@Policy` + `User@Business Rules`
Importing a new Policy	`Editor@Policy_Root` **Important:** `Contributor@Policy_Root` is the minimum required access permission to import a new Policy, however, you must use `Editor@Policy_Root` to import and maintain policies and use the Portal administration utilities.
Deleting a Policy	`Manager@Policy` + `User@Business Rules` **Deleting policies:** When you delete a policy, the associated rule is not deleted.

Table 205. Access permissions for Portal Settings

Sensitive operation and description	Required role assignment
Viewing current portal settings	`User@Portal Settings` **Virtual resource:** *Portal Settings* is a virtual resource.
Modifying current portal settings	`Editor@Portal Settings` **Virtual resource:** *Portal Settings* is a virtual resource.

Table 206. Access permissions for Portlet Applications

Sensitive operation and description	Required role assignment
Viewing the portlet application definition information for a portlet application *PA*	User@*PA*
Modifying a portlet application includes the following actions: Adding or removing a locale Setting default locale Modifying settings to, from, or of the portlet application *PA*.	Editor@*PA*
Duplicating a portlet application:Creating a portlet application based on an existing portlet application *PA*	Editor@*Portlet Applications* + User@*PA* **Virtual resource:** *Portlet Applications* is a virtual resource.
Deleting a portlet application and removing all corresponding portlets and portlet entities from all pages within the portal	Manager@*PA*
Enabling or disabling a portlet application:Temporarily enabling or disabling the portlet application *PA*	Manager@*PA*

Table 207. Access permissions for portlets

Sensitive operation and description	Required role assignment
Viewing an installed portlet:Viewing the portlet definition information of a portlet *PO*	User@*PO*
Modifying an installed portlet includes the following actions: Adding or removing a locale Setting default locale Modifying settings to, from, or of the portlet *PO*.	For adding or removing locales and setting default locale: Editor@*PO* For modifying settings: Manager@*PO*
Duplicating an installed portlet:Creating a new installed portlet based on an existing portlet *PO* that is part of a portlet application *PA*.	Editor@*Portlet Applications* + User@*PO* + User@*PA* **Virtual resource:** *Portlet Applications* is a virtual resource.
Deleting an installed portlet *PO* and removing all corresponding portlet entities from all pages within the portal	Manager@*PO*
Enabling or disabling an installed portlet:Temporarily enabling or disabling a portlet *PO*	Manager@*PO*
Providing portlet *PO* as a WSRP service	Editor@*WSRP Export* and Editor@*PO* **Virtual resource:** *WSRP Export* is a virtual resource.
Withdrawing portlet *PO* from WSRP service	Manager@*WSRP Export* and Editor@*PO* **Virtual resource:** *WSRP Export* is a virtual resource.
Integrating the portlet of a WSRP Producer *PR* into the portal	If no portlet application exists for the group of portlets: Editor@*Portlet Applications* and User@*PR* **Virtual resource:** *Portlet Applications* is a virtual resource. If a Portlet Applications *PA* exists for the group of portlets: Editor@*PA* and User@*PR*
Deleting an integrated WSRP portlet *PO* contained in the portlet application *PA* from the portal	If this portlet is the last portlet in Portlet Applications: Manager@*PA* If more than one portlet is in Portlet Applications: Manager@*PO*

Table 208. Access permissions for portlets on pages

Sensitive operation and description	Required role assignment
Viewing a portlet *PO* on page *P*	User@*P* + User@*PO*
Configuring an installed portlet:Entering the configure mode of a portlet *PO* and modifying its configuration	Manager@*PO*

Table 208. Access permissions for portlets on pages (continued)

Sensitive operation and description	Required role assignment
Modifying a portlet on a page:Entering the edit mode of a portlet *PO* on page *P* and modifying its configuration **Note:** If *P* is a non-private page and the user has no Editor role for this page, then modifying the configuration of the portlet results in the creation of an implicitly derived copy of page *P*.	`Editor@P + Editor@PO` Or `Privileged User@P + Privileged User@PO`
Modifying page content:Adding or removing a portlet *PO* to/from a page *P* **Note:** If *P* is a non-private page and the user has no Editor role for this page, then modifying the content of *P* results in the creation of an implicitly derived copy of page *P*.	For non-private pages: `Editor@P + User@PO` Or For private pages: `Privileged User@P + User@PO`
Adding web content to a page: Adding a web content viewer portlet *PO* that is configured to render web content *C* from site area *SA* in Web Content Manager. Portlet *PO* is configured with the option **Create content (based on selection)**, and page *P* is associated with site area *SA*. **Note:** If *P* is a non-private page and the user has no Editor role for this page, then modifying the content of *P* results in the creation of an implicitly derived copy of page *P*.	• For non-private pages: `Editor@P + User @ PO` + Web Content Manager view permissions on *C* and Web Content Manager create content permissions on *SA*. • For private pages: `Privileged User@P + User@PO` + Web Content Manager view permissions on *C* and Web Content Manager create content permissions on *SA*
Restricting the content of a page:Adding or removing a portlet from the Allowed Portlet List of a page	`Editor@P + User@PO`

Table 209. Access permissions for Property Broker

Sensitive operation and description	Required role assignment
Operating with ActionSets or PropertySets for a portlet *PO*	`User@PO`
Creating, updating, or deleting a wire from a portlet *PO1* on Page *P1* to a portlet *PO2* on Page *P2*	Global wire: `Editor@P1, User@PO1, Editor@P2, User@PO2` Personal wire: `Privileged User@P1, User@PO1, Privileged User@P2, User@PO2` **Important:** To update or delete a personal wire, the user must have the previous role assignments and created the wire that they are updating or deleting.
Creating a wire from a portlet PO1 on Page P1 to a portlet PO2 on Page P2	Global wire: `User@P1, User@PO1, User@P2, User@PO2` Personal wire: `Privileged User@P1, User@PO1, Privileged User@P2, User@PO2` **Important:** To create a personal wire, the user must have the previous role assignments and created the wire that they are starting.
Viewing a wire from a portlet PO1 on Page P1 to a portlet PO2 on Page P2	Global wire: `User@P1, User@PO1, User@P2, User@PO2` Personal wire: `Privileged User@P1, User@PO1, Privileged User@P2, User@PO2` **Important:** To view a personal wire, the user must have the previous role assignments and created the wire that they are viewing

Table 210. Access permissions for PSE Sources

Sensitive operation and description	Required role assignment
Creating a PSE Source:Creating a search collection	`Editor@PSE Sources` **Virtual resource:** *PSE Sources* is a virtual resource.
Viewing a PSE Source:Viewing a search collection *SC*	`User@SC`
Facilitating a PSE Source:Using a search collection *SC*	`User@SC`
Editing a PSE Source:Editing a search collection *SC*	`Editor@SC`
Deleting a PSE Source:Deleting a search collection *SC*	`Manager@SC`

Table 211. Access permissions for tagging and rating

Sensitive operation and description	Required role assignment
Viewing community tags and ratings that other users applied. Creating and deleting personal public tags and ratings. Deleting community tags regardless of ownership.	`Manager@Tags + Manager@Ratings` **Virtual resource:** *Tags* and *Ratings* are virtual resources.
Viewing community tags and ratings that other users applied. Creating and deleting personal public tags and ratings.	`Contributor@Tags + Contributor@Ratings`
Viewing community tags and ratings that other users applied. Creating and deleting personal private tags and ratings.	`Privileged user@Tags + Privileged user@Ratings`
Viewing community tags and ratings that other users applied.	`User@Tags + User@Ratings`

Table 212. Access permissions for themes, skins, and layout templates

Sensitive operation and description	Required role assignment
Creating, viewing, editing, and deleting a Theme, Skin, or Layout Template	`Manager@THEME MANAGEMENT` **Virtual resource:** *THEME MANAGEMENT* is a virtual resource.

Table 213. Access permissions for the Unique Names portlet

Sensitive operation and description	Required role assignment
Managing unique names:Viewing the portlet; deleting, modifying, and adding unique names in the Unique Names portlet	`Editor@R + User@Unique Names`

Table 214. Access permissions for URL Mapping Contexts

Sensitive operation and description	Required role assignment
Creating a URL mapping context *UMC*	`Editor@URL Mapping Contexts` **Virtual resource:** *URL Mapping Contexts* is a virtual resource.
Traversing a URL mapping context:The ability to traverse a URL mapping context due to a role assignment to some child context of *UMC*	`User@UMC` or @ some child context of *UMC*
Viewing the definition of a URL mapping context *UMC*	`User@UMC`
Assigning a URL:Creating or editing a mapping between a URL mapping context *UMC* and a portal resource *R*	`Editor@UMC + User@R`
Modifying a URL mapping context:Changing the properties of an existing URL mapping context *UMC*; for example, editing the label	`Editor@UMC` If Virtual Portal Mapping: `Editor@VP URL Mappings` **Virtual resource:** *VP URL Mappings* is a virtual resource.
Deleting a URL mapping context *UMC* and all of its child contexts	`Manager@UMC`

Table 215. Access permissions for User Groups

Sensitive operation and description	Required role assignment
Creating a User group within the user registry	`Editor@User Groups` **Virtual resource:** *User Groups* is a virtual resource.
Viewing the User group profile information of a user group *UG*	`User@UG`
Modifying the profile information of a User group *UG*	`Editor@UG`
Adding or removing an existing User *U* or a User group *UG2* to or from an existing User group *UG1*	`Security Administrator@Users + Editor@UG1` **Virtual resource:** *Users* is a virtual resource.
Deleting a user group *UG*	`Manager@UG` **Deleting the user group:** The owner of the user group can also delete it.

Table 216. Access permissions for users

Sensitive operation and description	Required role assignment
Creating a user in the user registry	`Editor@User Self Enrollment` or `Editor@Users` `Editor@User Self Enrollment` allows the user to add new users. You can modify other existing users with `Editor@Users` **Virtual resource:** *User Self Enrollment* is a virtual resource. *Users* is also a virtual resource.
Viewing the user profile information of a user *U*	`User@UG` and *U* is a member of user group *UG* or `User@Users` **Virtual resource:** *Users* is a virtual resource
Modifying the profile information of a user *U*	`Editor@UG` and *U* is a member of user group *UG* or `Editor@Users` **Virtual resource:** *Users* is a virtual resource.
Deleting a user from the user registry and deleting all private pages that are created by this user	`Manager@Users` **Virtual resource:** *Users* is a virtual resource.
Impersonating a user to troubleshoot problems and view pages, portlets, and other portal components.	`Can Run As User@Users` **Restriction:** To use the **Can Run As User** role, you must enable the impersonation feature and assign the **Can Run As User** role to an appropriate user.

Table 217. Access permissions for **Web Clipping**

Sensitive operation and description	Required role assignment
Creating new clippings	`Editor@Portlet Applications` **Virtual resource:** *Portlet Applications* is a virtual resource.

Table 218. Access permissions for web modules

Sensitive operation and description	Required role assignment
Installing a new portlet application WAR file	`Editor@Web Modules` **Virtual resource:** *Web Modules* is a virtual resource.
Updating a web module *WM* by installing a corresponding WAR file	`Editor@Web Modules` + `Manager@WM`
Uninstalling a web module and removing all corresponding portlet applications and portlets from all pages within the portal	`Manager@WM` + Manager @ all portlet applications that are contained in *WM*

Table 219. Access permissions for RESOURCE

Sensitive operation and description	Required role assignment
Adding a remote WSRP Producer *PR* to the Portal	`Editor@WSRP Producers` **Virtual resource:** *WSRP Producers* is a virtual resource.
Editing the settings of a remote Producer *PR*	`Editor@PR`
Viewing the settings or display the list of portlets that are provided by a remote WSRP Producer *PR*	`User@PR`
Deleting a remote WSRP Producer from the portal	`Manager@PR`

Table 220. Access permissions for XML Access

Sensitive operation and description	Required role assignment
Running commands with the XML configuration interface	`Security Administrator@Portal` + `Editor@XML Access` **Virtual resources:** *Portal* and *XML Access* are virtual resources.

Table 221. Access permissions for vanity URLs

Sensitive operation and description	Required role assignment
Creating, modifying, or deleting a vanity URL that points to page P	`Editor@P` and `Editor@VANITY_URL` **Virtual resources:** VANITY_URL is a virtual resource.

Note: If a user deletes a page, all vanity URLs that point to that page are also deleted, independent of the rights that the user has on the virtual resource VANITY_URL.

Overlay reports and site promotions

Table 222. Access permissions for overlay reports and site promotions

Resource	Sensitive operation and description	Required role assignment
Overlay reports	Can view overlay reports on a resource.	`User@OverlayReports` + `User@Resource` **Note:** `OVERLAY_REPORTS` is a virtual resource.
Overlay reports	Can view all existing site promotions.	`User@SitePromotions` **Note:** `SITE_PROMOTIONS` is a virtual resource.
Overlay reports	Can create a site promotion.	`Editor@SitePromotions`
Overlay reports	Can update an existing site promotion.	`Editor@SitePromotions`
Overlay reports	Can delete a site promotion.	`Editor@SitePromotions`
Overlay reports	Can add a site promotion assignment on specific resource.	`Editor@SitePromotions` + `User@Resource`
Overlay reports	Can view a site promotion assignment on specific resource.	`User@SitePromotions` + `User@Resource`
Site promotions	Can remove a site promotion assignment on specific resource.	`Editor@SitePromotions` + `User@Resource`

Role Mappings and WSRP services

On the WSRP producer side, you can set the configuration property **`wsrp.security.enabled`** to enforce the access control decision for the provided portlets. If this property value is set to `true`, then all access control decisions in the producing portal are based on the authenticated principal. If **`wsrp.security.enabled`** is set to `false`, then the producing portal does not enforce any access control on incoming client portal WSRP requests.

When you use identity propagation, the user who is authenticated on the client portal needs to have the required role assignments. If no identity propagation is configured, but SSL client certificate authentication is enabled, then the ID of the certificate needs to have the required role assignments. If no authentication method is used, then the request is treated as if it comes from the Anonymous Portal Users. In the latter case, the required roles need to be assigned to the Anonymous Portal User. This assignment implies allowing unauthenticated access to the corresponding resources for all users who can access the producer portal.

Related tasks:

"Securing a WSRP Producer portal" on page 1447
To secure provided portlets, you can configure the WSRP Producer for web service message security, for example, for message authentication. If you configure message authentication, you must also configure Portal Access Control.

"Configuring security on the Consumer portal" on page 1461
You can configure security for the WSRP Consumer. If you enable security, the WSRP Consumer sends a security token as part of the WSRP request message to the WSRP producer. The security token represents the identity of the user who is logged in to the Consumer Portal. The WSRP Producer uses the security token to process the WSRP requests under the user identity that is represented by the security token.

"Configuring Portal Access Control for a WSRP Producer portal" on page 1452
If you configure security for WSRP services, you must also configure Portal Access Control for the Producer.

"Adapting the list of required runtime configuration changes for your theme" on page 2819
You must adapt the list of required runtime configuration changes for your theme.

Initial Access Control Settings

The administrative user who installs IBM WebSphere Portal Express has a default set of access rights.

Portal administrative user access rights

The installation creates a dedicated administrative user and corresponding administrative user group. By default the name of the administrative user group is **wpsadmins**. The following information describes the initial access control settings. A user always has the permissions that are associated with the User, Editor, and Privileged User role types on itself. There is no explicit role assignment for these permissions. They are a part of the administration policy.

Administrative user
: The administrative user for each domain is identified during the installation and configured in the Access Control Data Management Service. The administrative user has unlimited access on all resource in the corresponding domain.

wpsadmins
: The administrative group for each domain is identified during the installation and configured in the Access Control Data Management Service. This group has the same role mappings as the administrative user.

All Authenticated Portal Users

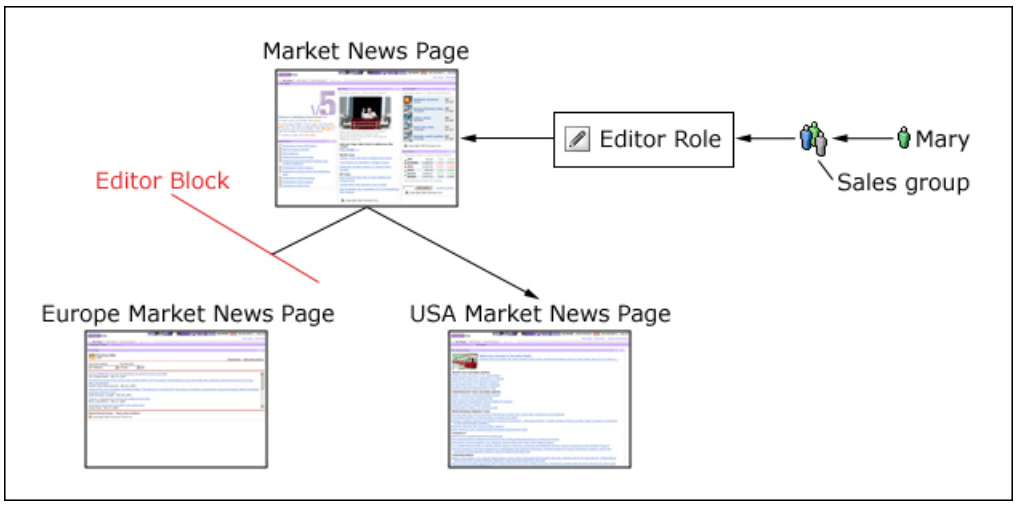
Access control scenarios

These scenarios provide helpful illustrations on how access control can be set up.

This section describes basic tasks for administering access control. The following examples use a hypothetical portal user called Mary and a hypothetical group called the Sales group. The following graphic helps illustrate the examples described in this topic.



Note: The tasks described here can be performed using either the administrative portlets or the XML configuration interface. For instructions about using the portlets mentioned here, refer to the portlet helps. For instructions about using the XML configuration interface, see the XML configuration interface section of the information center.

Give a user full access to the portal

Give the user the `Administrator@Portal` role. The `Administrator@Portal` role permits unrestricted access to all portal resources except the private pages of other users.

Give users this role in one of two ways:

- Add users to a group that has the `Administrator@Portal` role. The *wpsadmins* user group automatically receives the `Administrator@Portal` role during the portal installation. Use the `Manage Users and Groups` portlet to assign users to this group.
- Explicitly assign the `Administrator@Portal` role to specific users. Use the `Resource Permissions` portlet or the `User and Group Permissions` portlet to give users this role.

Allow a user to manage portlet applications with the Manage Applications portlet

Suppose that Mary needs to manage certain portlet applications. She must use the Manage Applications portlet to do this. Give Mary the following roles:

- User@*Web_Module*: This role permits Mary to see the information that is contained in a Web Module and to use the Manage Applications portlet to navigate to the Portlet Applications that are contained in this Web Module. You must assign Mary to a User role on each Web Module that she needs to access.
- Manager@*Portlet_Application*: This role permits Mary to administer the portlet application. You must assign Mary to a Manager role on each Portlet Application that she needs to administer.

There are two ways to give Mary these roles:

- Add Mary to a group that has these roles. Use the Manage Users and Groups portlet to assign her to this group.

- Explicitly assign the roles to Mary. Use the Resource Permissions portlet or the User and Group Permissions portlet to give her these roles.

Allow users to access a page and some subset of its child pages

Create an inheritance block on the appropriate page. For example, give the Sales group the `Editor@Market News Page` role. This allows members of the Sales group to edit the Market News page and all of its current and future child pages, including the Europe Market News page and the USA Market News page. To allow the Sales group to edit the USA Market News page, but not the Europe Market News page, insert an inheritance role block for the Editor role type on the Europe Market News Page. Use the Resource Permissions portlet or the XML configuration interface to insert this role block. This role block prevents members of the Sales group (and all other users and groups with an inherited or implicit Editor role on any parent pages of the Europe Market News page) from editing the Europe Market News page and all of its current and future child pages.

Allow users to access a portlet on a page

Give the group a role assignment on both the page and the portlet. Role assignments on a page do not contain access rights for portlets that appear on the page. Use the Resource Permissions portlet, the User and Group Permissions portlet, or the XML configuration interface to assign these roles.

For example, suppose there is a Market Targets portlet on the Market News Page. Give the Sales group (or a user group that contains the Sales group) the `Editor@Market Targets Portlet` role and the `Editor@Market News Page` role.

Allow users to access a page, but not its child pages

Use the Resource permissions portlet to create a propagation block on the appropriate page. For example, give the Sales group Editor access to the Market News page. To prevent this group from editing the USA Market News page and the Europe Market News page, create a propagation block for the Editor role type on the Market News page. It is not necessary to create a propagation block on the Market News child pages. This Market News page role block prevents the Sales group (and all other users and groups with an inherited or implicit `Editor@Market News Page` role) from editing all current and future child pages of the Market News Page.

Allow users to view and personalize a page and all of its child pages

Give the group the Privileged User role on the page and any portlets that appear on the page or its child pages. For example, give the Sales group to the `Privileged User@Market News Page` role. This allows all members of this group to view and personalize the Market News page and all of its current and future child pages. Then give the Sales group the Privileged User role on all portlets and portlet applications that appear on the Market News page and any of its child pages.

Giving the Sales group the Privileged User role instead of the Editor role allows members to create new private pages that are children of the Market News Page, but prevents members from creating new non-private pages.

The Editor role blocks that are created in the previous examples do not affect Privileged User roles in any way.

Allow a user to assign roles on a specific resource to members of a specific group

For example, to allow Mary to assign the Sales group to the role `Privileged User@Market News Page`, do either of the following steps:

- Give Mary the `Privileged User@Market News Page`, `Security Administrator@Market News Page`, and `Delegator@Sales Group` roles. This allows her to assign the Sales group (or individual members of this group) to the `Privileged User@Market News Page` role or the `User@Market News Page` role. Mary cannot assign anyone to the `Editor@Market News Page` role because she is not an Editor on the Market News Page. Mary cannot assign the Global Marketing group to the `Privileged User@Market News Page` role unless the Global Marketing group is a member of the Sales group.
- Give Mary the `Administrator@Portal` role. This allows her to assign any user or group to any role on any resource.

Note: To administer access control through the administrative portlets, Mary must have role assignments that allow her to view the User Group Permissions or the Resource Permissions portlets and the pages that contain these portlets. To administer access control through the XML configuration interface, Mary must have a role assignment that allows her to access the XmlAccess virtual resource.

Access control

You can restrict access to selected users and groups to the views within an authoring portlet, the items that are managed by the authoring portlet, and to elements and pages that are displayed within a website.

How access and security levels are set

There are three levels of access controls for web content

Library:
Library level access controls determine access to the library as a whole. If granted, it provides an entry point to the library. A user needs at least contributor access to a library to have access to it on the Authoring Portlet.

Item type per library:
Item Type access controls define the item type views and tasks a user can access within the authoring portlet for particular library. The permissions set for item types in a library do not automatically give you access to individual items. They give you access only to specific tasks and views within the authoring portlet.

Item level:
Item level access controls define the actions that a user can run on an individual item. For example, a Manager to the Components type has access to the Purge and Unlock actions but, if that user does not also have Manager access to an individual component, then the Purge and Unlock actions are not enabled when that component is selected.

"Users, Groups and Roles" on page 1557
Your content management system requires different types of users. You need to create a different group for each type of user and then assign those groups different roles within your system.

Users, Groups and Roles

Your content management system requires different types of users. You need to create a different group for each type of user and then assign those groups different roles within your system.

"Web content management roles"
You define the access of a user or group for a library to determine who has access to a library, and to define access to the different views within the authoring portlet.

"User roles and access" on page 1560
Different users will have different access to items and functions in your system depending on the role they are assigned. Roles can be assigned at the library level, and also assigned on individual items.

Related tasks:

"Setting up access" on page 1801
Access controls allow you to assign access to who has the ability to view rendered constant and pages, and who has the ability to edit or administer content, pages, or features.

Web content management roles:

You define the access of a user or group for a library to determine who has access to a library, and to define access to the different views within the authoring portlet.

Table 223. Roles

Roles	Rendering and authoring portlet access rights
• User	Users and groups that are assigned to this role can: • view items in a website or rendering portlet that they are assigned at least user access to. **Tip:** The simplest way to assign users to this role is to select any of the default user groups such as "All Authenticated Portal Users" or "Anonymous Portal User". Users require "user" access to an item before it is rendered in a website or rendering portlet.
• Reviewer	Users and groups that are assigned to this role can: • view items in a website or rendering portlet that they are assigned at least user access to. • run approve, next stage, and previous stage operations for workflowed items.
• Draft Creator	Users and groups that are assigned to this role can: • view items in a website or rendering portlet that they are assigned at least user access to. • access the create draft button if the user also has editor access. • access the restart workflow button if the user also has manager access.
• Contributor	Users and groups that are assigned to this role can: • view items in a rendering portlet or servlet-rendered website that they are assigned at least user access to. • view libraries that they are assigned contributor access to in an authoring portlet. • access the "My Items" and "All Items" views in an authoring portlet for libraries that they are assigned contributor access to. • access the item type view within the authoring portlet for item types that they are assigned at least user access to.

Table 223. Roles (continued)

Roles	Rendering and authoring portlet access rights
• Editor	Users and groups that are assigned to this role can: • view items in a rendering portlet or servlet-rendered website that they are assigned at least user access to. • view libraries that they are assigned contributor access to in an authoring portlet. • access the "My Items" and "All Items" views in an authoring portlet for libraries that they are assigned at least contributor access to. • for library item types that user and groups are assigned at least editor access to, editors can access the following actions in the authoring portlet: – access the item type view – create a new item – add/remove links – apply authoring template – copy – delete items they have created – edit – link to – move – restore a version – edit version labels
• Manager	Users and groups that are assigned to these roles can: • view items in a rendering portlet or servlet-rendered website that they are assigned at least user access to. • view libraries that they are assigned contributor access to in an authoring portlet. • access the "My Items" and "All Items" views in an authoring portlet for libraries that they are assigned at least contributor access to. For library item types that they are assigned manager access to, managers can access the all of the actions available to editors and also the following actions in the authoring portlet: • edit access settings • next stage • purge • unlock • edit user profile
• Administrator	Users and groups that are assigned to these roles can: • view items in a rendering portlet or servlet-rendered website that they are assigned at least user access to. • view libraries that they are assigned contributor access to in an authoring portlet. • access the "My Items" and "All Items" views in an authoring portlet for libraries that they are assigned at least contributor access to. • all actions in the authoring portlet for library item types that they are assigned administrator access to.

Table 223. Roles (continued)

Roles	Rendering and authoring portlet access rights
• Security Administrator • Privileged User • Markup Editor	These roles have no access to Web Content Manager items.

WebSphere Portal Administrators:

WebSphere Portal Express Administrators automatically have Administrator access to all item-types.

All Items view:

A user who is assigned access to an item can always view that item in the **All Items** view regardless of whether they have access to the related item-type view. For example, if a user does not have access to the presentation template view, but is granted editor access to a presentation template, they can still view, but not edit, the presentation template from the **All items** view.

Permission assignments for optimal performance

Inheriting permissions, instead of explicitly defining access rights on individual items, simplifies access rights maintenance and improves overall system performance. Define role assignments as high as possible in the library so that they apply to the largest set of items.

Explicitly defined permissions are a powerful and flexible way to control access to an item, but when the same user or group is being granted the same role on all items within an area, or across an entire library, then inherited permission is the best option

Assigning roles to anonymous or authenticated users

When accessing a website, users login as either anonymous users, or authenticated portal users.

The following pre-defined groups can be assigned roles in a library.

Table 224. pre-defined groups

Group	Details
Anonymous portal user	Select this user to assign a role to anonymous users.
All Authenticated Portal Users	Select this group to assign a role to users that have logged on to your server.
Users and User Groups	Select this group to assign a role to all users and groups.
All Portal User Groups	Select this group to assign a role to all groups.

User roles and access:

Different users will have different access to items and functions in your system depending on the role they are assigned. Roles can be assigned at the library level, and also assigned on individual items.

Assigning access to items

There are two methods that are used to assign roles to access controls on items:

- Selecting users or groups directly in the access section of an item.
- Allowing assigned roles to be inherited from parent items up to and including the library. Access roles are inherited in the following hierarchies:
  - Library/site area/content item
  - Library/taxonomy/category
  - Library/folder/component
  - Library/folder/authoring template
  - Library/folder/presentation template
  - Library/workflow
  - Library/workflow stage
  - Library/workflow action

  You can stop inheritance at any point in an inheritance hierarchy. For example, you might allow inheritance down to a site area, but assign access roles manually for each content item under that site area.

  Inheritance from a library is based on the role that is assigned to the overall library, not on the role that is assigned to specific item types. For example, you might not have access to the presentation template view on a library, but if you inherit the role of editor to a presentation template, you are able to view and edit that presentation template from the All Items view.

  Inheritance does not apply to draft items.

Note: By default, inheritance is enabled for all roles and items.

Viewing an item's security settings

The following sections are displayed on the security section of each item.

Table 225. Security settings

Section	Details
User Defined	If the item is not participating in a workflow, the user can edit access under user-defined.

Table 225. Security settings (continued)

Section	Details
Workflow	If an item is participating in a workflow, then the user-defined option does not appear and the workflow settings are displayed. This cannot be edited. Workflow-defined access is set in workflow stages. **Published items and workflow defined item security:** • If you grant a user editor access to an item in a workflow stage that uses a publish action, then those users are able to edit the published item directly. No draft is created. The same is true for administrator defined security when applied to published items. • If you grant a user manager access to an item in a workflow stage that uses a publish action, then those users are able to edit and delete the published item directly. No draft is created. The same is true for administrator defined security when applied to published items. • If you grant a user reviewer access to an item in a workflow stage that uses a publish action, then those users are able to create drafts of the published item.
Administrator Defined	Administrators can edit user access to an item at any time by changing the administrator defined settings.
Inheritance	You can also choose to inherit access that is assigned in the current web content library, or from an item's parent. Inheritance for all user roles is enabled by default.

How security is set

When a new item is created, the creator is automatically given manager access to the item. Extra user and group security can be added in the user-defined and system defined settings.

If an item is participating in a workflow, the creator is given manager access to the item only in the first workflow stage. As the item progresses through a workflow, the item security is determined by the combined workflow and system defined security.

Table 226. Security matrix

Security level	No workflow	First workflow stage	Extra workflow stages
User **Contributor** **Editor** **Manager** **Reviewer** **Draft Creator**	• User defined • Administrator defined • Inherited	• Administrator defined • Workflow defined	• Administrator defined • Workflow defined

Table 226. Security matrix (continued)

Security level	No workflow	First workflow stage	Extra workflow stages
Administrator	If you are assigned the administrator role to a library, you automatically inherit all administration access down to the item-level. It cannot be turned off.	If you are assigned the administrator role to a library, you automatically inherit all administration access down to the item-level. It cannot be turned off.	If you are assigned the administrator role to a library, you automatically inherit all administration access down to the item-level. It cannot be turned off.

Deleting items:

When a new item is created, the creator can also delete the item. If an item is participating in a workflow, the creator can delete the item in the first workflow stage only.

Assigning access to different types of users or groups

When you access a website or rendering portlet, users login as either anonymous users, or authenticated portal users.

The following user and groups can be used to grant access to items.

Table 227. Users and groups

User or group	Details
anonymous portal user	Select this user to grant access to anonymous users
[all users]	Select this group to grant access to all users, anonymous and authenticated.
[all authenticated portal users]	Select this group to grant access to all authenticated users.
[all portal user groups]	Select this group to grant access to all user groups.
[creator]	Select this group to grant access to the creator of the item.
[authors]	Select this group to grant access to users who are selected as an "author" of the item.
[owners]	Select this group to grant access to users who are selected as an "owner" of the item.

The access required to view a rendered item

To view an item on a rendered page, you need the following:

1. You need at least user access to the library the item is stored in.
2. You need at least user access to the presentation template used to display the current content item.
3. There must be a valid template map.
4. You must have sufficient access to view the item itself.

   Rendered item behavior varies depending on how you specify the `wcm.path.traversal.security` property in the `WCM WCMConfigService` service. If the property is not specified, the default value is `false`.

   If set to `false`:

   - Menus display content regardless of whether a user has access to all site areas in the content path.

- Navigators do not display site areas a user does not have access to, but can show content under these site areas in specific circumstances such as within breadcrumb navigators.
- URLs are only checked for content access, not site area access.

If set to `true`:

- Menus and navigators do not display content under secure site areas if the user does not have access to all site areas in the content path.
- Directly accessing content under secure site areas using a URL fails if the user does not have access to all site areas in the content path.

Rendering performance is slower if set to true.

Button access

You assign item-level access by assigning users and groups different roles for each item. The role that you assign determines what actions a user has access to for each item. The following table describes the minimum access that is required for access to each button in the user interface. If you enable inheritance at the library level, the library access level is inherited by item level access by default. For example, giving a user editor access to a library is automatically applied to new items they create if inheritance is enabled.

Table 228. Item access controls

Actions	Minimum item access	Minimum role access to library resources	Minimum library access	Item status
Add or move children	Contributor access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Add or remove child links	Contributor access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Add or remove workflows	Manager access or higher.	When first created, you require manager access to the library resource in any library. When saved, you require manager access to both the item and library resource in the library the item is stored in.	Contributor access or higher.	N.A.

Table 228. Item access controls (continued)

Actions	Minimum item access	Minimum role access to library resources	Minimum library access	Item status
Apply authoring template (authoring portlet)	N.A.	Manager access or higher to the authoring template library resource. **Note:** This default behavior can be changed to allow all users to apply authoring templates to items they have edit access to. See "Web content authoring options" on page 396 for further information.	Manager access or higher.	N.A.
Apply authoring template (content form)	Editor access or higher.	Contributor access or higher to the authoring template library resource.	Contributor access or higher.	N.A.
Approve	Reviewer or administrator.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Approve Project	Reviewer.	Not required.	Contributor access or higher.	N.A.
Batch-edit access controls	Editor access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Cancel draft	Manager access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Copy	Contributor access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Create draft	Draft Creator access.	Editor access or higher to the library resource type.	Contributor access or higher.	Only published or expired items.
Delete	Manager access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.

Table 228. Item access controls (continued)

Actions	Minimum item access	Minimum role access to library resources	Minimum library access	Item status
Edit	Editor access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Link to	Contributor access or higher, or Reviewer access.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Manage elements (In site areas and content items, not authoring templates.)	Administrator access If the **Allow elements to be managed by editors** option is selected on the authoring template that is used by an item, then this button is enabled for users with Editor access or higher. This option is enabled by default on Site Areas that are created by using the default Site Area template.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Move	Editor access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Next Stage	Reviewer access.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Preview item and view rendered item	User access or higher, or Reviewer access.	Not required.	Contributor access or higher.	N.A.
Previous Stage	Manager access or higher, or on workflow stages that have been configured to enable Reviewers access to the previous stage button.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Process now	N.A.	Not required.	Administrator access	N.A.

Table 228. Item access controls (continued)

Actions	Minimum item access	Minimum role access to library resources	Minimum library access	Item status
CF05 **Publish Project**	Editor access or higher.	Not required.	Not required.	Only when a project is in pending state.
Purge	Manager access or higher.	Not required.	Manager access or higher.	N.A.
Read	User access or higher, or Reviewer access.	Not required.	Contributor access or higher.	N.A.
Reference	User access or higher, or Reviewer access.	Not required.	Contributor access or higher.	N.A.
Reject	Reviewer or administrator access.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Reject Project	Reviewer.	Not required.	Contributor access or higher.	N.A.
Restart workflow	Draft Creator access.	Manager access or higher to the library resource type.	Contributor access or higher.	Only published or expired items.
Restore	Editor access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Save version	Editor access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Show hidden fields	N.A.	Not required.	Administrator access	N.A.
Submit for review(Workflows)	Reviewer access.	Editor access or higher to the library resource type.	Contributor access or higher.	N.A.
Submit for review (Projects)	Editor access or higher.	Editor access or higher to the library resource type.	Contributor access or higher.	Only when a project is in an active state.
System security	N.A.	Not required.	Administrator access	N.A.
Unlock	Manager access or higher.	Not required.	Manager access or higher.	N.A.
CF05 **Validate** (Projects)	User access or higher.	Not required.	Not required.	Only when a project is in active, review, pending, or publish failed states.

Table 228. Item access controls (continued)

Actions	Minimum item access	Minimum role access to library resources	Minimum library access	Item status
View references	User access or higher, or Reviewer access.	Not required.	Contributor access or higher.	N.A.
View versions	User access or higher, or Reviewer access.	Not required.	Contributor access or higher.	N.A.
Withdraw approval	Reviewer.	Not required.	Contributor access or higher.	Only when a project is in the review state. Only when Joint Approval is selected.
Withdraw from review	Reviewer.	Not required.	Contributor access or higher.	Only when a project is in the review state.

Creating new items:

The ability to create new items is set at the library level, not item level. You must have at least contributor access to a library and editor access to an item-type to create a new item. If you have access to create any item type, you can also create folders and projects.

Button access on content items:

You can choose to hide selected buttons on content item forms when you create an authoring template. This means that a user may not have access to all buttons on a content item form regardless of their role. Administrators can choose to display hidden buttons if required.

Profiling versus security:

Using profiling to personalize a site is different from using security to limit what items a user can access. In a profile-based personalized site, although a user might not be able to access all the pages by using personalized menus, they might still be able to access other pages by using navigators, or by searching for content. In a secured site, a user can only view items that they are granted access to.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Setting user and group permissions

The User and Group Permissions portlet lets you view and modify the roles that users and groups have on resources.

About this task

The User and Group Permissions portlet indicates whether roles are:

- Explicitly assigned
- Implicitly acquired through group membership
- Inherited through the resource hierarchy

Roles for virtual resources: Resource types have predefined sets of applicable roles. You can assign access to all roles, including the Can Run As User role, for the following virtual resources:

CONTENT_MAPPINGS
DESIGNER DEPLOY SERVICE
EVENT HANDLERS
MARKUPS
POLICY MAPPING CONTEXTS
PORTAL
PORTAL SETTINGS
RATINGS
STEP_UP_AUTHENTICATION
TAGS
TEMPLATE DEPLOYMENT
THEME MANAGEMENT
USER SELF ENROLLMENT
VP URL MAPPINGS
WSRP EXPORT
XML ACCESS

To access the User and Group Permissions portlet and find instructions for managing access rights for users and user groups, do the following:

Procedure

1. Log in to WebSphere Portal Express as an administrator.
2. Click the **Administration menu** icon ..
3. Select **Access** > **User and Group Permissions**. The User and Group Permissions portlet displays.
4. Click the portlet menu icon and select **Help** to access instructions for managing the access rights that users and user groups have for resources.

Setting resource permissions

Assign and control access for different types of resources.

The Resource Permissions portlet allows you to:

- Control whether or not a resource propagates or inherits its role assignments through the resource hierarchy
- Assign roles explicitly to specific users and groups
- Place resources under the control of an external security manager or bring back externalized resources under the control of IBM WebSphere Portal Express
- Create or delete roles on externalized resources

- View inherited role assignments for specific users and groups

See the Resource Permissions portlet help for detailed instructions on setting resource permissions.

Access the Resource Permissions portlet from the administration menu. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**. From there, you select the resource type that you want to work with, an example is Pages. An **Assign Access** icon is available for each page listed.

Delegated Access Control Administration

IBM WebSphere Portal Express supports delegated access control administration.

Description of delegated administration and policy

This topic describes the delegation of access control administration and policy, and gives an example of the delegated administrative policy.

Delegated Administration

WebSphere Portal Express supports delegated access control administration. An administrator is a user who is authorized to modify the access control configuration by changing role assignments and creating or deleting role blocks. Administrators can delegate specific subsets of their administrative privileges to other users or groups. These users or groups can in turn delegate subsets of their privileges to additional users and groups. The delegated administration policy determines how users are permitted to delegate their privileges.

Delegated Administration Policy:

The delegated administration policy defines which role assignments are necessary in order to perform specific changes to the access control configuration.

The general policy for creating or deleting role assignments is as follows: A user *U* can create or delete a role assignment for a specific user or group *UG* to a role identified by role type *RT* and resource *R* in either of the following cases:

- All of the following criteria are met:
  - *U* has the Security Administrator@*R* or Administrator@*R* role
  - *U* has at least a role of type *RT* on *R*
  - *U* has the Delegator@*UG*, Security Administrator@*UG*, or Administrator@*UG* role.
- *U* has the Administrator@Portal or Security Administrator@Portal role

For example, in order to assign a group to a role of type Editor on a resource, you must have at least the Delegator@*Group* + Security_Administrator@*Resource* + Editor@*Resource* roles.

Note: The `Security Administrator@Portal` and `Administrator@Portal` roles allow users to make unrestricted changes to the access control configuration of resources that are under internal portal control. Users also need the `Administrator@External Access Control` role or the `Security Administrator@External Access Control` role in order to change the access control configuration for resources that are externally controlled by a security manager such as Security Access Manager.

The general policy for creating or deleting role blocks is as follows: A user *U* can create or delete a role block on a specific resource *R* and a role type *RT* in either of the following cases:

- If both of the following criteria are met:
  - *U* has the `Security Administrator@R` or `Administrator@R` role
  - *U* has at least a role of type *RT* on *R*
- **or** if *U* has the `Security Administrator@Portal` or `Administrator@Portal` role.

Example of the delegated administration policy

Mary needs the authority to delete Hans from the `Editor@Market News Page` role. Hans is a member of the Marketing group. She can do this if all of the following conditions are true:

- Mary is either `Security Administrator@Market News Page` or `Administrator@Market News Page`. She can acquire this role through an explicit role assignment, through an Administrator or Security Administrator role assignment on a parent resource, or by belonging to a group that has the appropriate role assignment.
- Mary is at least `Editor@Marketing News Page`, since Hans will be deleted from the Editor role type.
- Mary has a `Delegator@Marketing Group` role. Mary cannot delete arbitrary users or groups from the `Editor@Market News Page` role. She can delete only those users and groups for which she has a `Delegator` role. Because Hans is a member of the Marketing group, Mary has a `Delegator` role for Hans.

Access Control Caching

Access Control internally uses several caches to improve the access control decision times. You can improve access control performance for special scenarios by setting the lifetime and size properties of these caches in the Cache Manager Service. In most cases, WebSphere Portal Express will run smoothly with the default cache settings. However, if you have a large number of resources or a large number of customized resources, you may want to adjust cache settings and conduct some tests to find the best performance trade-offs.

Cache Invalidation Behavior

In most cases, all necessary access control caches are immediately invalidated when a change to the access control configuration is done such as assigning roles to a user. If using External authorization, it is not possible to permanently synchronize the caches with changes to externally managed roles. For users that already have an authenticated portal session when the change becomes valid, they must wait for a cache timeout or logout and re-login for the changes to become active for that user. Performing a login or logout always enforces the invalidation of all caches related to the current user.

There are three additional cases where the invalidation is not performed immediately and require the user to re-login or to wait for a cache timeout:

- If a role assignment is granted to or revoked from a user group, the change of permissions is not propagated immediately to those members of this group that are currently logged in
- If a role block is set or removed, the resulting change of permissions is not propagated immediately to those users currently logged in

- If nested groups are enabled and group A is added or removed from group B, the permission changes are not propagated immediately to those members of group A that are currently logged in

As in the external case, you can enforce a permissions refresh by performing a logout and login for the user. Alternatively, modify the following properties in the `wp_profile_root/PortalServer/config/CacheManagerService.properties` file to influence the caching behavior:

- To switch it off completely and allow immediate propagation of all permission changes, remove the comment tag from the **cacheinstance.com.ibm.wps.ac.AccessControlUserContextCache.enabled** property and set the value to `false`. This can have a considerable performance impact.
- To speed up permission refresh by timeout, the lifetime of this cache can be decreased by setting the **cacheinstance.com.ibm.wps.ac.AccessControlUserContextCache.lifetime** property (in seconds) to a smaller numerical value. These settings can affect performance.
- If you configure access control to use nested groups, disable **cacheinstance.com.ibm.wps.ac.groupmanagement.GroupCache** and modify the values of the **enabled** and **lifetime** properties for **cacheinstance.com.ibm.wps.ac.groupmanagement.NestedGroupCache**.

  If you use group cache, disable **cacheinstance.com.ibm.wps.ac.groupmanagement.NestedGroupCache** and modify the values of the **enabled** and **lifetime** properties for **cacheinstance.com.ibm.wps.ac.groupmanagement.GroupCache**. These settings can affect performance.
- All user and user group specific cache data can be explicitly invalidated upon user login authentication through the following two configuration settings through the WebSphere Integrated Solutions Console:

  Note: These two settings will cause high Dynamic Replication Service load in the application server in a cluster environment and therefore can affect performance.

  – Navigate to **Resource environment providers** > **WP PACGroupManagementService** > **Custom properties**. Either add or update **accessControlGroupManagement.invalidateGroupCacheOnLoginLogout** with a value of `true`.

  – Navigate to **Resource environment providers** > **WP AccessControlDataManagementService** > **Custom properties**. Either add or update **accessControlDataManagement.invalidateResourceCacheOnLoginLogout** with a value of `true`.

Note: After modifying the `CacheManagerService.properties` file, run the following task, from the *wp_profile_root*`/ConfigEngine` directory, to make the changes effective:

- Linux: `./ConfigEngine.sh update-properties -DWasPassword=`*`password`*
- IBM i: `ConfigEngine.sh update-properties -DWasPassword=`*`password`*
- Windows: `ConfigEngine.bat update-properties -DWasPassword=`*`password`*

Enabling Attribute Based Security

Attribute based security for Web Content Manager content is an access filter in the product filter chain. You can extend the access control permission checks for Web Content Manager content beyond the user or group-based decisions. You can define your own criteria. The criteria might involve categories, keywords, textComponents, htmlComponents, or shortTextComponents for an item.

Procedure

1. Place your attribute-based security implementation class in the *PortalServer_root*/shared/app directory.
2. Restart the WebSphere_Portal server.
3. Log in to the WebSphere Integrated Solutions Console.
4. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
5. Go to **WP AccessControlDataManagementService** > **Custom properties**.
6. Change the **accessControlDataManagement.enableAttributeBasedSecurityFilter** property to true.
7. Change the **accessControlDataManagement.AccessControlAttributeBasedSecurityImpl** property to the value of the security implementation class in the *PortalServer_root*/shared/app directory. For example, enter com.ibm.portal.ac.AccessControlAttributeBasedSecurityImpl.
8. Save your changes.
9. Restart the WebSphere_Portal server.

Java 2 security with WebSphere Portal Express

Java 2 (J2SE) security provides a policy-based, fine-grain access control mechanism that increases overall system integrity by checking for permissions before allowing access to certain protected system resources. J2SE security allows you to set up individual policy files that control the privileges assigned to individual code sources. If the code does not have the required permissions and still tries to execute a protected operation, the Java Access Controller will throw a corresponding security exception.

Policy files assign individual permissions to individual code sources. The syntax and semantics of the policy files are defined in the Java Language Specification. WebSphere Application Server uses a specific set of policy files to set up Java 2 Security. The following table contains information on the policy files and their protection scope:

Table 229. Protection scope for policy files

Default location and policy file	Protection scope
AppServer_root//java/jre/lib/security/java.policy	This is the root policy file that contains permissions for all the processes launched by WebSphere Application Server.
wp_profile_root/properties/server.policy	This policy file grants default permissions to all product servers.
wp_profile_root/properties/client.policy	This policy file grants default permissions for all of the product client containers and applets on a node.

Table 229. Protection scope for policy files (continued)

Default location and policy file	Protection scope
wp_profile_root/config/cells/*cell_name*/nodes/*node_name*/spi.policy	This template is for the Service Provider Interface (SPI) or the third party resources that are embedded in the product. The default permission is java.security.AllPermissions.
wp_profile_root/config/cells/*cell_name*/nodes/*node_name*/library.policy	This policy grants default permissions (empty) to code contained in the shared library (Java library classes) to use in multiple product applications.
wp_profile_root/config/cells/*cell_name*/nodes/*node_name*/app.policy	This policy grants default permissions to all enterprise applications running on this node in this cell.
wp_profile_root/config/cells/*cell_name*/applications/*ear_file_name*/deployments/*application_name*/META-INF/was.policy	This policy assigns permissions to a specific enterprise application, imbedded within *EAR*:/META-INF/was.policy.
rar_filename/META-INF/was.policy.RAR	This file can have a permission specification that is defined in the ra.xml file. The ra.xml file is embedded in the RAR file.

All code artifacts, installed with the WebSphere Portal Express product, run with **java.security.AllPermission** specified either in the server.policy file for the portal shared libraries or in the individual was.policy files for the individual portlets.

Portlets that are installed on WebSphere Portal Express after installation can bring along their own was.policy files defining the allowed interactions of the portlet code with the system resources; see Portlet concepts for additional information.

Note: The application server searches for was.policy files in the enterprise application archive rather than the Web application archive comprising a portlet. Therefore, the portal server copies was.policy from the appname.war/META-INF directory to the generated appname.ear/META-INF directory during deployment of a portlet WAR file.

Java 2 Platform Security

Integrating with OpenID authentication

Web applications provide information and services to public users and personalized information and services to authenticated users. Users often work with multiple web applications, which require multiple IDs and passwords. This requirement can be difficult to maintain. Integrating identity providers (Google, Yahoo, or Facebook) into your site can simplify logging in for your users.

About this task

Google, Yahoo, Facebook, and other web platforms host information for users and they also provide access to their existing user communities. Reusing these communities on your website can increase acceptance of your business or services.

There are multiple approaches to creating a relationship between an identity provider and a service provider (IBM WebSphere Portal Express). WebSphere Portal Express uses OpenID and OAuth to integrate a relationship to an identity provider. OpenID provides a method of decentralized user management where users can select an identity provider to host their profile information, including user ID and password. Google and Yahoo are known identity providers that use OpenID specifications. Facebook uses OAuth.

WebSphere Portal Express requires that a trusted relationship exists between the identity provider and IBM WebSphere Application Server. Therefore, WebSphere Application Server provides a plug-in point, called a trust association interceptor (TAI), designed to create a trust based on the identity provider information.

WebSphere Portal Express provides a new implementation of this plug-in point that handles the communication between the identity provider and WebSphere Portal Express as the service provider. WebSphere Portal Express trusts the identity provider and grants the user entrance.

There are two options to integrate external users into the WebSphere Portal Express environment:

- You can require an existing binding between a local portal account and a remote identity provider account. This option provides you with the possibility to request additional validation from the users and to have internal accounts for the users. The binding is stored in a user attribute, which requires a writable user repository.
- You can give all users of an identity provider account access to your portal environment as an identified user. If you grant special access rights to these users, they do not need to register individually with WebSphere Portal Express. This option requires fewer steps for your business users.

Complete the following tasks to configure the identity providers that are appropriate for your business requirements.

"Configuring OpenID authentication" on page 1575
Identity providers include sites such as, but not limited to, Google, Yahoo, and Facebook. As an Administrator, you can select how to configure authentication to work with these identity providers.

"Modifying the list of OpenID providers" on page 1582
You can change the list of identity providers that your users can access. You can add or remove providers from the list. You can change the order that the identity providers display in the **Login** and **Profile Management** portlet user interfaces.

"Configuring transient users" on page 1583
In addition to the basic OpenID authentication option, you can give users, who are trusted and verified from an identity provider, access to IBM WebSphere Portal Express. These trusted and verified users do not require a local, registered Portal user account.

"Disabling transient users and OpenID authentication" on page 1586
After using the transient users and OpenID authentication, you might decide you want to stop using the function. You can permanently or temporarily disable the transient users function or the full OpenID authentication function.

Configuring OpenID authentication

Identity providers include sites such as, but not limited to, Google, Yahoo, and Facebook. As an Administrator, you can select how to configure authentication to work with these identity providers.

Before you begin

Set your system time to match your local time.

About this task

Users can always register and log in with WebSphere Portal Express credentials. With the **enable-identityprovider-tai** task, you can choose between the following configurations:

Remember: Google and Yahoo are known identity providers that use OpenID specifications. Facebook uses OAuth.

Limitation: If you configure portal to use OpenID authentication with YAHOO as the identity provider, attribute exchange does not work. This limitation means that user attributes from your YAHOO OpenID account are not transferred to your portal user account.

- Configure Facebook only, use the parameters that are designated as Facebook
- Configure OpenID only, use the parameters that are designated as OpenID
- Configure Facebook and OpenID, use the parameters that are designated as Facebook and OpenID

Procedure

1. If you plan to configure Facebook, register your WebSphere Portal Express server instances as Facebook applications. You must register two applications. One application is the protected path: `/wps/myportal`. One application is the public, unprotected path: `/wps/portal`.

   After you register, Facebook provides you with an application ID and an application secret. Use this information when you run the **enable-identityprovider-tai** task.

   Tip: Your Facebook application has a private and public URL. The private URL is `http://`*`yourserver`*`:`*`yourport`*`/wps/`*`myportal`*`/`. The public URL is `http://`*`yourserver`*`:`*`yourport`*`/wps/`*`portal`*`/`.
2. Required: Run the following task from the *wp_profile_root*`\ConfigEngine` directory with the appropriate parameters:

Cluster note: Complete this step only on the primary node.
CAUTION:
If you rerun the `enable-identityprovider-tai` task, the task sets new properties and does not preserve the old configuration data. If you want to keep the existing data, you must add the new values to the existing values before you rerun the task.

- IBM i: `ConfigEngine.sh enable-identityprovider-tai -DWasUserId=`*`username`* `-DWasPassword=`*`password`*
- Linux: `./ConfigEngine.sh enable-identityprovider-tai -DWasUserId=`*`username`* `-DWasPassword=`*`password`*
- Windows: `ConfigEngine.bat enable-identityprovider-tai -DWasUserId=`*`username`* `-DWasPassword=`*`password`*

Add the following parameters to customize the task for your business requirements:

`-Didp.providerlist`
Set the value to `facebook,openid` if you want to configure both options. Set the value to `facebook` to configure Facebook only. Set the value to `openid` to configure only identity providers that use the OpenID specifications. If you leave this field blank, the default value is `facebook`.

`-Dfacebook_apps`
If you are configuring Facebook, you can use Facebook for authentication (`app`), self enrollment (`pub`), or both (`app,pub`). The default value is `app`. Set the value to one of the following values:

`app` Configures authentication only.

`pub` Configures self enrollment only.

`app,pub`
Configures both authentication and self enrollment.

`-Dfacebook_app_id`
If you are configuring Facebook for authentication, set the value to *`yourprivatefacebookappid`*, which you received when you registered your Portal server as a private Facebook application. This value is for your private URL.

`-Dfacebook_app_secret`
If you are configuring Facebook for authentication, set the value to *`yourprivatefacebookappsecret`*, which you received when you registered your Portal server as a private Facebook application. This value is for your private URL.

`-Dfacebook_app_site`
If you are configuring Facebook for authentication, set the value to `http://`*`yourserver`*`:`*`yourport`*`/wps/`*`myportal`*`/`. This value is the URL for your private WebSphere Portal Express server that Facebook uses after a successful authentication. A protected area requires authentication to access and is not available to an anonymous user.

`-Dfacebook_pub_id`
If you are configuring Facebook for self enrollment, set the value to *`yourpublicfacebookappid`*, which you received when you registered your Portal server as a Facebook application. This value is for your public URL.

-Dfacebook_pub_secret
If you are configuring Facebook for self enrollment, set the value to *yourpublicfacebookappsecret*, which you received when you registered your Portal server as a Facebook application. This value is for your public URL.

-Dfacebook_pub_site
If you are configuring Facebook for self enrollment, set the value to `http://yourserver:yourport/wps/portal/`. This value is the URL for your public WebSphere Portal Express server that Facebook uses after a successful authentication. A public area does not require authentication to access and is available to an anonymous user.

-Dopenid.servicenames
If you are configuring identity providers that use the OpenID specifications, enter a comma-separated list of the identity providers that you want configured; for example: `Google,Yahoo`.

-Dopenid.servicenames.endpoints
If you are configuring identity providers that use the OpenID specifications, enter a comma-separated list of OpenID endpoints (access addresses). These endpoints are for the identity providers in the **openid.servicenames** parameter. For example, type `https://www.google.com/accounts/o8/id,https://me.yahoo.com/`. There must be a one-to-one correspondence between the **openid.servicenames** and the **openid.servicenames.endpoints** parameters. If you entered three identity providers in the **openid.servicenames** parameter, you must enter three endpoints in the **openid.servicenames.endpoints** parameter and in the same sequence.

-Dprovider.openid.nonce_valid_time
If you are configuring identity providers that use the OpenID specifications, enter a value in seconds to protect old communications from being reused in replay attacks. If this parameter is not set, you might have nonce errors in your `SystemOut.log` file.

3. Required: Complete the following steps to configure the Profile Management and Login portlets:

   Cluster note: Complete these steps on one node in the cluster.

   a. Log on to WebSphere Portal Express as the administrator.
   b. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
   c. Locate the Login portlet and click the **Configure portlet** icon.
   d. Configure the Login portlet with the following parameters:

      Tip: During authentication, WebSphere Portal Express server retrieves attributes from the Identity Provider. Custom parameters, such as languages preferences, are not automatically retrieved. You must add these parameters to Portal. If the parameter does not exist, enter the parameter name in **New Preference** and the parameter value in **New value**. Then, click **Add** to add the new parameter to the Login portlet.

      show_idp_option
      Set this required parameter to `true` to show the identity provider authentication feature on the portlet.

      show_idp_max
      Set this required parameter to the maximum number of identity

providers that are shown on the portlet. You define the list of providers when you run the **enable-identityprovider-tai** task. If you defined five identity providers and want two to show on the portlet, set this parameter to 2. On the portlet, two identity providers are shown. Click **More** to show the complete list of identity providers.

show_idp_freeform_field
Set this required parameter to `true` to use the full OpenID string and not restrict it to certain known services. This option shows a free-form field on the portlet. If set, users can enter any OpenID identifier.

***providername*.image**
providername represents the case-sensitive name of the identity provider. For example, you would create the **Google.image** parameter. Set this optional parameter to define an image for the configured identity provider buttons. You can define whether a text button or an image is shown. Enter the URL of the identity provider image.

e. Click **OK** to save your changes.

f. Locate the Profile Management portlet and click the **Configure portlet** icon.

g. Configure the Profile Management portlet with the following parameters:

Tip: If the parameter does not exist, enter the parameter name in the **New Preference** field and the parameter value in the **New value** field. Then, click **Add** to add the new parameter to the Profile Management portlet.

show_idp_option
Set this required parameter to `true` to show the identity provider authentication feature on the portlet.

show_idp_max
Set this required parameter to the maximum number of identity providers that are shown on the portlet. You define the list of providers when you run the **enable-identityprovider-tai** task. If you defined five identity providers and want two to show on the portlet, set this parameter to 2. On the portlet, two identity providers are shown. Click **More** to show the complete list of identity providers.

show_idp_freeform_field
Set this required parameter to `true` to use the full OpenID string and not restrict it to certain known services. This option shows a free-form field on the portlet. If set, users can enter any OpenID identifier.

***providername*.image**
providername represents the case-sensitive name of the identity provider. For example, you would create the **Google.image** parameter. Set this optional parameter to define an image for the configured identity provider buttons. You can define whether a text button or an image is shown. Enter the URL of the identity provider image.

***providername*.required**
providername represents the case-sensitive name of the identity provider service name. For example, you would create the **Google.required** parameter. Set this optional parameter to define

the attribute mappings you want required between the identity provider and the Profile Management portlet. Enter a semicolon-separated list of attribute mapping pairs that are combined with a vertical bar (|); for example, *attributename*|*openidattribute*. You must create a parameter for each supported identity provider; for example: **Google.required** and **aol.required**. Check the schema documentation of each identity provider for the supported attributes. Some mapping examples include:

Google: all in one line

```
ibm-primaryEmail|http://axschema.org/contact/email;
preferredLanguage|http://axschema.org/pref/language;
givenName|http://axschema.org/namePerson/first;
sn|http://axschema.org/namePerson/last
```

Facebook: all in one line

```
ibm-primaryEmail|email;
givenName|first_name;
sn|last_name;
uid|id;
preferredLanguage|locale
```

***providername*.optional**

providername represents the case-sensitive name of the identity provider. For example, you would create the **Google.optional** parameter. Set this parameter to define the attribute mappings you want optional between the identity provider and the Profile Management portlet. Enter a semicolon-separated list of attribute mapping pairs that are combined with a vertical bar (|). You can create a parameter for each supported identity provider; for example: **Google.optional** and **aol.optional**. Check the schema documentation of each identity provider for the supported attributes. Some mapping examples include:

Google: all in one line

```
ibm-primaryEmail|http://axschema.org/contact/email;
preferredLanguage|http://axschema.org/pref/language;
givenName|http://axschema.org/namePerson/first;
sn|http://axschema.org/namePerson/last
```

Facebook: all in one line

```
ibm-primaryEmail|email;
givenName|first_name;
sn|last_name;
uid|id;
preferredLanguage|locale
```

***providername*.protocol**

providername represents the case-sensitive name of the identity

provider. Set this required parameter to define the Identity Provider Attribute Exchange protocol. Simple Registration (SREG) and Attribute Exchange (AX) are supported. The supported values for the parameters are `openid.sreg` for SREG or `openid.ax` for AX. You must create a parameter for each supported identity provider service name; for example: **`Google.protocol`** and **`aol.protocol`**.

facebook.required
Set this parameter to define required attribute mappings between Facebook and the **Profile Management** portlet. Enter a semicolon separated list of attribute mapping pairs that are combined with a vertical bar (`|`).

Some mapping examples include: *all in one line*

```
attributename|facebookattribute;
attribute2|facebookattribute2
```

The following item is a mapping example: *all in one line*

```
uid|id;ibm-primaryEmail|email;
givenName|first_name;sn|last_name;
preferredLanguage|locale
```

h. Click **OK** to save your changes.

4. Verify that the following `.jar` files were copied to the *AppServer_root*`\lib\ext` directory:

   Cluster note: Complete this step on each node in the cluster.

   PortalServer_root`\prereqs.infra\prereq.commons.httpclient\lib\ext\commons-codec-1.6.jar`

   PortalServer_root`\prereqs.infra\prereq.commons.httpclient\lib\ext\commons-httpclient-3.0.1.jar`

5. Required: Complete the following steps to add SSL certificates for the configured identity providers; some providers require multiple certificates:

   Attention: If an identity provider uses multiple server endpoints that require different SSL certificates, you might receive error message EJPAK0062E.

   Cluster note: In a clustered environment, you must complete these steps only on the Deployment Manager.

   Farm note: In a farm environment, you must complete these steps on each server in your farm.

   a. Log on to the WebSphere Integrated Solutions Console.
   b. Go to **Security** > **SSL certificate and key management**.
   c. Under **Configuration settings**, click **Manage endpoint security configurations**.
   d. Under **Outbound** > ***hostname*** > **nodes** > ***node_name*** > **servers**, click the **WebSphere_Portal** server option.
   e. Under **Related Items**, click **Key stores and certificates**.
   f. Click **NodeDefaultTrustStore**.

      Cluster note: Click **`CellDefaultTrustStore`** instead of **`NodeDefaultTrustStore`**.

   g. Under **Additional Properties**, click **Signer certificates**.
   h. Click **Retrieve from port**.

i. Enter the following information and then click **Retrieve signer information**:

Host Enter the endpoint for the identity provider without specifying the protocol, for example, `http://` or `https://`. Type `www.google.com` for Google or `graph.facebook.com` for Facebook.

Port Enter the port number for the identity provider, for example, type `443`.

Alias Enter the certificate alias name, which is specified in the SSL configuration; for example type `graph.facebook.com_cert` for Facebook.

j. Verify the **Retrieved signer information** and then click **Apply**.

k. Click **Save**.

l. If you receive error message EJPAK0062E, you might be missing a certificate. Open the `SystemOut.log` file and search for CWPKI0022E: SSL HANDSHAKE FAILURE. If this error message is present, import the certificate where the **domainname** is part of the **SubjectDN**.

6. Required: Complete the following steps to stop and restart the WebSphere_Portal server:

   Cluster note: Recycle the server or cluster instance.

   a. Open a command prompt and change to the following directory:

      IBM i: *wp_profile_root*`/bin`

      Linux: *wp_profile_root*`/bin`

      Windows: *wp_profile_root*`\bin`

   b. Enter the following command to stop the *WebSphere_Portal* server, where *WebSphere_Portal* is the name of the WebSphere Portal Express server:

      IBM i: `stopServer` *`WebSphere_Portal`* `-username` *`admin_userid`* `-password` *`admin_password`*

      Linux: `./stopServer.sh` *`WebSphere_Portal`* `-username` *`admin_userid`* `-password` *`admin_password`*

      Windows: `stopServer.bat` *`WebSphere_Portal`* `-username` *`admin_userid`* `-password` *`admin_password`*

   c. Enter the following command to start the *WebSphere_Portal* server, where *WebSphere_Portal* is the name of the WebSphere Portal Express server:

      IBM i: `startServer` *`WebSphere_Portal`*

      Linux: `./startServer.sh` *`WebSphere_Portal`*

      Windows: `startServer.bat` *`WebSphere_Portal`*

7. Required: Complete the following steps in a clustered environment to configure the **OpenidObjCache** cache instance:

   a. Log on to the WebSphere Integrated Solutions Console.

   b. Go to **Resources** > **Cache instances** > **Object cache instances**.

   c. Select **OpenidObjCache**.

   d. Under the **Consistency settings** section, set the following values:

      Select the **Enable cache replication** check box.

      Select `Both Push and Pull` for the **Replication type**.

   e. Click **OK**.

   f. Click **Save**.

   g. Stop and restart the cluster servers to propagate the changes.

8. Optional: Depending on the security settings for your identity providers, you must modify attributes for your identity provider trust association. Complete the following steps to modify your trust association:

   Cluster note: Complete these steps on one node in the cluster.

   a. Log on to the WebSphere Integrated Solutions Console.
   b. Go to **Security** > **Global security** > **Web and SIP security** > **Trust association**.
   c. Select **Interceptors** and then select **com.ibm.portal.auth.OpenIDTAI**.
   d. Add or modify properties to change the default behavior. For example, you can add or modify the following properties:

      bindattribute
      This property stores the user profile attribute that contains the identity provider user ID. The default value is `labeledURI`.

      loginattribute
      This property defines the attribute that is retrieved from the repository that uniquely identifies the user. The default value is `uid`.

Results

New users can register a new WebSphere Portal Express profile with a valid identity provider specified in **labeledURI**. Existing users can update their profile with a valid identity provider specified in **labeledURI**. To support the profile update, a writable user repository must exist. They can then log on to WebSphere Portal Express with the alternative login field. They are redirected to the identity provider login page.

Modifying the list of OpenID providers

You can change the list of identity providers that your users can access. You can add or remove providers from the list. You can change the order that the identity providers display in the **Login** and **Profile Management** portlet user interfaces.

Procedure

1. Log on to the WebSphere Integrated Solutions Console.
2. Go to **Security** > **Global security** > **Web and SIP security** > **Trust association**.
3. Select **Interceptors** and then select **com.ibm.portal.auth.OpenIDTAI**.
4. Modify the following properties that are based on your business requirements:

openid.servicenames
This property defines a comma-separated list of your identity providers that your users see. For example, type `Google,Yahoo`. The order of the names affects the user interface and the order that the providers are displayed.

provider.openid.servicenames.endpoints
When you configure identity providers that use the OpenID specifications, enter a comma-separated list of OpenID endpoints (access addresses) for the identity providers that you entered in the **openid.servicenames** parameter. For example, type `https://www.google.com/accounts/o8/id,https://me.yahoo.com/`. There must be a one-to-one correspondence between the **openid.servicenames** and the **openid.servicenames.endpoints** parameters. If you entered three identity providers in the **openid.servicenames** parameter, you must enter three endpoints in the **openid.servicenames.endpoints** parameter and in the same sequence.

5. Restart the WebSphere_Portal server.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Configuring transient users

In addition to the basic OpenID authentication option, you can give users, who are trusted and verified from an identity provider, access to IBM WebSphere Portal Express. These trusted and verified users do not require a local, registered Portal user account.

About this task

Facebook and Google users can authenticate with the WebSphere Portal Express server instance with their identity provider credentials. They are granted access to certain data within WebSphere Portal Express without having a local account. You can grant the same access to all identity providers or you can configure different access rights that are based on the identity provider. With this option you, can provide a personalized view to unregistered users while still providing benefits to fully registered users.

Procedure

1. Run the following task from the *wp_profile_root*`\ConfigEngine` directory with the appropriate parameters:

   Cluster note: Complete this step only on the primary node.

   - IBM i: `ConfigEngine.sh enable-transient-user -DWasUserId=`*`username`* `-DWasPassword=`*`password`*
   - Linux: `./ConfigEngine.sh enable-transient-user -DWasUserId=`*`username`* `-DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat enable-transient-user -DWasUserId=`*`username`* `-DWasPassword=`*`password`*

   Add the following parameters to customize the task for your business requirements:

-Dtransparent.suffix
Set this value to a **dn** suffix that is used for transient users. The suffix must NOT match your current suffixes for fully registered users. The default value is `o=transparent`.

-Dtransparent.prefix
Set this value to a prefix that is used for transient users. For example, if you want to set the RDN attribute, set this value to `cn`.

Note: Complete the following steps if you entered the wrong value in the **transparent.suffix** parameter:

a. Log on to WebSphere Integrated Solutions Console as the administrator.
b. Go to **Security** > **Global Security**.
c. Go to **User account repository** > **Available realm definitions** and select **Federatedrepositories**.
d. Click **Configure**.
e. Go to **Repositories in the realm** and click the link in the Base Entry column for the **transientidp** repository identifier, for example, **o=transparent**.
f. Replace the value in the following fields with the new value:

Distinguished name of a base entry that uniquely identifies this set of entries in the realm For example, `o=transparent`.

Distinguished name of a base entry in this repository For example, `o=transparent`

g. Click **OK**.
h. Save your changes.
i. Stop and restart the WebSphere_Portal server.

2. Optional: Complete the following steps to create group objects for external providers to assign different access rights:

Important: After you run the **enable-transient-user** task, all identified users are identified with the all authenticated group and do not have explicit groups.

a. Log on to WebSphere Integrated Solutions Console as the administrator.
b. Go to **Security** > **Global Security**.
c. Go to **User account repository** > **Available realm definitions** and select **Federatedrepositories**.
d. Click **Configure**.
e. Go to **Repositories in the realm** and click **transientidp** in the **Repository Identifier** column.
f. Click **New** and add the following information:
   - **Name**: `buildgroupsfor`
   - **Value**: Enter the list of supported Identity Providers that you want to build groups for; for example: `facebook Google`. The items in the list must be separated by a space. The Identity Providers are case-sensitive and must match what you entered for the **idp.providerlist** and **openid.servicenames** parameters.
g. Click **OK**.
h. Save your changes.
i. Stop and restart the WebSphere_Portal server.

3. Optional: Complete the following steps to mark transient identity provider users as external:

Information: After you run the **enable-transient-user** task, the system builds internal groups for each identity provider. You can use these groups in the Resource Permissions portlet in the **Portal Administration** menu. Use the Resource Permissions portlet to build a set of pages and portlets that transient users can see and use.

You can also combine transient users with the external user feature in WebSphere Portal Express. You can identify a group of external or transient users with a database suffix. All external and transient users are then granted a special virtual principle in the access control. Use this virtual principle to grant a general set of access rights to these users.

a. Log on to WebSphere Integrated Solutions Console as the administrator.
b. Go to **Resources** > **Resource Environment** > **Resource Environment providers**.
c. Search for `WP PumaStoreService` and then click **Custom properties**.
d. Add the `parentDN.externalUsers` property with value you entered for **transparent.suffix**. If you did not enter a value in **transparent.suffix**, type `o=transparent`.
e. Save your changes.
f. Stop and restart the WebSphere_Portal server.

4. Complete the following steps to load user attributes during authentication:

Note: Transient users do not have attributes that are stored locally. Therefore, it is helpful to load attributes from the Identity Provider during authentication.

Note: If you want to allow transient users to create or modify pages, you must map a short name to the users. The attribute that is used for the short name is the User default search attribute. If you do not know the attribute name, you can find it defined in the PumaStoreService Resource Environment provider. The most common values are `uid` and `cn`.

a. Log on to WebSphere Integrated Solutions Console as the administrator.
b. Go to **Security** > **Global security** > **Web and SIP Security** > **Trust association** > **Interceptors**.
c. Select **com.ibm.portal.auth.tai.OpenidTAI**.
d. Add the following new properties for OpenID:
   - `provider.openid.loadattributes=provider|`*`method`*`;provider2|`*`method`*

     Note: *method* can either be `openid.sreg` or `openid.ax` depending on the type of OpenID your Identity Provider supports.
   - The following properties must be entered as one line.

     ```
     provider.openid.loadattributes.provider=portalattributename|
     idpattributename;portalattributename2|idpattributename2
     ```
   - The following properties must be entered as one line.

     ```
     provider.openid.loadattributes.provider2=portalattributename|
     idpattributename;portalattributename2|idpattributename2
     ```

   For example, you might add the following new properties for OpenID:
   - `provider.openid.loadattributes=google|openid.ax;yahoo|openid.ax`
   - The following properties must be entered as one line.

     ```
     provider.openid.loadattributes.google=cn|
     http://axschema.org/namePerson/first;sn|
     ```

```
http://axschema.org/namePerson/last;ibm-primaryEmail|
http://axschema.org/contact/email
```

e. Add the following new property for Facebook:

- The following properties must be entered as one line.

```
provider.facebook.loadattributes=portalattributename|
idpattributename;portalattributename2|idpattributename2
```

For example, you might add the following new property for Facebook:

- The following properties must be entered as one line.

```
provider.facebook.loadattributes=sn|
first_name;cn|last_name;uid|name
```

f. Save your changes.

g. Stop and restart the WebSphere_Portal server.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Disabling transient users and OpenID authentication

After using the transient users and OpenID authentication, you might decide you want to stop using the function. You can permanently or temporarily disable the transient users function or the full OpenID authentication function.

About this task

Complete the following steps to disable transient users and the OpenID authentication.

Procedure

1. Complete the following steps to disable transient users:
   a. Log on to WebSphere Integrated Solutions Console as the administrator.
   b. Go to **Security** > **Global security** > **Web and SIP Security** > **Trust association**.
   c. Select **com.ibm.portal.auth.tai.OpenIdTAI**.
   d. Select **Custom properties**.
   e. Change the value of the **create_user_during_logon** property to `false`.
   f. Save your changes.
   g. Stop and restart the WebSphere_Portal server.
2. Complete the following steps to disable the OpenID authentication function:
   a. Log on to WebSphere Integrated Solutions Console as the administrator.
   b. Go to **Security** > **Global security** > **Web and SIP Security** > **Trust association**.
   c. Delete **com.ibm.portal.auth.tai.OpenIdTAI**.
   d. Save your changes.
   e. Stop and restart the WebSphere_Portal server.

Related tasks:

Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Enabling step-up authentication and/or the Remember me cookie

Using step-up authentication and/or the Remember me cookie lets you fine-tune user authentication to pages and portlets.

"Enabling step-up authentication and the **Remember me** cookie"
Step-up authentication provides different authentication levels for pages and portlets. The **Remember me** cookie is an encrypted HTTP cookie that supports authentication. You can present personalized portlets and pages in a public area without the need for users to manually authenticate. Remembered users can view anonymous pages and portlets with a standard or identified authentication level. When you provide a valid **Remember me** cookie, a user can also access protected pages and portlets that require the identified authentication level. If the authentication level is set to authenticated, the user must provide a user ID and password to view the page or portlet.

Enabling step-up authentication and the Remember me cookie

Step-up authentication provides different authentication levels for pages and portlets. The **Remember me** cookie is an encrypted HTTP cookie that supports authentication. You can present personalized portlets and pages in a public area without the need for users to manually authenticate. Remembered users can view anonymous pages and portlets with a standard or identified authentication level. When you provide a valid **Remember me** cookie, a user can also access protected pages and portlets that require the identified authentication level. If the authentication level is set to authenticated, the user must provide a user ID and password to view the page or portlet.

About this task

You can enable step-up authentication only. You can enable the **Remember me** cookie only. Or you can enable both with one task.

Note: Authenticated and remembered users must have cookies enabled on their browser. Users can access portal sites without cookies enabled if they are anonymous users. If you turn on session tracking for anonymous users, then anonymous users also require cookies.

Remember me cookies: After you enable the **Remember me** cookie, you might need to adjust the settings to fit your business needs. You can use the WebSphere Integrated Solutions Console to create new properties, if necessary, or to update existing properties. The `RememberMeConfigService.properties` file, including a short description, is in the *wp_profile_root*`\PortalServer\config` directory. Log in to the WebSphere Integrated Solutions Console. Go to **Resources** > **Resource Environment Providers** > **WP RememberMeConfigService** > **Custom properties** to edit the properties file. All property changes require that you restart the WebSphere Portal Express server for the changes to take effect.

"Enabling step-up authentication, the Remember me cookie, or both" on page 1588
You can choose to enable either step-up authentication or the Remember me cookie individually or you can choose to enable these features together.

Enabling step-up authentication, the Remember me cookie, or both

You can choose to enable either step-up authentication or the Remember me cookie individually or you can choose to enable these features together.

Before you begin

Log on to the WebSphere Integrated Solutions Console and go to **Security** > **Global security** > **Web and SIP security** > **Single sign-on (SSO)**. Verify that both **Interoperability Mode** and **Web inbound security attribute propagation** are enabled.

You can use step-up authentication with Web Services for Remote Portlets (WSRP) extensions. The authentication level that is defined for portlets on the Producer portal is automatically set on the Consumer portal when it consumes WSRP services. If you apply step-up authentication mechanisms on the Producer, users are also challenged for stronger authentication credentials on the Consumer portal as required. To use step-up authentication with a WSRP extension, ensure that your environment meets the following requirements:

- The Producer and Consumer portals are WebSphere Portal Express Version 8.5 or later.
- You enable step-up authentication on both the Producer and Consumer portals.
- The authentication levels are the same on the Producer and Consumer portals.

  Notes:
  - Portal administrators can change authentication levels on both the Producer portal or Consumer portal at any time.
  - If the authentication level on the Consumer portal is less than the authentication level on the Producer portal, the Producer portal gives the following error message: `AccessDeniedFault EJPWC1118E: User authentication not strong enough`. Then, users cannot access the portlet. For this reason, the authentication level on the Consumer portal must be the same as the authentication level on the Producer portal.

About this task

Important: The Remember me cookie does not extend the Portal Personalization feature to the public area. When the Remember me cookie identifies a user in a public area, the user is still considered anonymous from an access control point of view.

Web Content Manager note: The authoring portlet and the web content viewer do not fully support step-up authentication or the Remember me cookie. However, the user name component is aware of the Remember me cookie. If the Remember me cookie is set on a request and a user is not logged in, the anonymous user design is not used. Instead, it uses the user name design complete with the name or distinguished name of the user that is specified by the Remember me cookie.

Restriction: Step-up authentication requires the LtpaToken2 for single sign-on. Read Implementing single sign-on to minimize web user authentications for details.

Note: When you enable both step-up authentication and the Remember me cookie, you receive the following authentication levels:

standard

identified

authenticated

If you enable step-up authentication only, you receive the following authentication levels:

standard

authenticated

Procedure

1. Go to the *wp_profile_root*/ConfigEngine/properties directory.
2. Open the wkplc.properties file with a text editor.
3. Enter one of the following values for the **enable_rememberme** parameter under the StepUp Authentication heading:

   Note: Add the **enable_rememberme** parameter to the wkplc.properties file if it does not exist.
   - If you are enabling both step-up authentication and the Remember me cookie, enter true.
   - If you are enabling step-up authentication only, enter false.
   - If you are enabling the Remember me cookie only, leave blank.
4. Enter a value for the following parameters under the StepUp Authentication heading if you are enabling the Remember me cookie:

   Note: Go to the properties file for specific information about the parameters.

   sua_user

   sua_serversecret_password
5. Save your changes to the wkplc.properties file.
6. Open a command prompt.
7. Change to the *wp_profile_root*/ConfigEngine directory.
8. Choose one of the following tasks to modify your environment:
   - If you are enabling step-up authentication and or the Remember me cookie, run the **enable-stepup-authentication** task.
   - If you are enabling the Remember me cookie only, run the **enable-rememberme** task.

   Use the following command syntax:
   - Linux : ./ConfigEngine.sh *task_name* -DWasPassword=*password*

- IBM i: `ConfigEngine.sh` *`task_name`* `-DWasPassword=`*`password`*
- Windows: `ConfigEngine.bat` *`task_name`* `-DWasPassword=`*`password`*

Where *`task_name`* is either **`enable-stepup-authentication`** or **`enable-rememberme`**.

9. Check the output for any error messages before you run any additional tasks. If any of the configuration tasks fail, verify the values in the `wkplc.properties` file.
10. In a clustered environment, copy the `wp.auth.base.sua_loginmodule.jar` file in the *AppServer_root*`/lib/ext/` directory of one of the Portal nodes to the *AppServer_root*`/lib/ext/` directory of the deployment manager.
11. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
12. Complete the following steps to change the authentication level on a page or portlet:
    a. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**.
    b. Click either the **Pages** link or the **Portlets** link.
    c. Locate the page or portlet you want to change and click the **Authentication Level** link.
    d. Choose one of the following levels:

       Note: The following Authentication Levels are provided. If you customized your step-up authentication, you might have different levels.

       Standard
       Set the Authentication Level to `Standard` if you want anonymous and identified users to view the page or portlet. The Standard level has the following two states that are based on the access control setting for the page or portlet:
       - If anonymous users have access to the page or portlet, no authentication is required.
       - If only authenticated users have access to the page or portlet, authentication is required.

       Identified (available if `enable_rememberme=true`)
       Set the Authentication Level to `Identified` if you want to control whether content is displayed to an unauthenticated user based on the existence of a persistent HTTP cookie. This option is intended for pages and portlets that are visible to anonymous users. An example is the **Remember me on this computer** option during login. This option generates the **`com.ibm.portal.RememberMe`** cookie.

       If a user previously authenticated to WebSphere Portal Express and then returns with the **`com.ibm.portal.RememberMe`** cookie, the user is "identified" and the content displays. If a user attempts to access WebSphere Portal Express without the **`com.ibm.portal.RememberMe`** cookie, the user is asked to authenticate before the content is displayed.

CAUTION:
Do not set the Access level to identified for the Login portlet. This action causes problems when a user logs in to WebSphere Portal Express.

Authenticated
Set the Authentication Level to `Authenticated` if you want anonymous and identified users to log in to view the page or portlet.

Configuring Remember me for Java Platform, Enterprise Edition authentication

You can configure a Remember me cookie for Java Platform, Enterprise Edition authentication that works with step-up authentication. When this feature is enabled, users are logged in automatically when they access a protected portal area by presenting a valid Remember me cookie.

About this task

If the portal area has a higher step-up authentication, users are asked to provider their user ID and password credentials. Otherwise, the users can enter the protected area without providing their credentials.

Procedure

1. Make sure the WebSphere_Portal server is running.
2. Log on to the WebSphere Integrated Solutions Console as an administrator.
3. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
4. Click **WP RememberMeConfigService** to open the properties view.
5. Click **Custom properties**.
6. Click **New**.
7. Enter the following values for the new property:
   a. **Name**: `j2eeAuthenticate`
   b. **Value**: `true`
   c. **Type**: `java.lang.Boolean`
8. Click **OK**.
9. Click the **Save** link in the Messages box to save the changes to the master configuration.

Disabling step-up authentication and the Remember me cookie

You can disable the step-up authentication feature or the Remember me cookie to remove them from your server.

Procedure

1. Go to the *wp_profile_root*`/ConfigEngine/properties` directory.
2. Open the `wkplc.properties` file with a text editor.
3. Enter one of the following values for the **`disable_rememberme`** parameter under the StepUp Authentication heading:

   Note: Add the **`disable_rememberme`** parameter to the `wkplc.properties` file if it does not exist.

   - If you are disabling both step-up authentication and the Remember me cookie, enter `true`.

- If you are disabling step-up authentication only, enter `false`.
- If you are disabling the Remember me cookie only, leave blank.

4. Save your changes to the `wkplc.properties` file.
5. Open a command prompt.
6. Change to the *wp_profile_root*`/ConfigEngine` directory.
7. Choose one of the following tasks to modify your environment:
   - If you are disabling step-up authentication and or the Remember me cookie, run the **disable-stepup-authentication** task.
   - If you are disabling the Remember me cookie only, run the **disable-rememberme** task.

   Use the following command syntax:
   - Linux : `./ConfigEngine.sh` *task_name* `-DWasPassword=`*password*
   - IBM i: `ConfigEngine.sh` *task_name* `-DWasPassword=`*password*
   - Windows: `ConfigEngine.bat` *task_name* `-DWasPassword=`*password*

   Where *task_name* is either **disable-stepup-authentication** or **disable-rememberme**.
8. Check the output for any error messages before you run any additional tasks. If any of the configuration tasks fail, verify the values in the `wkplc.properties` file.
9. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Step-up authentication properties

After you enable step-up authentication, you might want to adjust the settings to fit your business needs. You can use the WebSphere Integrated Solutions Console to create new properties, if necessary, or update existing properties.

For each additional authentication level you must create at least one properties file according to the following naming convention:

- The authentication level name.
- An underline character followed by a language locale. For example, en for English.
- The string `.properties`

For example, for an authentication level of `yourlevel`, you need to create a file such as `yourlevel.properties` or `yourlevel_en.properties`.

This file must be available in class path at `com/ibm/portal/auth/sua/nls/`.

The file must contain two key value pairs. For example, for the system specified authentication level `authenticated`, there are two definitions

```
display-name=authenticated
description=User authentication using username and password
```

These two strings are used to select the authentication level in the Administration portlet for configuration.

The following information contains all properties that apply to the appropriate portal configuration service, namely **WP StepUpConfigService**.

Log on to WebSphere Integrated Solutions Console and then go to **Resources** > **Resource Environment** > **Resource Environment Providers** > **WP StepUpConfigService** > **Custom properties** to access the properties.

Note: All property changes require that you restart the WebSphere_Portal server in order for the changes to take effect.

sua.enable
Use this property to enable and disable the step-up authentication mechanism.

Default: `false`

Type: `java.lang.Boolean`

sua.authLevel.enable
Use this property to provide a comma-separated list of authentication level names.

Notes:

- If step-up authentication is enabled, the authentication level name must be specified.
- If you want to use the **Remember me** cookie, make sure that it is enabled and add the authentication level name for this property.

Default: `authenticated`

Type: `java.lang.String`

sua.authLevel.*auth_level_name*.strength
Use this property to specify the authentication level strength of the authentication level with the name *auth_level_name*. The value is a non-negative integer that expresses the implied strength of a particular authentication method. The step-up authentication framework considers one authentication method to be stronger than another if it has a higher value.

Note: The value 0 is reserved by the step-up authentication engine, and therefore it is not allowed to assign values less than one. It is possible to leave gaps in the sequence of authentication level strengths. It is not possible to assign the same authentication level to multiple authentication level names.

Default: **sua.authLevel.identified.strength** =5
sua.authLevel.authenticated.strength =10

Type: `java.lang.Integer`

sua.authLevel.*auth_level_name*.required
Use this property to specify whether the authentication level with the name *auth_level_name* is optional or required. When a user accesses a resource with an optional authentication level, this resource might be accessed if the first required authentication level is verified. When an authentication level is flagged as required, it can be verified successfully only if all required authentication levels can be verified successfully.

Note: This property must not be set for the authentication level that is identified or authenticated. If one authentication level is set as optional, all previous levels must also be optional.

Default: `true`

Type: `java.lang.boolean`

sua.authLevel.*auth_level_name*.authLevelVerifier
Use this property to specify the fully qualified name of the class that implements the **com.ibm.portal.auth.stepup.AuthLevelVerifier** SPI. It also verifies whether the authentication level of **auth_level_name** is valid for a request.

Note: This property must not be set for the authentication level that is identified or authenticated.

Default: -

Type: `java.lang.String`

sua.authLevel.*auth_level_name*.stepUpAuthHandler
Use this property to specify the fully qualified name of the class that implements the **com.ibm.portal.auth.stepup.StepUpAuthHandler** SPI. It also establishes the authentication level of **auth_level_name**.

Note: This property must not be set for the authentication level that is identified or authenticated.

Default: -

Type: `java.lang.String`

sua.authLevel.*auth_level_name*.postRedirectionTargetProtected
The step-up authentication handler redirects a user with a certain authentication level to another page. For example, it redirects to a page with a login form. The step-up authentication framework redirects the user to the resource requested before the authentication level enforcement. This property specifies whether the redirection to the originally requested resource point to the public or the protected portal area. The implementation of the authentication level might move the user from an unauthenticated to an authenticated state.

Note: This property must not be set for the authentication level that is identified or authenticated.

Default: `false`

Type: `java.lang.Boolean`

Example: `true`

sua.authLevel.*auth_level_name*.property.*property_name*
Use this property to specify further properties that are available. The properties are received with their *property_name*. The prefix **sua.authLevel.auth_level_name.property** is omitted.

Default: -

Type: `java.lang.String`

Securing LTPA keys on a production environment

The Lightweight Third Party Authentication (LTPA) key holds cryptographic keys that secure the user authentication session and cookies. To secure the production server environment, regenerate the LTPA key using the WebSphere Integrated Solutions Console. If you plan to enable single sign-on at a later time, you must first disable the automatic key generation.

About this task

Complete the following steps to secure LTPA keys on a production environment:

Procedure

1. Complete the following steps to regenerate the LTPA keys:

   Note: These steps only need to be completed once in a clustered environment.

   a. Log on to the WebSphere Integrated Solutions Console.
   b. Navigate to **Security** > **Secure administration, applications, and infrastructure**.
   c. Click **Authentication mechanisms and expiration**.
   d. Click **NodeLTPAKeySetGroup** under Key Generation and then click **Generate Keys**.
   e. Click **Save** to save the changes to the master configuration.

   Restriction: By default, WebSphere Application Server is configured to automatically regenerate the LTPA keys every 90 days. If you setup single sign-on to export the LTPA key and then import it on another server, disable the automatic key generation; otherwise, single sign-on fails after 90 or 180 days because of regenerated keys.
2. Complete the following steps to disable automatic LTPA key generation on all servers of the single sign-on domain:
   a. Log on to the WebSphere Integrated Solutions Console.
   b. Navigate to **Security** > **Secure administration, applications, and infrastructure**.
   c. Click **Authentication mechanisms and expiration**.
   d. Click **Key generation - Key set groups**.
   e. Click **NodeLTPAKeySetGroup**.
   f. Disable the **Key generation - Automatically generate keys** checkbox.
   g. Click **OK**.
   h. Click **Save** to save the changes to the master configuration.

Configuring SSL

Secure socket layers (SSL) encrypt traffic between the client browser and the server to secure information exchanged over the network between the browser and IBM WebSphere Portal Express. You will need to configure your environment for SSL to activate this additional security feature.

About this task

Perform the following tasks to configure SSL:

1. "Setting up SSL" on page 1596
   Get an overview of the tasks that are required to configure SSL for IBM WebSphere Portal Express. Some of these tasks are completed on the IBM WebSphere Application Server and the web server. The steps that refer to the WebSphere Application Server and the web server are summarized here; refer to the WebSphere Application Server and the web server documentation for detailed information. Steps that are unique to WebSphere Portal Express are described in detail here.

2. “Configuring SSL only for the login process” on page 1601
   You can encrypt only the login process to IBM WebSphere Portal Express and then allow subsequent requests through HTTP.
3. “Setting up Client Certificate Authentication” on page 1603
   View the steps required to configure IBM WebSphere Portal Express for SSL client certificate authentication. The supported scenario is a "client certificate only" setup that switches completely to this authentication method and does not allow form-based login via username and password. Other configuration scenarios are possible, but are neither recommended nor supported.
4. “Cryptographic hardware for SSL acceleration” on page 1607
   If your portal environment makes extensive use of SSL, you might choose to use cryptographic hardware to offload encryption and improve performance. WebSphere Portal Express tolerates interfacing through WebSphere Application Server with cryptographic hardware for SSL acceleration. However, the tasks that are involved in setting up and configuring cryptographic hardware are specific to web servers or WebSphere Application Server and do not necessarily involve configuring WebSphere Portal Express.

Setting up SSL

Get an overview of the tasks that are required to configure SSL for IBM WebSphere Portal Express. Some of these tasks are completed on the IBM WebSphere Application Server and the web server. The steps that refer to the WebSphere Application Server and the web server are summarized here; refer to the WebSphere Application Server and the web server documentation for detailed information. Steps that are unique to WebSphere Portal Express are described in detail here.

About this task

Note: This procedure might be slightly different if a front-end security proxy server such as IBM Security Access Manager WebSEAL is used. In that case, the front-end security server handles the client SSL connections. The web server receives connections from the front-end security proxy server. Mutually authenticated SSL can be configured between the web server and the front-end security proxy server if needed. It is highly dependent on the security requirements of each deployment.

If you plan to use a Security Access Manager WebSEAL TAI with an SSL junction, complete only steps 1-3 of this procedure.

Important: If only the login process is secure over SSL, complete the first three steps and then go to Configuring SSL only for the login process.

Procedure

1. Configure the web server to support HTTPS. This configuration involves setting up the web server to accept inbound connections from client browsers over SSL.
2. Depending on the web server that you want to use, other software must be installed on the web Server. For example: instance Microsoft Internet Information Server and Microsoft Certificate Service.
3. The web server must have a port that is defined (usually 443), and the necessary certificates and keys must be installed.
   - Go to Securing with SSL communications in the related links section for information about how to enable SSL on an IBM HTTP Server.

4. In a production environment, you must obtain a certificate from a certificate authority. For testing purposes, you can use iKeyman to generate a self-signed certificate. For Internet Information Server, use the web server's resource toolkit to create SSL keys. Refer to the related links section for information about iKeyman and creating Secure Sockets Layer digital certificates.
5. Configure the WebSphere Application Server plug-in for the web server to forward WebSphere Portal Express traffic that is received over SSL to WebSphere Application Server (which then forwards the traffic to WebSphere Portal Express). Refer to the related links section for information about how to configure the plug-in.
6. In configurations where the web server and WebSphere Portal Express are on separate servers, requests are rerouted to the application server. Under these circumstances, you can also configure SSL between the web server and the application server to provide complete security. This configuration requires that you create extra keyfiles for the web server plug-in and for the embedded HTTPS of WebSphere Application Server.
   - For information about configuring SSL between the web server and the application server, use the IBM Redbooks called WebSphere Application Server V8.5 Security Guide, found in the related links section. Use the section that is called *Application server configuration: Web container configuration of the IBM WebSphere Application Server*.

   Note: Always create a new SSL keystore and truststore for the external web server and change the WebSphere_Portal server's secure transport channel to use the new SSL repository.
   CAUTION:
   Do not modify the default SSL key and truststore.
7. Required: Complete the following steps to create or modify the following two properties in the configuration services:
   a. Log on to the WebSphere Integrated Solutions Console.
   b. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
   c. Click **WP ConfigService**.
   d. Click **Custom Properties** under the Additional Properties heading.
   e. Locate the **redirect.login.ssl** property and complete one of the following options:

      Parameter values: The **redirect.login.ssl** determines the protocol to use after login completes. Specify one of the following values:
      - Set to `true` to use HTTPS.
      - Set to `false` to use HTTP.
      - If the property exists, click the property to modify it and change the value to `true`.
      - If the property does not exist, click **New** to create the property and enter the following information:
        - **Name**: `redirect.login.ssl`
        - **Value**: `true`
        - **Type**: `java.lang.String`

   f. Locate the **host.port.https** property and complete one of the following options:

- If the property exists, click the property to modify it and change the value to *alias_port*.

  Note: The *alias_port* is the port number that is used for the virtual host alias that is specified in a previous step (usually 443).
- If the property does not exist, click **New** to create the property and enter the following information:
  - **Name**: host.port.https
  - **Value**: 443
  - **Type**: java.lang.String

g. Click **Save** to save the changes to the master configuration.

h. Log out of the WebSphere Integrated Solutions Console.

8. Update the Transport Security Constraint in wps.ear. You can modify the transport so that WebSphere Application Server enforces the use of SSL for all pages under the /myportal/ URL. Use this step to completely secure the protected area over HTTPS.

   Clustered environments: Complete this step on the primary node, then complete a full resynchronize to propagate the changes to all nodes.

   a. Export wps.ear. See the related tasks section for instructions.

   b. Go to the directory where you exported wps.ear: *path_to_exported_EAR*/installedApps/*node_name*/wps.ear/wps.war/WEB-INF

      Note: You might need to extract the exported EAR before you can edit any files.

   c. Locate and open web.xml with any text editor.

   d. Set the value of the <transport-guarantee> element to CONFIDENTIAL under the <security-constraint> element for the /myportal/* URL. Do not change the values for the other <transport-guarantee> elements. Use the following information to update the XML file:

```
<security-constraint id="SecurityConstraint_1">
   <web-resource-collection id="WebResourceCollection_1">
      <web-resource-name></web-resource-name>
   <url-pattern>/myportal/*</url-pattern>
       <http-method>DELETE</http-method>
      <http-method>POST</http-method>
      <http-method>GET</http-method>
      <http-method>PUT</http-method>
   </web-resource-collection>
   <auth-constraint id="AuthConstraint_1">
      <description></description>
      <role-name>All Role</role-name>
   </auth-constraint>
   <user-data-constraint id="UserDataConstraint_4">
      <transport-guarantee>CONFIDENTIAL</transport-guarantee>
   </user-data-constraint>
</security-constraint>
```

   e. Save and close web.xml.

   f. Redeploy wps.ear. See the related tasks section for instructions.

   g. Synchronize the nodes in your clustered environment.

      1) Log in to the Deployment Manager.
      2) Select **System Administration** > **Nodes**.
      3) Select the nodes to synchronize from the list.
      4) Click **Full Resynchronize**.

9. Complete the following steps to update theme links:
   a. Edit the JSP and JSPF files that provide the login link. Locate the JSP and JSPF files that include the "wps.Login" string: Do not edit any of the themes that are included with WebSphere Portal Express because these themes are updated with fixes. Instead, copy the theme and make your changes to the copy.

      Finding theme resources: See the *Location of theme resources* link in the Related section.

      This attribute must appear in a tag similar to the following code:

      ```
      <portal-navigation:urlGeneration contentNode="wps.Login"
           portletWindowState="Normal">
      ```

      The exact structure of this tag can vary depending on how it was constructed by the page designer. The JSP comments might also be used to indicate where the login link is located:

      ```
      <%-- login button --%>
      ```

   b. After you find the login link, change or add the ssl="true" attribute to the <portal-navigation:urlGeneration> tag of the anchor. For example:

      ```
      <wps:if loggedIn="no" notSelection="wps.Login">
       <wps:urlGeneration contentNode="wps.Login"
                  portletWindowState="Normal" ssl="true">
        <td class="wpsToolBar" valign="middle" nowrap>
         <a href="<% wpsURL.write(escapeXmlWriter); %>" class="wpsToolBarLink">
         <wps:text key="link.login" bundle="nls.engine"/>
         </a>
        </td>
       </wps:urlGeneration>
      </wps:if>
      ```

      Note: The previous examples use the portal-navigation: prefix to designate JSP tags from the portal navigation tag library. Your custom JSP tags might use a different tag prefix.

10. Optional: Complete the following steps when you use a remote web server if you must allow direct access to the WebSphere_Portal node on the internal port. For example, http://*hostname.example.com*:*10039*/wps/portal, where *hostname.example.com* is the fully qualified host name of the server where Portal is running and *10039* is the default transport port that is created by WebSphere Application Server. The port number might be different for your environment.:
    a. From the WebSphere Integrated Solutions Console, go to **Servers** > **Server Types** > **WebSphere application servers** > **WebSphere_Portal** > **Web Container Settings** > **Web Container Transport Chains**.
    b. Click **New**.
    c. Select a name for the transport chain.
    d. Select the **WebContainer-Secure** template (templates/chains|webcontainer-chains.xml).
    e. Select **Next**.
    f. Specify the **Port name**. For example, port 443.
    g. Click **Next**.
    h. Click **Finish** to confirm the creation of the transport chain.
    i. Click **Save**.

j. In a clustered environment, repeat the previous steps for each node in the cluster. For example, WebSphere_Portal2, and then synchronize the changes to all nodes.

11. Optional: Complete the following steps only if you use the **Login** portlet:
    a. Log in to WebSphere Portal Express.
    b. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
    c. Locate the Login portlet and click the **Configure portlet** icon.
    d. Locate the **UseSecureLoginActionUrl** parameter and click the **Edit value** icon.
    e. Type `true` in the **Value** field and click **OK** to save your changes.
    f. Click **OK** to return to the **Manage Portlets** portlet.
12. In a stand-alone environment, stop and restart the WebSphere_Portal server. In a clustered environment, stop and restart the Deployment Manager and the WebSphere_Portal servers.

    Clustered environments: In the Deployment Manager, verify that the EAR changes were successfully synchronized to all nodes. Stop and restart the servers on all nodes.
13. Complete the following steps to test your changes:
    a. Start the home page in a web browser through an HTTP URL that is not secure. For example, `http://hostname.example.com:10039/wps/portal`, where *hostname.example.com* is the fully qualified host name of the server where Portal is running and *10039* is the default transport port that is created by WebSphere Application Server. The port number might be different for your environment..
    b. Verify that the login link in the banner area uses the HTTPS schema for the link to the login page.
    c. Enter your user name and password. Then, click the login link to verify that the page is protected. The URL must be HTTPS and the browser must indicate that the page is protected.

       Browser security prompt: After you click the login link to accept the server certificate, a browser security prompt might appear.
    d. Log off.
    e. Log in using an HTTP URL that is not secure and that points directly to the protected area. For example, `http://hostname.example.com:10039/wps/portal`, where *hostname.example.com* is the fully qualified host name of the server where Portal is running and *10039* is the default transport port that is created by WebSphere Application Server. The port number might be different for your environment.
    f. Verify that you are requested to log in and that the login page and the portal page are protected through SSL.

       Note: If the security-constraint was not modified to **CONFIDENTIAL**, SSL does not protect the login page and the portal pages.

Related concepts:

"Understanding the Portal Version 8.5 modularized theme" on page 2521
Modern websites and browsers enable incredible new capabilities that can greatly enhance your user's web experiences. However, these capabilities are not without cost in terms of large page sizes and more processing in the browser when each page is rendered. These capabilities are worth it when you need them, but removing them for an entire site or including them only on pages that take advantage of these capabilities provides for more flexibility.

Configuring SSL only for the login process

You can encrypt only the login process to IBM WebSphere Portal Express and then allow subsequent requests through HTTP.

About this task

Complete the following steps to configure SSL only for the login process:

Remember: These steps configure SSL only for the login; if you want to configure SSL for other features such as themes and skins, complete the steps in *Setting up SSL*.

Procedure

1. Configure SSL for the webserver plug-in if you have an external webserver that is configured for SSL. Consult with your webserver vendor for more details on how to configure SSL for your webserver. For more information, go to *Guide to properly setting up SSL within the IBM HTTP Server* topic in the related information section.

   Note: Proceeding with this task without configuring SSL for the webserver plug-in causes the login to fail.
2. Verify that the following parameters exist and are correctly set for your installation in the **WP ConfigService** application:

a. Log on to the WebSphere Integrated Solutions Console in a stand-alone environment or on the Deployment Manager WebSphere Integrated Solutions Console in a clustered environment.
b. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
c. Click **WP ConfigService**.
d. Click **Custom Properties** under the Additional Properties heading.
e. Locate the **redirect.login.ssl** property and do one of the following options:

   Note: The **redirect.login.ssl** parameter determines the protocol to use after login completes. If this parameter is set to `true`, https is used. If this parameter is set to `false`, http is used. This setting is not affected by the protocol that is used to access the main page.
   - If the property exists, click the property to modify it and change the value to `true`.
   - If the property does not exist, click **New** to create the property and enter the following information:
     - **Name**: `redirect.login.ssl`
     - **Value**: `true`
     - **Type**: `java.lang.String`

f. Locate the **host.port.https** property and do one of the following options:
   - If the property exists, click the property to modify it and change the value to *alias_port_for_HTTPS*.

     Note: The *alias_port_for_HTTPS* is the port number that is used for the virtual host alias (usually 443).
   - If the property does not exist, click **New** to create the property and enter the following information:
     - **Name**: `host.port.https`
     - **Value**: `443`
     - **Type**: `java.lang.String`

g. Locate the **host.port.http** property and do one of the following options:

   Note: Set the **host.port.http** if you are using a port other than the default 80.
   - If the property exists, click the property to modify it and change the value to *alias_port_for_HTTP*.

     Note: The *alias_port_for_HTTP* is the port number that is used for the virtual host alias (usually 80).
   - If the property does not exist, click **New** to create the property and enter the following information:
     - **Name**: `host.port.http`
     - **Value**: `80`
     - **Type**: `java.lang.String`

h. Click **Save** to save the changes to the master configuration.
i. Log out of the WebSphere Integrated Solutions Console.

3. Complete the following steps to encrypt the login process to WebSphere Portal Express and allow subsequent requests through HTTP:

The Login portlet uses the **UseSecureLoginActionUrl** parameter to control the generation of the login action URL. Set this parameter to `true` to use a secure URL for login.

a. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
b. Search for **Title start with = "Login"**.
c. Select the **Configure portlet** icon.
d. Edit the **UseSecureLoginActionUrl** parameter and set the parameter to `true`.

For more information about setting up SSL within the IBM HTTP Server, see *Guide to properly setting up SSL within the IBM HTTP Server*.

Results

You can test the SSL login by using the following unprotected URL: `http://portalserver.com/wps/myportal` and submitting your credentials. You notice that the URL does not change to https.

Note: Confirm that the login was encrypted by monitoring the packets through a network utility such as Ethereal or by reviewing the source code of the login form when accessed through an unprotected HTTP URL. The login form must have an action URL that is secured, for example `<form method="post" action="https://....">`. Set your browser to warn you when you change between secure and insecure modes to see the behavior on the client-side.

Guide to properly setting up SSL within the IBM HTTP Server

Setting up Client Certificate Authentication

View the steps required to configure IBM WebSphere Portal Express for SSL client certificate authentication. The supported scenario is a "client certificate only" setup that switches completely to this authentication method and does not allow form-based login via username and password. Other configuration scenarios are possible, but are neither recommended nor supported.

About this task

Complete the following steps to configure WebSphere Portal Express for SSL client certificate authentication:

Note: See related references section on how to setup WAS for SSL support with client certification.

Procedure

1. Ensure you complete the following steps when you configure IBM WebSphere Application Server for SSL support with client certificates:
   a. When you define the Quality of protection (QoP) settings for the new SSL Repertoire, do the following:
      1) Choose **Required** from the **Client Authentication** list
      2) Choose **SSL_TLS** from the **Protocol** list.
      3) In the **Provider** section, select **Predefined JSSE provider** then choose **IBMJSSE** from the **Select provider** list.

For more information, see the *Quality of Protection* topic in the WebSphere Application Server Information Center.

b. Ensure you reference the correct key and trust files. You should create new key and trust files using the IKEYMAN tool and the PKCS12 format for maximum browser compatibility.

   Note: The key file must contain the server certificate. The trust file must contain either all the client certificates of users that will be authenticated or a certification authority certificate (CA key) that can be used to verify the client certificates of users.

c. Associate the secure transport chain with the new SSL Repertoire.

d. Configure your advanced LDAP security settings. Certificate-based authentication requires that you configure the authentication mechanism so that one of the following conditions apply:

   - WebSphere Application Server maps the entire Distinguished Name (DN) from the subject field of the certificate to a corresponding Distinguished Name in your LDAP. To use this option, set the mapping technique in the LDAP configuration panel to `exact`.
   - WebSphere Application Server maps the entry in the subject field to a different attribute than the Distinguished Name in your user registry. To use this option, set up the mapping technique in the LDAP configuration panel to use the certificate filter option. Using the certificate filter option allows you more flexibility in using attributes other than the Distinguished Name to identify the users. For example, the filter `uid=${SubjectCN}` maps the `SubjectCN` field of the client certificate to the uid attribute in your LDAP.

2. Complete the following steps if you use an external HTTP server:

   a. Regenerate the plug-in. Go to **Servers** > **Web Servers**. Select the **Web server** and click **Generate Plug-in**. Update the HTTP server with the generated plug-in.

   b. Restart the HTTP server for the changes to take effect.

   c. Enable client certificate authentication in your Web server. For IBM HTTP Server (IHS), refer to http://www.redbooks.ibm.com/ and search for security handbook for the latest information about WebSphere Application Server.

3. Update `wps.ear` to change the authentication method and transport guarantee setting to support client certificate authentication.

   Clustered environments: Complete this step on the primary node, then complete a full resynchronize to propagate the changes to all nodes.

   a. Export `wps.ear`. See the following topic title in the Related task section for instructions: *Exporting the portal EAR file*.

   b. Go to the directory where you exported `wps.ear`: *`path_to_exported_EAR`*`/installedApps/`*`node_name`*`/wps.ear/wps.war/WEB-INF`

      Note: You might need to extract the exported EAR before you can edit any files.

   c. Edit the `web.xml` file located in the exported ear directory under `/wps.war/WEB-INF`.

   d. Change the login-config tag to the client certificate authentication method.

```
<login-config id="LoginConfig_1">
  <auth-method>CLIENT-CERT</auth-method>
  <realm-name>WPS</realm-name>
```

```
  <!--<form-login-config id="FormLoginConfig_1">
   <form-login-page>/redirect</form-login-page>
   <form-error-page>/error.html</form-error-page>
  </form-login-config> -->
</login-config>
```

e. Change the transport guarantee setting in the security constraint for the protected area to `CONFIDENTIAL`:

```
<security-constraint id="SecurityConstraint_1">
  <web-resource-collection id="WebResourceCollection_1">
   <web-resource-name/>
   <url-pattern>/myportal/*</url-pattern>
   <http-method>DELETE</http-method>
   <http-method>GET</http-method>
   <http-method>POST</http-method>
   <http-method>PUT</http-method>
   <http-method>HEAD</http-method>
  </web-resource-collection>
  <auth-constraint id="AuthConstraint_1">
   <description/>
   <role-name>All Role</role-name>
  </auth-constraint>
  <user-data-constraint id="UserDataConstraint_4">
   <transport-guarantee>CONFIDENTIAL</transport-guarantee>
  </user-data-constraint>
</security-constraint>
```

f. Save and close `web.xml`.

g. Redeploy `wps.ear`. See the following topic title in the Related task section for instructions: *Redeploying the portal EAR file*.

h. Clustered environments: Synchronize the nodes.

1) Log in to the Deployment Manager.

2) Select **System Administration** > **Nodes**.

3) Select the nodes to synchronize from the list.

4) Click **Full Resynchronize**.

4. Update the themes and settings.

a. Modify the URLs for login and logout in the themes that are used in your scenario. The files that contain the login and logout links can be different, depending on the theme. In more recent themes, these links might be located in `Default.jsp`. In older themes, these links might be located in either `banner.jspf` or `mainMenu.jsp`.

Finding theme resources: See the *Location of theme resources* link in the Related section.

Clustered environments: Complete the following steps. Notice that in a clustered environment, the steps must be completed on the Deployment Manager.

- For the login link, use an arbitrary protected page. The login link will then implicitly trigger the SSL handshake in WebSphere Application Server due to the security constraint. For example, you can generate the URL to point to the protected welcome page:

```
<%-- Login button --%>
<%-- comment this to enable screen login --%>
<portal-logic:if loggedIn="no">
<portal-navigation:urlGeneration
contentNode="ibm.portal.Home.Welcome" home="protected">
    <a tabIndex="7" class="toolbarLink" href='<%
```

```
wpsURL.write(escapeXmlWriter); %>'>
    <portal-fmt:text key="link.login" bundle="nls.engine"/>
</a></portal-navigation:urlGeneration>
</portal-logic:if>
```

- For the logout, you need to consider whether or not a logout should redirect you back to HTTP. If so, you need to set the property **redirect.logout.ssl** in the configuration service to `true`. Also, set the **host.port.http** in the same service to the correct port. If you want to stay in the HTTPS protocol after the logout, you do not need to complete any configuration steps here.

b. Remove the login portlet from all pages where it is placed; for example, the welcome and the login page.

c. If you want to completely disable the entry points 'login portlet' and 'login URL' to WebSphere Portal Express, complete the following steps: set the **command.login** property in the configuration service to the value `LoginUserBlocked`. This ensures that a login can only be triggered after being authenticated by WebSphere Application Server, in this case by the client certificate handshake.

1) Log on to the WebSphere Integrated Solutions Console.
2) Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
3) Click **WP ConfigService**.
4) Click **Custom Properties** under the Additional Properties heading.
5) Click **command.login** and change the value from `LoginUserAuth` to `LoginUserBlocked`.
6) Click **Save** to save the changes to the master configuration.
7) Log out of the WebSphere Integrated Solutions Console.

5. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see “Starting and stopping servers, deployment managers, and node agents” on page 1216.
6. Verify your setup.
   a. Import one of the client certificates that are accepted by the server to your browser.
   b. Launch the home page in this browser through an HTTP URL that is not secure; for example, `http://`*`hostname.example.com`*`:`*`10039`*`/wps/portal`, where *hostname.example.com* is the fully qualified host name of the server where Portal is running and *10039* is the default transport port that is created by WebSphere Application Server. The port number might be different for your environment..
   c. Click the login link.
   d. Verify that the server switches to HTTPS and you are prompted for the client certificate.
   e. After selecting and confirming the correct client certificate, you are redirected to the protected area served with HTTPS.

Cryptographic hardware for SSL acceleration

If your portal environment makes extensive use of SSL, you might choose to use cryptographic hardware to offload encryption and improve performance. WebSphere Portal Express tolerates interfacing through WebSphere Application Server with cryptographic hardware for SSL acceleration. However, the tasks that are involved in setting up and configuring cryptographic hardware are specific to web servers or WebSphere Application Server and do not necessarily involve configuring WebSphere Portal Express.

The WebSphere Application Server Information Center contains several topics for setting up and configuring password encryption with cryptographic hardware. Refer to these topics to get started with password encryption and learn more about available encryption features.

Most cryptographic hardware requires the PKCS11 support software for the host machine and internal firmware. To get started with cryptographic hardware, you must install the required support software, configure IBM HTTP Server, then install the necessary devices. Refer to *Getting started with the cryptographic hardware for SSL* at: http://www-01.ibm.com/support/knowledgecenter/SSEQTJ_8.5.5/com.ibm.websphere.ihs.doc/ihs/tihs_cryptossl.html

You can create a plug point to encrypt and decrypt all passwords in WebSphere Application Server that are currently encoded or decoded by using Base64-encoding. Refer to *Plug point for custom password encryption* at:

Stand-alone environments: http://www-01.ibm.com/support/knowledgecenter/SSEQTP_8.5.5/com.ibm.websphere.base.doc/ae/csec_plugpoint_custpass_encrypt.html

Clustered environments: http://www-01.ibm.com/support/knowledgecenter/SSAW57_8.5.5/com.ibm.websphere.nd.multiplatform.doc/ae/csec_plugpoint_custpass_encrypt.html

Create a custom class to encrypt passwords after you create your server profile. Refer to *Enabling custom password encryption* at:

Stand-alone environments:http://www-01.ibm.com/support/knowledgecenter/SSEQTP_8.5.5/com.ibm.websphere.base.doc/ae/tsec_enable_custpass_encrypt.html

Clustered environments: http://www-01.ibm.com/support/knowledgecenter/SSAW57_8.5.5/com.ibm.websphere.nd.multiplatform.doc/ae/tsec_enable_custpass_encrypt.html

In stand-alone environments, administrative functions such as installing `WAR` files or adding trace settings can fail when you meet both of the following conditions:

- Your WebSphere Portal Express server uses the **`RSA_token`** value for security.
- You enable cryptographic offloading of SSL decryption and encryption through an implementation of PKCS11.

If your stand-alone environment meets both of the preceding conditions, complete the following steps:

1. Log in to the WebSphere Integrated Solutions Console.
2. Go to **Security** > **Global Security** > **Administrative security** > **Administrative authentication**
3. Select **Only use the active application authentication mechanism**.
4. Click **Apply** then **OK** and save the changes to the master configuration.
5. Log out of the WebSphere Integrated Solutions Console.
6. Restart the WebSphere_Portal server.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Enabling FIPS and (NIST) SP800-131a

IBM WebSphere Portal Express tolerates IBM WebSphere Application Server support of Federal Information Processing Standards (FIPS) and National Institute of Standards and Technology (NIST) SP800-131a. You can configure WebSphere Application Server to activate FIPS 140-2 compliant security modules. When you enable FIPS, you can use only FIPS to securely encrypt data. For this reason, you must also configure FIPS for systems that require secure transactions, which can include HTTP servers and LDAP servers.

Before you begin

You must install WebSphere Portal Express before enabling FIPS.

If your portal environment includes an HTTP server or LDAP server or any other components that use secure connections, consult the related links section to determine the level of support for FIPS 140-2 and SP800-131a. However, your environment does not need to include an HTTP server or LDAP server. You can enable FIPS on an out-of-box WebSphere Portal Express installation. Likewise, you do not have to enable FIPS for systems that do not require secure transactions. For example, if your LDAP server is accessed via the LDAP protocol, rather than the secure LDAPS protocol, you do not need to enable FIPS for that LDAP server.

About this task

The tasks involved in enabling FIPS are specific to Web servers and WebSphere Application Server and do not involve any configuration steps in WebSphere Portal Express. The WebSphere Application Server Information Center contains several topics with information and instructions for enabling FIPS for HTTP servers. Refer to these topics as appropriate to learn whether you should enable FIPS and, if necessary, what steps to perform.

HTTP servers

See Securing applications at the transport level for Web services in the WebSphere Application Server Information Center for instructions. Configure your HTTP server to support TLS with FIPS enabled. Refer to the appropriate documentation for instructions.

LDAP servers

Refer to the appropriate documentation to configure your LDAP over SSL and to enable FIPS.

Remember: Enable FIPS for your LDAP server only if it requires a secure connection. If you do not use an LDAP server or you do not connect to your LDAP server over a secure connection, you do not need to enable FIPS for an LDAP server.

Related concepts:

"Federal Information Processing Standards and and (NIST) SP800-131a" on page 1520

Federal Information Processing Standards (FIPS) and NIST SP800-131a are standards and guidelines issued by the United States National Institute of Standards and Technology (NIST) for federal government computer systems. FIPS and SP800-131a are developed when there are compelling federal government requirements for standards, such as for security and interoperability, but acceptable industry standards or solutions do not exist.

Configuring Session Security Integration

IBM WebSphere Application Server protects your session from access by other users.

About this task

To use Session Security Integration, you must enable it on both IBM WebSphere Portal Express and WebSphere Application Server functionality as well. WebSphere Application Server will preserve an available security context even if an unprotected URI is accessed.

Procedure

1. In the WebSphere Integrated Solutions Console, click **ServersServer TypesWebSphere Application Servers**.
2. Select **WebSphere Portal**.
3. Expand the **Web Container Settings**. Then click **Web Container**.
4. Click **Session Management**.
5. Select **Security Integration**.
6. Save your changes.

Enable WebSphere Portal Express to create Security context on the unprotected URI

7. Click **Security** > **Global Security**.
8. Expand **Web and SIP security**. Then click **General Settings**.
9. Select **Use available authentication data when an unprotected URI is accessed**.
10. Save your changes.

Enabling HTTP Basic Authentication for simple clients

IBM WebSphere Portal Express provides an HTTP Basic Authentication Trust Association Interceptor that can be enabled to allow specific clients to log into the portal by using HTTP Basic Authentication instead of HTTP Form Based Authentication.

"The HTTP Basic Authentication Trust Association Interceptor"
The HTTP Basic Authentication Trust Association Interceptor (TAI) can be used to authenticate incoming requests using the HTTP Basic Authentication Protocol described in RFC 2617. This can be useful for clients that are not capable of doing HTTP FORM based authentication.

"Configuring the HTTP Basic Authentication Trust Association Interceptor" on page 1611
To configure the HTTP Basic Authentication Trust Association Interceptor according to your requirements, you set its properties.

"Reference: Properties for the Trust Association Interceptor" on page 1611
The HTTP Basic Authentication Trust Association Interceptor has several configuration properties.

"HTTP Basic Authentication Trust Association Interceptor in combination with external authentication servers" on page 1614
When you use the HTTP Basic Authentication Trust Association Interceptor (TAI) with external authentication servers, you can configure the TAI to work for a specific set of requests.

The HTTP Basic Authentication Trust Association Interceptor

The HTTP Basic Authentication Trust Association Interceptor (TAI) can be used to authenticate incoming requests using the HTTP Basic Authentication Protocol described in RFC 2617. This can be useful for clients that are not capable of doing HTTP FORM based authentication.

In general, HTTP Basic Authentication has the following two main disadvantages compared to HTTP Form based authentication:

- With HTTP Basic Authentication, the Web client sends the user ID and password information used for authentication with each individual request to the IBM WebSphere Application Server. This typically requires using transport layer security (SSL) for the complete portal related network traffic. Otherwise the user password is exposed on the network. Compared to this, when you use HTTP form based authentication, it can be sufficient that you use the transport layer security to cover only the user login flow.
- With HTTP Basic authentication the Web client sends the user credentials with each request, therefore, users cannot log out from the portal except by completely closing the Web client. For example, if a user logs out of the portal and leave the browser open, another user might be able to access pages that the first user visited previously.

If the HTTP Basic Authentication TAI is enabled, it decides on every incoming request whether it is responsible for the authentication of that request or not. This decision is based on black and white lists for the requested URL and the client's user agent. The TAI is responsible only if none of the patterns in the black lists match and at least one of the patterns in one of the white lists match. Therefore, if the TAI is configured with empty white lists, it will never authenticate a request.

If the TAI decides to authenticate the request and that request contains an authorization header that contains a user ID and password, the TAI tries to log on

with that credential. If no user ID and password is provided, the TAI will challenge the client according to RFC 2617.

RFC 2617

Configuring the HTTP Basic Authentication Trust Association Interceptor

To configure the HTTP Basic Authentication Trust Association Interceptor according to your requirements, you set its properties.

About this task

Complete the following steps to set the properties of the HTTP Basic Authentication Trust Association Interceptor:

Procedure

1. Log on to the WebSphere Integrated Solutions Console.
2. Click **Security** > **Global security**.
3. Click **Web and SIP security** > **Trust association**.
4. Make sure that the **Enable trust association** check box is checked.
5. Click **OK** and then click **Save** if you checked the **Enable trust association** check box.
6. Click **Web and SIP security** > **Trust association** again.
7. Click **Interceptors** > **com.ibm.portal.auth.tai.HTTPBasicAuthTAI**.

   Tip: If `com.ibm.portal.auth.tai.HTTPBasicAuthTAI` is not available, run the following task to enable the interceptor: `enable-http-basic-auth-tai-sitemgmt`. See the related links section for instructions.
8. Click **Custom properties**.
9. Click the property you that want to change.
10. Change the value for the property according to your requirements.
11. Click **OK**.
12. Select other properties and change their values as required.
13. Click **OK**.
14. Save your changes.
15. Restart the WebSphere Application Server.

Reference: Properties for the Trust Association Interceptor

The HTTP Basic Authentication Trust Association Interceptor has several configuration properties.

You can configure the following properties for the HTTP Basic Authentication Trust Association Interceptor.

Notes:

1. The default value for each parameter is given in parentheses.
2. In the descriptions, **TAI** refers to the portal HTTP Basic Authentication Trust Association Interceptor.

enabled = (true)

Use this property to determine whether the TAI is active or not. Possible values are `true` and `false`. The default is `true`. If you set this property to `true`, the TAI authenticates requests. If you set this property to `false`, the TAI does not authenticate requests.

loginTarget = (Portal_LTPA)

Use this property to specify the alias of the JAAS login configuration that is used by the TAI. The default value is `Portal_LTPA`. By this default, the TAI uses the same JAAS login configuration as the one that is used by portal HTTP form based log in.

authenticationRealm = (WPS)

Use this property to specify the name of an authentication realm as defined in RFC 2617. The TAI challenges the client to authenticate against this realm. The default is `WPS`. By this default, the TAI uses the same authentication realm name as the one that is used by portal HTTP form based login.

userAgentBlackList = (AllAgentsAllowed)

Use this property to specify a list of patterns for which you do not want the TAI to handle the requests. Separate the patterns by whitespaces.

Every product name in the HTTP header field `User-Agent` of incoming requests is compared with each of the patterns specified for this parameter. If the TAI is enabled and the URL matches at least one of the patterns specified for the `userAgentBlackList` property, the TAI will not handle the request.

The default value is `AllAgentsAllowed`. This default value means that the user agent black list is not active.

You can specify the patterns with an asterisk (`*`) as a wild card character. You can also define the patterns as Java regular expressions. In this case set the property `useRegExp` to `true`.

urlBlackList = (/wps/myportal*)

Use this property to specify a list of patterns for which you do not want the TAI to handle the requests. Separate the patterns by whitespaces.

The full path information of the URL of the incoming request is compared with each of the patterns specified for this parameter. Before comparing the URL to the patterns, the protocol, server, port, and query information is removed from the URL. If the TAI is enabled and the URL matches at least one of the patterns specified for the `urlBlackList` property, the TAI will not handle the request. The default value is `/wps/myportal*`.

Use the following syntax rules for specifying the patterns:

- You can use URI encoded patterns. For example, if you want to use the blank character as part of a pattern, you can encode it as `%20` . It is then interpreted as part of the pattern and not as a pattern separator. Make sure that you use only characters that are valid within a URI, and encode all other characters.
- You can use an asterisk (`*`) as a wild card character.
- You can define the patterns as Java regular expressions. In this case set the property `useRegExp` to `true`.

userAgentWhiteList = (NoAgentSpecified)

Use this property to specify a list of patterns for which you want the TAI to handle the requests. Separate the patterns by whitespaces. Every

product name in the HTTP header field User-Agent of the incoming request is compared with each of the patterns specified for this parameter.

If the TAI is enabled and the pattern specified for this property has at least one match and neither of the userAgentBlackList or the urlBlackList have a match, then the TAI handles the request.

The default is NoAgentSpecified. This default value means that the user agent white list is not active.

You can specify the patterns with an asterisk (*) as a wild card character. You can also define the patterns as Java regular expressions. In this case set the property useRegExp to true.

urlWhiteList = (/wps/mycontenthander*)

Use this property to specify a list of patterns for which you want the TAI to handle the requests. Separate the patterns by whitespaces. The full path information of the URL of the incoming request is compared with each of the patterns specified for this parameter. Before comparing the URL to the patterns, the protocol, server, port, and query information is removed from the URL.

If the TAI is enabled and the pattern specified for this property has at least one match and neither of the userAgentBlackList or the urlBlackList have a match, then the TAI handles the request.

The default value is /wps/mycontenthander*.

Use the following syntax rules for specifying the patterns:

- You can use URI encoded patterns. For example, if you want to use the blank character as part of a pattern, you can encode it as %20 . It is then interpreted as part of the pattern and not as a pattern separator. Make sure that you use only characters that are valid within a URI, and encode all other characters.
- You can use an asterisk (*) as a wild card character.
- You can define the patterns as Java regular expressions. In this case set the property useRegExp to true.

Note: Values that you specify for the userAgentWhiteList or urlWhiteList properties come into effect only if all of the following conditions apply:

- The TAI is enabled by specifying enabled = true.
- Neither of the properties userAgentBlackList or urlBlackList has the default value asterisk specified. To enable the values specified for the white list properties, you can remove the asterisk from the black list properties and leave them without a specified value.

useRegExp = (false)

Use this property to determine whether or not the patterns that you specified for the black list and white list the previous properties are to be interpreted as Java regular expressions. Possible values are true or false. The default value is false. The values have the following meanings and syntax rules:

true If you set the value for this property to true, all the patterns in the black and white lists are interpreted as Java regular expressions (RegExp). For more information about Java regular expressions syntax and usage refer to http://docs.oracle.com/javase/tutorial/essential/regex/. Examples:

- `[^X]*` will match every user agent that does not contain an uppercase `X` in its product name.
- `.*my_browser.*` will match every user agent that contains `my_browser` in its product name.
- `.*%5bX%5d` is URL encoded for `.*[X]` and will match every URL that ends with `X`.

false This is the default. If the value for this property is set to `false`, all patterns support only the asterisk (*) as a wildcard character that matches against any string. The asterisk (*) wildcard can appear anywhere in the pattern. You can use multiple asterisk (*) wildcards within the same pattern.

If you want to represent an asterisk as an actual character for matches in the pattern instead of using it as a wildcard, prefix it with a backslash like this: `\*` . To represent the backslash as a character for matching, code it by using a double backslash: `\\` .

Examples:

- `*my_browser*` will match every user agent that contains `my_browser` in its product name.
- `/myprefix*mysuffix` will match every URL that starts with `/myprefix` and ends with `mysuffix`.
- `Fun\* Ag\\ent` will only match a user agent hat has `Fun* Ag\ent` as product name.

HTTP Basic Authentication Trust Association Interceptor in combination with external authentication servers

When you use the HTTP Basic Authentication Trust Association Interceptor (TAI) with external authentication servers, you can configure the TAI to work for a specific set of requests.

IBM WebSphere Application Server can have multiple TAIs registered for authentication handling. This way you can use the HTTP Basic Authentication TAI together with other TAIs, for example, the WebSEAL TAI. However, you cannot configure an invocation sequence for the TAIs that you installed. You must ensure that the TAIs handle disjoint sets of requests. The HTTP Basic Authentication TAI is configured this way by default. For an alternative HTTP Basic Authentication TAI, you can configure the TAI properties for URL pattern filtering by black and white lists. Conflicts can arise if the security server relies on Basic Authentication or if other non-standard configurations are wanted.

Normal configuration of an external authentication server protects the HTML-based entry points into the portal, for example, /wps/myportal. When the authentication server handles the initial request, shared tokens known to the authentication server are exchanged and used for subsequent requests through the authentication server. Similarly, when the request makes it to the Portal Java virtual machine, the TAIs handle the initial authentication trust request. Then, they generate an LtpaToken or LtpaToken2 shared token for subsequent requests, including REST or XML-based requests.

Setting up custom user repositories

A custom user repository is any repository that WebSphere Portal Express does not support out-of-box. However, you can configure WebSphere Portal Express to support any type of repository in a federated or stand-alone user registry, whether an LDAP directory, database, file system, and so on. Setting up custom user repositories involves tasks such as defining additional repositories to the default federated user registry, creating a custom stand-alone user repository, and updating your user repository to reflect changes in your environment. Learn what steps are required to create and update custom user repositories and what specific interfaces you must implement to enable communication between WebSphere Portal Express and a repository.

About this task

A user registry is an implementation of the `UserRegistry` interface in WebSphere Application Server. The following user registries are available out-of-box:

Federated Repositories

An implementation of the `UserRegistry` interface that supports multiple repositories. To communicate with the federated repositories, both WebSphere Application Server and WebSphere Portal Express dispatch all operations to VMM.

WebSphere Portal Express accesses all user repositories through VMM. WebSphere Portal Express uses the Portal User Management Architecture (PUMA) System Programming Interface (SPI) to retrieve and set attributes on user objects. PUMA passes these requests to VMM, which then passes the requests on to a corresponding registry adapter that connects VMM to the repository. For this reason, registry adapters are required to enable communication between WebSphere Portal Express and any repository.

Important: You must create a user registry adapter if you plan to use a custom user repository. To create a user registry adapter, implement the `com.ibm.wsspi.wim.Repository` interface. Refer to the following topics in the WebSphere Application Server documentation for information and instructions:

Repository SPI (System programming interfaces for virtual member manager adapters)

Sample custom adapters for federated repositories examples

"Creating and updating federated repositories" on page 1616
You can define additional repositories as required for the out-of-box federated repositories user registry. For example, you can define one or more databases and/or LDAP directories for the user registry. Federated repositories also let you implement multiple realms. Realms define subsets of users and are spread across multiple repositories. For example, you can define one realm in a file-based repository and another realm in an LDAP directory. Because WebSphere Application Server provides an implementation of the `UserRegistry` interface for federated repositories out-of-box, you do not need to create a custom implementation of this interface.

Related concepts:

"Virtual Member Manager integration" on page 132
IBM WebSphere Application Server includes the Virtual Member Manager (VMM), which IBM WebSphere Portal Express uses to access user and group information. VMM provides an interface that enables communication between WebSphere Portal Express and any repository, whether federated repositories or your own custom user registry.

Setting up a custom user repository with Virtual Member Manager for IBM WebSphere Application Server and IBM WebSphere Portal

IBM WebSphere Developer Technical Journal: Expand your user registry options with a federated repository in WebSphere Application Server, Using the Virtual Member Manager

Creating and updating federated repositories

You can define additional repositories as required for the out-of-box federated repositories user registry. For example, you can define one or more databases and/or LDAP directories for the user registry. Federated repositories also let you implement multiple realms. Realms define subsets of users and are spread across multiple repositories. For example, you can define one realm in a file-based repository and another realm in an LDAP directory. Because WebSphere Application Server provides an implementation of the `UserRegistry` interface for federated repositories out-of-box, you do not need to create a custom implementation of this interface.

"Creating and configuring federated repositories"
Add your custom repository to the default federated repositories. You must implement a custom registry adapter so that WebSphere Portal Express can access the repository. After you implement your custom registry adapter, you must define several parameters for your environment and run a task to add your repository to the federated repositories.

"Updating federated repositories" on page 1618
You can update the environment parameters you defined when you created the federated repository. You should run the task to update your custom repository if you any environment settings have changed such as the base DN. You can also run the update task if you want to change any settings you specified when you created the repository. For example, run the update task if you want to change support for paging, sorting, and transactions.

Creating and configuring federated repositories

Add your custom repository to the default federated repositories. You must implement a custom registry adapter so that WebSphere Portal Express can access the repository. After you implement your custom registry adapter, you must define several parameters for your environment and run a task to add your repository to the federated repositories.

Before you begin

You must create a custom user registry adapter before you create your repository. To create the user registry adapter, implement the `wim.Repository` interface. Refer to the WebSphere Application Server documentation for information and instructions.

About this task

Procedure

1. Perform the following steps to create a federated repository:
   a. Open `wkplc.properties` with any text editor from the following directory:
      Windows: *wp_profile_root*`\ConfigEngine\properties`
      Linux: *wp_profile_root*`/ConfigEngine/properties`
      IBM i: *wp_profile_root*`/ConfigEngine/properties`
   b. Specify values for the following parameters under the **VMM Federated CUR Properties** heading:
      federated.cur.id
      federated.cur.adapterClassName
      federated.cur.baseDN
      federated.cur.isExtIdUnique
      federated.cur.supportExternalName
      federated.cur.supportPaging
      federated.cur.supportSorting
      federated.cur.supportTransactions
   c. Save and close `wkplc.properties`.
   d. Run the following task from the *wp_profile_root*`/ConfigEngine` directory:
      Windows: `ConfigEngine.bat wp-create-cur -DWasPassword=`*password*
      Linux: `./ConfigEngine.sh wp-create-cur -DWasPassword=`*password*
      IBM i: `ConfigEngine.sh wp-create-cur -DWasPassword=`*password*
   e. Restart the WebSphere_Portal server.
2. Perform the following steps to create custom properties for your federated repository:
   a. Open `wkplc.properties` with any text editor from the following directory:
      Windows: *wp_profile_root*`\ConfigEngine\properties`
      Linux: *wp_profile_root*`/ConfigEngine/properties`
      IBM i: *wp_profile_root*`/ConfigEngine/properties`
   b. Specify values for the following parameters under the **VMM Federated CUR Properties** heading in `wkplc.properties`:
      cur.id
      cur.name
      cur.value
   c. Save and close `wkplc.properties`.
   d. Run the following task from the *wp_profile_root*`/ConfigEngine` directory:
      Windows: `ConfigEngine.bat wp-create-cur-custom-property -DWasPassword=`*password*
      Linux: `./ConfigEngine.sh wp-create-cur-custom-property -DWasPassword=`*password*
      IBM i: `ConfigEngine.sh wp-create-cur-custom-property -DWasPassword=`*password*
   e. Restart the WebSphere_Portal server.

Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

External security managers

Use external security managers such as IBM Security Access Manager to perform authentication and authorization for IBM WebSphere Portal Express. You can use an external security manager for authentication only or for both authentication and authorization. Using an external security manager to perform only authorization is not supported at this time.

Perform the following tasks to configure external security managers:

"Planning for external security managers" on page 1620
By default, IBM WebSphere Application Server controls authentication to IBM WebSphere Portal Express and WebSphere Portal Express controls authorization (access control) to resources.

"Enabling and configuring single sign-on for HTTP requests using SPNEGO" on page 1625
You can create single sign-on requests for your HTTP server using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) available in IBM WebSphere Application Server. Creating single sign-on requests using SPNEGO allows HTTP users to log in and authenticate only once and receive automatic authentication from WebSphere Application Server.

"Security Access Manager" on page 1626
IBM WebSphere Portal Express supports the use of IBM Security Access Manager. Existing Security Access Manager users can use the Security Access Manager services to assist them in their deployment.

"Configuring eTrust SiteMinder" on page 1657
IBM WebSphere Portal Express supports the use of Computer Associates eTrust SiteMinder for authentication and authorization.

"Verifying Trust Association Interceptors for authentication" on page 1666
After configuring IBM WebSphere Portal Express to use an external security manager for authentication, you should verify that the Trust Association Interceptors (TAI) are working properly before continuing with any additional configuration tasks.

"Changing the login and logout pages" on page 1666
By default, when unauthenticated users attempt to access the `myportal` page, they get redirected to the login page to provide a user name and password. When using a WebSEAL or Computer Associates eTrust SiteMinder TAI for authentication, you no longer need to use the IBM WebSphere Portal Express login page. Instead, the login icon should point to the protected portal page.

"Managing access control with external security managers" on page 1668
IBM WebSphere Portal Express externalizes roles and uses access control to control role membership. From the perspective of the external security manager, these externalized roles contain only one permission: membership in the role. WebSphere Portal Express always determines the permissions associated with each role.

Planning for external security managers

By default, IBM WebSphere Application Server controls authentication to IBM WebSphere Portal Express and WebSphere Portal Express controls authorization (access control) to resources.

Note: When setting up security to use an external security manager in a cluster environment and across mixed nodes, there are additional considerations. For example, you should configure your external security manager after completing all other setup tasks, including ensuring that the cluster is functional.

"WebSphere Trust Association Interceptors"
Security Access Manager and Computer Associates eTrust SiteMinder provide Trust Association Interceptors (TAIs) that are used only as an authentication service.

"External authorization" on page 1621
WebSphere Portal Express always determines the permissions that are associated with each role, whether the role is externalized or not.

"Planning considerations for WebSEAL junctions" on page 1622
A junction acts as a single point of access into a web application network.

"Security Access Manager Permissions" on page 1625
In many installations, WebSEAL is behind Portal between the portlets and the back-end servers they access.

"WebSphere Portal Express Support Statement" on page 103
This support statement proposes a revision to the definition of "supported" and "unsupported" about the various products of which IBM WebSphere Portal Express depends on for proper operation.

WebSphere Trust Association Interceptors

Security Access Manager and Computer Associates eTrust SiteMinder provide Trust Association Interceptors (TAIs) that are used only as an authentication service.

External authentication

TAIs can be configured with the Portal configuration tasks. The Security Access Manager TAI requires an available Security Access Manager authorization server for successful single sign-on. For information about using TAI with WebSphere Application Server, see the related links section.

Whenever a request attempts to access a secured resource, WebSphere Application Server starts the TAI. The TAI validates that the request comes from a legitimate third-party authentication proxy and returns the user's authenticated identity to WebSphere Application Server. The TAI returns either a distinguished name (DN) or a short name. WebSphere Application Server performs a registry lookup to verify the distinguished name or convert the short name to a distinguished name before searching for group memberships for that user. If the registry lookup fails, WebSphere Application Server refuses to trust the user. If the registry lookup succeeds, WebSphere Application Server generates a Lightweight Third-Party Authentication (LTPA) token for the user. It stores it as a cookie for subsequent authentication during the user's session.

A TAI is not necessary if the third-party authentication proxy provides native WebSphere Application Server identity tokens, such as LTPA tokens. Currently, only Security Access Manager WebSEAL and Security Access Manager plug-in for Edge Server provide native WebSphere Application Server identity tokens. Consult

the WebSEAL Administration Guide for more information about configuring Security Access Manager to provide LTPA tokens. The authentication proxy determines the challenge mechanism.WebSphere Portal Express relies on the authentication proxy to relay success or failure of the user identifier through the TAI or LTPA token. WebSphere Application Server sees all requests from the TAI as authenticated, but WebSphere Application Server and WebSphere Portal Express performs a look up on each user anyway. Depending on the TAI and system configuration, WebSphere Application Server and WebSphere Portal Express can be configured to look up the group also. Even if the authentication proxy has successfully authenticated, WebSphere Application Server and WebSphere Portal Express deny access if they cannot query the user in the registry. For example, a user in an External Security Manager is not accessible from WebSphere Portal Express because it is configured to a different registry. Or that registry does not have the same registry configuration properties as the External Security Manager.

Custom TAIs

TAIs that allow other custom authentication services to interact with WebSphere Application Server can be written. If you use a different security configuration, you must provide and implement a TAI to communicate with the authentication proxy.

Extended Tivoli Access Manager Trust Association Interceptor Plus (ETAI)

External authorization

WebSphere Portal Express always determines the permissions that are associated with each role, whether the role is externalized or not.

Roles are always associated with a specific resource. Resources can be moved back and forth from internal to external control with the Resource Permissions portlet. Explicit role assignments are preserved when moving in both directions. However, inherited role memberships are blocked for externalized resources. When you externalize access control for a resource, the resource is administered only through the external security manager interface. After externalizing the resource, role membership must be assigned and removed using the external security manager. The Resource Permissions portlet can no longer control user access to the resource; however, the Resource Permissions portlet can move the object back to internal control.

Note the following issues:

- Private pages cannot be externalized.
- When you use the Resource Permissions portlet to externalize or internalize access control for a resource, access control for all of its public child resources moves with it. When you use the XML configuration interface (xmlaccess) to externalize or internalize access control for a resource, access control for public child resources does not change.
- After you externalize access control for a resource, you must use the external security manager to assign users to roles on the resource.

- After access control for a resource is externalized, you can use either the Resource Permissions portlet or the XML configuration interface to create additional role types on the resource. For example, suppose that you create only the Administrator and Manager role types on the Market News Page. Then you externalize access control for the Market News Page. You must use the external security manager to assign users to the Administrator@Market News Page or Manager@Market News Page roles. If you decide that you want to assign users to the Editor@Market News Page role, which is not yet externalized, follow these steps:
  1. Use the Resource Permissions portlet to create the Editor role type for the Market News Page.
  2. Use the external security manager to assign users to the Editor@Market News Page role by editing the ACL.

  Remember that WebSphere Portal Express still determines the permissions that are associated with the externalized Editor role type.
- If a user inherits access to a resource from a parent resource, the user loses the inherited access when the resource is externalized. If the user needs access to that resource, you must assign access through the external security manager.
- The user, who externalizes the resource, automatically receives the Administrator role on the parent resource of the externalized resource tree (if using the Resource Permissions portlet) or the resource (if using the XML configuration interface).

The decision to use an external security manager must be made with the understanding that the external security manager software's ACL semantics override WebSphere Portal Express semantics. For example, if you use Security Access Manager to grant anonymous membership on a role for an externally controlled portlet, you must set the ACL for that portlet to include the Security Access Manager unauthenticated user group.

Note: If you use Security Access Manager for authorization, you must also use it for authentication. Using Security Access Manager to perform only authorization is not supported.

Planning considerations for WebSEAL junctions

A junction acts as a single point of access into a web application network.

A junction is an HTTP or HTTPS connection between a front-end WebSEAL server and a back-end web application server. WebSEAL does authentication checks on all requests for resources before it passes those requests across a junction to the back-end server.

Starting with WebSphere Portal Express version 8.0, the supported junction types between the front-end WebSEAL server and a back-end WebSphere Portal Express server are:

- Virtual host junctions - this junction type is generally supported for all use cases.
- Transparent junctions - support for Transparent junctions with WebSphere Portal Express is limited to a simple use case. For example, one WebSphere Portal Express logical instance that uses the default `/wps` context root. The logical instance might be one server or cluster or set of related farm nodes that run a single logical instance of a Portal website, which might include virtual portals. Anything more complex than this simple use case requires the use of Virtual host junctions.

Prior releases supported the use of traditional non-transparent WebSEAL junctions, but this configuration is no longer supported by WebSphere Portal Express 8.0 and later. With the proliferation of WebSphere Portal Express URLs, the virtual host junction is now the most efficient way to make a WebSphere Portal Express server work behind a WebSEAL proxy. All discussions around encryption, Trust Association Interceptor (TAI) versus LTPA and other setup options continue to be applicable. The difference is the overall junction type, which determines how the junction is visible to the users.

A traditional non-transparent junction has a token in the URL that corresponds to the junction in WebSEAL. For example, the URL might be `http://webseal.hostname.yourco.com/junction1/wps/myportal`. A transparent junction uses an existing token in the URL to identify the junction; for example, it uses the `/wps` token in `/wps/myportal`. The problem with both of these methods is that WebSphere Portal Express has many URLs and not all of them start with `/wps`. They are also difficult to configure to use a consistent prefix.

Virtual host junctions use a virtual host name to identify the junction. To identify the junction, the host name might be `junction1.webseal.hostname.yourco.com`. This junction is only an example; you can use any host name that fits within your domain. The junction is then defined in WebSEAL to use the incoming host name, instead of a URL token, to identify the junction and the corresponding back-end servers.

In the configuration that is described here, the WebSEAL component of Security Access Manager handles the user authentication. A Trust Association Interceptor (TAI) is used by WebSphere Application Server and WebSphere Portal Express to accept the identity of the user as asserted by WebSEAL.

To properly secure the WebSphere Application Server and WebSphere Portal Express system against an attack, the TAI must still authenticate the WebSEAL server. So that only requests that are legitimately presented through that WebSEAL server are accepted. There are different ways to configure this authentication between WebSEAL and the TAI in WebSphere Application Server. You can choose between the different ways to configure depending on how much effort and performance you want to put into securing your network. The decisions that you make determines how you set up the junctions between the WebSEAL server and WebSphere Portal Express.

Note: By default, the XML configuration interface cannot access WebSphere Portal Express through a WebSEAL junction. To enable the XML configuration interface to access WebSphere Portal Express through a WebSEAL junction, use Security Access Manager to define the configuration URL (`/wps/config`) within the junction as unprotected. Use the WebSEAL documentation for specific instructions about defining separate URLs within the junction and assigning separate ACLs to these URLs. After the configuration URL is defined as unprotected, only WebSphere Portal Express enforces access control to this URL. Other resources that are protected within the WebSEAL junction (for example, the `wps/myportal` URL) are still protected by WebSEAL.

Nonencrypted junction using Basic Authentication

The identity of the user must be passed to the TAI in a header that is called `iv-user`. The header is inserted by WebSEAL into the request that is sent from WebSEAL to the WebSphere Application Server and the WebSphere Portal Express servers. The junction creation option to pass the user identity is `-c iv-user`. While

WebSEAL can be configured to pass the user identity in other ways, the `iv-user` header is the only one that is supported by the TAI.

Advanced junction configurations

For more details and options about how to configure junctions between WebSEAL with WebSphere Application Server and WebSphere Portal Express, including other options for specifying the WebSEAL server identity, use the WebSEAL Administration Guide and to the documentation for the HTTP Server that you are using with WebSphere Application Server.

The junctions between WebSEAL and WebSphere Application Server and WebSphere Portal Express can be configured to be encrypted or not. Encrypted junctions enhance security by making sure that no one can eavesdrop on information that is flowing between WebSEAL, WebSphere Application Server, and WebSphere Portal Express. However, encrypted junctions require more administration to move the necessary signing certificates between the systems, and also have a performance cost. If you are not comfortable that your network between the firewalls is secure against unauthorized access and observation, you must use encrypted junctions between WebSEAL and WebSphere Application Server/WebSphere Portal Express. If you are comfortable that your network is secure against unauthorized access and observation, especially for traffic across an inner firewall, you can use unencrypted junctions between WebSEAL and WebSphere Application Server/WebSphere Portal Express.

Setting up the WebSEAL -WebSphere Application Server/WebSphere Portal Express junction over SSL requires that you configure WebSphere Application Server and the HTTP server that is used by WebSphere Application Server to accept inbound SSL traffic and route this traffic correctly to WebSphere Application Server and WebSphere Portal Express. This process includes importing the necessary signing certificates into at least the WebSEAL certificate keystore, and possibly also the HTTP server certificate keystore.

If you choose to use encrypted junctions between WebSEAL and WebSphere Application Server and WebSphere Portal Express, you can also choose to have WebSEAL identify and authenticate itself to WebSphere Application Server and the TAI by using its own client-side certificate. In this case, you can configure the TAI to not further validate the WebSEAL server, relying on the mutual SSL connection to supply a trustable identity for the WebSEAL server.

If you choose not to use client-side certificates to identify the WebSEAL server, or if you choose not to use an SSL junction, you can identify the WebSEAL server to the TAI by using a Basic Authentication (BA) header. In this case, a password is placed into the BA header, and also configured into the TAI. This action represents a "shared secret" that only the TAI and the WebSEAL server know, which allows the TAI to trust that it really is the WebSEAL server that is asserting the user's identity, and the TAI can trust it. In this case, using an SSL junction provides more security by protecting this BA header from observation, but the TAI still relies on the BA header for identifying the WebSEAL server.

To set up the junction to use the Basic Authentication header to identify the WebSEAL server, use the `-b supply` option on the junction creation command. This option causes WebSEAL to build the BA header by using the user's user ID (which is ignored by the TAI, in favor of the `iv-user` header) and the password that is configured into WebSEAL from the `webseald-`*`instance`*`.conf` file, on the `basicauth-dummy-passwd` property. The password in the `webseald-`*`instance`*`.conf`

file must match the password for the ID that is specified on the `com.ibm.websphere.security.webseal.loginid` property of the TAI startup parameters in the WebSphere Integrated Solutions Console. For example, if you specify `com.ibm.websphere.security.webseal.loginid=mistered` on the TAI startup parameters, and the password for `mistered` is `wilbur`, then you must specify `wilbur` on the `basicauth-dummy-passwd` property in `webseald-`*`instance`*`.conf` on the WebSEAL server.

Security Access Manager Permissions

In many installations, WebSEAL is behind Portal between the portlets and the back-end servers they access.

Portlets accessing back-end services through an external security manager

Portlets require some method of getting through the ESM to the back-end, and that the portlets can use the Portal credential vault. The portlets are themselves designed to reuse existing security tokens from the Portal security context.

Enabling and configuring single sign-on for HTTP requests using SPNEGO

You can create single sign-on requests for your HTTP server using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) available in IBM WebSphere Application Server. Creating single sign-on requests using SPNEGO allows HTTP users to log in and authenticate only once and receive automatic authentication from WebSphere Application Server.

About this task

To enable SPNEGO Web authentication, complete the steps in the following topic, available in the WebSphere Application Server documentation, *Enabling and configuring SPNEGO Web authentication using the administrative console*.

For more information about SPNEGO Web authentication, go to the related topics in the WebSphere Application Server documentation.

"Re-enabling the SPNEGO TAI" on page 1626
The IBM WebSphere Portal Express installation removes the Simple and Protected GSS-API Negotiation Mechanism trust association interceptor (SPNEGO TAI) from the list of available trust association interceptors. For this reason, you need to re-enable the SPNEGO TAI. You do not need to complete this task if you plan to use SPNEGO Web authentication.

Related information:

WebSphere Application Server Information Center: Configure and enable SPNEGO web authentication using the administrative console on your WebSphere Application Server machine

WebSphere Application Server Information Center: Single sign-on for HTTP requests using SPNEGO web authentication

WebSphere Application Server Information Center:Creating a single sign-on for HTTP requests using the SPNEGO TAI (deprecated)

Re-enabling the SPNEGO TAI

The IBM WebSphere Portal Express installation removes the Simple and Protected GSS-API Negotiation Mechanism trust association interceptor (SPNEGO TAI) from the list of available trust association interceptors. For this reason, you need to re-enable the SPNEGO TAI. You do not need to complete this task if you plan to use SPNEGO Web authentication.

Procedure

1. Log on to the WebSphere Integrated Solutions Console.
2. Click **Security** > **Global security**.
3. Click **Trust association** under **Web and SIP security**.
4. Ensure that the **Enable trust association** check box is checked and then click **Interceptors**.
5. Click **New** and then type `com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl` in the **Interceptor class name** text field.
6. Click **OK** and then click the **Save** link to save changes to the master configuration.

Security Access Manager

IBM WebSphere Portal Express supports the use of IBM Security Access Manager. Existing Security Access Manager users can use the Security Access Manager services to assist them in their deployment.

About this task

You can use the following services:

- WebSEAL Single Signon (SSO) for authentication
- Protected Object Space and Access Control List Management for authorization
- Global Sign-on (GSO) lockbox credential vault integration
- Automatic user provisioning from WebSphere Portal Express self-registration to Security Access Manager

Perform the following tasks to configure Security Access Manager:

"Configuring Security Access Manager" on page 1627
WebSphere Portal Express can be integrated with IBM Security Access Manager to provide authentication services, authorization, and to link WebSphere Portal Express's credential vault to the ISAM GSO Lockbox feature.

"Enabling user provisioning" on page 1653
When users are created in WebSphere Portal Express, they are not automatically imported into Security Access Manager. Enabling automatic user provisioning to Security Access Manager changes this behavior. After this feature is enabled, users are automatically imported into Security Access Manager whenever they are created in WebSphere Portal Express. When user provisioning is enabled, anyone with access to the public URL can become an active user in Security Access Manager if the self-registration feature remains enabled.

"Verifying external authorization to Security Access Manager" on page 1655
After configuring IBM WebSphere Portal Express to use Security Access Manager for externalized authorization, you should verify that it works properly before continuing with any additional configuration tasks.

"Removing the Credential Vault adapter" on page 1656
If you no longer require the use of the credential vault adapter that you created, you can remove it from your configuration.

"Disabling user provisioning" on page 1657
After you enable and use the user provisioning feature within IBM Security Access Manager, you can disable the feature.

Configuring Security Access Manager

WebSphere Portal Express can be integrated with IBM Security Access Manager to provide authentication services, authorization, and to link WebSphere Portal Express's credential vault to the ISAM GSO Lockbox feature.

About this task

Authentication, Authorization and Credential Vault features can be configured in the following combinations:

- Authentication can be configured either with or without the other features
- Credential Vault integration can be configured either with or without the other features
- Authorization cannot be configured without configuring Authentication.

As part of the Authentication integration, you can also configure WebSphere Portal Express user provisioning to fully activate the created users as Security Access Manager users. By default, users that are created in LDAP by WebSphere Portal Express are not Security Access Manager users. This configuration is necessary only if you do not have an enterprise Identity Management system and provisioning process that is integrated with IBM Security Access Manager, and are using WebSphere Portal Express as your user creation tool.

Important information about authentication: To integrate WebSphere Portal Express and IBM Security Access Manager for authentication, you must create one or more junctions in WebSEAL that points to WebSphere Portal Express. Starting with WebSphere Portal Express Version 8.0, the type of junction that is supported depends on your specific use case:

Table 230. Use cases for junction type

Use case	Supported junction type
Simple use case A single, logical WebSphere Portal Express instance behind the WebSEAL layer, by using the default `/wps` context root. The WebSphere Portal Express instance can be one of the following deployments: • A stand-alone server • A single cluster • A common set of Portal instances in a farm	Either a transparent junction or a virtual host junction can be used. The junctions can be either TCP or SSL. They can use a TAI in WebSphere, or generate LTPA tokens in WebSEAL for identity assertion. Not all WebSphere Portal Express URLs start with `/wps`. Therefore, if you use transparent junctions, you must configure multiple transparent junctions to get all requests passed back to WebSphere Portal Express from WebSEAL. To avoid this complication, use a single virtual host junction. **Tip:** If you plan to change the WebSphere Portal Express context root, use virtual host junctions.

Table 230. Use cases for junction type (continued)

Use case	Supported junction type
Other use cases Anything other than a simple use case.	The supported junction type for the general case is virtual host junctions. The virtual host junctions can be either TCP or SSL. They can use a TAI in WebSphere, or generate LTPA tokens in WebSEAL for identity assertion.

Integrating WebSEAL and WebSphere Portal by using virtual portals:

Virtual Portals can be defined and identified in an incoming request by using either a token in the URL, or a virtual host name. If the URL token is used, it comes immediately after the servlet mapping of the URL, for example the `portal` or `myportal` token. If a virtual host name is used, then the host name for a request that targets the virtual portal has a different host name than requests to other virtual portals or the base portal.

When WebSphere Portal Express , using the virtual hostname-defined virtual portals, is integrated behind WebSEAL as a proxy, the configuration is to have one virtual host junction in WebSEAL, per virtual portal in WebSphere Portal Express (one to one in both directions). In addition, the virtual host junction host name in WebSEAL must be identical to the corresponding virtual portal host name on WebSphere Portal. The virtual host junction itself can be defined by using either the virtual portal host name identical to the virtual host junction host name, or the real portal or HTTP server host name, as the backend server host (the value of the **-h** parameter on the junction definition). It is better to use the virtual portal host name because some operations (such as redirect calculations) depend on the value of the HOST header, and the **-h** parameter on the junction definition causes WebSEAL to set the HOST header to this value. If the virtual portal host name is used, then either a secondary, internal DNS resolution, or manipulation of the hosts file, must be used by WebSEAL to resolve that host name to the IP address of the HTTP Server or Portal host.

Choose the appropriate tasks to configure IBM Security Access Manager:

"Security Access Manager prerequisites" on page 1629
Complete the prerequisite tasks before you configure IBM Security Access Manager.

"Creating the `PdPerm.properties` file" on page 1629
The `PdPerm.properties` file configures the Access Manager Java Run Time Environment (AMJRTE). You must create the `PdPerm.properties` file before you configure IBM Security Access Manager for authentication, authorization, Credential Vault, or user provisioning. Run the **`run-svrssl-config`** task to create the files. This task also creates the keystore file that is used to encrypt communication with Security Access Manager.

"Configuring Security Access Manager for authentication only" on page 1631
IBM WebSphere Portal Express and IBM WebSphere Application Server support the Trust Association Interceptors (TAI) that IBM Security Access Manager provides. If you use Security Access Manager for authorization, you must also use Security Access Manager for authentication. Using Security Access Manager only for authorization is not supported.

"Configuring Security Access Manager for authorization" on page 1637
You can configure IBM Security Access Manager for both authentication and authorization for IBM WebSphere Portal Express. If you configure these

functions at different times as independent tasks, configure Security Access Manager for authentication first. Using Security Access Manager only for authorization is not supported.

"Configuring the Credential Vault adapter for Security Access Manager" on page 1642
You can use IBM Security Access Manager in the IBM WebSphere Portal Express Credential Vault service. WebSphere Portal Express includes a vault adapter to access the Security Access Manager Global Sign-on (GSO) lockbox. Any existing Tivoli resource or resource credentials can be used in your portlets that access the credential vault service without any additional configuration. In addition, the credential vault service and credential vault management portlet can create or update an existing GSO lockbox entry.

"Configuring Security Access Manager for authentication, authorization, and the Credential Vault" on page 1644
You can configure Security Access Manager for authentication, authorization, and the vault adapter with one task.

"Removing Security Access Manager" on page 1652
After you install and use IBM Security Access Manager, you might find that you no longer require its use. You can then remove it from the IBM WebSphere Portal Express environment and restore authentication capabilities to IBM WebSphere Application Server and authorization capabilities to WebSphere Portal Express.

Security Access Manager prerequisites:

Complete the prerequisite tasks before you configure IBM Security Access Manager.

Complete the following task before you configure Security Access Manager:

1. Install IBM WebSphere Portal Express.
2. Run the appropriate configuration wizard option to configure WebSphere Portal Express. The stand-alone server and production server options include a database transfer and LDAP server configuration.
3. Install and configure Security Access Manager.
4. Configure the WebSEAL security proxy. Refer to the WebSEAL installation guide for information.

Tip: IBM WebSphere Application Server ships a PD.jar file that WebSphere Portal Express uses to configure Security Access Manager. The file is in the *AppServer_root*/tivoli/tam directory. WebSphere Application Server maintenance packages contain fixes for the PD.jar file. However, the Security Access Manager typically contains a newer version of the PD.jar file. Therefore, if you have access to the Security Access Manager server, use that version. After you apply the WebSphere Application Server maintenance, create a backup of the PD.jar file. Then, replace the original file with a copy of the newer version from the Security Access Manager server.

Creating the `PdPerm.properties` file:

The `PdPerm.properties` file configures the Access Manager Java Run Time Environment (AMJRTE). You must create the `PdPerm.properties` file before you configure IBM Security Access Manager for authentication, authorization, Credential Vault, or user provisioning. Run the **`run-svrssl-config`** task to create

the files. This task also creates the keystore file that is used to encrypt communication with Security Access Manager.

About this task

Cluster note: Complete these steps on every node in the cluster.

Procedure

1. Use a text editor to open the `wkplc_comp.properties` file in the *wp_profile_root*`/ConfigEngine/properties` directory.
2. Enter the following parameters in the `wkplc_comp.properties` file; go to the AMJRTE connection parameters heading:

   Cluster note: Complete this step on all nodes in the cluster. The following parameters must match on all nodes in the clustered environment. The one exception is the **wp.ac.impl.PDServerName** parameter.

   a. For **wp.ac.impl.PDAdminId**, type the user ID for the administrative Security Access Manager user.
   b. For **wp.ac.impl.PDPermPath**, type the fully qualified path and file name where the `PdPerm.properties` file is created.
   c. For **wp.ac.impl.PDServerName**, type the unique application name that is used to create a server in the Security Access Manager Policy server. The application name is an arbitrary name but must be unique for this server instance. You might want to use the node name for this WebSphere Portal Express server instance.

      Cluster note: The **wp.ac.impl.PDServerName** parameter represents an individually configured AMJRTE connection to Security Access Manager. Therefore, each node in the cluster must specify a unique value for the **wp.ac.impl.PDServerName** parameter before you run the **run-svrssl-config** task. If the cluster has four nodes, set this parameter differently on each node; for example, `amwp81`, `amwp82`, `amwp83`, and `amwp84`.
   d. For **wp.ac.impl.SvrSslCfgPort**, type the configuration port for the application name. The property is ignored by the SvrSslCfgPort.
   e. For **wp.ac.impl.SvrSslCfgMode**, type the configuration mode of the SvrSslCfg command. The only valid value is remote.
   f. For **wp.ac.impl.TamHost**, type the host name of the Security Access Manager Policy server that is used when you run **PDJrteCfg**.
   g. For **wp.ac.impl.PDPolicyServerList**, type the host name, port, and priority combinations for your Security Access Manager Policy servers that are used when you run **SvrSslCfg**.
   h. For **wp.ac.impl.PDAuthzServerList**, type the host name, port, and priority combination for your Security Access Manager authorization servers.
   i. For the **wp.ac.impl.PDKeyPath**, type the fully qualified path and file name of the location for the keystore file. This file is created when you run the **run-svrssl-config** task. The keystore file holds the keys that are used to encrypt communication between the Portal node and the Security Access Manager server.
3. Save your changes to the properties file.
4. Open a command prompt and change to the *wp_profile_root*`/ConfigEngine` directory.
5. Run the following task to create the `PdPerm.properties` file:

- Linux : `./ConfigEngine.sh run-svrssl-config -Dwp.ac.impl.PDAdminPwd=password -DWasPassword=password`
- IBM i: `ConfigEngine.sh run-svrssl-config -Dwp.ac.impl.PDAdminPwd=password -DWasPassword=password`
- Windows: `ConfigEngine.bat run-svrssl-config -Dwp.ac.impl.PDAdminPwd=password -DWasPassword=password`

Note: If the configuration task fails, validate the values in the `wkplc_comp.properties` file.
The following files are created:

- `PdPerm.properties`

  Note: This file is in the directory path you specified for the **wp.ac.impl.PDPermPath** parameter.
- `pdperm.ks`

  Note: This file is in the directory path you specified for the **wp.ac.impl.PDKeyPath** parameter.

Configuring Security Access Manager for authentication only:

IBM WebSphere Portal Express and IBM WebSphere Application Server support the Trust Association Interceptors (TAI) that IBM Security Access Manager provides. If you use Security Access Manager for authorization, you must also use Security Access Manager for authentication. Using Security Access Manager only for authorization is not supported.

About this task

Important information:

- The `pdadmin` command is a utility that supports Security Access Manager administrative functions.
- This procedure requires that you are familiar with WebSEAL administration concepts as presented in the WebSEAL Administrator Guide. For complete descriptions of all the `pdadmin` command options to create junctions, refer to the *Security Access Manager* documentation, particularly the *WebSEAL Administration Guide*.
- The following example assumes that a web server is located between the WebSEAL and WebSphere Portal Express in the request flow. Thus, the junctions that are defined in the following instructions are configured for WebSEAL to forward requests to the HTTP server and then to WebSphere Portal Express. If there is no HTTP server, modify the junction target host name and port values to enable direct communication from WebSEAL to WebSphere Portal Express.
- The following examples do not show any load balancing or other performance-related request features in WebSEAL. For more information about these advanced options, consult the *Security Access Manager* documentation.
- The following examples show simple junction creation cases. Refer to the appropriate *WebSEAL Administration Guide* and *WebSphere Application Server* documentation for information about advanced options, including generating WebSEAL LTPA Tokens in WebSEAL for SSO to WebSphere Application Server.

Clustered environments: Complete the **validate-pdadmin-connection** task on all nodes in the cluster. Complete all other steps on the primary node.

Procedure

1. Start the Security Access Manager policy and authorization servers, which are mandatory for successful configuration and for single sign-on (SSO) to occur.
2. Create your junctions on the WebSEAL server. Refer to the *IBM Security Access Manager for e-business* documentation for guidance on junction creation. Complete the following steps to create a virtual host TCP junction:
   a. Open a `pdadmin` command from any node that has a Security Access Manager run time component installed. You can use the Security Access Manager Server node, WebSEAL node, or the WebSphere Portal Express node.
   b. The general format for the `pdadmin` command to create a virtual host junction is

      ```
      pdadmin> server task WebSEAL-instance_name-webseald-WebSEAL-HostName virtualhost create -t t
      ```

      The following information describes the mandatory parameters in the `pdadmin` command:

      - The *WebSEAL-instance_name*-webseald-*WebSEAL-HostName* has three parts, as documented in the WebSEAL Administration Guide:
        1) The configured name of a single WebSEAL instance, for example *web 1*
        2) The literal string `-websealed-`
        3) The host name, for example, *webseal.yourco.com*

        The resulting combination would be *web 1*-websealed-*webseal.yourco.com*. You can use the `pdadmin server list` command to display the correct format of the server name.
      - The virtual host label (`vhost-label`) is the name for the virtual host junction.
        - Virtual host junctions are always mounted at the root of the WebSEAL object space.
        - You can refer to a junction in the `pdadmin` utility with this label.
        - The virtual host junction label must be unique within each instance of WebSEAL.
        - Because the label represents virtual host junctions in the protected object space, the label name must not contain the forward slash character (/).
      - **`-t type`**: This parameter defines whether the junction is encrypted (`-t ssl`) or not encrypted (`-t tcp`). This parameter is mandatory when you create a virtual host junction. For more information about other possible values, see the *WebSEAL Administration Guide*.
      - **`-h hostname`**: This parameter defines the backend server to which the junction connects. In most situations, the host name is the HTTP server that sits in front of WebSphere Portal Express. This parameter is mandatory when you create a virtual host junction.

      The *[options]* includes the following parameters:

      - **`-p port`**: This parameter defines the port number for the backend server to which the junction connects. If not specified, the default value is `80` for HTTP or `443` for HTTPS. It is best to specify this value explicitly in the junction creation command even if the default values are in use.
      - **`-v vhost_name[:port]`**: This parameter is the virtual host name and port number that defines the junction. WebSEAL maps incoming requests to this host name and port to this junction. If not specified, the values default to the **`-h hostname`** and **`-p port`** values.

- **-c header_type**: This parameter inserts the Security Access Manager client identity in HTTP headers across the junction. The **header_type** argument can include any combination of the following Security Access Manager HTTP header types:
  - {iv_user|iv_user-l}
  - iv_groups
  - iv_creds
  - all

  The header types must be comma-separated, and cannot have a space between the types. For example: **-c iv_user,iv_groups**. Specifying **-c all** is the same as specifying **-c iv_user,iv_groups,iv_creds**. This parameter is valid for all junctions except for the type of local. The setting here depends on how you want your TAI running within WebSphere Application Server to operate. In certain modes, the TAI might be looking for the presence of one or more of these headers. The TAI looks for these headers to know that it must claim the request when interrogated by WebSphere Application Server security. This setting must be set to match what the TAI is looking for. Consult your WebSphere system administrator if you are in doubt as to how the TAI is configured.
- **-b**: This option controls how WebSEAL passes authentication information to the backend server. Usually this setting depends on how you want the TAI to be configured in WebSphere to validate a trust relationship with WebSEAL. The usual option that is chosen is **-b supply**. For more information, see the *WebSEAL Administration Guide* or the *ETAI installation and configuration* documentation.
- **-k**: This option controls whether WebSEAL includes its own session cookie in the request to the backend server. In some situations, sending the WebSEAL session cookie to the backend server is necessary. This action is necessary to support single sign-on from WebSphere Portal Express to other backend services where WebSEAL also protects those backend services.
-

  Note: Junctions to WebSphere Portal Express whether direct or through an HTTP server does not support the **-q option** the query_contents function. Query_contents is not possible on WebSphere Portal Express

The following information is a sample command to create a virtual host TCP junction, on the *web 1* WebSEAL instance that is running on a host *webseal.yourco.com*, for the virtual host name *portalvhost.yourco.com* running on port 80 that requires a TAI in WebSphere Application Server. The virtual host junction is labeled *vhost_junction_portal_1*. The virtual host junction host name must be mapped in DNS to the WebSEAL server. The portal or http server is running on host *portal.yourco.com* and is using port 8080:

```
pdadmin> server task web1-webseald-webseal.yourco.com virtualhost create -t tcp -v portalv
```

3. Optional: If you plan to use an SSL junction, more steps are needed before you can create the junction. The necessary key and truststore must be set up with the correct certificates to enable SSL. Follow the instructions in steps 1 - 3 of the topic about *configuring SSL*. Then, complete the following steps to create the virtual host junction:

a. Use the IBM Key Management utility to load the web server certificate into the key ring for the appropriate instance of WebSEAL. See the *HTTP Server* documentation for more details.
b. Restart WebSEAL.
c. Follow the steps that are mentioned earlier to create the junction. But change the **-t** value to `ssl` and add the appropriate set of options from the Mutually Authenticated SSL junctions portion of the WebSEAL Administration Guide: **-B**, **-D**, **-K**, **-U**, and **-W**.

4. Enter the following tasks on the `pdadmin` command to create the trusted user account:

   Tip: This step is mandatory for TAI junctions only. Skip this step if you created an LTPA junction. An LTPA junction is created when you use the **-A** parameter. Refer to the *Security Access Manager for e-business* documentation for this advanced configuration.

   The trusted user account in the Security Access Manager user registry must be the same as the one that the TAI within WebSphere Application Server is configured to use. It is the ID that WebSEAL uses to identify itself to WebSphere Application Server by using the **-b supply** option, and it is one of the underlying TAI security requirements.

   Note: To prevent potential vulnerabilities, do not use the `sec_master` or *`wpsadmin`* users for the trusted user account. The trusted user account must be a dedicated user account for the purposes of communication between WebSEAL and the TAI.

   a. `pdadmin> user create` *`webseal_userid webseal_userid_DN firstname surname password`*
   b. `pdadmin> user modify` *`webseal_userid`* `account-valid yes`

5. **Clustered environments:** Complete this step on all nodes.
   Run the following task in the *wp_profile_root*`/ConfigEngine` directory to validate that the `PdPerm.properties` file is correct and that communication between WebSphere Portal Express and the Security Access Manager server works:

   Tip: Run the **validate-pdadmin-connection** task on the WebSphere Portal Express node or on each node in a clustered environment. In a clustered environment, **WasPassword** is the Deployment Manager administrator password. The **wp.ac.impl.PDAdminPwd** is the Security Access Manager administrative user password.

Table 231. Task to validate that the `PdPerm.properties` file exists by operating system

Operating system	Task
IBM i	`ConfigEngine.sh validate-pdadmin-connection -DWasPassword=`*`password`* `-Dwp.ac.impl.PDdAdminPwd=`*`password`*
Linux	`./ConfigEngine.sh validate-pdadmin-connection -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`*
Windows	`ConfigEngine.bat validate-pdadmin-connection -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`*

If the task does not run successfully: Run the **run-svrssl-config** task to create the properties file. For information, refer to *Creating the PdPerm.properties file*. Then, run the **validate-pdadmin-connection** task again. If the task is not successful after a second attempt, do not proceed with any subsequent steps. The fact that the task does not run successfully indicates that your portal cannot connect to the Security Access Manager server. Troubleshoot the connectivity issue between your portal instance and the Security Access Manager server.

6. If you are using junctions that require a Trust Association Interceptor in WebSphere Application Server, you must install and configure the TAI if it is not already been set up. The Extended TAI implementation is new from IBM Security, which must be downloaded and installed from *IBM Security website*. The older TAIs that are included with WebSphere Application Server are deprecated and must not be used.
7. The WebSphere Portal Express ConfigEngine tasks that are used to configure TAIs in previous releases, are no longer supported by the new ETAI, and cannot be used to configure the new ETAI. Follow the directions in the documentation that accompanies the download. Install and configure the Extended TAI implementation into WebSphere Application Server, including specifying the necessary custom properties that control the operation of the ETAI.
8. If for some reason you must use the deprecated TAI implementation, complete the following steps:
   a. Use a text editor to open the `wkplc_comp.properties` file in the *wp_profile_root*`/ConfigEngine/properties` directory. Enter the following parameters under the WebSphere Application Server WebSEAL TAI parameters heading:
   b. Add the **TAMTAIName** parameter to the WebSphere Application Server WebSEAL TAI section.
   c. Enter `com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus` as the value.
   d. For **wp.ac.impl.TAICreds**, type the headers that are inserted by WebSEAL that the TAI uses to identify the request as originating from WebSEAL. Refer to the values entered for the **-c header_type** parameter. For example, if you entered **-c iv-user**, then the value for **wp.ac.impl.TAICreds** is `iv-user`. If you entered **-c all**, then the value for **wp.ac.impl.TAICreds** is `iv-user,iv-groups,iv-creds`.

      Important: Never specify a header name for **wp.ac.impl.TAICreds** that the WebSEAL server is not sending over the junction.
   e. For **wp.ac.impl.hostnames**, enter the fully qualified URL for WebSphere Portal Express. This value must match the **-h** and **-p** parameters from the junction creation command.
   f. For **wp.ac.impl.ports**, enter the port number that is used to access the host server that is identified in **wp.ac.impl.hostnames**. This value must match the **-p** parameter from the junction creation command.
   g. For **wp.ac.impl.loginId**, enter the reverse proxy identity that is used when you create a TCP junction. This value must match the trusted user account.
   h. For **wp.ac.impl.BaUserName**, enter the reverse proxy identity that is used when you create an SSL junction.
   i. For **wp.ac.impl.BaPassword**, enter the password for the SSL junction reverse proxy ID.

      Save your changes to the properties file.

j. Run the following task to configure TAI for Security Access Manager:

Clustered environments: The **WasPassword** is the Deployment Manager administrative password. The `wp.ac.impl.PDAdminPWD` is the Security Access Manager administrative password.

Table 232. Task to configure TAI for Security Access Manager by operating system

Operating system	Task
IBM i	`ConfigEngine.sh enable-tam-tai -DWasPassword=`*password* `-Dwp.ac.impl.PDAdminPwd=`*password*
Linux	`./ConfigEngine.sh enable-tam-tai -DWasPassword=`*password* `-Dwp.ac.impl.PDAdminPwd=`*password*
Windows	`ConfigEngine.bat enable-tam-tai -DWasPassword=`*password* `-Dwp.ac.impl.PDAdminPwd=`*password*

9. Optional: Enable user provisioning. You must do this task only if you are using WebSphere Portal Express to create and provision new users directly in LDAP, and you need these users to also be recognized by Security Access Manager. In an enterprise deployment of WebSphere Portal Express this task would be unusual, as most large deployments have a separate user provisioning process, perhaps by using IBM Security Identity Manager. WebSphere Portal Express reads from LDAP but does not create new users. For more information, see the related links section.
10. If you are using Security Access Manager integrated with WebSphere Portal Express in a stand-alone environment that does not include a web server between WebSEAL and Portal, complete the following steps:
    a. Log on to the WebSphere Integrated Solutions Console.
    b. Go to **Servers** > **Server Types** > **Web application servers** > **WebSphere_Portal** > **Web container settings** > **Web Container** and then click **Additional Properties** > **Custom properties**.
    c. Click **New** and then add the **com.ibm.ws.webcontainer.extracthostheaderport** custom property with a value of `true`.
    d. Click **OK**.
    e. Click **New** and add the **trusthostheaderport** custom property with a value of `true`.
    f. Click **OK**.
    g. Click **Save** to save your changes.
    h. Log out of the WebSphere Integrated Solutions Console.
11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see “Starting and stopping servers, deployment managers, and node agents” on page 1216.
12. Go to the WebSEAL node and edit the `webseald-`*instance*`.conf` file for the appropriate WebSEAL instance. An example is `webseald-default.conf`. This file sets the `basicauth-dummy-passwd` value to the password for the ID that WebSEAL uses to identify itself to WebSphere Application Server. This password is the trusted user ID and password that were created in an earlier step. Stop and start the WebSEAL server before you continue.

13. If your WebSEAL instance is on the Windows operating system, limit the length of the generated URLs. Edit the `webseald-instance.conf` file and change the **process-root-requests** property value to `filter` to avoid problems with WebSEAL processing.
14. Import WebSphere Portal Express users and groups into Security Access Manager. Enter the following commands on the Security Access Manager administrative command, where *wpsadmin* is the user ID for the administrator, and *wpsadmins* is the administrators group name. The fully distinguished names of the user and group IDs vary depending on your LDAP settings.

```
user import wpsadmin uid=wpsadmin,cn=users,dc=ibm,dc=com
user modify wpsadmin account-valid yes
group import wpsadmins cn=wpsadmins,cn=groups,dc=ibm,dc=com
```

15. Some functions of WebSphere Portal Express require the use of the PUT, and DELETE HTTP method. By default, WebSEAL does not allow these requests. You must either allow this method at the applicable WebSEAL ACL and web server, or change the HTTP methods in the x-method-override configuration in the WebSEAL config file `webseald-instance.conf`.

Related tasks:

"Migrating Security Access Manager" on page 899
The IBM WebSphere Portal Express migration process migrates the security configurations. However, there is no provision for the automatic migration of any junction definitions that exist for the previous version of WebSphere Portal Express in WebSEAL. You must replace the old junction definitions with the new virtual host junction definitions.

"Creating the `PdPerm.properties` file" on page 1629
The `PdPerm.properties` file configures the Access Manager Java Run Time Environment (AMJRTE). You must create the `PdPerm.properties` file before you configure IBM Security Access Manager for authentication, authorization, Credential Vault, or user provisioning. Run the **run-svrssl-config** task to create the files. This task also creates the keystore file that is used to encrypt communication with Security Access Manager.

"Setting up SSL" on page 1596
Get an overview of the tasks that are required to configure SSL for IBM WebSphere Portal Express. Some of these tasks are completed on the IBM WebSphere Application Server and the web server. The steps that refer to the WebSphere Application Server and the web server are summarized here; refer to the WebSphere Application Server and the web server documentation for detailed information. Steps that are unique to WebSphere Portal Express are described in detail here.

Configuring Security Access Manager for authorization:

You can configure IBM Security Access Manager for both authentication and authorization for IBM WebSphere Portal Express. If you configure these functions at different times as independent tasks, configure Security Access Manager for authentication first. Using Security Access Manager only for authorization is not supported.

Before you begin

Complete the steps in "Configuring Security Access Manager for authentication only" on page 1631 before you configure Security Access Manager for authorization.

About this task

You can configure WebSphere Portal to delegate the decisions about what users or groups are granted access to Portal resources, to IBM Security Access Manager. This action is also called externalizing the access control for Portal resources. Normally these decisions are made by consulting the principal-to-role mappings that are stored in the Portal database. The following task configures the Portal code that is used to obtain access control decisions for Portal resources from Security Access Manager instead of from the Portal database. It includes configuration of properties that determine how the Portal resources are represented in the Security Access Manager protected object namespace. It also configures how permissions are represented in the Security Access Manager access control lists. After this task is run, you can use the Resource Permissions portlet or XMLAccess to place portal resources such as pages and portlets under Security Access Manager control.

Important: There are more considerations when you set up security to use an external security manager in a cluster environment and across mixed nodes. For instance, complete any configuration for an external security manager after you completed all other configuration tasks, including ensuring that the cluster is functional.

Implementation details of externalized access control:

When Portal resources are moved to Security Access Manager access control, WebSphere Portal creates entries corresponding to individual roles on the externalized resources in the Security Access Manager protected object space. The roles in this case are the Portal roles on Portal resources; for example, in simplified form, User@Welcome page or Administrator@Some Portlet.

Access Control Lists (ACLs) are attached to these Security Access Manager objects. The ACLs use the *PDAction* and *PDActionGroup* property values to determine what users are granted the various roles. WebSphere Portal security code queries Security Access Manager for the users that have the <PDAction> within <PDActionGroup> permission on entries in the Security Access Manager object space, and interprets that as granting the user the corresponding Portal role on the resource.

Any subset of Portal resources can be placed under external access control. WebSphere Portal can maintain internal control of other resources.

There are multiple entries in the Security Access Manager object space for every externalized resource, one entry per existing Portal role on that resource. Recall that in WebSphere Portal there are multiple different role types; for example, User, Privileged User, Editor, Manager, Administrator. Not every Portal role might be instantiated for every resource instance, and entries in Security Access Manager exist only if the corresponding actual role on that Portal resource exists.

Format of the entries in Security Access Manager

By default, the entries in the Security Access Manager object space have the following format:

```
<PDRoot_Value>/<Portal Rolename-on-resource>[/<EACappname_value>/<EACserverName_value>/<EACcellNam
```

By default, the `Portal Rolename-on-resource` is in the form of `<Portal_RoleType>@<Portal_Resource_Identifier>`. For example: `Administrator@VIRTUAL_EXTERNAL_ACCESS_CONTROL`.

The Security Access Manager object space entries might be different from the default, depending on the following properties:

- If the reorderRoles property is set to `true`, the `Portal Rolename-on-resource` displays as `Portal_Resource_Identifier@Portal_Roletype`. For example, `VIRTUAL_EXTERNAL_ACCESS_CONTROL@Administrator`.
- Set all three of the `EACserverName`, `EACcellName`, and `EACappname` properties; otherwise, they are not included in the object space entries.

Procedure

1.

Clustered environments: Complete this step on all nodes.
Run the following task in the *wp_profile_root*`/ConfigEngine` directory to validate that the `PdPerm.properties` file is correct and that communication between WebSphere Portal Express and the Security Access Manager server works:

Tip: Run the **`validate-pdadmin-connection`** task on the WebSphere Portal Express node or on each node in a clustered environment. In a clustered environment, **`WasPassword`** is the Deployment Manager administrator password. The **`wp.ac.impl.PDAdminPwd`** is the Security Access Manager administrative user password.

Table 233. Task to validate that the `PdPerm.properties` file exists by operating system

Operating system	Task
IBM i	`ConfigEngine.sh validate-pdadmin-connection -DWasPassword=`*`password`* `-Dwp.ac.impl.PDdAdminPwd=`*`password`*
Linux	`./ConfigEngine.sh validate-pdadmin-connection -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`*
Windows	`ConfigEngine.bat validate-pdadmin-connection -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`*

If the task does not run successfully: Run the **`run-svrssl-config`** task to create the properties file. For information, refer to *Creating the `PdPerm.properties` file*. Then, run the **`validate-pdadmin-connection`** task again. If the task is not successful after a second attempt, do not proceed with any subsequent steps. The fact that the task does not run successfully indicates that your portal cannot connect to the Security Access Manager server. Troubleshoot the connectivity issue between your portal instance and the Security Access Manager server.

2. Update the Namespace management parameters in the `wkplc_comp.properties` file

a. For **wp.ac.impl.EACserverName**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

   Note: If set, **wp.ac.impl.EACcellName** and **wp.ac.impl.EACappname** must also be set. All three parameters must be set or none of them.

b. For **wp.ac.impl.EACcellName**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

   Note: If set, **wp.ac.impl.EACserverName** and **wp.ac.impl.EACappname** must also be set.

c. For **wp.ac.impl.EACappname**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

   Note: If set, **wp.ac.impl.EACcellName** and **wp.ac.impl.EACserverName** must also be set.

d. For **wp.ac.impl.reorderRoles**, type `false` to keep the role order or `true` to reorder the roles by resource type first.

3. Update the following parameters in the `wkplc_comp.properties` file; go to the Portal authorization parameters heading:

   a. For **wp.ac.impl.PDRoot**, type the root object space name in the Security Access Manager namespace for the resource entries for this portal. All Portal roles are installed with this entry. For multiple profiles and portal instances that all share a common Security Access Manager instance, choose a unique name for each root object space entry. This unique name helps to easily distinguish the resources for different instances. Or use a common *PDRoot* value for all Portal instances so that all Portal roles from any instance have a common parent. You can then use the **EACappname** parameter to distinguish between instances. If it better suits your administration models, you can also mix these two approaches, by using a common *PDRoot* value for some instances, and unique *PDRoot* values for others.

   b. For **wp.ac.impl.PDAction**, type the Custom Action created by the Security Access Manager external authorization plug-in. The combination of the action group and the action determines the Security Access Manager permission string. The permission string is used to assign membership to externalized portal roles. You might want to check with your Security Access Manager administrator to determine what they want the *PDActionGroup* and *PDAction* values to be.

      Note: After you create ACLs in Security Access Manager by using a *PDAction* and *PDActionRoot* value, these values must remain constant. Changing these values after you create ACLs that use the original settings, results in losing permissions.

   c. For **wp.ac.impl.PDActionGroup**, type the Custom Action group that is created by the Security Access Manager external authorization plug-in. The combination of the action group and the action determines the Security Access Manager permission string. The permission string is used to assign membership to externalized portal roles.

Note: After you create ACLs in Security Access Manager by using a *PDAction* and *PDActionRoot* value, these values must remain constant. Changing these values after you create ACLs that use the original settings, results in losing permissions.

d. For **wp.ac.impl.PDCreateAcl**, set the value to `true` to automatically create and attach a Security Access Manager ACL when WebSphere Portal Express externalizes the roles for a resource. Set the value to `false` to not create and attach a Security Access Manager ACL when WebSphere Portal Express externalizes the roles for a resource. In this case, the Security Access Manager Administrator must manually create and attach ACLs to the object space entries for the externalized portal resources and roles. Any ACLs created manually in this way, must use the *PDAction* and *PDActionGroup* values in order for the permissions to be found.

4. Save your changes to the properties file.
5. Run the following task to enable Security Access Manager authorization:

Table 234. Enable Security Access Manager authorization tasks by operating system

Operating system	Task
IBM i	`ConfigEngine.sh enable-tam-authorization -DWasPassword=`*`password`*
Linux	`./ConfigEngine.sh enable-tam-authorization -DWasPassword=`*`password`*
Windows	`ConfigEngine.bat enable-tam-authorization -DWasPassword=`*`password`*

Clustered note: In a clustered environment, complete this step on all nodes. The **WasPassword** value is the Deployment Manager administrative password.

If the task does not run successfully: Ensure the values in the `wkplc_comp.properties` file are valid.

6. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Results

After you complete the authorization procedure, you can then use the WebSphere Portal administration tools (the Resource Permission portlet or XMLAccess scripting) to externalize the access control decisions for Portal resources. For any resources placed under IBM Security Manager access control, the Security Access Manager protected object space contains entries for roles in the following format

PortalServer_root`/role_name/application_name/server_name/cell_name`

For example: If the **wp.ac.impl.PDRoot** value was *Portal_Instance_1* and **wp.ac.impl.EACcellName** was *Cell_A*, **Wp.ac.impl.EACserverName** was *Server_B*, and **wp.ac.impl.EACappName** was *Application_C*, then an object space entry corresponding to a Portal role name approximately looks like

`Portal_Instance_1/Administrator@VIRTUAL_EXTERNAL_ACCESS_CONTROL/Application_C/Server_B/Cell_A`.

Where the Portal role name *Administrator@VIRTUAL_EXTERNAL_ACCESS_CONTROL* is simplified from its actual appearance, which might include a generated UUID value or custom unique name.

Note: The `EACappname`, `EACserverName`, and `EACcellName` must all be specified, or none of them appears in the Security Access Manager object space entries.

Related tasks:

"Creating the `PdPerm.properties` file" on page 1629
The `PdPerm.properties` file configures the Access Manager Java Run Time Environment (AMJRTE). You must create the `PdPerm.properties` file before you configure IBM Security Access Manager for authentication, authorization, Credential Vault, or user provisioning. Run the **`run-svrssl-config`** task to create the files. This task also creates the keystore file that is used to encrypt communication with Security Access Manager.

Configuring the Credential Vault adapter for Security Access Manager:

You can use IBM Security Access Manager in the IBM WebSphere Portal Express Credential Vault service. WebSphere Portal Express includes a vault adapter to access the Security Access Manager Global Sign-on (GSO) lockbox. Any existing Tivoli resource or resource credentials can be used in your portlets that access the credential vault service without any additional configuration. In addition, the credential vault service and credential vault management portlet can create or update an existing GSO lockbox entry.

About this task

Note: Users who are storing credentials in the `accessmanagervault.properties` file must be defined in Security Access Manager as global signon (GSO) users.

Clustered note: In a clustered environment, complete steps 1 and 2 on each node. The **`WasPassword`** value is the Deployment Manager administrative password.

Procedure

1.

Clustered environments: Complete this step on all nodes.
Run the following task in the *wp_profile_root*`/ConfigEngine` directory to validate that the `PdPerm.properties` file is correct and that communication between WebSphere Portal Express and the Security Access Manager server works:

Tip: Run the **`validate-pdadmin-connection`** task on the WebSphere Portal Express node or on each node in a clustered environment. In a clustered environment, **`WasPassword`** is the Deployment Manager administrator password. The **`wp.ac.impl.PDAdminPwd`** is the Security Access Manager administrative user password.

Table 235. Task to validate that the `PdPerm.properties` file exists by operating system

Operating system	Task
IBM i	`ConfigEngine.sh validate-pdadmin-connection -DWasPassword=`*`password`* `-Dwp.ac.impl.PDdAdminPwd=`*`password`*

Table 235. Task to validate that the `PdPerm.properties` file exists by operating system (continued)

Operating system	Task
Linux	`./ConfigEngine.sh validate-pdadmin-connection -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`*
Windows	`ConfigEngine.bat validate-pdadmin-connection -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`*

If the task does not run successfully: Run the **run-svrssl-config** task to create the properties file. For information, refer to *Creating the `PdPerm.properties` file*. Then, run the **validate-pdadmin-connection** task again. If the task is not successful after a second attempt, do not proceed with any subsequent steps. The fact that the task does not run successfully indicates that your portal cannot connect to the Security Access Manager server. Troubleshoot the connectivity issue between your portal instance and the Security Access Manager server.

2. Run the following task to create and populate the *wp_profile_root*`/PortalServer/config/config/accessmanagervault.properties` file:

Table 236. Task to create and populate the properties file by operating system

Operating system	Task
IBM i	`ConfigEngine.sh enable-tam-vault -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`*
Linux	`./ConfigEngine.sh enable-tam-vault -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`*
Windows	`ConfigEngine.bat enable-tam-vault -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`*

3. Complete the following steps to set the value for the **systemcred.dn** property:

   Note: The **systemcred.dn** property defines the distinguished name of the vault administrative user. All system credentials are stored under the user account. For Security Access Manager, this user must be an existing Security Access Manager user. The Security Access Manager adapter checks if the user exists in Security Access Manager before the slots are accessed.

   a. Log on to the WebSphere Integrated Solutions Console.
   b. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
   c. Click **WP CredentialVaultService**.
   d. Under **Additional Properties**, click **Custom properties**.
   e. Edit the **systemcred.dn** property. Set the value to an existing Security Access Manager user.

4. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see "Starting and stopping servers, deployment managers, and node agents" on page 1216.
5. Create a Credential Vault segment and slot to be used by Security Access Manager:

a. Click the **Administration menu** icon. Then, click **Access** > **Credential Vault**. Then, click **Add a vault segment**.
b. Select the **AccessManager** vault from the **Vaults** list, by default it is named `AccessManager`.
c. Enter a **Vault segment name** and click **OK**.
d. Click **Add a vault slot**.
e. Select the `AccessManager` vault from the **Vault** menu.
f. Enter a **Name** for the vault slot and click **OK**.

6. Optional: Use the WebSphere Application Server encoding mechanism to mask the passwords in the `accessmanagervault.properties` file and the Security Access Manager administrative password in the **pdpw** property.

Related tasks:

"Creating the `PdPerm.properties` file" on page 1629
The `PdPerm.properties` file configures the Access Manager Java Run Time Environment (AMJRTE). You must create the `PdPerm.properties` file before you configure IBM Security Access Manager for authentication, authorization, Credential Vault, or user provisioning. Run the **run-svrssl-config** task to create the files. This task also creates the keystore file that is used to encrypt communication with Security Access Manager.

Related information:

Encoding passwords in files

Configuring Security Access Manager for authentication, authorization, and the Credential Vault:

You can configure Security Access Manager for authentication, authorization, and the vault adapter with one task.

About this task

Procedure

1. Start the Security Access Manager policy and authorization servers, which are mandatory for successful configuration and for single sign-on (SSO) to occur.
2. Create your junctions on the WebSEAL server. Refer to the *IBM Security Access Manager for e-business* documentation for guidance on junction creation. Complete the following steps to create a virtual host TCP junction:
   a. Open a `pdadmin` command from any node that has a Security Access Manager run time component installed. You can use the Security Access Manager Server node, WebSEAL node, or the WebSphere Portal Express node.
   b. The general format for the `pdadmin` command to create a virtual host junction is

      ```
      pdadmin> server task WebSEAL-instance_name-webseald-WebSEAL-HostName virtualhost create -t t
      ```

      The following information describes the mandatory parameters in the `pdadmin` command:
      - The *WebSEAL-instance_name*-webseald-*WebSEAL-HostName* has three parts, as documented in the WebSEAL Administration Guide:
        1) The configured name of a single WebSEAL instance, for example *web 1*
        2) The literal string `-websealed-`

3) The host name, for example, *webseal.yourco.com*

The resulting combination would be *web 1*-websealed-*webseal.yourco.com*. You can use the pdadmin server list command to display the correct format of the server name.

- The virtual host label (vhost-label) is the name for the virtual host junction.
  - Virtual host junctions are always mounted at the root of the WebSEAL object space.
  - You can refer to a junction in the pdadmin utility with this label.
  - The virtual host junction label must be unique within each instance of WebSEAL.
  - Because the label represents virtual host junctions in the protected object space, the label name must not contain the forward slash character (/).
- **-t type**: This parameter defines whether the junction is encrypted (-t ssl) or not encrypted (-t tcp). This parameter is mandatory when you create a virtual host junction. For more information about other possible values, see the *WebSEAL Administration Guide*.
- **-h hostname**: This parameter defines the backend server to which the junction connects. In most situations, the host name is the HTTP server that sits in front of WebSphere Portal Express. This parameter is mandatory when you create a virtual host junction.

The *[options]* includes the following parameters:

- **-p port**: This parameter defines the port number for the backend server to which the junction connects. If not specified, the default value is 80 for HTTP or 443 for HTTPS. It is best to specify this value explicitly in the junction creation command even if the default values are in use.
- **-v vhost_name[:port]**: This parameter is the virtual host name and port number that defines the junction. WebSEAL maps incoming requests to this host name and port to this junction. If not specified, the values default to the **-h hostname** and **-p port** values.
- **-c header_type**: This parameter inserts the Security Access Manager client identity in HTTP headers across the junction. The **header_type** argument can include any combination of the following Security Access Manager HTTP header types:
  - {iv_user|iv_user-l}
  - iv_groups
  - iv_creds
  - all

  The header types must be comma-separated, and cannot have a space between the types. For example: **-c iv_user,iv_groups**. Specifying **-c all** is the same as specifying **-c iv_user,iv_groups,iv_creds**. This parameter is valid for all junctions except for the type of local. The setting here depends on how you want your TAI running within WebSphere Application Server to operate. In certain modes, the TAI might be looking for the presence of one or more of these headers. The TAI looks for these headers to know that it must claim the request when interrogated by WebSphere Application Server security. This setting must be set to match what the TAI is looking for. Consult your WebSphere system administrator if you are in doubt as to how the TAI is configured.

- **-b**: This option controls how WebSEAL passes authentication information to the backend server. Usually this setting depends on how you want the TAI to be configured in WebSphere to validate a trust relationship with WebSEAL. The usual option that is chosen is **-b supply**. For more information, see the *WebSEAL Administration Guide* or the *ETAI installation and configuration* documentation.
- **-k**: This option controls whether WebSEAL includes its own session cookie in the request to the backend server. In some situations, sending the WebSEAL session cookie to the backend server is necessary. This action is necessary to support single sign-on from WebSphere Portal Express to other backend services where WebSEAL also protects those backend services.
-

  Note: Junctions to WebSphere Portal Express whether direct or through an HTTP server does not support the **-q option** the query_contents function. Query_contents is not possible on WebSphere Portal Express

The following information is a sample command to create a virtual host TCP junction, on the *web 1* WebSEAL instance that is running on a host *webseal.yourco.com*, for the virtual host name *portalvhost.yourco.com* running on port 80 that requires a TAI in WebSphere Application Server. The virtual host junction is labeled *vhost_junction_portal_1*. The virtual host junction host name must be mapped in DNS to the WebSEAL server. The portal or http server is running on host *portal.yourco.com* and is using port 8080:

```
pdadmin> server task web1-webseald-webseal.yourco.com virtualhost create -t tcp -v portalvho
```

3. Optional: If you plan to use an SSL junction, more steps are needed before you can create the junction. The necessary key and truststore must be set up with the correct certificates to enable SSL. Follow the instructions in steps 1 - 3 of the topic about *configuring SSL*. Then, complete the following steps to create the virtual host junction:
   a. Use the IBM Key Management utility to load the web server certificate into the key ring for the appropriate instance of WebSEAL. See the *HTTP Server* documentation for more details.
   b. Restart WebSEAL.
   c. Follow the steps that are mentioned earlier to create the junction. But change the **-t** value to `ssl` and add the appropriate set of options from the Mutually Authenticated SSL junctions portion of the WebSEAL Administration Guide: **-B**, **-D**, **-K**, **-U**, and **-W**.
4. Enter the following tasks on the `pdadmin` command to create the trusted user account:

   Tip: This step is mandatory for TAI junctions only. Skip this step if you created an LTPA junction. An LTPA junction is created when you use the **-A** parameter. Refer to the *Security Access Manager for e-business* documentation for this advanced configuration.

   The trusted user account in the Security Access Manager user registry must be the same as the one that the TAI within WebSphere Application Server is configured to use. It is the ID that WebSEAL uses to identify itself to WebSphere Application Server by using the **-b supply** option, and it is one of the underlying TAI security requirements.

Note: To prevent potential vulnerabilities, do not use the `sec_master` or *wpsadmin* users for the trusted user account. The trusted user account must be a dedicated user account for the purposes of communication between WebSEAL and the TAI.

a. `pdadmin> user create webseal_userid webseal_userid_DN firstname surname password`

b. `pdadmin> user modify webseal_userid account-valid yes`

5.

Clustered environments: Complete this step on all nodes.
Run the following task in the *wp_profile_root*`/ConfigEngine` directory to validate that the `PdPerm.properties` file is correct and that communication between WebSphere Portal Express and the Security Access Manager server works:

Tip: Run the **validate-pdadmin-connection** task on the WebSphere Portal Express node or on each node in a clustered environment. In a clustered environment, **WasPassword** is the Deployment Manager administrator password. The **wp.ac.impl.PDAdminPwd** is the Security Access Manager administrative user password.

Table 237. Task to validate that the `PdPerm.properties` file exists by operating system

Operating system	Task
IBM i	`ConfigEngine.sh validate-pdadmin-connection -DWasPassword=password -Dwp.ac.impl.PDdAdminPwd=password`
Linux	`./ConfigEngine.sh validate-pdadmin-connection -DWasPassword=password -Dwp.ac.impl.PDAdminPwd=password`
Windows	`ConfigEngine.bat validate-pdadmin-connection -DWasPassword=password -Dwp.ac.impl.PDAdminPwd=password`

If the task does not run successfully: Run the **run-svrssl-config** task to create the properties file. For information, refer to *Creating the `PdPerm.properties` file*. Then, run the **validate-pdadmin-connection** task again. If the task is not successful after a second attempt, do not proceed with any subsequent steps. The fact that the task does not run successfully indicates that your portal cannot connect to the Security Access Manager server. Troubleshoot the connectivity issue between your portal instance and the Security Access Manager server.

6. Use a text editor to open the `wkplc_comp.properties` file in the following directory:
   - Linux : *wp_profile_root*`/ConfigEngine/properties`
   - IBM i: *wp_profile_root*`/ConfigEngine/properties`
   - Windows: *wp_profile_root*`\ConfigEngine\properties`

   Clustered environments: Complete this step on all nodes.

7. Updating properties in the `wkplc_comp.properties`.
   a. Update the Namespace management parameters in the `wkplc_comp.properties` file for Advanced Security Configuration by using External Security Managers

1) For **wp.ac.impl.EACserverName**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

   Note: If set, **wp.ac.impl.EACcellName** and **wp.ac.impl.EACappname** must also be set. All three parameters must be set or none of them.

2) For **wp.ac.impl.EACcellName**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

   Note: If set, **wp.ac.impl.EACserverName** and **wp.ac.impl.EACappname** must also be set.

3) For **wp.ac.impl.EACappname**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

   Note: If set, **wp.ac.impl.EACcellName** and **wp.ac.impl.EACserverName** must also be set.

4) For **wp.ac.impl.reorderRoles**, type `false` to keep the role order or `true` to reorder the roles by resource type first.

b. PDJrteCfg command and file system parameters

1) For **wp.ac.impl.TamHost** under the SvrSslCfg command parameter heading in the `wkplc_comp.properties` file, type the Security Access Manager Policy Server that is used when you run **PDJrteCfg**.

c. WebSphere Application Server WebSEAL TAI parameters

1) Enter the following parameter in the `wkplc_comp.properties` file; go to the WebSEAL junction parameters heading:

   Cluster note: Complete this step on all nodes in the cluster. The following parameters must match on all nodes in the clustered environment. The one exception is the **wp.ac.impl.PDServerName** parameter.

   - For **wp.ac.impl.TAICreds**, type the headers that are inserted by WebSEAL that the TAI uses to identify the request as originating from WebSEAL.

2) Enter the following parameters in the `wkplc_comp.properties` file; go to the WebSEAL TAI parameters heading:

   Cluster note: Complete this step on all nodes in the cluster. The following parameters must match on all nodes in the clustered environment. The one exception is the **wp.ac.impl.PDServerName** parameter.

   - Optional: For **wp.ac.impl.hostnames**, type the host name that sets the WebSEAL TAI's host name parameter. This value must match the **-h** and **-p** parameters from the junction creation command.
   - Optional: For **wp.ac.impl.ports**, type the port that is used to set the WebSEAL TAI's ports parameter. This value must match the **-p** parameter from the junction creation command.
   - For **wp.ac.impl.loginId**, type the reverse proxy identity that is used when you create a TCP junction. This value must match the trusted user account.

d. Update the following parameters in the `wkplc_comp.properties` file; go to the Portal authorization parameters heading:

1) For **wp.ac.impl.PDRoot**, type the root object space name in the Security Access Manager namespace for the resource entries for this portal. All Portal roles are installed with this entry. For multiple profiles and portal instances that all share a common Security Access Manager instance, choose a unique name for each root object space entry. This unique name helps to easily distinguish the resources for different instances. Or use a common *PDRoot* value for all Portal instances so that all Portal roles from any instance have a common parent. You can then use the **EACappname** parameter to distinguish between instances. If it better suits your administration models, you can also mix these two approaches, by using a common *PDRoot* value for some instances, and unique *PDRoot* values for others.
2) For **wp.ac.impl.PDAction**, type the Custom Action created by the Security Access Manager external authorization plug-in. The combination of the action group and the action determines the Security Access Manager permission string. The permission string is used to assign membership to externalized portal roles. You might want to check with your Security Access Manager administrator to determine what they want the *PDActionGroup* and *PDAction* values to be.
3) For **wp.ac.impl.PDActionGroup**, type the Custom Action group that is created by the Security Access Manager external authorization plug-in. The combination of the action group and the action determines the Security Access Manager permission string. The permission string is used to assign membership to externalized portal roles.
4) For **wp.ac.impl.PDCreateAcl**, set the value to `true` to automatically create and attach a Security Access Manager ACL when WebSphere Portal Express externalizes the roles for a resource. Set the value to `false` to not create and attach a Security Access Manager ACL when WebSphere Portal Express externalizes the roles for a resource. In this case, the Security Access Manager Administrator must manually create and attach ACLs to the object space entries for the externalized portal resources and roles. Any ACLs created manually in this way, must use the *PDAction* and *PDActionGroup* values in order for the permissions to be found.

e.

Enter the following parameters in the `wkplc_comp.properties` file; go to the Portal vault parameters heading:

Cluster note: Complete this step on all nodes in the cluster. The following parameters must match on all nodes in the clustered environment. The one exception is the **wp.ac.impl.PDServerName** parameter.

1) For **wp.ac.impl.vaultType**, type the new vault type identifier that represents the Tivoli GSO lockbox vault.
2) For **wp.ac.impl.vaultProperties**, type the file that is used to configure the vault with Security Access Manager specific user and SSL connection information.
3) For **wp.ac.impl.manageResources**, type `true` if the credential vault or any custom portlets are allowed to create new resource objects in Security Access Manager. Or type `false` to allow only the Security Access Manager administrator to define the accessible resources to associate users with from the command line or graphical user interface.
4) For **wp.ac.impl.readOnly**, type `true` to allow credential vault or any custom portlets to modify the secrets that are stored in Security Access

Manager. Or type `false` to allow only the Security Access Manager administrator to modify the secrets from the command line or graphical user interface.

8. Save your changes to the properties file.
9. The new TAI implementation version is only available as a download and must be added to the system. See the related links section to download the Extended Security Access Manager Trust Association Interceptor Plus (ETAI) and add the binary files to your environment. WebSphere Application Server deprecated the TAI implementation that is available with WebSphere Portal Express.
10. Optional: If you must use the deprecated TAI implementation, complete the following steps:
    a. Open the `wkplc_comp.properties` file.
    b. Add the **`TAMTAIName`** parameter to the `WAS WebSEAL TAI` section.
    c. Enter `com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus` as the value.
11. The WebSphere Portal Express ConfigEngine tasks that are used to configure TAIs in previous releases, are no longer supported by the new ETAI, and cannot be used to configure the new ETAI. Follow the directions in the documentation that accompanies the download. Install and configure the Extended TAI implementation into WebSphere Application Server, including specifying the necessary custom properties that control the operation of the ETAI.
12. Open a command prompt and change to the *wp_profile_root*`/ConfigEngine` directory.
13. Run the following task to enable Security Access Manager authentication, authorization, and the credential vault:
    - IBM i: `ConfigEngine.sh enable-tam-all -DWasPassword=`*`password`*
    - Linux: `./ConfigEngine.sh enable-tam-all -DWasPassword=`*`password`*
    - Windows: `ConfigEngine.bat enable-tam-all -DWasPassword=`*`password`*

    Clustered environments:

    Complete this step on all nodes.

    `WasPassword` is the Deployment Manager administrative password.

    If the task does not run successfully: Ensure the values that you specified in `wkplc_comp.properties` are valid.
14. Complete the following steps to set the value for the **`systemcred.dn`** property:

    Note: The **`systemcred.dn`** property defines the distinguished name of the vault administrative user. All system credentials are stored under the user account. For Security Access Manager, this user must be an existing Security Access Manager user. The Security Access Manager adapter checks if the user exists in Security Access Manager before the slots are accessed.
    a. Log on to the WebSphere Integrated Solutions Console.
    b. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
    c. Click **WP CredentialVaultService**.
    d. Under **Additional Properties**, click **Custom properties**.
    e. Edit the **`systemcred.dn`** property. Set the value to an existing Security Access Manager user.

15. If you are using Security Access Manager integrated with WebSphere Portal Express in a stand-alone environment that does not include a web server between WebSEAL and Portal, complete the following steps:
    a. Log on to the WebSphere Integrated Solutions Console.
    b. Go to **Servers** > **Server Types** > **Web application servers** > **WebSphere_Portal** > **Web container settings** > **Web Container** and then click **Additional Properties** > **Custom properties**.
    c. Click **New** and then add the **com.ibm.ws.webcontainer.extracthostheaderport** custom property with a value of `true`.
    d. Click **OK**.
    e. Click **New** and add the **trusthostheaderport** custom property with a value of `true`.
    f. Click **OK**.
    g. Click **Save** to save your changes.
    h. Log out of the WebSphere Integrated Solutions Console.
16. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see "Starting and stopping servers, deployment managers, and node agents" on page 1216.
17. Go to the WebSEAL node and edit the `webseald-`*instance*`.conf` file for the appropriate WebSEAL instance. An example is `webseald-default.conf`. This file sets the `basicauth-dummy-passwd` value to the password for the ID that WebSEAL uses to identify itself to WebSphere Application Server. This password is the trusted user ID and password that were created in an earlier step. Stop and start the WebSEAL server before you continue.
18. If your WebSEAL instance is on the Windows operating system, limit the length of the generated URLs. Edit the `webseald-`*instance*`.conf` file and change the **process-root-requests** property value to `filter` to avoid problems with WebSEAL processing.
19. Some functions of WebSphere Portal Express require the use of the PUT, and DELETE HTTP method. By default, WebSEAL does not allow these requests. You must either allow this method at the applicable WebSEAL ACL and web server, or change the HTTP methods in the x-method-override configuration in the WebSEAL config file `webseald-instance.conf`.

Related tasks:

"Migrating Security Access Manager" on page 899
The IBM WebSphere Portal Express migration process migrates the security configurations. However, there is no provision for the automatic migration of any junction definitions that exist for the previous version of WebSphere Portal Express in WebSEAL. You must replace the old junction definitions with the new virtual host junction definitions.

"Creating the `PdPerm.properties` file" on page 1629
The `PdPerm.properties` file configures the Access Manager Java Run Time Environment (AMJRTE). You must create the `PdPerm.properties` file before you configure IBM Security Access Manager for authentication, authorization, Credential Vault, or user provisioning. Run the **run-svrssl-config** task to create the files. This task also creates the keystore file that is used to encrypt communication with Security Access Manager.

"Setting up SSL" on page 1596
Get an overview of the tasks that are required to configure SSL for IBM WebSphere Portal Express. Some of these tasks are completed on the IBM WebSphere Application Server and the web server. The steps that refer to the WebSphere Application Server and the web server are summarized here; refer to the WebSphere Application Server and the web server documentation for detailed information. Steps that are unique to WebSphere Portal Express are described in detail here.

Removing Security Access Manager:

After you install and use IBM Security Access Manager, you might find that you no longer require its use. You can then remove it from the IBM WebSphere Portal Express environment and restore authentication capabilities to IBM WebSphere Application Server and authorization capabilities to WebSphere Portal Express.

About this task

Complete the following steps to remove Security Access Manager from the WebSphere Portal Express environment:

Procedure

1. Complete the following steps, from the WebSphere Integrated Solutions Console, if you configured Security Access Manager for authentication:
   a. Select **Security** > **Global security** > **Web and SIP security** > **Trust association** > **Interceptors**.
   b. Delete **com.ibm.sec.authn.tai.TAMETai** or if you are still using the deprecated Trust Association Interceptors (TAIs) implementation, delete **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus**.
   c. Click **OK** then **Save**.
2. Optional: Complete the following steps, from the WebSphere Integrated Solutions Console, if you configured Security Access Manager for authorization:
   a. Change the **enableExternalization** property to `false` in WP AccessControlService in the Integrated Solutions Console. This action prevents the **Externalize/Internalize** icon from appearing in the Administrative Access portlet after Security Access Manager is removed.
   b. Use either the Resource Permissions portlet or the XML configuration interface to internalize any resources that Security Access Manager manages.
   c. Edit the `services.properties` file that is found in the *wp_profile_root*/`PortalServer/config/config` directory; find the value `com.ibm.wps.services.ac.ExternalAccessControlService`, and change it to `com.ibm.wps.ac.impl.ExternalAccessControlDefaultImpl`.

      Note: Complete step 2.c. on all nodes.
3. Optional: Complete the following steps to remove the credential vault adapter and its associated segments if you configured it for Security Access Manager:

a. Use the **Credential Vault portlet** to remove any segments that are added since installation.

   Note: Do not remove **DefaultAdminSegment**.

b. Remove the **Vault.AccessManager** Credential Vault adapter implementation properties; including class, config, manager, and read-only; from the portal Credential Vault Service configuration.

   Note: The **systemcred.dn** property cannot be removed.

c. Remove the accessmanagervault.properties file from the *wp_profile_root*/PortalServer/config/config directory.

   Note: Complete step 3.c. on all nodes.

4. Optional: If you enabled user provisioning, go to "Disabling user provisioning" on page 1657.
5. Optional: Restore the backup copy of the theme so that the login and logout pages restore to the default before Security Access Manager was enabled.
6. Optional: Remove all junction points, access control lists (ACLs), protected objectspace entries (POS entries), custom actions, and custom action groups.
7. Optional: Run the following task to remove the connection to Security Access Manager:
   - Linux : ./ConfigEngine.sh run-svrssl-unconfig -DWasPassword=*password* -Dwp.ac.impl.PDAdminPwd=*password* from the *wp_profile_root*/ConfigEngine directory
   - IBM i: ConfigEngine.sh run-svrssl-unconfig -DWasPassword=*password* -Dwp.ac.impl.PDAdminPwd=*password* from the *wp_profile_root*/ConfigEngine directory
   - Windows: ConfigEngine.bat run-svrssl-unconfig -DWasPassword=*password* -Dwp.ac.impl.PDAdminPwd=*password* from the *wp_profile_root*\ConfigEngine directory

   Clustered environments:

   Complete this step on all nodes.

   WasPassword is the Deployment Manager administrative password.

   Tip: If the connection still shows up after you run this task, go to Invalid or Stale Server Definitions for more information.
8. If necessary, uninstall any Security Access Manager components.
9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Enabling user provisioning

When users are created in WebSphere Portal Express, they are not automatically imported into Security Access Manager. Enabling automatic user provisioning to Security Access Manager changes this behavior. After this feature is enabled, users are automatically imported into Security Access Manager whenever they are created in WebSphere Portal Express. When user provisioning is enabled, anyone with access to the public URL can become an active user in Security Access Manager if the self-registration feature remains enabled.

About this task

Note: There are two ways to create users in WebSphere Portal Express:

- **Self-registration:** This feature is enabled by default.
- **Manage Users and Groups portlet:** Administrators can use this portlet to create WebSphere Portal Express users.

Complete the following steps to enable user provisioning within Security Access Manager:

Note: In a clustered environment, run the following tasks on each node in the cluster.

Procedure

1.

Clustered environments: Complete this step on all nodes.
Run the following task in the *wp_profile_root*/ConfigEngine directory to validate that the PdPerm.properties file is correct and that communication between WebSphere Portal Express and the Security Access Manager server works:

Tip: Run the **validate-pdadmin-connection** task on the WebSphere Portal Express node or on each node in a clustered environment. In a clustered environment, **WasPassword** is the Deployment Manager administrator password. The **wp.ac.impl.PDAdminPwd** is the Security Access Manager administrative user password.

Table 238. Task to validate that the PdPerm.properties file exists by operating system

Operating system	Task
IBM i	ConfigEngine.sh validate-pdadmin-connection -DWasPassword=*password* -Dwp.ac.impl.PDdAdminPwd=*password*
Linux	./ConfigEngine.sh validate-pdadmin-connection -DWasPassword=*password* -Dwp.ac.impl.PDAdminPwd=*password*
Windows	ConfigEngine.bat validate-pdadmin-connection -DWasPassword=*password* -Dwp.ac.impl.PDAdminPwd=*password*

If the task does not run successfully: Run the **run-svrssl-config** task to create the properties file. For information, refer to *Creating the PdPerm.properties file*. Then, run the **validate-pdadmin-connection** task again. If the task is not successful after a second attempt, do not proceed with any subsequent steps. The fact that the task does not run successfully indicates that your portal cannot connect to the Security Access Manager server. Troubleshoot the connectivity issue between your portal instance and the Security Access Manager server.

2. Start all servers before you run the **enable-tam-userprov** task.
3. Run the following task to enable user provisioning:

Table 239. Task to enable user provisioning by operating system

Operating system	Task
Linux	`./ConfigEngine.sh enable-tam-userprov -DPortalAdminId=`*password* `-DPortalAdminPwd=`*password* from the *wp_profile_root*`/ConfigEngine` directory
IBM i	`ConfigEngine.sh enable-tam-userprov -DPortalAdminId=`*password* `-DPortalAdminPwd=`*password* from the *wp_profile_root*`/ConfigEngine` directory
Windows	`ConfigEngine.bat enable-tam-userprov -DPortalAdminId=`*password* `-DPortalAdminPwd=`*password* from the *wp_profile_root*`\ConfigEngine` directory

4. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Related tasks:

"Creating the `PdPerm.properties` file" on page 1629
The `PdPerm.properties` file configures the Access Manager Java Run Time Environment (AMJRTE). You must create the `PdPerm.properties` file before you configure IBM Security Access Manager for authentication, authorization, Credential Vault, or user provisioning. Run the **`run-svrssl-config`** task to create the files. This task also creates the keystore file that is used to encrypt communication with Security Access Manager.

Verifying external authorization to Security Access Manager

After configuring IBM WebSphere Portal Express to use Security Access Manager for externalized authorization, you should verify that it works properly before continuing with any additional configuration tasks.

About this task

Perform the following steps to verify that Security Access Manager is working properly:

Procedure

1. Verify that your topology matches the topology described in the protected object space. For example, ensure the value of the **`wp.ac.impl.PDroot`** parameter exists in the Security Access Manager protected object space.
2. Perform the following steps to verify that at least one user, typically the administrator, has the `Administrator@VIRTUAL/EXTERNAL ACCESS CONTROL_1` role:
   a. Enter the `pdadmin> acl show WPS_Administrator-VIRTUAL_wps-EXTERNAL_ACCESS_CONTROL_1` command on the pdadmin command line to verify that the administrator and administrator group have the `Administrator@VIRTUAL/EXTERNAL ACCESS CONTROL_1` role.
   b. Optional: Enter the following commands to add the administrator to the `Administrator@VIRTUAL/EXTERNAL ACCESS CONTROL_1` role if no entry is found:

```
pdadmin> acl modify WPS_Administrator-VIRTUAL_wps-
EXTERNAL_ACCESS_CONTROL_1 set user wpsadmin T[WPS]m
```

```
pdadmin> acl modify WPS_Administrator-VIRTUAL_wps-
EXTERNAL_ACCESS_CONTROL_1 set group wpsadmins T[WPS]m
```

where *wpsadmin* is the administrator user ID and *wpsadmins* is the administrator group.

3. Perform the following steps from the Resource Permissions portlet:
   a. Select a resource type.
   b. Click the **Assign Access** icon for the specific resource.
   c. Click the **Edit Role** icon for a role that you want to externalize.
   d. Click **Add** to explicitly assign at least one user or group to your chosen role for the resource.
   e. Click **Search for Users or User Groups** or click the pull down for the **Search by** option where the default is set to **All available** to select specific users or user groups. Then click **OK**. An informational message box should display the message that members were successfully added to the role.
   f. Optional: Explicitly assign additional roles. If you do not assign at least one user or group to each role type for the resource, you must use the external security manager interface to create this role type later. For example, if you do not assign any users or groups to the Editor role type for the resource, then you must use the external security manager interface to create the Editor role type later.
   g. Click the **Externalize** icon for the resource. These steps move every role that is defined for each resource you assigned to the Security Access Manager protected object space. One ACL is created for each externalized role.
4. Add users to the ACLs that are attached to the role types on that resource by using either the Security Access Manager GUI or the pdadmin command line.

   Remember: If you log on as an administrator to externalize resources to Security Access Manager,

   You must be a member of the `wpsadmins` group.

   The `wpsadmins` group must appear in the `VIRTUAL/EXTERNAL_ACCESS_CONTROL_1` ACL.

Removing the Credential Vault adapter

If you no longer require the use of the credential vault adapter that you created, you can remove it from your configuration.

About this task

Perform the following steps to remove the credential vault adapter:

Procedure

1. Use the **Credential Vault portlet** to remove any segments created in the Security Access Manager Vault. See the Credential Vault portlet help for more information.

   Note: Do not remove **`DefaultAdminSegment`**.
2. Remove the **`Vault.AccessManager`** Credential Vault Adapter implementation properties from the Credential Vault Segment configuration; including class, config, manager, and read only.

   Note: Do not remove the **`systemcred.dn`** parameter.

3. Remove the `accessmanagervault.properties` file from the *wp_profile_root*/`PortalServer/config/config` directory.

   Clustered environments: Perform this step on all portal nodes.

Disabling user provisioning

After you enable and use the user provisioning feature within IBM Security Access Manager, you can disable the feature.

About this task

Perform the following steps to disable user provisioning within Security Access Manager:

Important: Perform these steps on one portal node in a clustered environment.

Procedure

1. Run the following task to disable user provisioning:
   - Linux : `./ConfigEngine.sh disable-tam-userprov -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`* from the *wp_profile_root*`/ConfigEngine` directory.
   - IBM i: `ConfigEngine.sh disable-tam-userprov -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`* from the *wp_profile_root*`/ConfigEngine` directory.
   - Windows: `ConfigEngine.bat disable-tam-userprov -DWasPassword=`*`password`* `-Dwp.ac.impl.PDAdminPwd=`*`password`* from the *wp_profile_root*`\ConfigEngine` directory.

   Note: In a clustered environment **`WasPassword`** is the Deployment Manager administrative password.
2. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Configuring eTrust SiteMinder

IBM WebSphere Portal Express supports the use of Computer Associates eTrust SiteMinder for authentication and authorization.

About this task

Before you configure eTrust SiteMinder for authentication or authorization, you must complete the following tasks:

Procedure

1. Install and configure WebSphere Portal Express, including databases and LDAP user registry.
2. Install Computer Associate's Policy Server.
3. Install the eTrust SiteMinder Software Development Kit on the same server as WebSphere Portal Express if you plan to use eTrust SiteMinder for both authentication and authorization. Refer to the eTrust SiteMinder documentation for more information.

4. Install the eTrust SiteMinder Application Server Agent. Configure the eTrust SiteMinder Trust Association Interceptor (TAI). Follow the instructions in the eTrust SiteMinder documentation

   Note: Copy the `smagent.properties` file from the eTrust SiteMinder application server agent installation directory to the *wp_profile_root*`/ConfigEngine/properties` directory. By default, the Application Server Agent installation enables agents other than the one used for authentication. These agents are not tested with WebSphere Portal Express and should be disabled. Modify the following files in the eTrust SiteMinder installation directory to set **`EnableWebAgent=`**`no`:
   By default, the Application Server Agent installation enables agents other than the one used for authentication. These agents are not tested with WebSphere Portal Express and must be disabled. Modify the following files in the eTrust SiteMinder installation directory to set **`EnableWebAgent=`**`no`:

   `AsaAgent-az.conf`

   `AsaAgent-auth.conf`
5. If you plan to use eTrust SiteMinder for both authentication and authorization, ensure that the following two files are in the WebSphere Application Server `lib/ext` directory.
   - `smjavasdk2.jar`
   - `cryptoj.jar`

   If the directory is missing the JAR files, copy them from the eTrust SiteMinder SDK `CA/sdk/java` directory.
6. Configure the security provider. Go to Configure the JVM to Use the JSafeJCE Security Provider for instructions.
7. Create and specify the following eTrust SiteMinder Domain objects if you plan to use eTrust SiteMinder for both authentication and authorization. Refer to the eTrust SiteMinder Policy Design documentation for information about how to create these objects:
   - **User Directory**: The LDAP server and suffix
   - **Authentication Scheme**: Associates with the eTrust SiteMinder realms that WebSphere Portal Express creates.

     Note: An eTrust SiteMinder realm is different from an LDAP realm or a basic authentication realm. Within the eTrust SiteMinder administrative console, a realm is an administrative object that represents a protected URL root. An example is `/wps/myportal`. eTrust SiteMinder realms in combination with eTrust SiteMinder policies determine which users and groups are allowed to go to the protected URL root and its child URL.
   - **Agent**: An eTrust SiteMinder WebAgent that is configured to support 4.x agents or a custom eTrust SiteMinder agent. The agent must have a static shared secret to allow communication with the eTrust SiteMinder Policy Server.

What to do next

Choose the appropriate task to configure eTrust SiteMinder:

"Configuring eTrust SiteMinder for authentication and authorization" on page 1659
You can configure Computer Associates eTrust SiteMinder to perform both authentication and authorization for IBM WebSphere Portal Express. Using eTrust SiteMinder to perform only authorization is not supported at this time.

"Configuring eTrust SiteMinder to perform authentication" on page 1661
IBM WebSphere Portal Express includes a configuration task called `enable-sm-tai`. This task interacts with IBM WebSphere Application Server security configuration to enable the eTrust SiteMinder TAI and to create it as one of the interceptors. You can configure eTrust SiteMinder to provide authentication independently from configuring it to provide authorization. Using it to perform authorization only is not supported at this time.

"Configuring eTrust SiteMinder to perform authorization" on page 1662
You can configure Computer Associates eTrust SiteMinder to perform authorization independently from configuring it to perform authentication. However, if you use eTrust SiteMinder to perform authorization for IBM WebSphere Portal Express, you should also use it to perform authentication. Using eTrust SiteMinder to perform only authorization is not supported at this time.

"Removing eTrust SiteMinder" on page 1665
After you have installed and used Computer Associates eTrust SiteMinder, you may find that you no longer require its use. You can then remove it from the IBM WebSphere Portal Express environment and restore authentication capabilities to IBM WebSphere Application Server and authorization capabilities to WebSphere Portal Express.

Configuring eTrust SiteMinder for authentication and authorization

You can configure Computer Associates eTrust SiteMinder to perform both authentication and authorization for IBM WebSphere Portal Express. Using eTrust SiteMinder to perform only authorization is not supported at this time.

About this task

Install Computer Associates eTrust SiteMinder Trust Association Interceptor (TAI) distribution on the same machine as WebSphere Portal Express. If you are completing this task in a clustered environment, you must install the eTrust SiteMinder TAI distribution on each node in the cluster.

Complete the following steps to configure eTrust SiteMinder for authentication and authorization:

Procedure

1. Copy the `smagent.properties` file from the eTrust SiteMinder application server agent installation directory to the *wp_profile_root*`/properties` directory.

   Clustered environments: Complete this step on all nodes.
2. By default, the Application Server Agent installation enables agents other than the one used for authentication. These agents are not tested with WebSphere Portal Express and must be disabled. Modify the following files in the eTrust SiteMinder installation directory to set **`EnableWebAgent=`**`no`:

   ```
   AsaAgent-az.conf
   AsaAgent-auth.conf
   ```

   Clustered environments: Complete this step on all nodes.
3. Update the Namespace management parameters in the `wkplc_comp.properties` file

a. For **wp.ac.impl.EACserverName**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

   Note: If set, **wp.ac.impl.EACcellName** and **wp.ac.impl.EACappname** must also be set. All three parameters must be set or none of them.

b. For **wp.ac.impl.EACcellName**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

   Note: If set, **wp.ac.impl.EACserverName** and **wp.ac.impl.EACappname** must also be set.

c. For **wp.ac.impl.EACappname**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

   Note: If set, **wp.ac.impl.EACcellName** and **wp.ac.impl.EACserverName** must also be set.

d. For **wp.ac.impl.reorderRoles**, type `false` to keep the role order or `true` to reorder the roles by resource type first.

4. Enter the following parameters in the `wkplc_comp.properties` file; go to the SiteMinder heading:

   Clustered environments: Complete this step on all nodes.

   Cluster note: Complete this step on all nodes in the cluster. The following parameters must match on all nodes in the clustered environment. The one exception is the **wp.ac.impl.PDServerName** parameter.

   a. For **wp.ac.imp.SMDomain**, type the eTrust SiteMinder Domain containing all externalized resources.
   b. For **wp.ac.impl.SMScheme**, type the eTrust SiteMinder Authentication scheme object name to use when you create realms.
   c. For **wp.ac.impl.SMAgent**, type the agent name that is created on eTrust SiteMinder for a specific external security manager instance.
   d. For **wp.ac.impl.SMAgentPwd**, type the password for **wp.ac.impl.SMAgent**.
   e. For **wp.ac.impl.SMadminId**, type the administrative user ID that eTrust SiteMinder uses to access the eTrust SiteMinder policy server.
   f. For **wp.ac.impl.SMAdminPwd**, type the password for **wp.ac.impl.SMadminId**.
   g. For **wp.ac.impl.SMUserDir**, type the eTrust SiteMinder User Directory object that references the LDAP user registry.
   h. For **wp.ac.impl.SMFailover**, type `true` if more than one server is listed in **wp.ac.impl.SMServers** or type `false` if no additional servers are available for failover.
   i. For **wp.ac.impl.SMServers**, type a comma-delimited list of servers for the eTrust SiteMinder agent.

5. Save your changes to the properties file.
6. Run the following task to configure eTrust SiteMinder for authentication and authorization:
   - Linux : `./ConfigEngine.sh enable-sm-all` from the *wp_profile_root*`/ConfigEngine` directory
   - IBM i: `ConfigEngine.sh enable-sm-all` from the *wp_profile_root*`/ConfigEngine` directory

- Windows: `ConfigEngine.bat enable-sm-all` from the *wp_profile_root*`\ConfigEngine` directory

Clustered environments: Complete this step on all nodes.

7. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see "Starting and stopping servers, deployment managers, and node agents" on page 1216.

What to do next

Depending on your configuration, the XML configuration interface might not be able to access WebSphere Portal Express through eTrust SiteMinder. To allow the XML configuration interface access, use eTrust SiteMinder to define the configuration URL (`/wps/config`) as unprotected. Refer to the eTrust SiteMinder documentation for specific instructions.

Configuring eTrust SiteMinder to perform authentication

IBM WebSphere Portal Express includes a configuration task called `enable-sm-tai`. This task interacts with IBM WebSphere Application Server security configuration to enable the eTrust SiteMinder TAI and to create it as one of the interceptors. You can configure eTrust SiteMinder to provide authentication independently from configuring it to provide authorization. Using it to perform authorization only is not supported at this time.

Before you begin

Install Computer Associates eTrust SiteMinder Trust Association Interceptor (TAI) distribution on the same machine as WebSphere Portal Express. If you are performing this task in a clustered environment, you must install the eTrust SiteMinder TAI distribution on each node in the cluster.

Important: If you have completed the TAI installation and configuration instructions included with the Computer Associates eTrust SiteMinder distribution, including registering the TAI with WebSphere Application Server, execution of this configuration task is not required.

About this task

Perform the following steps to enable the eTrust SiteMinder TAI and create a new interceptor:

Procedure

1. Copy the `smagent.properties` file from the eTrust SiteMinder application server agent installation directory to the *wp_profile_root*`/properties` directory:

   Clustered environments: Complete this step on all nodes.

2. By default, the Application Server Agent installation enables agents other than the one used for authentication. These agents are not tested with WebSphere Portal Express and must be disabled. Modify the following files in the eTrust SiteMinder installation directory to set **`EnableWebAgent=`**`no`:

   ```
   AsaAgent-az.conf
   AsaAgent-auth.conf
   ```

   Clustered environments: Complete this step on all nodes.

3. Run the following task to enable eTrust SiteMinder TAI:

- Windows: `ConfigEngine.bat enable-sm-tai -DWasPassword=password` from the *wp_profile_root*`\ConfigEngine` directory
- Linux: `./ConfigEngine.sh enable-sm-tai -DWasPassword=password` from the *wp_profile_root*`/ConfigEngine` directory

4. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see "Starting and stopping servers, deployment managers, and node agents" on page 1216.
5. Go to the "Verifying Trust Association Interceptors for authentication" on page 1666 file to verify that the TAI is working properly.

What to do next

Depending on your configuration, the XML configuration interface might not be able to access WebSphere Portal Express through eTrust SiteMinder. To allow the XML configuration interface access, use eTrust SiteMinder to define the configuration URL (`/wps/config`) as unprotected. Refer to the eTrust SiteMinder documentation for specific instructions.

Configuring eTrust SiteMinder to perform authorization

You can configure Computer Associates eTrust SiteMinder to perform authorization independently from configuring it to perform authentication. However, if you use eTrust SiteMinder to perform authorization for IBM WebSphere Portal Express, you should also use it to perform authentication. Using eTrust SiteMinder to perform only authorization is not supported at this time.

About this task

Complete the following steps to configure eTrust SiteMinder for authorization:

Procedure

1. Optional: In eTrust SiteMinder version 5.5 and higher, the configuration for eTrust SiteMinder Web Agents, including shared secrets, is centrally administered and can be dynamic. You may create a new custom agent to ensure a static shared secret. Follow these steps to create a custom agent in eTrust SiteMinder:
   a. Open the eTrust SiteMinder Administration console.
   b. Select **Agent Types** from the **View** > **Agent Types** menu.
   c. Right-click **Agent Types**, and select **Create Agent Type** from the pop-up menu.
   d. Enter a **Name** and an **Action** for the new agent type. Other fields are optional.
   e. Click **OK**.
   f. Select **Agents** from the **View** > **Agents** menu.
   g. Right-click **Agent**, and select **Create Agent** to create an agent object of the new agent type.
2. Optional: Ensure that users are no longer created through WebSphere Portal Express.

   If you use eTrust SiteMinder, you probably have a user provisioning process for creating and updating users and groups and administering group membership. You will probably want to continue using that user provisioning process instead of managing your directory through WebSphere Portal Express. WebSphere Portal Express creates entries in the directory in two ways:

- Administrators can create entries with the Manage Users and Groups portlet
- Users can create entries with the self-registration screen

3. Use a text editor to open the `wkplc_comp.properties` file in the following directory:
   - Linux: *wp_profile_root*`/ConfigEngine/properties`
   - IBM i: *wp_profile_root*`/ConfigEngine/properties`
   - Windows: *wp_profile_root*`\ConfigEngine\properties`
4. Update the Namespace management parameters in the `wkplc_comp.properties` file
   a. For **wp.ac.impl.EACserverName**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

      Note: If set, **wp.ac.impl.EACcellName** and **wp.ac.impl.EACappname** must also be set. All three parameters must be set or none of them.
   b. For **wp.ac.impl.EACcellName**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

      Note: If set, **wp.ac.impl.EACserverName** and **wp.ac.impl.EACappname** must also be set.
   c. For **wp.ac.impl.EACappname**, type the Namespace context information to further distinguish externalized portal role names from other role names in the namespace.

      Note: If set, **wp.ac.impl.EACcellName** and **wp.ac.impl.EACserverName** must also be set.
   d. For **wp.ac.impl.reorderRoles**, type `false` to keep the role order or `true` to reorder the roles by resource type first.
5. Enter the following parameters in the `wkplc_comp.properties` file; go to the SiteMinder heading:

   Clustered environments: Complete this step on all nodes.

   Cluster note: Complete this step on all nodes in the cluster. The following parameters must match on all nodes in the clustered environment. The one exception is the **wp.ac.impl.PDServerName** parameter.
   a. For **wp.ac.imp.SMDomain**, type the eTrust SiteMinder Domain containing all externalized resources.
   b. For **wp.ac.impl.SMScheme**, type the eTrust SiteMinder Authentication scheme object name to use when you create realms.
   c. For **wp.ac.impl.SMAgent**, type the agent name that is created on eTrust SiteMinder for a specific external security manager instance.
   d. For **wp.ac.impl.SMAgentPwd**, type the password for **wp.ac.impl.SMAgent**.
   e. For **wp.ac.impl.SMadminId**, type the administrative user ID that eTrust SiteMinder uses to access the eTrust SiteMinder policy server.
   f. For **wp.ac.impl.SMAdminPwd**, type the password for **wp.ac.impl.SMadminId**.
   g. For **wp.ac.impl.SMUserDir**, type the eTrust SiteMinder User Directory object that references the LDAP user registry.

h. For **wp.ac.impl.SMFailover**, type `true` if more than one server is listed in **wp.ac.impl.SMServers** or type `false` if no additional servers are available for failover.

i. For **wp.ac.impl.SMServers**, type a comma-delimited list of servers for the eTrust SiteMinder agent.

6. If any of the policy servers listed in the **wp.ac.impl.SMServers** parameter are configured to use ports other than the defaults, you can customize the following values for each server listed:

   ipaddress.accountingPort=44441

   ipaddress.authenticationPort=44442

   ipaddress.authorizationPort=44443

   ipaddress.connectionMax=30

   ipaddress.connectionMin=10

   ipaddress.connectionStep=5

   ipaddress.timeout=60

   Where *ipaddress* is the specific server IP listed in the **wp.ac.impl.SMServers** parameter.

   Clustered environments: Complete this step on all nodes.

7. Save your changes to the properties file.
8. Run the following task to configure eTrust SiteMinder for authorization:
   - Windows: `ConfigEngine.bat enable-sm-authorization -DWasPassword=`*password* `-Dwp.ac.impl.SmAgentPw=`*password* `-Dwp.ac.impl.SmAdminPw=`*password* from the *wp_profile_root*`\ConfigEngine` directory
   - Linux: `./ConfigEngine.sh enable-sm-authorization -DWasPassword=`*password* `-Dwp.ac.impl.SmAgentPw=`*password* `-Dwp.ac.impl.SmAdminPw=`*password* from the *wp_profile_root*`/ConfigEngine` directory

   Clustered environments: Complete this step on all nodes.

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see "Starting and stopping servers, deployment managers, and node agents" on page 1216.
10. If users other than the administrator are allowed to externalize resources, add those users to the eTrust SiteMinder realm representing the Administrator of EXTERNAL_ACCESS_CONTROL.
11. Complete the following steps from the Resource Permissions portlet:
    a. Select a resource type.
    b. Click the **Assign Access** icon for the specific resource.
    c. Click the **Edit Role** icon for a role that you want to externalize.
    d. Click **Add** to explicitly assign at least one user or group to your chosen role for the resource.
    e. Select the specific users or user groups by clicking on **Search for Users or User Groups** or clicking on the pull down for the **Search by** option where the default is set to All available. Click **OK**.
    f. An informational message box should display the message that members were successfully added to the role.
    g. Optional: Explicitly assign additional roles. If you do not assign at least one user or group to each role type for the resource, you must use the

external security manager interface to create this role type later. For example, if you do not assign any users or groups to the Editor role type for the resource, then you must use the external security manager interface to create the Editor role type later.

h. Click the **Externalize** icon for the resource. These steps move every role that is defined for each resource you assigned to the eTrust SiteMinder Policy Domain. One policy is defined for each externalized role.

12. Add users and groups to the eTrust SiteMinder policies corresponding to the appropriate roles.

Removing eTrust SiteMinder

After you have installed and used Computer Associates eTrust SiteMinder, you may find that you no longer require its use. You can then remove it from the IBM WebSphere Portal Express environment and restore authentication capabilities to IBM WebSphere Application Server and authorization capabilities to WebSphere Portal Express.

About this task

Perform the following steps to remove eTrust SiteMinder from the WebSphere Portal Express environment:

Procedure

1. Perform the following steps if you used eTrust SiteMinder for authorization:
   a. Use either the Resource Permissions portlet or, if you are set up to execute it, the XML Configuration Interface (xmlaccess) to internalize any resources managed by eTrust SiteMinder.
   b. Edit the *wp_profile_root*`/PortalServer/config/config/services.properties` file and change the value of **`com.ibm.wps.services.ac.ExternalAccessControlService`** to `com.ibm.wps.ac.impl.ExternalAccessControlDefaultImpl`.

      Note: In a cluster environment, you must edit the `services.properties` file on all nodes.

   c. Change the **`enableExternalization`** property to `false` in the External Access Control Service. This will prevent the Externalize/Internalize icon from appearing in the Administration Access portlet after removing eTrust SiteMinder.
2. If you previously disabled the ability to create users through WebSphere Portal Express, restore it. Re-enable WebSphere Portal Express auto-registration. Restore the backup copy of the theme as appropriate to remove any features specific to eTrust SiteMinder.
3. Optional: Complete the following steps to remove the eTrust SiteMinder TAI module from the WebSphere Application Server console:
   a. In the WebSphere Application Server Administration Console, click **Securiry** > **Global security** > **Web and SIP security** > **Trust association** > **Interceptors.**.
   b. Select the eTrust SiteMinder TAI module and then click **Delete**.
   c. Click **OK** and then click **Save**.
4. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see "Starting and stopping servers, deployment managers, and node agents" on page 1216.
5. If necessary, uninstall any Computer Associates components.

Verifying Trust Association Interceptors for authentication

After configuring IBM WebSphere Portal Express to use an external security manager for authentication, you should verify that the Trust Association Interceptors (TAI) are working properly before continuing with any additional configuration tasks.

About this task

Complete the following steps to verify that the Trust Association Interceptors are working properly for authentication:

Procedure

1. Enter the appropriate URL in the Web browser address bar:
   - IBM Security Access Manager: `https://`*`WebSEAL_hostname:WebSEAL_port/junction`*`/wps/myportal`
   - Computer Associates eTrust SiteMinder: `http://`*`SM_agent_hostname:SM_agent_port`*`/wps/myportal`
2. Authenticate through the external security managers. After you log in, you should be directed to the secure and personalized `myportal` page. If you are directed to the login page or the public page, there is a problem with the TAI configuration. If you are using the Security Access Manager TAI (**com.ibm.sec.authn.tai.TAMETai** or **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus**) that WebSphere Portal Express set up, ensure that the Security Access Manager authorization server is up and running.

Changing the login and logout pages

By default, when unauthenticated users attempt to access the `myportal` page, they get redirected to the login page to provide a user name and password. When using a WebSEAL or Computer Associates eTrust SiteMinder TAI for authentication, you no longer need to use the IBM WebSphere Portal Express login page. Instead, the login icon should point to the protected portal page.

About this task

Complete the following steps to change the login and logout pages:

Procedure

1. Locate the theme files that contain the login and logout links. The files that contain the login and logout links can be different, depending on the theme. In more recent themes, these links might be located in `Default.jsp`. In older themes, the links might be located in `banner.jspf`.

   Finding theme resources: See the *Location of theme resources* link in the Related section.
2. Create a backup copy of the theme file before proceeding.
3. Open the theme file and locate the section for the login button.
4. Replace the login button anchor tag that is not commented out with the following JSP fragment:

```
<%-- comment this to enable screen login --%>
            <%-- loginOnClick is provided so the client-side aggregation
theme can add this link without creating a different copy of this file.
--%>
            <portal-logic:if loggedIn="no">
```

```
            <c:if test="${empty loginOnClick}">
            <li class="wptheme-toolbar-last"><a
href='<portal-navigation:url
                 home="protected" screen="Home"/>'
<%=bidiDirAttr%>><portal-fmt:text key="link.login"
bundle="nls.engine"/></a></li>
            </c:if>
        </portal-logic:if>
        --%>
```

Note: The previous example uses the 'portal-fmt:' prefix to designate JSP tags from the tag library in `portal.tld`. Your custom JSPs might use a different tag prefix.

5. Touch the `Default.jsp` file after editing any JSP files and before any restart. This updates the timestamp on the file to the current time and will signal a recompile of `Default.jsp` to incorporate the edit changes from other JSP files. Type: `touch Default.jsp`. An alternative is to edit (open and save) `Default.jsp`, which has the same effect as the touch command.
6. Optional: Redirect the browser to navigate to the logoff page of the external security manager (ESM) after the WebSphere Portal Express logoff command executes. Learn how to invalidate the single sign on session of the ESM by reviewing the documentation provided by the ESM relating to logoff pages.

   Security Access Manager WebSEAL provides `http://webseal/pkmslogout` as a special URL to terminate the WebSEAL single sign on session

   In eTrust SiteMinder, the Web Agent configuration object contains a property named **`LogoffUri`** where you can supply a URL to terminate the eTrust SiteMinder login session

   Complete the following steps to enable WebSphere Portal Express to execute the external security manager logoff URL after completing its logoff command:

   a. Specify the following values in the *wp_profile_root*`/PortalServer/config/ConfigService.properties` file:

      `redirect.logout=``true`

      `redirect.logout.ssl=``false` or `true`, depending on your environment

      `redirect.logout.url=`*`protocol://host_name/logout_page`*

      where *protocol* is the protocol of the ESM machine: `http` or `https`, *host_name* is the fully qualified host name of the ESM machine, and *logout_page* is the ESM page that users will be directed to when they log out. Refer to the ESM Administrator's Guide for information about using logout forms.

   b. Run the following task to update the property:

Table 240. `update-properties` task and parameters by operating system

Operating system	Task
Windows:	`ConfigEngine.bat update-properties -DWasPassword=`*`password`* from the *wp_profile_root*`\ConfigEngine` directory
Linux:	`./ConfigEngine.sh update-properties -DWasPassword=`*`password`* from the *wp_profile_root*`/ConfigEngine` directory

   c. Restart the WebSphere_Portal server on the standalone server or on each cluster member.

Related concepts:

"Understanding the Portal Version 8.5 modularized theme" on page 2521
Modern websites and browsers enable incredible new capabilities that can greatly enhance your user's web experiences. However, these capabilities are not without cost in terms of large page sizes and more processing in the browser when each page is rendered. These capabilities are worth it when you need them, but removing them for an entire site or including them only on pages that take advantage of these capabilities provides for more flexibility.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Managing access control with external security managers

IBM WebSphere Portal Express externalizes roles and uses access control to control role membership. From the perspective of the external security manager, these externalized roles contain only one permission: membership in the role. WebSphere Portal Express always determines the permissions associated with each role.

About this task

Note: It is not possible to combine the usage of externalizes roles and externalized role mappings with portal managed pages feature. Portal pages cannot be externalized when being edited within a project and externalized resources cannot be added to projects.

For example, if you externalize the Editor@Market News Page role, you must use the external security manager to edit the access control for that role. WebSphere Portal Express still determines the permissions that are associated with the Editor role type. Roles are always associated with a specific resource, so the role Editor@Market News Page contains specific permissions on the Market News Page only. Use the Resource Permissions portlet or the XML configuration interface to move resources back and forth from internal to external access control.

By default, externalized roles appear in the external security manager as *Role Type@Resource Type/Name/Object ID*. For example, Administrator@PORTLET_APPLICATION/Welcome/1_1_1G.

You can change this format to *Resource Type/Name/Object ID@Role type*. This format change groups the roles by resource name instead of by role type. For example, PORTLET_APPLICATION/Welcome/1_0_1G@Administrator. This format change is visible only when the roles are externalized. This change does not affect the way roles are displayed in WebSphere Portal Express.

The `Administrator@VIRTUAL/wps.EXTERNAL ACCESS CONTROL/1` role is never affected by this format change. This role always appears with the role type Administrator.

Complete the following steps to manage access control with external security managers:

Procedure

1. Use the Resource Permissions portlet to internalize any external roles.
2. Log on to the WebSphere Integrated Solutions Console.

3. Modify the **WP AccessControlDataManagementService** Resource Environment Provider; change the **accessControlDataManagement.reorderRoleNames** parameter to `true`.

   Note: Add the **accessControlDataManagement.reorderRoleNames** parameter if it does not exist.
4. Save your changes and restart the WebSphere_Portal server.
5. Use the **Resource Permissions** portlet to externalize the resources you internalized in the first step.

Example

Example of roles list with **reorderRoleNames**=`false`:

```
Administrator@WEB_MODULE/Tracing.war/1_0_3K
Administrator@PORTLET_APPLICATION/Welcome/1_0_1G
User@WEB_MODULE/Tracing.war/1_0_3K
Privileged User@WEB_MODULE/Tracing.war/1_0_3K
Privileged User@PORTLET_APPLICATION/Welcome/1_0_1G
```

Example of roles list with **reorderRoleNames**=`true`:

```
PORTLET_APPLICATION/Welcome/1_0_1G@Administrator
PORTLET_APPLICATION/Welcome/1_0_1G@Privileged User
WEB_MODULE/Tracing.war/1_0_3K@Administrator
WEB_MODULE/Tracing.war/1_0_3K@Privileged User
WEB_MODULE/Tracing.war/1_0_3K@User
```

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Deleting passwords from properties files

The configuration tasks might require you to write security-sensitive information, such as passwords, into multiple properties files. When you no longer need this security-sensitive information for your configuration, you should remove them and move the files to a safe place or set the file permissions so that only authorized users can read them.

About this task

Complete the following steps to delete passwords and other security-sensitive information from the properties files:

Note: After completing the tasks to clean up the work directory and delete the passwords, you might find that in order to successfully perform additional configuration tasks, you need these passwords. Some tasks require you to add the passwords back to the `wkplc.properties`, `wkplc_comp.properties`, `wkplc_dbdomain.properties`, and `wkplc_sourceDb.properties` files while other tasks allow you to specify the passwords on the command line using the –D flag. Refer to the configuration task documentation to determine which method is required.

Procedure

1. Complete the following steps to access the WebSphere Portal Express configuration directory:

Table 241. Steps to access the configuration directory by operating system

Operating system	Steps
Windows	Complete the following steps to access the configuration directory: 1. Open a command prompt. 2. Change to the *wp_profile_root*\ `ConfigEngine` directory.
Linux	Complete the following steps to access the configuration directory: 1. Open a terminal session. 2. Change to the *wp_profile_root*/ `ConfigEngine` directory.
IBM i	Complete the following steps to access the configuration directory: 1. Type `STRQSH` on an OS/400 command line to start the Qshell Interpreter. 2. Change to the *wp_profile_root*/ `ConfigEngine` directory.

2. Remove the work directory that was created during the installation:
   - Windows: `ConfigEngine.bat cleanup-work-dir -DWasPassword=`*`password`*
   - Linux: `./ConfigEngine.sh cleanup-work-dir -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh cleanup-work-dir -DWasPassword=`*`password`*

   Note: Before running additional tasks, check the output for any error messages and, if instructed, correct any items before rerunning the task.
3. Enter the following commands from the configuration directory to remove all passwords from the `wkplc.properties`, `wkplc_comp.properties`, `wkplc_sourceDb.properties`, and `wkplc_dbdomain.properties` files:
   - Windows: `ConfigEngine.bat delete-passwords -DWasPassword=`*`password`*
   - Linux: `./ConfigEngine.sh delete-passwords -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh delete-passwords -DWasPassword=`*`password`*

   Note: Before running additional tasks, check the output for any error messages and, if instructed, correct any items before rerunning the task.

Updating user ID and passwords

IBM WebSphere Portal Express and IBM WebSphere Application Server use some accounts from the registry (for example, the LDAP server) including administrative and bind IDs for authenticated access to databases and LDAP severs respectively, as well as the WebSphere Portal Express and WebSphere Application Server administrative IDs. Often this means that the account passwords are stored in the WebSphere Portal Express and WebSphere Application Server bootstraps configuration files, which allows the authentication process to work.

About this task

Note: Before updating any user ID or password, review "User IDs and passwords" located under Planning for WebSphere Portal Express.

If the password for any ID is changed (either through WebSphere Portal Express or through any other means, including directly through the LDAP administration interfaces), then the password value stored in the appropriate configuration file must be changed at the same time. The following instructions describe how to make the appropriate changes based on which account passwords might have changed.

Remember: If you reuse the same account ID/password for multiple purposes, such as using `wpsbind` as the administrative ID and the LDAP access ID, then you might have to do more than one of the following steps to accommodate the password change. Some changes, particularly changes made through the WebSphere Integrated Solutions Console, require that the WebSphere Integrated Solutions Console is open and the current ID/password logged in before actually making the password change in the registry. Carefully plan which steps are required and in what order to avoid not being able to bring up server processes or log in.

Use the following topics to change passwords to better secure your environment.

"Changing the WebSphere Portal Express administrator password" on page 1672
IBM WebSphere Portal Express treats `wpsadmin` (the administrator) as any other user, just with more permissions granted. With a normal configuration, it is possible to change the `wpsadmin` or equivalent password through the user interface, just like any other user can manage their own password through the user interface. However, if the `wpsadmin` account is also used for more than just the administrator, then additional changes, outlined in other steps in this section, must be made to accommodate the change.

"Changing the WebSphere Application Server administrator password in the file registry" on page 1672
If you are using the file registry in the federation repository to store passwords, you need to change the passwords in the file registry.

"Changing the WebSphere Application Server administrator password in the LDAP server using the LDAP administration interface" on page 1673
If you are using the IBM Directory Server or IBM SecureWay Security Server for z/OS and OS/390 LDAP server, you can change the IBM WebSphere Application Server administrator password in the LDAP server using the LDAP administration interface. If you are using any other LDAP server, refer to the product documentation for information about changing passwords.

"Replacing the WebSphere Application Server administrator user ID" on page 1674
If you change your security configuration, you might need to replace your old IBM WebSphere Application Server administrator user ID with a new WebSphere Application Server administrator user ID.

"Replacing the WebSphere Portal Express administrator user ID" on page 1675
If you change your security configuration, you might need to replace your old IBM WebSphere Portal Express administrator user ID with a new WebSphere Portal Express administrator user ID.

"Changing the LDAP bind password" on page 1676
If you use an LDAP user registry, you must adapt the LDAP bind user ID.

"Changing database passwords that are used by WebSphere Portal Express" on page 1677
If database passwords are modified or expired, you must specify the new

passwords on the IBM WebSphere Application Server and on the IBM DB2 Universal Database Enterprise Server Edition server so that IBM WebSphere Portal Express can access them.

Changing the WebSphere Portal Express administrator password

IBM WebSphere Portal Express treats `wpsadmin` (the administrator) as any other user, just with more permissions granted. With a normal configuration, it is possible to change the `wpsadmin` or equivalent password through the user interface, just like any other user can manage their own password through the user interface. However, if the `wpsadmin` account is also used for more than just the administrator, then additional changes, outlined in other steps in this section, must be made to accommodate the change.

About this task

Perform the following steps to change the administrator password:

Note: You can also change the Administrator password, like any other user password, using an LDAP editor.

Procedure

1. Log in to WebSphere Portal Express as an administrator.
2. Click your user ID.
3. Complete the appropriate fields to change your password.
4. Click **OK**.
5. Complete the following steps to change the information stored in the **SearchAdminUser** alias:
   a. Log in to the WebSphere Integrated Solutions Console.
   b. Click **Security** > **Global security**.
   c. Under Authentication, click **Java Authentication and Authorization Service** > **J2C authentication data**.
   d. Edit the **SearchAdminUser** alias.
   e. Update the user ID and/or password to match your WebSphere Portal Express administrator information.

What to do next

Additionally, you should also change the password in the `wkplc.properties` file, located in the *wp_profile_root*`/ConfigEngine/properties` directory.

Changing the WebSphere Application Server administrator password in the file registry

If you are using the file registry in the federation repository to store passwords, you need to change the passwords in the file registry.

About this task

Complete the following steps to change the WebSphere Application Server administrator password stored in the file registry:

Procedure

1. Using a command prompt, change to the *wp_profile_root*/bin directory.
2. Issue the wsadmin -conntype NONE command and press **Enter**.
3. Issue the $AdminTask changeFileRegistryAccountPassword {-userId <wpsadmin_ID> -password <wpsadmin_new_password>} command and press **Enter**.
4. Issue the $AdminConfig save command and press **Enter**.
5. Complete the following steps to update the **RunAsRole**, which changes the stored password:

   You can change the password for the WebSphere Application Server administrator user ID using the WebSphere Portal Express Edit My Profile portlet, the native utilities for the user repository, such as the LDAP administration interface or the WebSphere Application Server Administrative utilities. Regardless of which option you choose, once you have updated the password, you must also update the **RunAsRole** for the PZNScheduler application.

   a. Log on to the WebSphere Integrated Solutions Console with your new password.
   b. Go to **Applications** > **Application Types** > **WebSphere enterprise applications**.
   c. Locate and click the **pznscheduler** application.
   d. Click **User RunAs Roles** under Detail Properties.
   e. Select **RuleEventRunAsRole** and then click **Remove**.
   f. Enter the fully distinguished name (DN) of the WebSphere Application Server Administrator in the **username** field and the new password in the **password** field.
   g. Select **RuleEventRunAsRole** and then click **Apply** to apply your changes.
   h. Click **OK**, save your changes, and then restart the server.

Changing the WebSphere Application Server administrator password in the LDAP server using the LDAP administration interface

If you are using the IBM Directory Server or IBM SecureWay Security Server for z/OS and OS/390 LDAP server, you can change the IBM WebSphere Application Server administrator password in the LDAP server using the LDAP administration interface. If you are using any other LDAP server, refer to the product documentation for information about changing passwords.

About this task

Perform the following steps to change the WebSphere Application Server administrator password in the LDAP server using the LDAP administration interface:

Attention: The following directions assume an LDAP tree layout where the users are all in the cn=users,o=wps subtree in the directory server. You should adjust these directions based on your own LDAP server layout.

Tip: When you change the WebSphere Application Server administrator password, you should also change it in LDAP server.

Procedure

1. Log in to the LDAP server Web Administration Tool.
2. Click **Directory management** > **Manage entries**.
3. Select the **o=wps RDN** and click **Expand**.
4. Select **cn=users** and click **Expand**.
5. Select the WebSphere Application Server administrator user and click **Edit Attributes**.

   Note: If this is your first time navigating to this screen, you may need to click **Next** before you can click the **Optional attributes** link.
6. Click **Optional attributes**.
7. Enter the new password in the **userPassword** field.
8. Click **OK**.
9. Exit the Web Administration Tool.
10. Complete the following steps to update the **RunAsRole**, which changes the stored password:

    You can change the password for the WebSphere Application Server administrator user ID using the WebSphere Portal Express Edit My Profile portlet, the native utilities for the user repository, such as the LDAP administration interface or the WebSphere Application Server Administrative utilities. Regardless of which option you choose, once you have updated the password, you must also update the **RunAsRole** for the PZNScheduler application.
    a. Log on to the WebSphere Integrated Solutions Console with your new password.
    b. Go to **Applications** > **Application Types** > **WebSphere enterprise applications**.
    c. Locate and click the **pznscheduler** application.
    d. Click **User RunAs Roles** under Detail Properties.
    e. Select **RuleEventRunAsRole** and then click **Remove**.
    f. Enter the fully distinguished name (DN) of the WebSphere Application Server Administrator in the **username** field and the new password in the **password** field.
    g. Select **RuleEventRunAsRole** and then click **Apply** to apply your changes.
    h. Click **OK**, save your changes, and then restart the server.

Replacing the WebSphere Application Server administrator user ID

If you change your security configuration, you might need to replace your old IBM WebSphere Application Server administrator user ID with a new WebSphere Application Server administrator user ID.

About this task

Complete the following steps to replace the WebSphere Application Server administrator user ID:

Procedure

1. Create a user in the **Manage Users and Groups** portlet to replace the current WebSphere Application Server administrative user.

2. Run the following task to replace the old WebSphere Application Server administrative user with the new user:
   - Linux : `./ConfigEngine.sh wp-change-was-admin-user -DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* from the *wp_profile_root*`/ConfigEngine` directory.
   - IBM i: `ConfigEngine.sh wp-change-was-admin-user -DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* from the *wp_profile_root*`\ConfigEngine` directory.
   - Windows: `ConfigEngine.bat wp-change-was-admin-user -DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* from the *wp_profile_root*`\ConfigEngine` directory.

   Note: Refer to the description of the `newAdminId` property in `wkplc.properties` under `wp_profile_root\ConfigEngine\properties\` for guidance on populating the value in the command line.

   Additional parameter for stopped servers: This task verifies the user against a running server instance. If the server is stopped, add the **`-Dskip.ldap.validation`**`=true` parameter to the task to skip the validation.
3. Verify that the task completed successfully. Stop and restart all required servers.

What to do next

If you use an external security manager such as Security Access Manager, you must manually remove the old administrator user ID from the external security manager.

Replacing the WebSphere Portal Express administrator user ID

If you change your security configuration, you might need to replace your old IBM WebSphere Portal Express administrator user ID with a new WebSphere Portal Express administrator user ID.

About this task

Complete the following steps to replace the WebSphere Portal Express administrator user ID:

Important cluster note: If you are using IBM Web Content Manager within your clustered environment, you must complete these steps on every node in the cluster. If Web Content Manager is not configured, complete these steps only on the primary node.

Procedure

1. Create a user in the **Manage Users and Groups** portlet to replace the current WebSphere Portal Express administrative user.
2. Run the following task to replace the old WebSphere Portal Express administrative user with the new user:
   - **Linux :** `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* `-DnewAdminGroupId=`*`newadmingroupid`* from the *wp_profile_root*`/ConfigEngine` directory. The `-DnewAdminGroupId` parameter is required only if you plan to replace the old administrative group ID.

- **IBM i:** `ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* `-DnewAdminGroupId=`*`newadmingroupid`* from the *wp_profile_root*`/ConfigEngine` directory. The `-DnewAdminGroupId` parameter is required only if you plan to replace the old administrative group ID.
- **Windows:** `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* `-DnewAdminGroupId=`*`newadmingroupid`* from the *wp_profile_root*`\ConfigEngine` directory. The `-DnewAdminGroupId` parameter is required only if you plan to replace the old administrative group ID.

Additional parameter for stopped servers: This task verifies the user against a running server instance. If the server is stopped, add the **`-Dskip.ldap.validation`**`=true` parameter to the task to skip the validation.

3. Verify that the task completed successfully. Stop and restart all required servers.
4. Complete the following steps to change the information stored in the **SearchAdminUser** alias:
   a. Log in to the WebSphere Integrated Solutions Console.
   b. Click **Security** > **Global security**.
   c. Under Authentication, click **Java Authentication and Authorization Service** > **J2C authentication data**.
   d. Edit the **SearchAdminUser** alias.
   e. Update the user ID and/or password to match your WebSphere Portal Express administrator information.
5. Clustered environments: Synchronize the nodes.
   a. Log on to the Deployment Manager.
   b. Go to **System Administration** > **Nodes**.
   c. Select the nodes to synchronize from the list.
   d. Click **Full Resynchronize**.

What to do next

Notes:

- If you use an external security manager such as Security Access Manager, you must manually remove the old administrator user ID from the external security manager.
- If you set the default portal administrator user ID to be used as the crawler user ID for Portal Search, you need to adapt that crawler user ID accordingly. For more information, see the topic about *Managing the content sources of a search collection*.

Related tasks:

"Managing the content sources of a search collection" on page 701
Search collections consist of one or more content sources. You can administer the content sources.

Changing the LDAP bind password

If you use an LDAP user registry, you must adapt the LDAP bind user ID.

About this task

Go to "Updating the federated LDAP user registry" on page 594 to view information about how to change the LDAP bind password:

Changing database passwords that are used by WebSphere Portal Express

If database passwords are modified or expired, you must specify the new passwords on the IBM WebSphere Application Server and on the IBM DB2 Universal Database Enterprise Server Edition server so that IBM WebSphere Portal Express can access them.

Before you begin

- Ensure that the administrative server for WebSphere Application Server is running.
- If this server is a clustered environment, you must have the Deployment Manager and the nodes up and the WebSphere Portal Express server stopped.
- If the Virtual Member Manager (VMM) is using the database, see *Changing the password for a repository under a federated repositories configuration* in the related links for instructions on updating the VMM database password.

Procedure

1. Check whether the database user was disabled because of invalid login attempts. Re-enable the database user if necessary.
2. Update the data sources for WebSphere Portal Express:
   a. Log in to the WebSphere Integrated Solutions Console.
   b. Click **Security** > **Global security** > **Java Authentication and Authorization Service** > **J2C Authentication Data**.
   c. Select the alias that you want to change; for example:
      wpsDBAuth
      jcrDBAuth
      fbkDBAuth
      lmDBAuth
      wcmDBAuth
   d. Update the password accordingly.
   e. Click **Apply**, and then click **Save** to save the configuration. You are informed that `security.xml` was changed.
3. If you are an administrator and must change the DB2 password, you must change the database administrator user password on the system.
   a. Stop the DB2 server.
   b. Use the `passwd` command to change the password.
   c. Restart the DB2 server. You can verify the new password by running the `db2 CONNECT TO WPSDB user db2admin using password` task.
4. Restart the WebSphere Integrated Solutions Console.
5. On the DB2 server, complete the following steps:
   a. Click **Administrative Tools** > **Services**.
   b. Stop all running DB2 services.
   c. For each service that your DB2 instance uses, display the menu and select **Properties**.

d. Select the **Log On** tab and change the DB2 administrator's user name and password.

If you do not change the DB2 administrator's user name and password in the properties of each DB2 service, the DB2 database application does not start.

Results

Repeat for each JDBC Provider, data source, and alias that is affected.

Results:

WebSphere Application Server and WebSphere Portal Express were updated to use your new database passwords. Verify that the WebSphere Portal Express application server is running by opening the following URL in a browser: `http://hostname.example.com:10039/wps/portal`, where *hostname.example.com* is the fully qualified host name of the server where Portal is running and *10039* is the default transport port that is created by WebSphere Application Server. The port number might be different for your environment..

Chapter 13. Monitoring

WebSphere Portal includes tools and features to help you monitor the portal site.

"Portlet load monitoring for WebSphere Portal Express"
IBM WebSphere Portal Express now provides Portlet load monitoring. This can make your portal safer and more responsive.

"Analyzing portal usage data" on page 1687
You can collect data about the usage of your portal and analyze them.

"Auditing" on page 1731
IBM WebSphere Portal Express includes an auditing function that allows users to log certain events and their originators in to a separate log file. This file can then be used to track administrative activities.

Portlet load monitoring for WebSphere Portal Express

IBM WebSphere Portal Express now provides Portlet load monitoring. This can make your portal safer and more responsive.

Portlet load monitoring allows WebSphere Portal Express administrators to protect their portal by limiting the number of concurrent requests and the average response time allowed for JSR 168 or JSR 286 portlets. If a portlet exceeds either the defined maximum number of concurrent requests, or the average response time, then Portlet Load Monitoring no longer allows further requests by the portlet. Instead, the portal renders the portlet as unavailable, and the portlet code is no longer called for further requests. This way, the portal installation is protected from non-responsive portlets consuming an increasing number of threads.

These topics describe how you configure, administer, and use Portlet load monitoring and provides other useful information about it.

Note: Portlet load monitoring monitors JSR 168 and JSR 286 portlets only.

"Configuring and administering Portlet load monitoring" on page 1680
Here is an overview of the configuration and administration tasks and parameters for Portlet load monitoring.

"Portlet load monitoring properties" on page 1680
By setting the portal and portlet configuration parameters, you can monitor the session load and configure the parameters to increase performance.

"Administering Portlet load monitoring" on page 1682
You can administer Portlet load monitoring and the portlets that it monitors. You can determine whether and in which cases Portlet load monitoring blocks or reenables a portlet by setting its portlet preferences. You can also check which portlets Portlet load monitoring monitors, and you can manually block or activate these portlets. For example, you can reenable a portlet after Portlet load monitoring has blocked it.

"Logging and auditing events" on page 1684
Portlet load monitoring allows you to log events. For example, this can help you audit events. When Portlet load monitoring blocks or enables a portlet, it creates a log file entry in the IBM WebSphere Portal Express log file `SystemOut.log`. This log file entry contains the portlet object ID, the portlet name, the WAR file name of the portlet and the EAR file display name. The log

file entries consist of translated messages. If you use tools that monitor log files for events, you can check for log file entries that are related to Portlet load monitoring as described here.

"API for accessing Portlet load monitoring data" on page 1686
Portlet load monitoring provides an API for accessing the monitoring data. You can use this API to write custom code to access that data.

Configuring and administering Portlet load monitoring

Here is an overview of the configuration and administration tasks and parameters for Portlet load monitoring.

Portal wide configuration

You can do the following configuration tasks for Portlet load monitoring:

- Enabling or disabling Portlet load monitoring in your portal.
- Setting the sample number of requests by which the average response time for portlets is calculated. For example, if you set the sample number to 50, the average response time is calculated from the latest 50 requests that this portlet served. This setting is related to the average response time setting listed under administrative tasks.

Perform both of these tasks in the WebSphere Integrated Solutions Console. These settings apply to all portlets that Portlet load monitoring monitors.

Portlet preferences configuration and administration

You can set the following parameters for individual portlets in the portlet preferences. You can either configure these parameters in the `portlet.xml` file before you deploy the portlet or administer them later by using the **Manage Portlets** administration portlet:

- Maximum number of concurrent requests that are allowed for a portlet
- Reactivation limit of concurrent requests that are allowed for reactivating the portlet
- Allowed average response time. You can configure the sample number of requests by which this average response time for portlets is calculated as mentioned previously under configuration tasks.

Portlet load monitoring administration

You can also do the following administrative tasks on individual portlets by using the **Manage Portlets** portlet only:

- Check whether a portlet is being monitored by Portlet load monitoring
- Manually reenable a portlet that Portlet load monitoring has blocked
- Manually block a portlet that is being monitored by Portlet load monitoring from responding to requests.

Portlet load monitoring properties

By setting the portal and portlet configuration parameters, you can monitor the session load and configure the parameters to increase performance.

Portal configuration

After you set the service configuration properties, add the following custom properties for resource environment provider WP ConfigService. These parameters affect all parameters in the portal:

com.ibm.wps.plm.enabled = false

Use this parameter to enable and disable Portlet load monitoring in the

portal. By default Portlet load monitoring is disabled. To enable it, set the entry **com.ibm.wps.plm.enabled** to **true** in the WebSphere Integrated Solutions Console. If you want to disable Portlet load monitoring, set **com.ibm.wps.plm.enabled** to **false**.

com.ibm.wps.plm.statistics.requestnumber = 50
Use this parameter to define the number of samples for the calculation of the average response time for a portlet. The default value is 50. The average response time for the portlet is calculated from the 50 latest requests that this portlet served. You can change the number of samples used for the average response time calculation. Add an entry with the name **com.ibm.wps.plm.statistics.requestnumber** to the WebSphere Integrated Solutions Console. Set its value to the number of requests that you want to be used for average response time calculation. For example: If you want to consider the latest 75 requests for the average response time calculation, set the property **com.ibm.wps.plm.statistics.requestnumber** to a value of **75**.

Portlet configuration

Portlet load monitoring can monitor every JSR 168 or JSR 286 portlet installed in your WebSphere Portal Express. By default, Portlet load monitoring does not monitor portlets. If you want Portlet load monitoring to monitor a portlet, you need to set specific portlet preferences for a portlet definition.

You can configure these portlet preferences for a portlet either by setting them in the portlet.xml file before you deploy the portlet. Or you can administer them after the portlet was deployed by using the **Manage Portlets** administration portlet.

com.ibm.wps.pe.plm.maxrequest
Use this parameter to define the maximum number of concurrent requests that is allowed for a portlet. If the number of requests that the portlet serves at any time exceeds the maximum number of concurrent requests that you specify here, then Portlet load monitoring blocks further requests to this portlet. Instead of responding to the requests the portlet renders with a message that states the portlet is not available. To re-enable this portlet for rendering, a portal administrator can enable the portlet by using the Manage Portlets administration portlet.

Example: If you want to allow no more than a maximum of 10 concurrent requests for a portlet, set the portlet preference **com.ibm.wps.pe.plm.maxrequest** to a value of **10**.

com.ibm.wps.pe.plm.minrequest
Use this parameter to define the reactivation limit for a portlet. Use this parameter for a recovery process. If Portlet load monitoring blocked the portlet because it exceeded the maximum number of allowed concurrent requests, then no more requests to this portlet are allowed. If the portlet then completes its active requests after some time, the number of concurrent requests that are currently served by the portlet decreases. If the number of concurrent requests in the portlet falls back down to the reactivation limit that you specified for the portlet preference parameter **com.ibm.wps.pe.plm.minrequest**, Portlet load monitoring enables the portlet for responding to requests and rendering again. This setting is subject to two restrictions:

1. This setting is only evaluated when you set the maximum number of concurrent requests by using the parameter **com.ibm.wps.pe.plm.maxrequest**.
2. This value must be less than the maximum number of concurrent requests that you entered for the parameter **com.ibm.wps.pe.plm.maxrequest**.

Example 1: If you want the portlet to respond to requests again when it has no more than three active requests open, set the portlet preference parameter **com.ibm.wps.pe.plm.minrequest** to 3.

Example 2: If you set the maximum number of concurrent requests for a portlet to 10 by using the parameter **com.ibm.wps.pe.plm.maxrequest** and the reactivation limit of concurrent requests for the same portlet to three using the parameter **com.ibm.wps.pe.plm.minrequest**, Portlet load monitoring works as follows:

1. When the portlet exceeds 10 and reaches 11 concurrent requests, Portlet load monitoring blocks the portlet from further requests.
2. When the portlet completes 8 active requests and has three active requests to complete, Portlet load monitoring allows the portlet to respond to incoming requests again.

com.ibm.wps.pe.plm.average.time.processing

Use this parameter to define the allowed average response time for the portlet. Specify a value in milliseconds. If the portlet exceeds the average response time that you specified, then Portlet load monitoring blocks further requests to this portlet. To reenable this portlet for rendering, a portal administrator can enable the portlet by using the Manage Portlets administration portlet.

For example: If you want to specify 3 seconds as the average response time allowed for a portlet, set the portlet preference `com.ibm.wps.pe.plm.average.time.processing` to `3000` (milliseconds) for this portlet.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Administering Portlet load monitoring

You can administer Portlet load monitoring and the portlets that it monitors. You can determine whether and in which cases Portlet load monitoring blocks or reenables a portlet by setting its portlet preferences. You can also check which portlets Portlet load monitoring monitors, and you can manually block or activate these portlets. For example, you can reenable a portlet after Portlet load monitoring has blocked it.

"Administering portlet preferences for Portlet load monitoring" on page 1683
You can set portlet preferences to influence in which cases Portlet load monitoring blocks or reenables JSR portlets.

"Administering portlets for Portlet load monitoring" on page 1684
You can administer the portlets that Portlet load monitoring monitors. You can check which portlets Portlet load monitoring monitors, and you can manually block or activate these portlets. For example, you can reenable a portlet after Portlet load monitoring blocked it.

Administering portlet preferences for Portlet load monitoring

You can set portlet preferences to influence in which cases Portlet load monitoring blocks or reenables JSR portlets.

About this task

You can configure parameters for the following:

- Maximum number of concurrent requests
- Reactivation limit of concurrent requests for reactivating the portlet
- Allowed average response time. You can configure the sample number of requests by which this average response time for portlets is calculated as mentioned in configuration tasks.

For more information about these three parameters and their meaning, refer to the topic about Portlet configuration parameters for Portlet load monitoring. For information about setting the sample by which the average response time is calculated refer to the topic about Portal configuration parameters for Portlet load monitoring.

Procedure

1. Log in to the portal by using a portal administrator user ID.
2. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**. The Manage Portlets portlet is displayed. It lists the portlets in your portal.
3. Search for the portlet for which you want to set portlet preferences.
4. Select the **Configure Portlet** icon.
5. Add a new portlet preference as required and type **number** for the new portlet preference as required:
   - To set the maximum number of requests that you want to allow for this portlet, add `com.ibm.wps.pe.plm.`*`max`*`request = `*`xyz`* for the new portlet preference. For example, if you want to allow this portlet no more than 15 concurring requests, specify `com.ibm.wps.pe.plm.maxrequest = 15`.
   - To set the reactivation limit for this portlet, add `com.ibm.wps.pe.plm.`*`min`*`request = `*`xyz`* for the new portlet preference. For example, if you want this portlet to be reenabled when its concurrent requests fall back to 5 or less, specify `com.ibm.wps.pe.plm.minrequest = 5`.
   - To set the allowed average response time for this portlet, add `com.ibm.wps.pe.plm.average.time.processing = `*`xyz`*, where `xyz` is the average response time in milliseconds. For example, if you specify `com.ibm.wps.pe.plm.average.time.processing = 3000` and the average response time for this portlet exceeds 3 seconds, then Portlet load monitoring blocks further requests to this portlet.
6. Click the **Add** button to add the preference.
7. Save your changes by clicking the **OK** button.

What to do next

As an alternative, you can define a portlet preference before you deploy the portlet. In this case add the portlet preference to the `portlet.xml` deployment descriptor of your WAR file.

Administering portlets for Portlet load monitoring

You can administer the portlets that Portlet load monitoring monitors. You can check which portlets Portlet load monitoring monitors, and you can manually block or activate these portlets. For example, you can reenable a portlet after Portlet load monitoring blocked it.

Procedure

1. Log in to the portal by using a portal administrator user ID.
2. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**. The Manage Portlets portlet is displayed. It lists the portlets in your portal.
3. Search for the portlet that you want to administer.
4. Administer the portlet as required:
   - For each portlet that is monitored by Portlet load monitoring, the Manage Portlets portlet displays an icon for disabling or enabling that portlet.
   - If a portlet that is monitored by Portlet load monitoring is active, the list shows an icon for disabling that portlet. If you click this icon, the portlet is blocked by Portlet load monitoring and is no longer rendered in the portal.
   - If a portlet that is monitored by Portlet load monitoring is blocked and inactive, the list shows an icon for enabling that portlet. If you click this icon, the portlet is enabled for rendering again.

   Notes:

   a. If the portlet was blocked for exceeding the maximum number of concurrent requests and the number of requests did not decrease and you did not set the value for maximum number of requests to a higher value, clicking this icon has no effect. In this case, the portlet is blocked again with the next request that arrives for this portlet.

   b. Activating a blocked portlet clears the response times that are stored for this portlet.

Logging and auditing events

Portlet load monitoring allows you to log events. For example, this can help you audit events. When Portlet load monitoring blocks or enables a portlet, it creates a log file entry in the IBM WebSphere Portal Express log file `SystemOut.log`. This log file entry contains the portlet object ID, the portlet name, the WAR file name of the portlet and the EAR file display name. The log file entries consist of translated messages. If you use tools that monitor log files for events, you can check for log file entries that are related to Portlet load monitoring as described here.

About this task

Portlet load monitoring creates log file entries for the events that are described in the following list.

Portlet load monitoring blocks a portlet because the portlet exceeds the maximum number of requests.

If Portlet load monitoring blocks a portlet because it exceeded the maximum number of concurrent requests that are specified for it, Portlet load monitoring creates the following log file entry with the message code `EJPPG3001W`:

```
EJPPG3001W: Portlet load monitoring disabled the portlet with
object ID: Object_ID, portlet name: Portlet_Name,
WAR file name: WAR_File_Name, EAR file display name: EAR_File_Display_Name,
because the portlet exceeded its maximum number of requests.
```

Portlet load monitoring blocks a portlet because the portlet exceeds the average response time.

If Portlet load monitoring blocks a portlet because that portlet exceeded the average response time that is specified for this portlet, Portlet load monitoring creates the following log file entry with the message code EJPPG3002W:

```
EJPPG3002W: Portlet load monitoring disabled the portlet with
object ID: Object_ID, portlet name: Portlet_Name,
WAR file name: WAR_File_Name, EAR file display name: EAR_File_Display_Name,
because the portlet exceeded its average response time.
```

Portlet load monitoring activates a portlet because the portlet returns to the reactivation limit.

If Portlet load monitoring reenables a blocked portlet because the blocked portlet falls back down to the reactivation limit of concurrent requests that are defined for the portlet, Portlet load monitoring creates the following log file entry with the message code EJPPG3003I:

```
EJPPG3003I: Portlet load monitoring reenabled the portlet
with object ID: Object_ID, portlet name: Portlet_Name,
WAR file name: WAR_File_Name, EAR file display name: EAR_File_Display_Name
because number of portlet requests fell below the reactivation limit.
```

Administrator manually blocks requests to a portlet.

If a portal administrator manually blocks requests to a portlet, Portlet load monitoring creates the following log file entry with the message code EJPPD0101I:

```
EJPPD0101I: Portal administrator admin_user_ID manually blocked requests
to the portlet with object ID: Object_ID, portlet name: Portlet_Name,
WAR file name: WAR_File_Name, EAR file display name: EAR_File_Display_Name
```

Administrator manually unblocks requests to a portlet.

If an administrator manually unblocks requests to a blocked portlet, Portlet load monitoring creates the following log file entry with the message code EJPPD0100I:

```
EJPPD0100I: Portal administrator admin_user_ID manually unblocked requests
to the portlet with object ID: Object_ID, portlet name: Portlet_Name,
WAR file name: WAR_File_Name, EAR file display name: EAR_File_Display_Name.
```

In the log entry, the variables *Object_ID*, *Portlet_Name*, *War_File_Name*, *EAR_File_Dislay_Name*, *admin_user_ID* are substituted with the corresponding values for the affected portlet and the administrative user.

Example: If Portlet load monitoring blocks a portlet with the portlet name **StdWorldClock** because the portlet exceeded the maximum number of requests that are allowed, then the log file entry might look like this:

```
EJPPG3001W: Portlet load monitoring disabled the portlet with
   ObjectID: [ObjectIDImpl '3_MLSU3F540O0360ISG212TT2003',
             PORTLET_DEFINITION, VP: 0,
             [Domain: rel], DB: 0000-B6723F5E2100836180E45004D1BB0060],
   portlet name: StdWorldClock,
   WAR file name: StdWorldClock.war,
   EAR file display name: PA_StandardWorldClock
because portlet exceeded its maximum number of requests.
```

API for accessing Portlet load monitoring data

Portlet load monitoring provides an API for accessing the monitoring data. You can use this API to write custom code to access that data.

Portlet load metrics interface

The PortletLoadMetrics object is defined in the package com.ibm.portal.plm.PortletLoadMetrics. It contains metrics data for one specific PortletDefinition. The interface looks as follows:

```
package com.ibm.portal.plm;

/*
 *  This interface provides access to portlet metrics stored for Portlet Load Monitoring.
 */
public interface PortletLoadMetrics {

 /*
  * Returns true if the portlet is enabled for rendering (either by admin or by PLM).
  * If the portlet is disabled for rendering, this method returns false.
  *
  * @return boolean true if the portlet is enabled either by admin or by PLM.
  */
 public abstract boolean isPortletEnabled();

 /*
  * Checks if the Portlet is currently enabled for rendering due to PLM constraints.
  * If PLM disabled the portlet for rendering, this method returns false.
  *
  * @return boolean true if the Portlet is enabled for rendering,
                    false if the Portlet is disabled for rendering.
  */
 public abstract boolean isPortletEnabledByPLM();

 /*
  * Returns true if the portlet is manually enabled by the portal administrator.
  * If the portal administrator disabled the portlet for rendering, this method returns false.
  *
  * @return boolean true if the portlet is enabled for rendering by the portal administrator.
  */
 public abstract boolean isPortletEnabledByAdmin();

 /*
  * Returns the number of requests this portlet currently serves.
  *
  * @return int number of requests this portlet currently serves.
  */
 public abstract int getCurrentNumberOfRequests();

 /*
  * Calculates the average response time for requests of this portlet in milliseconds.
  *
  * @return int average response time of the portlet in milliseconds.
  */
 public abstract int getAverageResponseTime();
```

Portlet load metrics service

The isPortletLoadMetricsService is contained in the package com.ibm.portal.plm.service.PortletLoadMetricsService. You can use this service to access PortletLoadMetrics objects. It also allows you to query general Portlet load monitoring related information. In order to obtain the PortletLoadMetricsService, you have to perform a JNDI lookup in the following way:

```
     PortletLoadMetricsEnabled(ObjectID portletID) plm;
      javax.naming.Context ctx = new javax.naming.InitialContext();
      try {
           plm = (PortletLoadMetricsService
              ctx.lookup(PortletLoadMetricsService.JNDI_NAME);
      } catch(javax.naming.NameNotFoundException ex) {
           ... error handling ...
      }
```

Once you successfully obtained the PortletLoadMetricsService, you can use methods as defined in the PortletLoadMetrics interface:

```
public interface PortletLoadMetricsService {

 String JNDI_NAME = "portal:service/plm/PortletLoadMetrics";

 /**
  * Determines if PLM is enabled for a given portlet.
  *
  * @param portletID ObjectID of the portlet.
  * @return true If PLM is enable for a given portlet.
  *       false If PLM is not enabled for a given portlet or if portlet does not exist.
  */
 boolean isPortletLoadMetricsEnabled(ObjectID portletID);

 /**
  * Returns a PortletLoadMetrics object for the portlet.
  * Creates the PortletLoadMetrics if PLM is enabled for this portlet and
  * it the PortletLoadMetrics object does not yet exist.
  *
  * @param portletID ObjectID of the portlet.
  * @return Reference to a PortletLoadMetrics object.
  *       Null if PLM is not enabled for the specified portlet.
  */
 PortletLoadMetrics getPortletLoadMetrics(ObjectID portletID);

 /**
  * Returns a String object containing the portlet preference value set for maximum concurrent
  * requests allowed for this portlet.
  *
  * @param portletID ObjectID of the portlet.
  * @return String containing the portlet preference value set for maximum concurrent
  *          requests allowed for this portlet. Returns "null" if the portlet did not set the
  *          portlet preference for maximum concurrent requests.
  */
 String getMaximumRequestPreferenceValue(ObjectID portletID);

 /**
  * Returns a String object containing the portlet preference value set for the
  * reactivation limit for this portlet (PLM self-healing)
  *
  * @param portletID ObjectID of the portlet.
  * @return String containing the portlet preference value set for the reactivation
  *          limit for this portlet (PLM self-healing). Returns "null" if the portlet
  *          did not set the portlet preference for the reactivation limit.
  */
 String getMinimumRequestPreferenceValue(ObjectID portletID);

 /**
  * Returns a String object containing the portlet preference value set for allowed average
  * response time for this portlet
  *
  * @param portletID ObjectID of the portlet.
  * @return String containing the portlet preference value set for allowed average
  *          response time for this portlet. Returns "null" if the portlet
  *          did not set the portlet preference for allowed average response time.
  */
 String getAverageResponseTimePreferenceValue(ObjectID portletID);

 /**
  * Returns a Map containing all PortletLoadMetrics objects.
  *
  * @return Map<ObjectID, PortletLoadMetrics> containig all PortletLoadMetrics objects.
  *          Key of the Map is the ObjectID of the PortletDefinition.
  *          The value of the Map is the PortletLoadMetrics object of the PortletDefinition.
  */
 Map<ObjectID, PortletLoadMetrics> getAllPortletLoadMetricsObjects();

}
```

Analyzing portal usage data

You can collect data about the usage of your portal and analyze them.

About this task

You can collect these types of data:

- Server side data of your portal site. This consists mainly of technical data internal to the portal.
- Server side data of your IBM Web Content Manager items.
- Data about the behavior of your client users. You analyze this data by using Active Site Analytics (ASA).

  "Logging and analyzing server side site data"
  IBM WebSphere Portal Express implements a logging function for your usage data. The portal writes usage records to a dedicated log file if site analysis logging is enabled. Multiple types of site analyzer loggers allow portal administrators to collect statistical data in various areas. The portal server manages the collection of data on its own, but from a business point of view you can also log custom details of business events. You can configure the portal for site analysis logging for the web content viewer.

  "Analyzing user behavior by Active Site Analytics" on page 1696
  You can collect data about user behavior in your portal and send that data to a service for analysis. For this purpose the portal provides Active Site Analytics (ASA).

Related tasks:

"Setting up site analysis for the Web Content Viewer" on page 411
To track usage data for the Web Content Viewer, you can configure the portal for site analysis logging for the Web Content Viewer.

Logging and analyzing server side site data

IBM WebSphere Portal Express implements a logging function for your usage data. The portal writes usage records to a dedicated log file if site analysis logging is enabled. Multiple types of site analyzer loggers allow portal administrators to collect statistical data in various areas. The portal server manages the collection of data on its own, but from a business point of view you can also log custom details of business events. You can configure the portal for site analysis logging for the web content viewer.

The portal configuration service SiteAnalyzerLogService determines the type of site analysis data that the portal logs at run time. Depending on the service configuration, the portal logs the following events:

- Page management, such as creating, reading, updating, deleting pages.
- Requests of pages by users.
- Requests of portlets by users.
- Session activities, such as login, logout, time out, login failed.
- User management actions, such as creating, reading, updating, and deleting users and groups.

The resulting log entries comply with the NCSA Combined industry standard. By analyzing the log entries, you can monitor applications that are running on your portal site. The site analysis infrastructure that is provided by the portal accommodates most scenarios.

Note: To obtain a more sophisticated evaluation of the portal usage, or to generate reports for portlet actions, you must write a custom report to log custom business events that occur in portlets.

"Enabling site analysis logging"
Site analysis logging is not enabled by default. To enable site analysis logging, specify the names and locations of the log files as values for the following parameters in the WP SiteAnalyzerLogService.

"Analysis loggers reference" on page 1690
The following table lists and describes available loggers.

"Understanding the site analysis log" on page 1691
Learn more details about how to read the site analysis log.

"Logging custom details of business events for site analysis" on page 1692
From a business point of view, you might want to log custom details of business events.

Enabling site analysis logging

Site analysis logging is not enabled by default. To enable site analysis logging, specify the names and locations of the log files as values for the following parameters in the WP SiteAnalyzerLogService.

About this task

For details, see *Setting service configuration properties*.

Procedure

1. Specify the names for the log files and backup log files.

   SiteAnalyzerFileHandler.fileName
   Specify the location and file name of the log file. The default value is logs/*$APPSERVER_NAME*/sa.log.

   SiteAnalyzerFileHandler.backupFileName
   Specify the location and file name of the backup file for the log file. The default value is logs/*$APPSERVER_NAME*/sa_*$CREATE_TIME*.log. When the log file is backed up, the current data is stored in the backup file, sa_*$CREATE_TIME*.log, and a new log file, sa.log, is created.

   You can specify the following tokens as part of the directory location or file name:

   $APPSERVER_NAME
   Name of the application server. Use this token for vertical clusters to enforce that the different application servers write into different files if they share file system.

   $CREATE_TIME
   Date and time the file is created. Specify the format of this token in this parameter: **SiteAnalyzerFileHandler.dateFormat**.

   $CLOSE_TIME
   Date and time the file is closed. Specify the format of this token in this parameter: **SiteAnalyzerFileHandler.dateFormat**.

   For example, you can specify log file locations and names as follows: log/backup/$APPSERVER_NAME/sa_$CREATE_TIME_$CLOSE_TIME.log.

   Note: If WebSphere Portal Express is writing to a file, the values for $CLOSE_TIME and $CREATE_TIME are the same.

2. Specify the date format for tokens in the log file names.

   SiteAnalyzerFileHandler.dateFormat
   Specify a value to format the date and time for the $CLOSE_TIME and

$CREATE_TIME tokens. For example, SiteAnalyzerFileHandler.dateFormat=yyyy.MM.dd-HH.mm.ss.

3. Specify the interval to back up log files.

   SiteAnalyzerFileHandler.minutesPerLogFile
   Sets the backup interval in minutes. Specify a value between 1 and 60.

   SiteAnalyzerFileHandler.hoursPerLogFile
   Sets the backup interval in hours. Specify a value between 1 and 24.

   SiteAnalyzerFileHandler.daysPerLogFile
   Sets the backup interval in days. Specify any value that indicates the number of days between backups.

   Notes:

   - If you enable more than one date format interval, the smallest interval is used.
   - If you specify 60 minutes, the file is backed up after 60 minutes. If you specify 1 hour, the file is backed up on the next full hour; for example, 01:00, 02:00 and so on. If you specify an interval of days, the file is backed up at 24:00 (midnight). For more information about the date format, see the Javadoc documentation for java.text.SimpleDateFormat.

4. Activate loggers as appropriate: To activate a logger, select the logger that you plan to activate and set the value to true. For example, SiteAnalyzerSessionLogger.isLogging=true. For a list of available loggers, refer to *Analysis loggers reference*.

   Tip: Site analysis logging can affect performance. For this reason, you might choose to disable loggers when necessary. To disable loggers, set the value to false.

5. Restart WebSphere Portal Express.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Analysis loggers reference

The following table lists and describes available loggers.

Table 242. Description and activity logged for each available logger

WebSphere Portal Express Server Analysis Logger	Description and Activity Logged
SiteAnalyzerSessionLogger.isLogging	HTTP requests that include the URLs: /Command/Login /Command/Logout
SiteAnalyzerUserManagementLogger.isLogging	HTTP requests that include the URLs: /Command/UserManagement/CreateUser /Command/UserManagement/DeleteUser /Command/UserManagement/CreateGroup /Command/UserManagement/DeleteGroup

Table 242. Description and activity logged for each available logger (continued)

WebSphere Portal Express Server Analysis Logger	Description and Activity Logged
SiteAnalyzerPageLogger.isLogging	HTTP requests that include the URLs: `/Page/*` `/Command/Customizer/CreatePage` `/Command/Customizer/EditPage` `/Command/Customizer/DeletePage`
SiteAnalyzerPortletLogger.isLogging	HTTP requests that include the URLs: `/Portlet/*`
SiteAnalyzerPortletActionLogger.isLogging	HTTP requests that include the URLs: `/PortletAction/*`
SiteAnalyzerErrorLogger.isLogging	HTTP requests that include the URLs: `/Error/Portlet` `/Error/Page` The referrer field points to a portlet name or a page name. Examples of such referrer fields are: `http://your.server.name/Portlet/1/PortletName` `http://your.server.name/Page/1/PageName`
SiteAnalyzerApplicationActionLogger.isLogging	HTTP requests that include the URLs: `/ApplicationAction/*`
SiteAnalyzerJSRPortletLogger.isLogging	web content viewer

Understanding the site analysis log

Learn more details about how to read the site analysis log.

The IBM WebSphere Portal Express site analysis log information is collected in the following file:

wp_profile_root`/logs/app_server_name/sa_`*date_time*`.log`

where *wp_profile_root* is the WebSphere Portal Express root directory and *date_time* is the date and time when the file was created. The current (active) log file is named **sa.log**. As explained in the previous section, the dateFormat parameter determines the interval at which the file is created.

The site analysis log uses the NCSA Combined log format, which is a combination of NCSA Common log format and three additional fields: the referrer field, the user_agent field, and the cookie field. The following example displays a sample entry in the site analysis log. The table describes each field of the log format:

```
9.37.3.88 - customer2 [10/Apr/2002:21:33:16 +0000]
"GET /Portlet/146/Welcome_Portlet?PortletPID=146&PortletMode=View&PortletState=Normal
HTTP/1.1" 200 -1 "http://myserver.company.com/Page/110/Welcome"

"JSESSIONID=OXDFAPVR4SXYZOIHSLVGA2Y"
```

Table 243. Log fields, names, and explanations

Field in the Example	Log Field Name and Explanation
9.37.3.88	**host** The IP address of the HTTP client that sent the request. **Important:** If there is a reverse proxy server between the client and the portal, the IP address logged is that of the reverse proxy server rather than the HTTP client. To log the IP address of the HTTP client, you must remove the reverse proxy server from the environment.
-	**rcf931** The identifier used to identify the client making the request. This field is always set to the hyphen character (-).
customer2	**username** The user ID for the client. If the user ID is not known, the field is set to the hyphen character (-).
[10/APR/2002:21:33:16 +0000]	**date:time: timezone** The date and time of the HTTP request.
"GET /Portlet/146/Welcome_Portlet? PortletMode= View&PortletState= Normal HTTP/1.1"	**request** The HTTP method, the URL of the requested resource and the version of HTTP used by the client.
200	**statuscode** The HTTP status code for the request.
-1	**bytes** The number of bytes of data transferred from the client as part of the request. A value of -1 means unknown.
"http://myserver.company.com/Page/110/ Welcome"	**referrer** The URL that linked the client to the website. For some requests, the referrer might not be logged. In such cases, the field is set to empty double quotes: ""
"Firefox/2.0 (compatible; MSIE 5.5; Windows NT 4.0)"	**user_agent** The type of Web browser used by the client.
"JSESSIONID=OXDFAPVR4SXYZOIHSLVGA2Y"	**cookies** The name and value of a cookie that was sent to the client browser. If multiple cookies were sent, the list is delimited by the semicolon character.

Logging custom details of business events for site analysis

From a business point of view, you might want to log custom details of business events.

About this task

Note: The procedures that are described in the following topic and subtopics work only for standard (JSR 168 or JSR 286) portlets.

The following are main components of the site analysis logging framework for standard portlets:

com.ibm.portal.portlet.service.siteanalyzer.PortletSiteAnalyzerLoggingServiceHome
This portlet service exposes methods to obtain a logger instance that is specialized on the specified request type. This request type is either an

ActionRequest, an EventRequest, a RenderRequest, or a ResourceRequest. Portlets obtain this portlet service through a JNDI lookup.

com.ibm.portal.portlet.service.siteanalyzer.PortletSiteAnalyzerLogger
Portlets can retrieve an instance of this logger from the PortletSiteAnalyzerLoggingServiceHome. It is valid for the request for which it was created, and it provides methods to query the logger state - enabled or disabled - and to create a site analysis log entry.

com.ibm.portal.portlet.service.siteanalyzer.ParameterNamesProcessor
Request parameter names, in particular render parameter names that are encoded into portal URLs, should be as short in length as possible. This recommendation does not leave much space for meaningful parameter names in site analysis log entries. The ParameterNamesProcessor interface allows portlet developers to provide the PortletSiteAnalyzerLogger with a callback for processing request parameter names. Implementations of this interface are called by the site analytics framework before assembling the query string section of the request URI that is written to the site analysis log file.

To activate and use the portal site analyzer logger for standard portlets, proceed by the following steps:

Procedure

1. Activating the site analyzer logger for standard portlets: You enable the site analyzer logger for standard portlets by using the portal configuration service SiteAnalyzerLogService. You set its property in the WebSphere Integrated Solutions Console through the resource environment provider WP SiteAnalyzerLogService. To do this step, proceed as follows:
   a. Select the appropriate WebSphere Integrated Solutions Console, depending on your environment:
      - If your portal runs stand-alone, use the local WebSphere Integrated Solutions Console.
      - If your portal is installed in a cluster, use the WebSphere Integrated Solutions Console of the Deployment Manager.
   b. Start the WebSphere Integrated Solutions Console by entering the following URL in the **URL location** field of a web browser:
      `http://your_server.com:admin_port/ibm/console`

      where *your_server.com* is the name of your server and *admin_port* is the port that is assigned to the WebSphere Integrated Solutions Console.
   c. In the navigation click **Resources** > **Resource Environment** > **Resource Environment Providers**.
   d. In the **Resource environment providers** page, elect the appropriate node or cluster from the scopes pull-down list, or clear the **Show Scope** selection drop-down check box and select one of the following options, depending on your portal environment:
      - If your portal runs as a single server, select **Browse Nodes** and select the node.
      - If your portal is installed in a cluster, select **Browse Clusters** and select the portal cluster.
   e. Select **WP SiteAnalyzerLogService**.
   f. Click **Custom Properties**.
   g. Do one of the following:

- Select the property **SiteAnalyzerJSRPortletLogger.isLogging** and change its value to `true`.
- Create a new property named `SiteAnalyzerJSRPortletLogger.isLogging` and set its value to `true`. Use `java.lang.String` as the property type.

h. When you are done, click **Save** at the start of the page under **Message(s)**.

i. Click **Save** again when prompted to confirm your change.

j. Optional: If your portal runs in a cluster configuration, replicate your changes to the cluster.

k. Restart the portal to activate the changes.

2. Implementing a parameter names processor: The following code sample shows an implementation of the `ParameterNamesProcessor` interface. The sample holds a static mapping of possible request parameter names to a more descriptive expression that you want to be used in site analysis log entries instead. If there is no replacement for a parameter name, the original key is returned to be written to the site analysis log entry as it is. Sample:

```
public class ParameterNamesProcessorSample implements ParameterNamesProcessor
{
   private static final Hashtable<String, String> PARAM_NAMES_MAP;

   static
   {
      PARAM_NAMES_MAP = new Hashtable();
      PARAM_NAMES_MAP.put("ci", "CurrentItem");
   }

   public String processParameterName(String paramName)
   {
      // get a replacement for the given parameter name or
      // return the original key if not replacement exists
      if (PARAM_NAMES_MAP.containsKey(paramName))
      {
         return PARAM_NAMES_MAP.get(paramName);
      }
      else
      {
         return paramName;
      }
   }
}
```

3. Retrieving the portlet site analyzer logging service: The following code sample shows the `init` method of a portlet class that looks up an instance of the portlet site analyzer logging service. Additionally, it instantiates a sample implementation of the `ParameterNamesProcessor` interface.

```
private PortletSiteAnalyzerLoggingServiceHome iSALogServiceHome = null;

private ParameterNamesProcessorSample iParamNamesProc = null;

public void init() throws PortletException
{
  com.ibm.portal.portlet.service.PortletServiceHome psh;
  javax.naming.Context ctx = new javax.naming.InitialContext();

  try
  {
    psh = (PortletServiceHome) ctx
      .lookup(PortletSiteAnalyzerLoggingServiceHome.JNDI_NAME);
  }
  catch (javax.naming.NameNotFoundException e) {
    // error handling
  }
```

```
  // obtain the service object
  PortletSiteAnalyzerLoggingServiceHome iSALogServiceHome =
    (PortletSiteAnalyzerLoggingServiceHome) psh
      .getPortletService(PortletSiteAnalyzerLoggingServiceHome.class);

  // instantiate the sample parameter names processor
  paramNamesProc = new ParameterNamesProcessorSample();
}
```

4. Retrieving an instance of the portlet site analyzer logger: A logger instance depends on a specific portlet request. Its validity is bound to a single request processing cycle. Therefore, the instantiation of the logger must be performed for each request. The service object that is obtained in the previous step makes various methods available to obtain a logger instance. The following code sample shows the retrieval of a logger instance for the current `RenderRequest` in the `doView` method of a portlet. The instance of the parameter names processor sample is also passed in to the `getLogger` method in order to register this callback for the returned logger. Sample:

```
protected void doView(final RenderRequest renderRequest, final RenderResponse
       renderResponse) throws PortletException, IOException
{
  final PortletSiteAnalyzerLogger saLogger = iSALogServiceHome.getLogger(renderRequest,
       renderResponse, iParamNamesProc);

  // further request processing
}
```

5. Logging a business event: When a portlet uses the instance of the `PortletSiteAnalyzerLogger`, the logger writes a business event to the site analysis log file. Sample:

```
protected void doView(final RenderRequest renderRequest, final RenderResponse
     renderResponse) throws PortletException, IOException
{
  // request processing

  // check whether the logger is enabled
  if (saLogger.isLogging())
  {
    // create a site analysis log entry
    saLogger.log("A sample business event");
  }

  // further request processing
}
```

Results

Understanding the site analysis log for standard portlets: The site analysis log entries that are written by the PortletSiteAnalyzerLogger have the same structure as log entries created by other types of site analyzer loggers that the portal provides. This particular logger also implements the industry standard NCSA Combined.

The following example shows how the URL-encoded representation of the custom business event is written to the request URI section of a log record. Non-ASCII characters are first encoded as sequences of 2 or 3 bytes, by using the UTF-8 algorithm, before they are encoded as `%HH` escapes. The encoded business event precedes the query fragment, which starts with a question mark. Furthermore, the name of the request parameter `ci`was replaced by `ParameterNamesProcessorSample` and now displays in the query fragment of the request URI section of the log record as `CurrentItem`.

Analyzing user behavior by Active Site Analytics

You can collect data about user behavior in your portal and send that data to a service for analysis. For this purpose the portal provides Active Site Analytics (ASA).

About this task

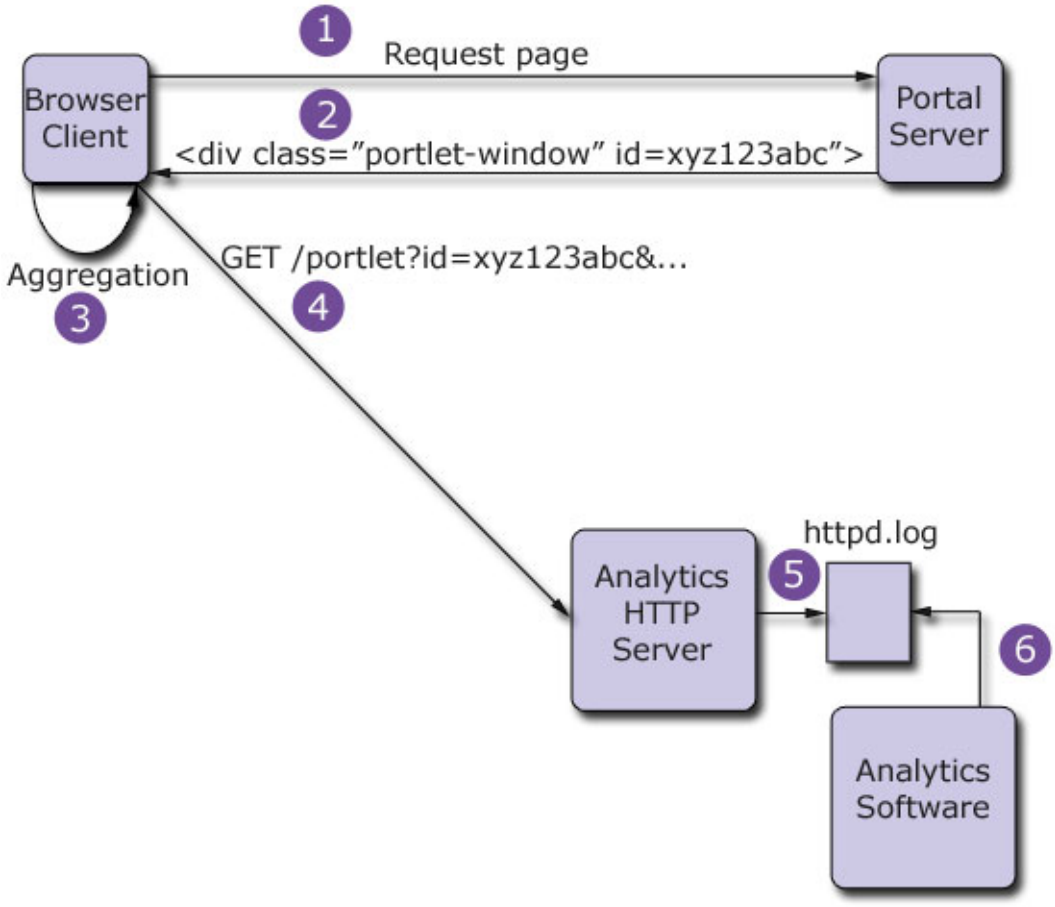
The portal provides a rich set of page metadata as part of its themes and skins. Examples are:

- Page title
- Page identifier
- Portlet title
- Portlet identifier.

You can write scripts to retrieve the data. Such scripts are called aggregators. WebSphere Portal Express provides several sample aggregators. They are located in the *PortalServer_root*/doc/js-samples directory of your portal installation. You can customize these or write your own aggregators to collect page metadata and more. For the samples, refer to the topic Writing an aggregator for active site analytics.

Administrators add the aggregator scripts to pages as required. When they do this, the aggregator is injected into markup of the page the next time it is rendered. You can select the point of injection arbitrarily; for example, this can be just before the

closing body tag of the HTML markup. Refer to the following flow graphic:



"Collecting analytics data" on page 1698
Before you can send data about user behavior in your portal to a service for analysis, you need to collect that data. See the following topics for information about how to do this.

"Displaying overlay analytics reports" on page 1714
You can use Active Site Analytics to show graphical statistics reports about individual portal resources, such as pages or portlets. These reports are called Active Site Analytics overlay reports.

"Analytics tags and site promotions" on page 1724
To obtain further analytics information from your portal, you can use analytics tags for your portal resources. You can also use analytics tags for site promotions.

Related tasks:

"Writing an aggregator for Active Site Analytics" on page 1701
You can write your own scripts to retrieve the data for Active Site Analytics from the portal themes and skins and connect to your analytics service provider. Such scripts are called aggregators.

Related information:

IBM WebSphere Portal V 8 Integration with IBM Digital Analytics (Coremetrics)

Collecting analytics data

Before you can send data about user behavior in your portal to a service for analysis, you need to collect that data. See the following topics for information about how to do this.

"How Active Site Analytics data is represented in the portal"
The data for the analysis of user behavior is retrieved from markup embedded in the portal pages.

"Writing an aggregator for Active Site Analytics" on page 1701
You can write your own scripts to retrieve the data for Active Site Analytics from the portal themes and skins and connect to your analytics service provider. Such scripts are called aggregators.

"Adding an Active Site Analytics aggregator to a portal page" on page 1709
Portal administrators can manage the aggregators. They can assign an aggregator to one or more portal labels or pages.

"Instrumenting a theme for Active Site Analytics" on page 1710
The portal theme provided with IBM WebSphere Portal Express is prepared and suitable for use with Active Site Analytics. You can also create your own custom theme to use the Active Site Analytics functionality.

"Configuring an aggregator at run time" on page 1713
If you want to configure the behavior of an aggregator at run time, you can pass additional meta data values to the aggregator.

How Active Site Analytics data is represented in the portal:

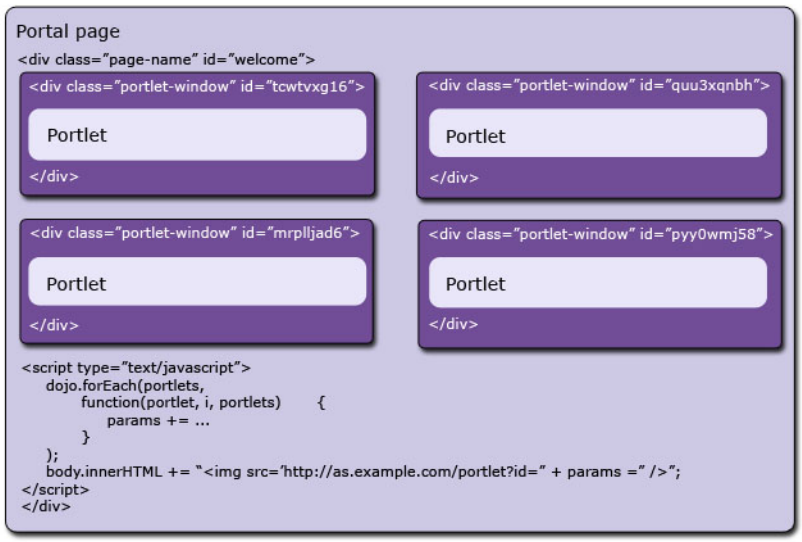
The data for the analysis of user behavior is retrieved from markup embedded in the portal pages.

The aggregator associated with the page formats the data, so that it corresponds to the requirements of the external analytics service to which it is finally submitted. By changing the Javascript the administrator can change the information that is retrieved from the page and submitted for analysis.

The data is represented as a microformat in the portal page HTML DOM tree and tagged with CSS classes. An example of such microformat is:

```
<span class="asa.portlet.title">My Portlet</span>
```

The structure of a page with annotated portlets is shown here:



"Supported aggregator tags"
The portal supports the aggregator tags listed in the following for Active Site Analytics.

Supported aggregator tags:

The portal supports the aggregator tags listed in the following for Active Site Analytics.

Page Breadcrumb
Page breadcrumb is the ObjectID for the breadcrumb of the current page. Tag it as `asa.page.breadcrumb`. It contains the path to the page within the hierarchical tree of pages. The path is made of the names of the pages, which are separated by a forward slash character.

Page ID
Page ID is the ObjectID of the page. Tag it as `asa.page.id` and add it to the theme markup.

Page Title
Page Title is the title of the page in the portal default language. Tag it as `asa.page.title` and add it to the theme markup.

Page Locale
Page locale is the locale of the page. Tag it as `asa.page.locale` and add it to the theme markup.

Page Locale Direction
Page locale direction is the direction of the locale of the page. Tag it as `asa.page.direction` and add it to the theme markup.

Friendly URL
Friendly URL is the URL of the current page without navigational state. Tag it as `asa.url` and add it to the theme markup. This element is empty if no friendly URL is set for the page.

Visitor ID
Visitor ID is the object ID of the user who currently logged in. If the user is anonymous, the visitor ID remains empty. Tag it as `asa.visitor` and add it to the theme markup.

Portlet Window Title
Portlet window title is the title of the portlet as it is delivered to the client. Tag it as `asa.portlet.title` and add it to the skin markup.

Portlet Locale
Portlet locale is the locale of the portlet as it is delivered to the client. Tag it as `asa.portlet.locale` and add it to the skin markup.

Portlet Locale Direction
Portlet locale direction is the direction of the locale of the portlet as it is delivered to the client. Tag it as `asa.portlet.direction` and add it to the skin markup.

Portlet Window ID
Portlet window ID is the unique identifier of the portlet. Tag it as `asa.portlet.id`. It is published to the Dojo topic queue by the topic name `com.ibm.portal.theme.portlet_ready`.

Portlet Screen ID
Portlet screen ID is the unique identifier of the screen or view that is

displayed in a portlet. Tag it as `asa.portlet.screen.id`. The portlet developer can add it to the custom portlet.

Portlet Screen Title
Portlet screen title is the localized title of the screen or view that is displayed in a portlet. Tag it as `asa.portlet.screen.title`. The portlet developer can add it to the custom portlet.

Selected Portlet
This tag marks the portlet with which the user interacted. Tag it as `asa.portlet.selected` and add it to the skin markup by the portal framework. For developers: do not manually add this tag to the skin.

Analytics Tags
The analytics tags are associated with a resource. Tag them as `asa.tag`*`analyticstag_name`* and add them to the page or portlet markup.

Site Promotions
These tags are the site promotions that are associated with a resource. Tag them as `asa.tag.SitePromotion` and add them to the page or portlet markup.

Web Content Manager Content Querystring
The Content Querystring is the unique identifier of the Web Content Manager content item that is displayed in a portlet. Tag it as `asa.wcm.content_item.path` and add it to the markup of the Web Content Manager Rendering portlet.

Web Content Manager Content Title
The Content title is the title of the Web Content Manager content item that is displayed in the Web Content Manager Rendering portlet. This tag must not be identical to the portlet window title. Tag it as `asa.wcm.content_item.title` and add it to the Web Content Manager Rendering portlet.

Web Content Manager Content ID
The Content ID is the unique identifier of the Web Content Manager content item that is displayed in a portlet. Tag it as `asa.wcm.content_item.id` and add it to the markup of the Web Content Manager Rendering portlet.

Web Content Manager Content Authors
The Content authors is the name of the author of the Web Content Manager content item that is displayed in a portlet. Tag it as `asa.wcm.content_item.authors` and add it to the markup of the Web Content Manager Rendering portlet. This tag can occur more than once.

Search term
Tag the search term as `asa.search.query` and add it to the markup of the Search Center portlet.

Number of search results
This the number value of the search results. Tag it as `asa.search.results` and add it to the markup of the Search Center portlet.

Search Scope ID
Tag the search scope ID as `asa.search.scope.id` and add it to the markup of the Search Center portlet.

Search Scope Label
Tag the search scope label as `asa.search.scope.label` and add it to the markup of the Search Center portlet.

Writing an aggregator for Active Site Analytics:

You can write your own scripts to retrieve the data for Active Site Analytics from the portal themes and skins and connect to your analytics service provider. Such scripts are called aggregators.

About this task

The portal themes that come with WebSphere Portal Express write the data that Active Site analytics needs into the markup. The data is provided in the form of microformats, which are injected into the markup during rendering.

The scripts that retrieve this data from the page markup are called aggregators. After retrieving the relevant microformat instances, the aggregator typically submits the collected data to an external analytics service where the data is then recorded, processed, and formatted in the form of reports.

The portal provides a client side JavaScript SPI that you can use to implement aggregators. The SPI is named **Active Site Analytics Mediator SPI**.

Aggregators that are based on the Active Site Analytics Mediator SPI behave consistently in WebSphere Portal Express, irrespective of the render mode of the portal page to which the aggregator is applied. This includes server side aggregation rendering and client side aggregation rendering modes. An aggregator can capture the latest data that is relevant for Active Site Analytics even in the client side aggregation mode that uses Ajax technologies to refresh individual page parts that are part of the DOM. Beyond that, the SPI also supports custom Ajax applications that can be part of a portal page.

From a programming model perspective, the Active Site Analytics Mediator SPI allows aggregator implementations to register callback functions; the portal framework calls these functions to notify the aggregator about DOM changes that can be relevant for Active Site Analytics. Upon receiving such notifications, aggregators can parse the DOM to find the relevant microformats to send this information to the analytics service.

For typical portal pages use the Active Site Analytics Mediator SPI for implementing your aggregators. However, for simpler pages you can also implement your aggregator by using a simple inline script which is executed at the end of your portal page. In this case the page must fulfill both of the following conditions:

- The page does not exploit client side aggregation rendering.
- Your applications on the page do not use Ajax technologies to refresh single page parts that might contain analytics-relevant microformats.

The SPI does not affect the way you can configure aggregators. For details about how to configure aggregators see the topic about *Adding an Active Site Analytics aggregator to a portal page*.

"The Active Site Analytics Mediator SPI" on page 1702
The portal provides a client side JavaScript SPI named Active Site Analytics Mediator SPI. You can use it to implement aggregators. The Active Site Analytics Mediator SPI allows aggregators to register callback functions; the portal framework calls these functions to notify the aggregator about DOM changes that can be relevant for Active Site Analytics.

"Guidelines for implementing an aggregator" on page 1703
When you implement an aggregator by using the Active Site Analytics Mediator SPI, the following guidelines can be helpful.

"Aggregator patterns and samples" on page 1704
The aggregator patterns and samples section provides common aggregator patterns and samples that you might want to adopt to implement your own aggregator.

"How to identify and resolve problems with your aggregator" on page 1708
If your custom aggregator is not working correctly, perform the checks listed here.

Related tasks:

"Adding an Active Site Analytics aggregator to a portal page" on page 1709
Portal administrators can manage the aggregators. They can assign an aggregator to one or more portal labels or pages.

The Active Site Analytics Mediator SPI:

The portal provides a client side JavaScript SPI named Active Site Analytics Mediator SPI. You can use it to implement aggregators. The Active Site Analytics Mediator SPI allows aggregators to register callback functions; the portal framework calls these functions to notify the aggregator about DOM changes that can be relevant for Active Site Analytics.

You can get access to the Active Site Analytics Mediator SPI by using the following global JavaScript variable:

com.ibm.portal.analytics.SiteAnalyticsMediator
Note that the `SiteAnalyticsMediator` object is not available until the page has finished loading. The `SiteAnalyticsMediator` object defines the following JavaScript functions:

register: function(/*Function*/ listener)
Use this function to register a listener function. You can invoke this listener function by using the portal framework in case of DOM changes that might be relevant for the aggregator. Typically, an aggregator registers one function. The register function returns a string identifier that you can use for unregistering the listener later on.

The provided listener function must conform to the following function signature:
`function (/*DOMNode[]?*/ node, /*Function?*/ callback)`
The optional argument `DOMNode[]` indicates the areas in the DOM that have changed. If no `DOMNode` array is provided, the aggregator can assume that major parts of the DOM have changed. In this case make the aggregator operate on the global document object. You can use the second argument by the framework to optionally pass in a callback function. That callback function must be called by the aggregator after finishing the DOM parsing process.

deregister : function(/*String*/ listenerID)
Use this function to unregister a listener function with the identifier that you have obtained during listener registration.

notify : function(/*DOMNode[]?*/ node, /*Function?*/ callback)
Use this function to notify all registered listeners about DOM changes. If you know the specific DOM area that has changed, you can pass in the corresponding DOM nodes. This function is

typically called by the portal framework to notify the registered aggregators about DOM changes. It can also be used by AJAX applications that partially update the DOM. If no specific DOM nodes are provided, the aggregator may assume that the notification refers to the portal page. If DOM nodes are provided, the notification refers to portal page elements. In addition to the `DOMNode` array you can optionally provide a callback function.

Guidelines for implementing an aggregator:

When you implement an aggregator by using the Active Site Analytics Mediator SPI, the following guidelines can be helpful.

1. Implement the function that parses the DOM to collect and format all Active Site Analytics-specific data.
2. Subscribe for the DOM notifications. Register the function that you implemented in the previous step with the object `SiteAnalyticsMediator`.
3. Implement the logic that sends the collected data to the external analytics service.

When performing these steps, apply the following considerations:

1. Implement the function that parses the DOM to collect and format all Active Site Analytics-specific data.
   - The implementation for collecting the data greatly depends on the themes, skins, and all the other components that might produce analytics-specific microformats. So, there is a dependency between the theme and its skins on the one hand and the aggregator.
   - The aggregator implementation can affect the performance, as it increases the page rendering time in the browser. To mitigate this time increase, take care that the DOM processing required to collect the data is implemented efficiently. To achieve a good performance, you can use implementation details of your themes and skins. For example, you can use HTML identifiers in the theme markup to isolate the nodes that contain the Active Site Analytics-specific data into a DOM subtree that your aggregator can access efficiently. In any case, avoid traversing the entire DOM.
2. Subscribe for the DOM notifications. Register the function that you implemented in the previous step with the object `SiteAnalyticsMediator`.
   - It is only during this registration step that you directly invoke the Active Site Analytics Mediator SPI. Register your function with the `SiteAnalyticsMediator` before the browser sends the onload event.
3. Implement the logic that sends the collected data to the external analytics service.
   - To have your data analyzed, you send them to an external analytics service. This step is separated from step 1, as the aggregator cannot make assumptions as to how often it is notified about DOM changes. In a Web 2.0 portal environment with many Ajax components, multiple notifications per portal page or even per portlet interaction can occur. Therefore, this step requires a deep understanding of the analytics service. Even the contract with your analytics service provider can influence when and how frequently you want to send the collected data to the analytics service.
   - If it does not matter how frequently data is transmitted to the analytics service, you can combine steps 1 and 3. For example, you can send the data directly to the analytics service after or even during the DOM parsing process. If the transmission frequency is relevant, store the data in a buffer, for example a JSON object or a cookie, during the DOM parsing process in

step 1. To trigger sending the buffer contents to the analytics service, you can either use an external event or a specific data change. The trigger can be based on a time interval, for example a JavaScript timeout. You can also use the `beforeunload` event that the browser fires whenever the entire browser page is refreshed, or when a browser window or browser tab is closed.

- You have several options for how to send the collected data to the external analytics service. A widely spread method is to use a so-called tracking image. In this case, the aggregator adds an HTML image element to the DOM, which is hidden via CSS. The image source URL that points to the external analytics service is used to transport the collected data. After adding the image element to the DOM, the browser initiates an HTTP GET request to load the tracking image. As an alternative, you can also use an asynchronous `XmlHttpRequest` (XHR) to send the data to the external analytics service. This method is useful if you want to use HTTP POST requests to submit a large amount of data.

The following list gives a summary of the guidelines:

1. Register your handler before the page finishes loading, that is, before the browser sends the onload event.
2. Do not make assumptions about the frequency by which your aggregator gets notified about DOM changes. For a single page, multiple notifications can occur.
3. Use separate steps for collecting and formatting the data, and for submitting the data to the external analytics server.
4. The processing that is done by your aggregator affects the page rendering time in the browser.
5. To ensure a better performance, use theme and skin implementation details. For example, use HTML identifiers for efficient DOM node lookups if available. Avoid traversing the entire DOM.
6. Carefully decide when and how often you want to send the collected data to the analytics service. This decision might depend on your analytics service provider.
7. Use an asynchronous way to send the collected data to the analytics service, for example a tracking image or an asynchronous XHR.
8. You can use a JavaScript framework to implement your aggregator.

For code samples see *Aggregator patterns and samples.*

Related reference:

"Aggregator patterns and samples"
The aggregator patterns and samples section provides common aggregator patterns and samples that you might want to adopt to implement your own aggregator.

Aggregator patterns and samples:

The aggregator patterns and samples section provides common aggregator patterns and samples that you might want to adopt to implement your own aggregator.

JavaScript module pattern template

You can use the following JavaScript module pattern as a general template:

```
/**
 * Check if the aggregator module is already defined.
 */
if (typeof(ibm_analytics_MyAggregator) === "undefined") {
```

```
/**
 * Function to construct the aggregator
 */
ibm_analytics_MyAggregator = function(/* Arguments needed internally */) {

  /**
   * The aggregator instance
   */
  var aggregator = {};

  // define your internal variables
  var a = ...;
  var b = ...;
  // ...

  /**
   * Public function which parses the given DOM nodes to detect
   * the microformats the aggregator is interested in.
   */
  aggregator.parse = function(/*DOMNode[]*/ nodes, /*Function?*/ callback) {
    // check if a specific part of the DOM should be parsed
    if (nodes && nodes.length > 0) {
      /*
       * Page element notification
       */
      // invoke your internal parsing code here
      // ...
    } else {
      /*
       * Page notification
       */
      // invoke your internal parsing code here
      // ...
    }
    // invoke the callback (if any)
    if (callback) {
      callback();
    }
  };

  /**
   * Public function to submit the collected data to the
   * analytics service.
   */
  aggregator.submit = function() {
    // send the collected data off to the external analytics service
    // use your preferred technique here (tracking image, XHR etc.)
    // ...
  };

  // define your internal functions
  var parseNode = function(/*DOMNode*/ node) {
    // ...
  };

  // ...

  // return the aggregator
  return aggregator;

};

};
```

By using this pattern, the aggregator module exports two functions:

1. The `parse()` function is responsible for handling the DOM notifications that are sent by the SiteAnalyticsMediator. It complies with the function signature that is defined by the Active Site Analytics Mediator SPI as discussed in the topic about *The Active Site Analytics Mediator SPI*. Use this function to parse the DOM to find the analytics-specific microformats that interest you. Typically, the parse function stores the found microformats in an internal bucket, for example a JSON object, that is transmitted to the external analytics service later on. In the JavaScript module pattern template, you can also see how the aggregator can distinguish between page notifications and page element notifications (a page element can either be a portlet or an Ajax component).
2. The `submit()` function is responsible for sending the collected data to the external analytics service. Use your preferred technique to initiate an HTTP request, which carries the data to the analytics service. For performance reasons, communicate the data asynchronously, for example by a tracking image or an asynchronous XmlHTTPRequest.

Note: The registration aspect and the logic that triggers the data transmission are not part of the aggregator module. These aspects need to be handled outside of the aggregator module.

Registering with the Site Analytics Mediator

Register your `parse()` function with the Site Analytics Mediator immediately after the definition of the aggregator module:

```
// instantiate and initialize the aggregator
var ibm_analytics_aggregator = new ibm_analytics_MyAggregator(/* arguments as needed...*/);
// register the parse function of the aggregator with the mediator
com.ibm.portal.analytics.SiteAnalyticsMediator.register(function() {
  ibm_analytics_aggregator.parse.apply(ibm_analytics_aggregator, arguments);
});
```

Submitting the analytics data

You can submit the data in various ways. You can submit the data internally by using the aggregator. For example, you can submit data upon receiving a notification or based on the internal state of the aggregator. Or you can trigger data submission from outside based on an external event. This decision can depend on the business model of your external analytics service provider. For more information, see *Guidelines for implementing an aggregator*.

To trigger the data submission that is based on an external event, you can either use the DOM `beforeunload` event of the browser or a time-based solution. The time-based solution sends the data periodically. You can also combine the two approaches.

To use the DOM `beforeunload` event of the browser, subscribe to the `beforeunload` event by using the `submit()` function of your aggregator as shown by the following sample:

```
// instantiate and initialize the aggregator
var ibm_analytics_aggregator = new ibm_analytics_MyAggregator(/* arguments...*/);

// register the parse function of the aggregator with the mediator
com.ibm.portal.analytics.SiteAnalyticsMediator.register(function() {
  ibm_analytics_aggregator.parse.apply(ibm_analytics_aggregator, arguments);
});

// callback function to submit the collected data to the external analytics service
var ibm_analytics_MyAggregator_submit = function() {
```

```
  ibm_analytics_aggregator.submit.apply(ibm_analytics_aggregator, arguments);
}

// register the callback functions
if (window.addEventListener) {
  // W3C
  window.addEventListener("beforeunload", ibm_analytics_MyAggregator_submit, false);
} else if (window.attachEvent) {
  // Microsoft
  window.attachEvent("onbeforeunload", ibm_analytics_MyAggregator_submit);
}
```

If you use client-side aggregation rendering for your portal pages, full page refreshes and therefore DOM unload events do not occur often. In this case and with this approach, the aggregator collects data for a long time without sending the collected data to the external analytics service. To avoid this behavior, you can combine the unload approach with a time-based approach. For example, you can submit the collected data periodically, in addition to sending it off upon receiving a `beforeunload` event. To implement the periodic data submission, use the `setInterval()` JavaScript API that all major browsers provide. In this case, you register the `submit()` function as the interval handler within your onload handler. The following code sample uses a time interval of 30 seconds. This action means that the data is submitted every 30 seconds at the latest if no `beforeunload` event is received.

```
// instantiate and initialize the aggregator
var ibm_analytics_aggregator = new ibm_analytics_MyAggregator(/* arguments...*/);

// register the parse function of the aggregator with the mediator
com.ibm.portal.analytics.SiteAnalyticsMediator.register(function() {
  ibm_analytics_aggregator.parse.apply(ibm_analytics_aggregator, arguments);
});

// callback function to initialize and register the aggregator
var ibm_analytics_MyAggregator_init = function() {
  // register the interval handler
  setInterval(ibm_analytics_MyAggregator_submit, 30000);
};

// callback function to submit the collected data to the external analytics service
var ibm_analytics_MyAggregator_submit = function() {
  ibm_analytics_aggregator.submit.apply(ibm_analytics_aggregator, arguments);
}

// register the callback functions
if (window.addEventListener) {
  // W3C
  window.addEventListener("load", ibm_analytics_MyAggregator_init, false);
  window.addEventListener("beforeunload", ibm_analytics_MyAggregator_submit, false);
} else if (window.attachEvent) {
  // Microsoft
  window.attachEvent("onload", ibm_analytics_MyAggregator_init);
  window.attachEvent("onbeforeunload", ibm_analytics_MyAggregator_submit);
}
```

If you have Ajax applications on your portal sites that change markup dynamically by using JavaScript, you need to notify the SiteAnalyitcsMediator framework manually. You can notify by calling the `notify()` function that is provided by the SiteAnalyticsMediator object.

```
// determine the root nodes of the DOM subtrees that have changed
var nodes = ...;
com.ibm.portal.analytics.SiteAnalyticsMediator.notify(nodes, callback);
```

Aggregator samples

WebSphere Portal Express provides several sample aggregators. They are in the *PortalServer_root*/doc/js-samples directory of your portal installation. Although the provided sample code does not require any special JavaScript library, you might want to use the JavaScript framework of your choice. With the JavaScript framework, you can reduce the size and complexity of your aggregator implementations. And the JavaScript framework might support you in achieving a good performance. To explain the concepts that are discussed in the previous topics, the sample aggregators are simplified with regards to the data that is evaluated. You can install each of the provided sample aggregators on WebSphere Portal Express as described in the topic about *Adding an Active Site Analytics aggregator to a portal page*. WebSphere Portal Express provides the following sample aggregators:

CoremetricsAggregator.js
: This sample aggregator collects the analytics data and sends it to the IBM Coremetrics Web Analytics service. It uses a Coremetrics specific JavaScript API to submit the data. You need to configure this API as an aggregator dependency. The target URL is `http://libs.coremetrics.com/eluminate.js`. Before you can use the aggregator, you also need to edit the aggregator code to specify your Coremetrics client ID, cookie domain, and data collection domain.

SampleAggregator.js
: This aggregator is a generic aggregator. It collects all the analytics data and sends it to the URL `http://example.org` by using a tracking image. The collected data is appended to the image URL as a query string. The names of the URL parameters correspond with the microformat names as defined in *Supported aggregator tags*.

Related tasks:

"Adding an Active Site Analytics aggregator to a portal page" on page 1709
Portal administrators can manage the aggregators. They can assign an aggregator to one or more portal labels or pages.

Related reference:

"Guidelines for implementing an aggregator" on page 1703
When you implement an aggregator by using the Active Site Analytics Mediator SPI, the following guidelines can be helpful.

"Supported aggregator tags" on page 1699
The portal supports the aggregator tags listed in the following for Active Site Analytics.

How to identify and resolve problems with your aggregator:

If your custom aggregator is not working correctly, perform the checks listed here.

1. Verify that the HTML markup of the portal page contains the microformats that the aggregator expects.
2. Verify that the tagging method that is used in the themes, skins, and portlets matches the expected behavior of the aggregator.
3. If you use the SiteAnalyticsMediator API and your aggregator is not notified about DOM changes as expected, you can enable client side tracing by using the resource environment provider **WP CommonComponentConfigService**. Set the following two configuration properties:

   ```
   cc.isDebug=true
   cc.traceConfig=["com.ibm.wps.analytics.*"]
   ```

After you have done this, save your changes and restart the portal server.

4. To review what occurs in the server side aggregator inclusion code, specify the trace `com.ibm.wps.theme.extensions.*=debug` .

Remember that aggregators are regular JavaScript files. Consequently, you can also use all JavaScript debugging tools and browser developer tools for debugging an aggregator.

Adding an Active Site Analytics aggregator to a portal page:

Portal administrators can manage the aggregators. They can assign an aggregator to one or more portal labels or pages.

About this task

As a portal administrator, you assign an aggregator to a page by editing the page properties and adding a new parameter. To do this by using the portal administration portlets, proceed by the following steps:

Procedure

1. Add the aggregator to the directory `js` in the theme directory. For example, for the portal theme, the WebDAV location is as follows:

   ```
   mycontenthandler/dav/themelist
   ```

   Take a note of the name of the aggregator file. You need it in later steps. Go to the **Analytics** section of *Modules that are provided with the modularized theme* for information.
2. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
3. Locate the page to which you want to assign the aggregator. Use the Manage Pages portlet to locate the page.

   Note: The page must be located as a child of the portal content root.
4. Click **Edit Page Properties** for the page that you selected.

   Note: You cannot add an Active Site Analytics aggregator to the content root. **Edit Page Properties** is not available for the content root.
5. To expand the available choices, click the plus sign (**+**) icon next to **Advanced Options**.
6. Click **I want to set parameters**.
7. In the field **New parameter**, type a string that starts with `asa_aggregator` or `asa_dependency`. Values that correspond to names that start with the string `asa_aggregator` are added to the page body, names that start with `asa_dependency` are added to the head. Both the aggregators and dependencies are added to the portal page in alphabetical order according to the Java method `Collections.sort()`.
8. In the **New value** field, type the name of the aggregator script file.
9. Click **Add**.
10. Verify that the new parameter is added to the list.
11. Repeat steps 6 - 9 for all aggregators and dependencies.
12. Click **OK** to return to the main Page Properties screen.
13. Click **OK** to save your changes and return to the **Manage Pages** screen.

What to do next

Note: Children pages inherit the script that is set on the parent page. If you want to use a different aggregator on a child page, follow the same procedure that is previously addressed for the child page to make the appropriate assignment. If you want to block inheriting the aggregator setting from the parent page, follow the same procedure, but leave the value empty. As a result, the page has no aggregator that is assigned anymore and all children of the page inherit the new setting.

Related concepts:

"Modules that are provided with the modularized theme" on page 2608
WebSphere Portal Express provides a set of ready-to-use modules.

Instrumenting a theme for Active Site Analytics:

The portal theme provided with IBM WebSphere Portal Express is prepared and suitable for use with Active Site Analytics. You can also create your own custom theme to use the Active Site Analytics functionality.

About this task

In order make Active Site Analytics work in a custom theme, you need to do the following tasks:

1. Add metadata to the page.
2. Include an aggregator with the page.
3. Include dependencies with the page.
4. Include microformats of interest, that is related to the statistical data that you want to collect.

For more details about these tasks refer to the following sections:

Adding metadata to the page

An aggregator picks up information stored in the DOM (document object model) tree of a page. This information must be present in the HTML source of the page. The recommended approach to add this information to a page is to implement the theme or skin so that they write all the necessary information into the DOM tree of the page. Examples:

1. You can add the identifier of a portlet to the DOM tree by adding the following line to the file `skin.html` in the theme WebDAV folder:

   ```
   <span class="asa.portlet.id" style="display:none;"><%= myPortletID %></span>
   ```

   Note: If the `span` element is styled in an external CSS file, you need to escape each period in the class name by a backslash. Example: `asa\.portlet\.id{display:none;}`
   With the code sample, the aggregator can fetch the identifiers of all portlets on a page by iterating over all occurrences of `"span"` elements with a class attribute of `"asa.portlet.id"`.

   The correct function of the code sample depends on the definition of `myPortletID` earlier in the file `skin.html`. By default, it is defined by using the following JSP code:

   ```
   <portal-skin:portletID var="myPortletID"/>
   <jsp:useBean id="myPortletID" class="java.lang.String" scope="page"/>
   ```

2. You can add the portlet title to the DOM tree by wrapping the `<portal-skin:portletTitle>` statement in the file `skin.html` with a span element that has a class attribute of `"asa.portlet.title"`:

```
<span class="asa.portlet.title"><portal-skin:portletTitle></portal-skin:portletTitle</span>
```

Including aggregators with the page

The portal includes a default implementation of the theme extension point `com.ibm.portal.theme.plugin.ActiveSiteAnalyticsAggregators`. The extension point locates a JavaScript file that is specified in the page metadata. The extension point includes the content of that file in the HTML code of the page. The metadata key must start with `asa_aggregator` or `asa_js` , and its value is the JavaScript file name. For details see the topic about *Adding an Active Site Analytics aggregator to a portal page*. Add the following code somewhere near the closing body tag (`</body>`) of the file *themeName*`\nls\theme_`*languageCode*`.html` of the theme WebDAV folder:

```
<portal-theme-ext:themeExtension id="com.ibm.portal.theme.plugin.ActiveSiteAnalyticsAggregators">
   <portal-theme-ext:themeExtensionLoop>
      <portal-theme-ext:themeExtensionItemText />
   </portal-theme-ext:themeExtensionLoop>
</portal-theme-ext:themeExtension>
```

This code loops over every implementation of the theme extension point and executes it. The default implementation included with the portal follows the approach previously outlined.

Note: WebSphere Portal Express Version 8.5 does not support the extension point with the ID `com.ibm.portal.theme.plugin.ActiveSiteAnalyticsItems` from previous versions. If you have migrated a theme from an earlier portal version, make sure to use the extension ID `com.ibm.portal.theme.plugin.ActiveSiteAnalyticsAggregators` .

Including dependencies with the page

If you want dependencies to be used by more than one aggregator, add them to the head of the html page. The portal includes a default implementation of the theme extension point `com.ibm.portal.theme.plugin.ActiveSiteAnalyticsDependencies` . The extension point locates a JavaScript file that is specified in the page metadata. The extension point includes the content of that file in the HTML code of the page. The metadata key must start with `asa_dependency` , and its value is the JavaScript file name. For details see the topic about *Adding an Active Site Analytics aggregator to a portal page*. Add the following code to the head of the theme:

```
<portal-theme-ext:themeExtension id="com.ibm.portal.theme.plugin.ActiveSiteAnalyticsDependencies">
   <portal-theme-ext:themeExtensionLoop>
      <portal-theme-ext:themeExtensionItemText />
   </portal-theme-ext:themeExtensionLoop>
</portal-theme-ext:themeExtension>
```

This code loops over every implementation of the theme extension point and executes it. The default implementation included with the portal follows the approach previously outlined.

Including an aggregator JSP with the page

Active Site Analytics can include a dedicated JSP fragment as part of the aggregator inclusion on the page. The portal appends the contents of the JSP fragment to the content that is injected into the `theme.html` of the theme.

You configure the JSP similarly to the aggregator itself: Add page metadata with the key of `asa_jsp` to the page. The portal interprets the value as a file name relative to the `theme.html` of the theme in WebDAV. For example, if you want to add markup from a JSP in a file named `page.jsp` , you can

put this JSP next to `theme.html` using WebDAV and configure a new page property with the key `asa_jsp` and the value `page.jsp` .

Example: If the key of a piece of metadata is `asa_jsp` and its value is set to `asa_sample.jsp`, then the portal searches for a JSP with a file name `asa_sample.jsp` and, if it finds such a file, it includes it in the page contents.

You can use the extension point `com.ibm.portal.theme.plugin.ActiveSiteAnalyticsInclude` to include a JSP into the page content. The metadata key must start with `asa_jsp` . Add the following code in the theme:

```
<portal-theme-ext:themeExtension id="com.ibm.portal.theme.plugin.ActiveSiteAnalyticsInclude">
   <portal-theme-ext:themeExtensionLoop>
      <portal-theme-ext:themeExtensionRenderInclude/>
   </portal-theme-ext:themeExtensionLoop>
</portal-theme-ext:themeExtension>
```

This code loops over each implementation of the theme extension point and executes it. The default implementation included with the portal follows the approach outlined earlier.

Including microformats of interest

You might need to modify the skins used by a theme so that all of the microformat information that you want to be captured is present when the page is rendered. For example, you can add this code to the `skin.html` file of a skin to ensure the portlet ID of all portlets on the page is available for the aggregator script to discover:

```
<span class="asa.portlet.id" style="display:none;"><%= myPortletID %></span>
```

In this case the file `asa_sample.js` looks for elements with the class `asa.portlet.id` to find the portlet ID of all portlets present on the page. Portlet titles can be rendered by using code similar to this:

```
<portal-skin:portletTitle />
```

To capture such portlet titles, you can add an additional span element with a class defined for titles that the analytics JavaScript file will look for:

```
<span class="asa.portlet.title"><portal-skin:portletTitle /></span>
```

In this case, `asa.portlet.title` is recognized as the class for all span elements that encompass the rendered text of the portlet titles.

"Injecting custom aggregators"
By implementing a new theme extension point, you can apply different approaches to Active Site Analytics.

Related tasks:

"Adding an Active Site Analytics aggregator to a portal page" on page 1709
Portal administrators can manage the aggregators. They can assign an aggregator to one or more portal labels or pages.

Related information:

"Tags used by the portal JSPs" on page 2790
Learn about the most commonly used tags in the portal JSPs. Use these tags to modify the appearance and layout of the portal page.

Injecting custom aggregators:

By implementing a new theme extension point, you can apply different approaches to Active Site Analytics.

About this task

To do this, define your implementation within the following theme extension point in the file `plugin.xml`:

`com.ibm.portal.theme.plugin.ActiveSiteAnalyticsAggregators`

If the theme extension loop is in place, it picks up the custom implementation of the extension point, and its output is added to the markup of the portal page. If you want to have the output added to the head of the HTML page, implement the following extension point:

`com.ibm.portal.theme.plugin.ActiveSiteAnalyticsDependencies`

For details about the extension loop refer to the topic about Instrumenting a special theme for Active Site Analytics under the section about Including microformats of interest.

Alternatively, you can use the following JSP code to iterate over the page metadata and add the aggregator JavaScript include statement to the page:

```
<portal-logic:pageMetaData varname="pageMetaData">
   <portal-logic:urlFindInTheme file='js/${pageMetaData["asa_aggregator"]}'
         id="asa_aggregator_file"/>
   <c:if test="${asa_aggregator_file != null}">
      <script type="text/javascript" src='<%=asa_aggregator_file%>'></script>
   </c:if>
</portal-logic:pageMetaData>
```

Note: The result of `urlFindInTheme` is cached. To clear the cache, restart the portal. Redeploying the theme is not sufficient to trigger a reevaluation of `urlFindInTheme`.

Related information:

"Tags used by the portal JSPs" on page 2790
Learn about the most commonly used tags in the portal JSPs. Use these tags to modify the appearance and layout of the portal page.

Configuring an aggregator at run time:

If you want to configure the behavior of an aggregator at run time, you can pass additional meta data values to the aggregator.

About this task

All page metadata with names that start with `asa_js` is an attribute of the global Javascript object called `ibm_page_metadata`. This object is only defined if at least one page metadata exists the key of which starts with `asa_js` .

There are two different ways by which metadata values are evaluated:

1. If the value starts with an equals sign (`=`), the value is interpreted as a JavaScript snippet. This evaluation starts with the first character after the equals sign.

   Example: If the key of a metadata is `<code>asa_js_foo</code>` and its value is set to `<code>='foo' + 'bar'</code>` , then the page meta data object `<code>ibm_page_metadata</code>` defines an attribute `<code>foo</code>` with a value of `<code>foobar</code>` . Refer to the following code snippet:

   ```
   <script language='JavaScript'>
        var ibm_page_metadata = {
             'foo' : 'foo' + 'bar'     }
   </script>
   ```

The aggregator can then access the metadata by either of the following ways: <code>ibm_page_metadata['foo']</code> or <code>ibm_page_metadata.foo</code> . It will evaluate to foobar .

The value part of page metadata is evaluated at run time in the client browser.

2. All other values are treated as JavaScript strings. No further escape mechanism is applied.

   Example: If the key of a piece of metadata is <code>asa_js_bar</code> , and its value is set to <code>foo</code> , then the page metadata object <code>ibm_page_metadata</code> defines an attribute <code>bar</code> with a value of <code>foo</code> .

   ```
   <script language='JavaScript'>
        var ibm_page_metadata = {
             'bar' : 'foo'     }
   </script>
   ```

   The aggregator can then access the meta data by either of the following ways: <code>ibm_page_metadata['bar']</code> or <code>ibm_page_metadata.bar</code> .

   Note: As the page metadata section requires administrative rights for the page, the portal performs no further checks. It passes all values entered as metadata keys and values to the JavaScript object literally.
   If an error in the metadata value prevents the page from being rendered, you can still change or remove the value by using other administrative ways to access the portal. For example, this can be WebDAV, the XML configuration interface, or the Portal Scripting Interface.

Displaying overlay analytics reports

You can use Active Site Analytics to show graphical statistics reports about individual portal resources, such as pages or portlets. These reports are called Active Site Analytics overlay reports.

About this task

The statistics graph is shown on the portal page in the format of an overlay over the portal resource to which they apply, such as the portlet. Examples of what statistical graphs can show:

- A simple view count of a portal page, that is how many users visited and viewed the page on a particular day.
- A statistical curve of the usage for a specific portlet over time.

The statistics are generated as follows:

1. The data collected by the portal site analytics are collected and forwarded to your business partners for portal analytics.
2. Your business partner analyses and evaluates the portal data and sends back a report to your portal.
3. The portal then displays the report as the overlay graph.

You can define which users can view the reports by setting the appropriate access rights.

The user must at least be in the **USER** role on the virtual resource **OVERLAYREPORTS** and at least in the **USER** role of the resource he wants to view reports for.

Note: You can enable overlay statistics only if you already use **Active Site Analytics** on your portal site.

To set up Active Site Analytics overlay reports, perform the procedures given here.

Procedure

1. Enable data collection. For example, you can do this by adding an Active Site Analytics aggregator to a portal page:
   a. Access the IBM Coremetrics Web Analytics website or contact your Coremetrics representative.
   b. Retrieve the appropriate aggregator file from Coremetrics.
   c. Upload the aggregator file to your portal theme folder, for example, by using WebDAV.
   d. Perform the procedure described under *Adding an Active Site Analytics aggregator to a portal page*.

   As a result of these steps, analytics data is sent from browsers of your portal users to the Coremetrics data collection servers. You can log on to Coremetrics and analyze the portal usage.
2. Enable inline display of Coremetrics reports by enabling overlay reports:
   a. Establish trust with Coremetrics servers. For more information, see *Configuring overlay reports*.
   b. Optional: Set up security for overlay reports. For details see *Configuring security for overlay analytics reports*.
   c. Configure your Coremetrics user ID. For more information, see *Configuring a Credential Vault for overlay reports*.
   d. Configure your theme to integrate the overlay report features into the **Actions** menu. For more information, see *Configuring the theme for overlay reports*.
   e. Display overlay reports by choosing **Show Portlet Reports** or **Show Page Reports**. For more information, see *Viewing overlay analytics statistics*.
   f. Optional: Customize the overlay report by providing additional configuration parameters. For more information, see *Customizing overlay reports*.
3. Optional: To further customize the tagging of your site, assign site promotions to pages and portlets as required.

What to do next

For more information about enabling inline display of overlay reports, see the following topics.

1. "Configuring overlay reports" on page 1716
   In order to activate overlay reports for your site, you need to configure some security-related settings.
2. "Configuring security for overlay analytics reports" on page 1717
   You can administer which users can view overlay reports. To do this, you use the virtual resource `OVERLAY_REPORTS`.
3. "Configuring a Credential Vault for overlay reports" on page 1718
   To access the IBM Coremetrics Web Analytics system, you have to store your user information in a Credential Vault slot. If you do not do this, the portal overlay reports cannot show data from the Coremetrics system.

4. "Configuring the theme for overlay reports" on page 1720
   To integrate the overlay analytics features into your theme, add a theme module to the theme profiles of your modular theme. If you do not add the theme, the overlay menu items are not displayed.
5. "Viewing overlay analytics statistics" on page 1721
   Users with the appropriate access rights can use Active Site Analytics to view graphical statistics about individual portal resources, such as pages or portlets.
6. "Customizing overlay reports" on page 1721
   You can customize your own overlay reports by setting specific parameters as required. Learn about the parameters and the levels at which you can specify them.

Portal administrators can manage the aggregators. They can assign an aggregator to one or more portal labels or pages.

Related information:

IBM WebSphere Portal V 8 Integration with IBM Digital Analytics (Coremetrics)

Configuring overlay reports:

In order to activate overlay reports for your site, you need to configure some security-related settings.

About this task

To allow connections with the report provider, you need to configure the AJAX Proxy. Proceed as follows:

Procedure

1. Add the IBM Coremetrics Web Analytics site to the default dynamic policy. To do this, proceed with the following steps:
   a. Open the WebSphere Integrated Solutions Console.
   b. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **WP ConfigService** > **Custom Properties** > **New...**.
   c. Use the property name `wp.proxy.config.urlreplacement.default_policy.1` and the value `https://welcome.coremetrics.com/*` .

      Note: If this name is already in use, increment the counter of the key `wp.proxy.config.urlreplacement.default_policy` .
   d. Click **Apply**.
   e. Click **Save**.
2. Import the Coremetrics certificate into your server truststore. You can complete this step either by using the `wsadmin` command `retrieveSignerFromPort` of the `AdminTask` object, or manually as described here:
   a. Open the WebSphere Integrated Solutions Console.
   b. In a stand-alone enviroment: Click **Security** > **SSL certificate and key management** > **SSL Configurations** > **NodeDefaultSSLSettings** > **Key stores and certificates** > **NodeDefaultTrustStore** > **Signer certificates** > **Retrieve from port**.

In a portal cluster environment: Click **Security** > **SSL certificate and key management** > **SSL Configurations** > **CellDefaultSSLSettings** > **Key stores and certificates** > **CellDefaultTrustStore** > **Signer certificates** > **Retrieve from port**. By alternative, you can also select each node individually and apply the following settings to each node in the cell.

c. Fill the fields as follows:
   - For the host: `welcome.coremetrics.com`
   - For the port: `443`
   - For the alias: `coremetrics` or another identifying string of your choice.

d. Click **Retrieve signer information**.

e. Click **Apply**.

f. Click **Save**.

3. Store your Coremetrics user information in a credential vault slot as described under Configuring credential vaults for overlay reports.
4. Restart the portal server for the changes to take effect.
5. Optional: If required, configure the limit of outbound HTTP connections. The data for the overlay reports is retrieved through the AJAX proxy. The AJAX proxy has a configuration parameter for setting the maximum number of concurrent outbound connections. This limit also affects the number of overlay reports that can be retrieved from the Coremetrics API server concurrently. If you want to have more overlay reports retrieved, configure the limit as described under *Configuration metadata for outbound HTTP connections*.

What to do next

Note: Additional to the limit set by the AJAX proxy, Coremetrics also enforces a limit on the number of concurrent connections from the same host. When that limit is reached, the portal displays message `EJQGB0000E` instead of the overlay report. In this case the user can refresh the portal page until the error message disappears; the successful analytics results are cached in the browser.

Related reference:

"Configuration metadata for outbound HTTP connections" on page 3008
You can add general proxy configuration parameters to the file `proxy-config.xml` by using `meta-data` settings.

Configuring security for overlay analytics reports:

You can administer which users can view overlay reports. To do this, you use the virtual resource `OVERLAY_REPORTS`.

About this task

This resource allows you to determine the user rights that are related to the overlay reports. The following description explains which roles a user requires to view overlay reports. The user actions correspond to the normal portal roles. Privileges are inherited.

In a default portal installation the `wpsadmins` group has the `USER` role. There is no role assigned to the anonymous user or to the group All authenticated users.

Notes:

- To view overlay reports, users need at least the USER role to the virtual resource OVERLAY_REPORTS , ADMIN_SLOTS , and to the resource on which they want to see the overlay report.
- In a default portal installation only the group wpsadmins has the USER role on OVERLAY_REPORTS.

USER Can view overlay reports on all resources, for example pages or portlets where at least the USER role is given.

Configuring a Credential Vault for overlay reports:

To access the IBM Coremetrics Web Analytics system, you have to store your user information in a Credential Vault slot. If you do not do this, the portal overlay reports cannot show data from the Coremetrics system.

About this task

You can set up the Credential Vault by one of the following three methods:

- Manually by using the Credential Vault portlet in the section for Access and Managing credential information of the portal administration. For details, refer to the portlet help about *Managing credential information* and *Adding a vault slot*.
- By using the XML configuration interface portlet. For details refer to the Import XML portlet help *Importing an XML configuration file*.
- By importing an XML configuration interface script. For details, refer to the topics about working with the portal XML configuration interface.

Also refer to *Portlet authentication*.

Make sure you store the following Coremetrics user information:

- The Coremetrics client ID
- The Coremetrics user name
- The Coremetrics authentication key.

Notes:

1. The Credential Vault slot used for storing the user information must have the slot name com.ibm.portal.asa.coremetrics.slot .
2. In the credential slot, you need to enter the Coremetrics user name and client ID, separated by a hash sign (#), either as a shared user ID in the portal Administration user interface, or as an external-id in the XML configuration interface script.

For example: If you have a Coremetrics user name Bob and a Coremetrics client ID 123456789, enter these values as "Bob#123456789" in the credential slot. Here is a sample XML configuraion interface script for creating required Credential Vault entries:

```
<request
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
   type="update" create-oids="true">
   <!-- Sample for updating the Credential Vault.
        This script creates a new segment containing one slot in the portal Credential Vault.
        The credentials (user ID and password pairs) that are stored in the vault cannot be
        accessed by using the XML configuration interface. You can only set the credentials
        by using the portal administration portlets for the Credential Vault. -->
   <portal action="locate">
      <credential-segment action="update" adapter-type="default"
```

```
                    name="com.ibm.portal.asa.coremetrics.segment" user-mapped="false">
        <description>Segment containing credentials for Coremetrics</description>
        <credential-slot action="update" name="com.ibm.portal.asa.coremetrics.slot"
                    active="false" system="true" resource="none"
                    secrettype="userid-password">
          <localedata locale="en">
            <description>Credentials for accessing the CoreMetrics server</description>
            <keywords>CoreMetrics</keywords>
          </localedata>
          <password-secret action="create" user="user_id"
            external-id="coremetrics_user_name#coremetrics_client_id">coremetrics_auth_key
          </password-secret>
        </credential-slot>
      </credential-segment>
   </portal>
</request>
```

In the sample XML script, replace the following variables with your actual Coremetrics user data values:

user_id
: Replace this variable with the user ID that is defined under the Resource Environment Provider **WP_VaultService** in the entry `systemcred.dn` .

coremetrics_user_name
: Replace this variable by your Coremetrics user name.

coremetrics_client_id
: Replace this by your Coremetrics client ID.

coremetrics_auth_key
: Replace this by your authentication key used by Coremetrics. This allows URL queries to the Coremetrics system.

Related concepts:

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

Related tasks:

"Importing pages or page hierarchies by using the XML Import portlet" on page 1063
You can import an XML configuration file by using the XML Import portlet.

Related information:

Portlet authentication
For resources protected by the portal, IBM WebSphere Portal Express uses CORBA credentials and an encrypted LTPA cookie to authenticate users. However, for backend systems that require their own authentication, portlets need to provide some form of authentication to access these remote applications. To provide a single sign-on user experience, portlets must be able to store and retrieve user credentials for their particular associated application. Then, they use those credentials to log in on behalf of the user. WebSphere Portal Express supports the use of a credential vault where users and administrators can safely store credentials for authentication. Portlets that are written to extract the user's credentials from the vault can hide the login challenge from the user.

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Configuring the theme for overlay reports:

To integrate the overlay analytics features into your theme, add a theme module to the theme profiles of your modular theme. If you do not add the theme, the overlay menu items are not displayed.

Before you begin

Locate the **overlay analytics features** that are provided by the theme module `wp_analytics_overlay_reports`. This theme module contains a menu contribution, which defines the menu entries that display or hide the overlay reports in the portal user interface. In the default theme, these menu entries are integrated into the **Actions** menu of the theme.

About this task

The theme module for analytics overlay reports is not part of the theme profiles that are provided by the default theme. You need to explicitly add this module to one or multiple theme profiles.

Procedure

1. Open the menu definition file for the **Actions** menu. It is in WebDAV at `fs-type1/themes/Portal8.5/menuDefinitions/pageAction.json`
2. In the menu definition file, find the menu entry of type `ModuleRef`, which references the theme module `wp_analytics_overlay_reports`. For example:

```
{
        "type":"ModuleRef",
        "id":"wp_analytics_overlay_reports"
},
```

3. To add the theme module for analytics overlay to a deferred theme profile, add the module code to the deferred section of the profile in WebDAV to `fs-type1/themes/Portal8.5/profiles/profile_deferred.json`. In the following example, add the `deferredModuleIDs` code between the `ModuleIDs` and the `wp_analytics_overlay_reports` line.

```
{
   "moduleIDs": [
        ... modules that are loaded immediately...
        ...
   ],
   "deferredModuleIDs": [
       ... modules that are deferred...
       ...
       "wp_analytics_overlay_reports",
       ...
   ],
   ...
}
```

4. Restart your Portal server or invalidate the resource aggregator cache. To invalidate your cache, click **Theme Analyzer** > **Utilities** > **Control Center** > **Invalidate Cache**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

What to do next

The theme module menu entries are displayed only if the theme module `wp_analytics_overlay_reports` is part of the theme profile. The theme profile is associated with the portal page that is being rendered.

If you have a custom modular theme, you can use the same approach to integrate the overlay features into a different menu.

Viewing overlay analytics statistics:

Users with the appropriate access rights can use Active Site Analytics to view graphical statistics about individual portal resources, such as pages or portlets.

About this task

To enable overlay statistics, the user opens the page actions menu and selects either **Show Portlet Reports** or **Show Page Reports**. The portal refreshes and shows boxes with the statistics coupled with the corresponding resource.

When the user clicks a report type in the actions menu, the **display reports** setting is persisted in the navigational state. This means that the user can now navigate through the portal and view statistics on every page that the user visits. To view more details about the resource or the statistics, the user clicks the **Details** link in the overlay box. The portal redirects the user to the website of the analytics business partner.

To disable overlay statistics, the user opens the page actions menu again and clicks the menu item **Close Analytics Reports**. This disables the display of overlay statistics and removes the setting from the navigational state.

Notes:

- Analytics providers might have a policy in place that limits the amount of concurrent API calls against their servers. Such a policy can affect the maximum number of overlay reports that can be displayed on a single portal page. In such cases work with the analytics provider to raise that limit.
- To be able to view graphical statistics about portal resources, the user needs to have the appropriate roles and access rights, both for viewing the reports and for the portal resources for which the reports are shown. The menu items for displaying statistics are only added to the page actions menu if the user has the access rights to work with analytics and overlay reports.
- Depending on the height of the portlet window on the portal page, the overlay window can display different graphics. For smaller portlet windows the graphic is smaller than for larger portlet windows.
- The option to view overlay reports is not available for pages that are currently being updated with new content. For the option to become available, save the page or draft of the page.

Customizing overlay reports:

You can customize your own overlay reports by setting specific parameters as required. Learn about the parameters and the levels at which you can specify them.

The scheme described here applies to all parameters that are available for overlay reports.

Report parameters for customizing overlay reports

To customize the display of overlay reports, you can provide the additional query parameters listed in the following. You can provide all these parameters at six different levels. The levels are listed and described in a table later in this topic. Depending on the level, you have to prefix the parameters with `asa.report` . Also depending on the level, you specify the parameters and their values in different locations and ways, for example as part of code with an equal sign, or by typing them into fields in a user interface.

metrics [page|portlet]

You can specify metrics for the page only, for the portlets only, or for a page and all portlets on it:

metrics
This affects both page and portlet metrics.

metrics.page
This affects only page metrics.

metrics.portlet
This affects only portlet metrics.

For these parameters, specify a comma separated list of metrics that you want to show in the overlay report. Do not include spaces between the items in the comma separated list. Specify the metrics by their column ID. You can use all metrics that are available in an IBM Coremetrics Web Analytics trend report. The default value is `SESSIONS,PAGE_VIEWS`. Note that the type of the overlay reports is optimized for displaying two metrics. Specifying fewer than one or more than two metrics may yield unexpected display results. The list of applicable metrics depends on the type of your Coremetrics account.

granularity
Specify the interval granularity of the displayed metrics. Specify an uppercase letter. The default value is `W` for weekly reports. Possible values are as follows:

D Daily

W Weekly. This is the default.

M Monthly

Q Quarterly

Y Yearly

numPeriods
Specify the number of periods that you want to have reported. This starts backwards from the value that you specify for the parameter `period_a`. Specify a numerical value larger than `1` . The default value is `4` .

period_a
Specify the ending date for reports in the format `YYYYMMDD` . Specify a valid date in the past. Reports will show data from this date backwards, with the number of periods as specified by the parameter `numPeriods` and the

granularity as specified by the parameter `granularity` . The default value is `yesterday` ; it is computed at the time of the HTTP request in the format `YYYYMMDD` .

Providing parameters at multiple levels

You can set the parameters for the customized display of overlay reports at six different levels as shown by the following table. Depending on the level, you have to prefix the parameters with `asa.report` , for example, `asa.report.granularity` .

Table 244. Customized display of overlay reports: levels for specifying parameters. Setting parameters for the customized display of overlay reports at multiple levels

Level hierarchy	Specify the parameter at this level:	Prefix the parameter with the following string:	Configure the parameter at this layer:	Set this parameter by using the following method:
1	HTTP request parameter	—	HTTP request	Custom code in the theme or skin
2	Portlet parameter - metadata	`asa.report.`	portlet window	XML configuration interface
3	Portlet preference	`asa.report.`	portlet	Portlet Edit mode, XML configuration interface
4	Page parameter - metadata	`asa.report.`	page	Page Properties dialog, XML configuration interface
5	Portal Configuration Service parameter	`asa.report.`	WP Config Service	WebSphere Integrated Solutions Console
6	Default value	—	WebSphere Portal Express product code	N/A - product code. You cannot change this default value, but you can override it in the layers listed previously.

If you provide parameters at multiple levels, the settings are applied in the hierarchical order of levels as given in the first table column Level hierarchy. Parameters specified at levels shown in earlier rows in table 1 override parameters shown in last table rows.

Customization examples

The following examples for customizing overlay reports show how the override precedence works between different levels in the hierarchy of levels. The examples use the granularity parameter. The precedence hierarchy works the same way for all other report parameters.

Example 1:

Scenario: No configuration provided.

Parameter settings:

Table 245. Example 1 parameter settings. No configuration provided.

Level hierarchy	Level	Interval granularity key	Interval granularity value
1	Request parameter	—	—
2	Portlet parameter - metadata	—	—
3	Portlet preference	—	—
4	Page parameter - metadata	—	—
5	Configuration parameter	—	—
6	Default value	`granularity`	`W` (weekly)

Result: All defaults apply. All overlay reports will show sessions and page views in weekly interval granularity for four weeks, starting backwards from yesterday.

Example 2:

Scenario: Interval granularity is overridden on the page level.

Parameter settings:

Table 246. Example 2 parameter settings. Interval granularity is overridden on the page level.

Level hierarchy	Level	Interval granularity key	Interval granularity value
1	Request parameter	—	—
2	Portlet parameter - metadata	—	—
3	Portlet preference	—	—
4	Page parameter - metadata	`asa.report.granularity`	`M` (monthly)
5	Configuration parameter	—	—
6	Default value	`granularity`	`W` (weekly)

Result: As the granularity setting at the higher level overrules the one at the subordinate level, overlay reports at the page where `asa.report.granularity` is set show sessions and page views with monthly granularity for four weeks, starting backwards from yesterday. Reports on all other pages will show as specified by the default configuration.

Example 3:

Scenario: Interval granularity is overridden at request level.

Parameter settings:

Table 247. Example 3 parameter settings. Interval granularity is overridden at request level.

Level hierarchy	Level	Interval granularity key	Interval granularity value
1	Request parameter	`granularity`	`W` (weekly)
2	Portlet parameter - metadata	—	—
3	Portlet preference	—	—
4	Page parameter - metadata	`asa.report.granularity`	`M` (monthly)
5	Configuration parameter	—	—
6	Default value	`granularity`	`W` (weekly)

Result: As the request parameter has the highest precedence, overlay reports will show sessions and page views with weekly interval granularity for four weeks, starting backwards from yesterday. Reports on all other pages will show as specified by the default configuration.

Analytics tags and site promotions

To obtain further analytics information from your portal, you can use analytics tags for your portal resources. You can also use analytics tags for site promotions.

"Analytics tags" on page 1725
You can obtain specific analytics information from your portal by using analytics tags for your portal resources. You might want to know which types of users visit your portal site most frequently, for example by age group or

other characteristics. If you want to address mostly young professionals, you can create an analytics tag `targetAudience:youngProfessionals` ; you can then associate the tag with all resources that contain content for this target user group. By looking at the visits on these pages you can determine whether the main user group of your portal site is young and new in their job.

"Site promotions" on page 1727
You can use analytics tags to set up site promotions. A site promotion is part of a marketing campaign that has the objective to introduce a new product, service, or event, or better position an existing one. A marketing campaign can consist of mailings, posters, banners, articles, games or other web content. In IBM WebSphere Portal Express, a site promotion covers the web content part of the marketing campaign. For example, a site promotion named "Christmas 2011" can reference pictures, blogs, and gift-shops on a website.

"Security for analytics tags and site promotions" on page 1729
Security for analytics tags allows you to administer which users can view, create, or assign analytic tags, including site promotions. The portal provides a virtual resource for site promotions and roles on this virtual resource.

"Using the XML configuration interface to administer analytics tags" on page 1729
You can use the XML configuration interface to manage analytics tags and site promotions in the portal.

Analytics tags:

You can obtain specific analytics information from your portal by using analytics tags for your portal resources. You might want to know which types of users visit your portal site most frequently, for example by age group or other characteristics. If you want to address mostly young professionals, you can create an analytics tag `targetAudience:youngProfessionals` ; you can then associate the tag with all resources that contain content for this target user group. By looking at the visits on these pages you can determine whether the main user group of your portal site is young and new in their job.

An analytics tag in the portal consists of a name-value pair that you can associate with portal or Web Content Manager resources. When you add a resource to an analytics tag, a microformat is injected into the markup of the resource. Analytics provider applications can read this microformat and track which resources associated with the analytics tag users visited.

The association of a resource to an analytics tag is called an analytics tag mapping. Resources that can be associated to an analytics tag include portal pages, portlets, and Web Content Manager content items. The relation between a resource and an analytics tag is as follows:

- One resource can be added to several general analytics tags, but it can be added only once to each analytics tag.
- One analytics tag can contain several resources but only one of each resource.

To associate a resource with an analytics tag, you add the tag name and value to the resource. For example, the tag name can be `season promotion` , and values can be `christmas` or `easter` . This way you can use the analytics tags to group your portal resources by purpose and then analyze which user groups visit these resources most frequently.

The portal stores analytics tags as regular portal tagging and rating tags, but with the following specific naming convention for analytics tags only:

```
name#value
```

where the tagging and rating tag is made up by a combination of the `name` and `value` of the analytics tag, separated by a hash sign character (`#`). Tags that are encoded like this show in the Tag Center under the tab **Analytics**.

"Working with analytics tags"
To work with analytics tags, the portal provides a dialog. You can create new analytics tag mappings and view and delete existing ones.

Working with analytics tags:

To work with analytics tags, the portal provides a dialog. You can create new analytics tag mappings and view and delete existing ones.

About this task

You can open this dialog from the resource that you want to associate with an analytics tag.

Procedure

1. To **add** a page or portlet to an analytics tag, proceed as follows:
   a. Open the page **Actions** menu or the portlet menu. The menu provides a section for Analytics.
   b. Select the menu entry **Analytics Tags**. The analytics tag dialog opens; it offers the following controls:
      - Two fields for entering the **Analytics tag name** of the tag to which you want to add the resource, and the **Analytics tag value** for that tag. Your input is matched against a regular expression.

        Notes:

        1) Special characters and all of the following characters are not valid: parentheses, brackets, angle brackets, hash signs, single and double quotes: `( , ) , [ , ] , < , > , # , ' , " .`
        2) The maximum allowed length for a name or a value is 100 characters.
        3) You cannot associate the same analytics tag with the same resource twice.
      - A list of existing analytics tag mappings, that is analytics tags that are associated with the portal resource. They have Delete icons next to them. You can view these icons and delete mappings only if you have the appropriate access rights. For details, see the topic about security for analytics tags.
      - An **Add** button. To save the mapping between the entered analytics tag and the currently viewed portal resource, click **Add**.
      - A **Done** button. Click **Done** when you have completed working with analytics tags for the currently viewed resource.
   c. To add a new analytics tag to the resource, type the analytics tag in the tag name field. The field provides a typeahead feature. After you type three characters, it lists the existing tags that start with these three characters.
   d. Type the value for the analytics tag in the second field. You must fill both fields.

e. To add and save the analytics tag mapping, click **Add**. The portal saves your tag mapping. If this mapping was not used before, it is created new. The tag and its value are shown in the dialog and added to the markup immediately .

2. To **delete** an existing tag mapping, proceed as follows:
   a. Open the page **Actions** menu or the portlet menu. The menu provides a section for Analytics.
   b. Select the menu entry **Analytics Tags**.
   c. Click the **Delete** icon for the tag mapping that you want to delete.
   d. Click **Done**. The portal removes the tag mapping from the resource.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Site promotions:

You can use analytics tags to set up site promotions. A site promotion is part of a marketing campaign that has the objective to introduce a new product, service, or event, or better position an existing one. A marketing campaign can consist of mailings, posters, banners, articles, games or other web content. In IBM WebSphere Portal Express, a site promotion covers the web content part of the marketing campaign. For example, a site promotion named "Christmas 2011" can reference pictures, blogs, and gift-shops on a website.

In WebSphere Portal Express, a site promotion can be associated with WebSphere Portal Express or IBM Web Content Manager resources. If a resource is assigned to a site promotion, a microformat is injected into the markup of the resource. This microformat can be picked up by an aggregator of the analytics provider. The analytics provider is able to track which site promotion resources were visited or which links were most often followed to get to the campaign content.

The assignment of a resource to a site promotion is called a site promotion mapping. Resources that can be assigned to a site promotion include portal pages, portlets, and Web Content Manager content items. The relation between a resource and a site promotion is as follows:

- One resource can be assigned to several site promotions, but can be assigned only once to each site promotion.
- One site promotion can contain several resources but only one of each resource.

For information about the security of site promotions, refer to the topic about Security for analytics tags and site promotions.

"Working with site promotions"
To work with site promotions, the portal provides a dialog. You can create new site promotion mappings and view and delete existing ones.

Working with site promotions:

To work with site promotions, the portal provides a dialog. You can create new site promotion mappings and view and delete existing ones.

About this task

You can open this dialog from the resource that you want to associate with a site promotion.

Procedure

1. To **add** a page or portlet to a site promotion, proceed as follows:
   a. Open the page **Actions** menu or the portlet menu. The menu provides a section for Analytics.
   b. Select the menu entry **Site promotions**. The site promotion dialog opens; it offers the following controls:
      - A field for entering the **Site promotion name** of the site promotion to which you want to add the resource. Your input is matched against a regular expression.

        Notes:

        1) Special characters and all of the following characters are not valid: parentheses, brackets, angle brackets, hash signs, single and double quotation marks: `( , ) , [ , ] , < , > , # , ' , " .`
        2) The maximum allowed length for a site promotion name is 100 characters.
        3) You cannot associate the same site promotion with the same resource twice.
      - A list of existing site promotion mappings, that is site promotions that are associated with the portal resource. They have Delete icons next to them. You can view these icons and delete mappings only if you have the appropriate access rights. For details, see the topic about security for site promotions.
      - An **Add** button. To save the mapping between the entered site promotion and the currently viewed portal resource, click **Add**.
      - A **Done** button. Click **Done** when you complete working with site promotions for the currently viewed resource.
   c. To add a new site promotion to the resource, type the site promotion name in the site promotion name field. The field provides a type-ahead feature. After you type 3 characters, it suggests existing site promotions that start with these 3 characters.
   d. To add and save the site promotion mapping, click **Add**. The portal saves your site promotion mapping. If this mapping was not used before, it is created new. The site promotion is shown in the dialog and added to the markup immediately.
2. To **delete** an existing site promotion mapping, proceed as follows:
   a. Open the page **Actions** menu or the portlet menu. The menu provides a section for Analytics.
   b. Select the menu entry **Site promotions**.
   c. Click the **Delete** icon for the site promotion mapping that you want to delete.
   d. Click **Done**. The portal removes the site promotion mapping from the resource.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Security for analytics tags and site promotions:

Security for analytics tags allows you to administer which users can view, create, or assign analytic tags, including site promotions. The portal provides a virtual resource for site promotions and roles on this virtual resource.

The portal provides the virtual resource **ANALYTICS_TAGS** to administer which users can manage analytics tags. This resource allows you to determine user rights that are related to analytics tags. The following list explains which roles users need in order to manage analytics tags. The user actions correspond to the usual portal roles. Privileges are inherited.

In a default portal installation the group **wpsadmins** has the role **EDITOR**. There is no role assigned to the anonymous user or to the group **All authenticated users**. Note that all users need to have at least the **EDITOR** role on the virtual resource **ANALYTICS_TAGS** and the **USER** role on the resource to be able to edit analytics tags assignments.

USER
- Can view existing analytics tag mappings.
- Can view existing analytics tag assignments on all resources, for example pages or portlets, on which the user has at least the **USER** role.

EDITOR
- Includes all **USER** actions.
- Can create analytics tags and analytics tag mappings.
- Can add and remove analytics tag mappings on all resources, for example pages or portlets, on which the user has at least the **USER** role.

MANAGER
- Includes all **USER** and **EDITOR** actions.
- Can delete analytics tags.

Note: In a default portal installation only the group **wpsadmins** has the **MANAGER** role on **ANALYTICS_TAGS**.

Using the XML configuration interface to administer analytics tags:

You can use the XML configuration interface to manage analytics tags and site promotions in the portal.

The XML resource related to analytics tags is `tag` . The attributes are listed in the following.

Notes:
1. When you create tags, you need to specify all attributes except the attribute `locale` marked as optional in the attributes list.

2. When you export tags, the export result file will contain all the tags that exist in your portal system, including the tags created for tagging and rating.
3. Tag names of analytics tags must start with `com.ibm.portal.asa.` and must match the following pattern: `com.ibm.portal.asa.`*`tag_name#tag_value`* .
4. The tag name for site promotions must be `com.ibm.portal.asa.SitePromotion` .
5. You must escape all special characters. This includes the blank space.

tag This is the XML resource tag for analytics tags. Use the following attributes with this tag:

resourceref = "object_ID"
Use this attribute to specify the reference to the resource that is being tagged.

domain = "comm"
For analytics tags, specify a value of `"comm"` for this attribute. For tagging and rating this attribute is used to specify the database domain for the tagged resource. The only accepted value for analytics tags is `"comm"` .

owner = "*user*"
Use this attribute to specify the owner of the tag.

locale = "*locale*"
Use this attribute to specify the locale of the tag. This attribute is optional. If you do not specify this attribute, it defaults to `null` .

For examples refer to the following code samples:

Example: Exporting analytics tags

```
<?xml version="1.0" encoding="UTF-8"?>
<request
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
   type="export">
   <!-- This sample exports all tags.
        In addition to all analytics tags (starting with 'com.ibm.portal.asa.'),
        all tags (see tagging and rating) are exported.
   -->
   <portal action="locate">
      <tag action="export" objectid="*"/>
      <!-- Export all tags with a specific locale in the system -->
      <!-- <tag action="export" objectid="*" locale="SPECIFIC_LOCALE"/> -->
   </portal>
</request>
```

Example: Creating analytics tags

```
<?xml version="1.0" encoding="UTF-8"?>
<request
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
   type="update">
   <!-- This sample creates analytics tags and site compositions.
        NOTE: This sample file needs to be modified before execution.
        Update the value of the 'owner' attributes of the 'access-control',
        and 'tag' tags, and specify an existing user.
   -->
   <portal action="locate">
      <!-- Locate the page. -->
      <content-node action="locate" objectid="gettingStartedPage"
                    uniquename="ibm.portal.Home.Getting Started"/>
      <!--  NOTE:
            Pattern:  <tag-name>#<tag-value>
```

```
            Special characters (including 'blank space') must be escaped!
            All tag names must start with 'com.ibm.portal.asa.'
            Tag name for site promotions must be 'com.ibm.portal.asa.SitePromotion'
      -->
      <!-- Assignment of the site promotion "Christmas 2011" to the gettingStartedPage -->
      <tag action="update" objectid="ZCI_B1L68B1A00DO80IG7PCV0I6000"
           resourceref="gettingStartedPage" domain="comm"
           owner="uid=wpsadmin,o=defaultwimfilebasedrealm"
           locale="en">com.ibm.portal.asa.SitePromotion#Christmas%202011</tag>
      <!-- Assignment of the analytics tag 'Target Audience#Young Professionals'
           to the gettingStartedPage -->
      <tag action="update" objectid="ZCI_B1L68B1A00DO80IG7PCV0I7000"
           resourceref="gettingStartedPage" domain="comm"
           owner="uid=wpsadmin,o=defaultwimfilebasedrealm"
           locale="en">com.ibm.portal.asa.Target%20Audience#Young%20Professionals</tag>
   </portal>
</request>
```

Example: Deleting analytics tags

```
<?xml version="1.0" encoding="UTF-8"?>
<request
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
   type="update">
   <!-- This sample deletes analytics tags.
        NOTE: This sample assumes that the CreateAnalyticsTags.xml
        sample was executed before.
   -->
   <portal action="locate">
      <!-- Delete the analytics tags created by sample CreateAnalyticsTags.xml -->
      <tag action="delete" objectid="ZCI_B1L68B1A00DO80IG7PCV0I6000"/>
      <tag action="delete" objectid="ZCI_B1L68B1A00DO80IG7PCV0I7000"/>
      <!-- Delete all tags with a specific locale in the system -->
      <!-- <tag action="delete" objectid="*" locale="SPECIFIC_LOCALE"/> -->
  </portal>
</request>
```

You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Auditing

IBM WebSphere Portal Express includes an auditing function that allows users to log certain events and their originators in to a separate log file. This file can then be used to track administrative activities.

The following details are logged for each event:

- The time stamp
- An optional transaction ID
- An optional project ID
- The user action
- Individual event details

If the user who does the action (for example, Bob) is impersonated by another user (for example, Alice), the user is shown as [Bob[Alice]] in the log file.

You can use the auditing function on the following events:

- Creating, modifying, and deleting users and groups
- Assigning and revoking roles to and from users
- Modifying role blocks
- Modifying resource ownership
- Creating, modifying, and deleting protected resources
- Externalizing and internalizing resources
- Installing and uninstalling web modules
- Creating and deleting application roles
- Assigning and revoking application roles to and from users
- Adding and deleting roles to application roles
- Initializing a database domain
- Creating, modifying, and deleting portlet applications by using IBM Lotus Component Designer
- Starting and ending impersonating a user or impersonating a user without the appropriate permission.

To activate and configure the auditing function, modify the auditing service settings in the Auditing Service by following the steps that are provided in the Setting service configuration properties file.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Chapter 14. Setting up a website

Setting up a website includes, creating pages, adding navigation, setting up search, and adding content to the site. Themes are used to customize the portal's look-and-feel. Out-of-the-box templates and the site wizard can help you set up your portal site faster. You can add wikis and blogs to your site and let users tag and rate content on your site.

The new IBM Syndicated Feed Portlet for IBM WebSphere Portal Express offers enhanced feed subscription and presentation capabilities.

Website building blocks

Unless you are familiar with the IBM WebSphere Portal Express and IBM Web Content Manager website model, review the building blocks. Building blocks are the different parts that make up the website framework, such as pages, navigation, themes, content, content libraries, and more.

"Themes, profiles, and skins"
The theme controls the presentation layer of your website. The theme profile contains modules and controls which modules load per page. A skin surrounds the portlet on a page.

"Pages" on page 1736
A page is an organization element that contains portlets. Since version 8.0, pages are stored in the Portal Site web content library and managed by IBM Web Content Manager. Pages are stored as content in the library. By managing portal pages from within Web Content Manager, you can apply features like workflow, version control, and syndication to portal pages.

"Portlets" on page 1744
Portlets are small applications that are independently developed, deployed, managed, and displayed. After the portlet is deployed, you can use it multiple times on different pages.

"Content" on page 1746
Rich content and elegant user experiences drive the success of websites. Each digital experience consists of many different types of content from many various sources.

Themes, profiles, and skins

The theme controls the presentation layer of your website. The theme profile contains modules and controls which modules load per page. A skin surrounds the portlet on a page.

To some extent, the theme governs aspects of the entire website. In the following wireframe, the theme controls the navigation placement, the styles and branding, the visual treatment of portlets on the page, the JavaScript modules that are available, and more.

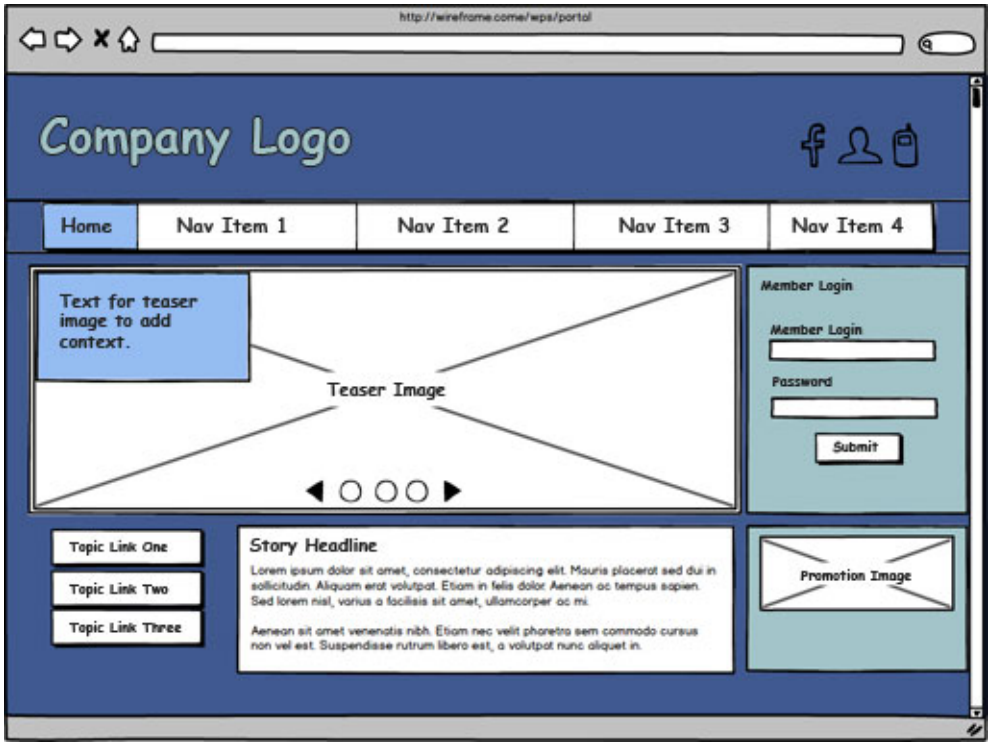

Figure 17. Wireframe of website

Themes

In addition to branding, themes provide a wide range of capability. The theme includes page layouts, styles, and modules. The page layouts and styles are visible to content authors from the site toolbar. Modules within a theme are grouped into profiles. Profiles are associated with pages to ensure each page loads the appropriate modules.

The default theme, Portal 8.5, is designed using Responsive Web Design principles. Therefore, the site renders well on mobile devices. You can make a copy of this theme and customize it.

Theme profiles

Use profiles to load only the modules that are required for a page. If a portlet require specific extra modules, you can group those modules into a profile. Then, assign the profile to the page that contains the portlet. For example, the Web Dock Portlet requires extra modules to render third-party content in an iFrame. Those modules are grouped into a profile called Web Dock profile. Only the pages that contain Web Dock Portlets need to load the additional modules. Assign the Web Dock profile to pages that contain the Web Dock Portlet. Pages that do not contain a Web Dock Portlet do not need to waste resources loading extra modules.

Note: CF03 Starting with CF03, the Web Dock profile no longer exists. If you are using the Resource Aggregator for Portlets, no additional steps are necessary. If you are not using the Resource Aggregator for Portlets, add the **wp_webdock** module to an existing profile on your page. You do not need any extra profiles when module autoLoad is turned on.

Skins

Skins include more capability and can be used to visually indicate portlets on a page. However, depending on your website design that might not be wanted. The skin that is immediately available and active is a hidden skin. On the rendered website, the skin is not visible. However, the hidden skin is visible when Edit Mode is on. The outline of each portlet helps the author identify the portlets on the page. The skin also includes capability for inline editing.

"JavaScript libraries"
WebSphere Portal Express includes JavaScript libraries to support various features.

Related concepts:

"Included profiles" on page 2606
Portal includes profiles that contain modules that change how your portal site is rendered.

"Modules that are provided with the modularized theme" on page 2608
WebSphere Portal Express provides a set of ready-to-use modules.

"Default skins" on page 2687
The default theme includes these skins that can be used as a basis for creating custom skins: Hidden, Standard, and NoSkin.

"Customizing the theme" on page 2658
The module framework allows themes to be customized in order to provide flexibility, enhance the user experience, and maximize performance.

JavaScript libraries

WebSphere Portal Express includes JavaScript libraries to support various features.

Dojo

WebSphere Portal Express contains an instance of the IBM Dojo Toolkit, a JavaScript library that is based on the Dojo toolkit (http://dojotoolkit.org). All Dojo packages can be used by IBM and non-IBM components.

jQuery

WebSphere Portal Express includes a jQuery module for the jQuery core so you can use jQuery in a theme.

Java messaging services for web content

Web Content Manager provides support for the notification of events such as item state changes, or services starting and stopping. These notifications can be delivered as messages to the Java messaging service.

Pages

A page is an organization element that contains portlets. Since version 8.0, pages are stored in the Portal Site web content library and managed by IBM Web Content Manager. Pages are stored as content in the library. By managing portal pages from within Web Content Manager, you can apply features like workflow, version control, and syndication to portal pages.

In the example wireframe, the home page portion is highlighted. The page contains five portlets. Most of the portlets render content by using the Web Content Viewer portlet. The Member Login portlet is providing access to the LDAP user registry

for member authentication.

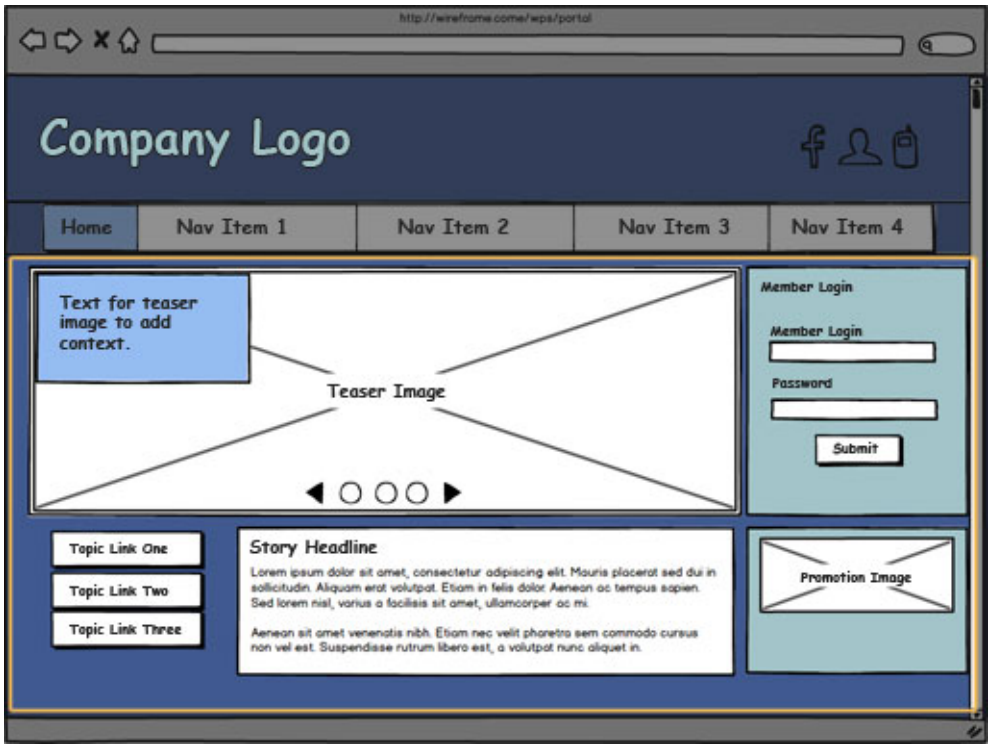

Figure 18. Wireframe with a page highlighted.

Pages and navigation

You can use the page hierarchy to establish the navigation structure in your website. The underlying information architecture is revealed in the navigation. There are other navigation approaches, but the page hierarchy is the simplest.

Types of pages

Page types include static, dynamic, derived, private, and hidden.

Static pages
Static pages use HTML templates to organize layout containers and controls, and are used as the default page type since version 7.0.

Dynamic pages
Dynamically created based on the definition of an existing page. In most cases, a dynamic page is a transient copy of a template page, often referred to as base page. This transient copy behaves like a snapshot of the base page from the time when the copy was created. It contains all portlets of the base page and all its properties. The benefit of using dynamic pages instead of static pages is that you can create multiple copies or instances of the base page. A user can then manually switch or be redirected between these instances.

Derived pages
Derived pages are child pages of the original page and inherit the properties of the original page. Creating a derived page is equivalent to creating a new, specialized layer on the original page. The original page and the new layer are aggregated together at rendering time. The new

layer is contained within and controlled by the original page. Reference an existing page to give administrative access to the other users, but still maintain the content and layout from the original page.

Private pages
A private page can be accessed only by its owner, who must be a Privileged User. A Privileged User can explicitly create new private pages that are accessible only by themselves. Additionally, a Privileged User on a non-private page can personalize the page and create new private pages underneath it. Customizing a non-private page usually creates a private copy of the corresponding non-private page. Any changes that a Privileged User makes to a non-private page are not accessible by other users.

Hidden pages
Hidden pages do not show in the portal, but contain portlets that can be opened from other pages. These hidden pages do not appear in the site navigation, but are opened from generated links in portlets or theme code. For ease of administration and conserving system resources, you can place and manage such pages in one place, for example, in the Edit Page Properties portlet: users can open from a link in the theme, but the portlet instance itself is on a hidden page in the content model.

Page templates are stored as hidden pages under the context root, **Context Root** > **Hidden Pages** > **Page Templates**.

Pages and the portal theme

Using the portal theme that is available for immediate use, you can

- Create, reorder, delete, and edit the properties of pages, labels, and URLs
- Reorder pages, labels, and URLs
- Assign access to pages, labels, and URLs
- Move pages to a new location in the portal hierarchy

Both administrators and users with appropriate access can create and delete pages. Users can delete only the pages they create or the pages for which they have at least Manager access.

Versioning and syndication of pages

You can create version and use syndication to publish the following portal artifacts:

- Portal page definitions that are stored in the release domain, including page properties, metadata, and layout settings
- Content targeting rules
- Access control that you grant to portal pages
- Public wires that connect portlets on the same page or on different pages
- Portlet preferences that are made in the **Edit Shared Settings** mode
- Vanity URLs

You cannot create version or use syndication to publish the following portal artifacts:

- Explicitly derived pages
- Private pages
- Personalization rules that are defined in Personalization and not in Web Content Manager

- Tags and ratings
- Themes and skins
- URL mappings
- Artifacts that are stored in the WebDAV file store by portlets or iWidgets
- WSRP Producers

Pages and the authoring portlet

By default, the display name of the portal page site area is based on the title of the portal page. Web Content Manager assigns a unique name in the library for each portal page site area. You can have pages with the same title organized in separate portal page site areas.

The operations that you can do on the portal page site areas in the authoring portlet are restricted. You can set Web Content Manager properties in the authoring portlet, and you can also move portal pages through the authoring portlet. But you cannot change the name, title, or description of Portal pages. For changing the title or description, you must use the portal user interface.

Note: If you delete a portal page, the portal page site area is deleted from the web content library. If the portal page site area contains any other site areas or content items, they are also deleted.

Pages and portal page site areas

The portal page site area is a special site area. In addition, to the usual Web Content Manager data site area pages contain an XML document that represents the portal page in the portal release domain database. This XML document is updated whenever a new version of the page is created or during a JCR import.

"System content associations"
System content associations are used to associate a portal page with its corresponding artifacts in IBM Web Content Manager. A system content association is an extension of the standard content association.

"Best practices for pages" on page 1740
Use these tips and guidelines to develop and deploy pages more effectively.

"Troubleshooting pages" on page 1741
When you work with pages, you might encounter problems that are related to projects, access rights, or other issues.

"Known issues for pages" on page 1743
You can review known issues for pages.

System content associations

System content associations are used to associate a portal page with its corresponding artifacts in IBM Web Content Manager. A system content association is an extension of the standard content association.

A standard content association maps a web content page or web content viewer to content in a web content library. For a system content association, there is an additional `system` flag that distinguishes the association from a content association. Like web content associations, system content associations point to objects in a web content library. However, the objects are associated with a page rather than content. System content associations are managed by the portal. The system content association acts as an automatic default content mapping of the portal page to the portal page site area and allows to automatically find content underneath

that portal page site area. The content mappings can be used in addition to the system mapping and define extra content contributions to the page and it is also possible to change the default from using the system mapping to another content mapping.

The `system` flag is a private, read-only flag. You can use the public API or the REST API to query a content association to determine whether it is a system content association or standard content association. You cannot use these interfaces to modify the `system` flag. To modify `system` data, use the XML configuration interface (XML Access).

Best practices for pages

Use these tips and guidelines to develop and deploy pages more effectively.

Create links in web content to portal pages

When you enable pages, you can create links to portal pages from within the authoring portlet in IBM Web Content Manager. You can create links to portal pages in two ways:

- By editing a content item in the rich text editor and inserting a link.
- By creating a link component.

To select the portal page, click **Browse content** in the **Link** field, and browse to the page in the Portal Site library.

Referential integrity applies for links to portal pages. You cannot delete a portal page if a link pointing to that page exists. You can view or remove such link references in the following ways:

- Edit the page properties in the portal user interface and select **View References**.
- Select the page item in the authoring portlet in Web Content Manager and click **More** > **View References**.

When users click a link, the link is resolved according to the system content mapping for the portal page item in the Portal Site library. Based on the system content mapping, the appropriate portal page is displayed.

Important: You cannot change system content mappings through typical operations with the user interface. However, it is possible to change system content mappings through programmatic interfaces, like the XML configuration interface (**`xmlaccess`** command), or other low-level database operations. If a system content mapping is changed or corrupted through such a method, the link can no longer be resolved.

Use unique friendly URLs with pages

When you create pages, it is not possible to programmatically enforce uniqueness of friendly URLs in all circumstances. Because of this behavior, it is possible to create multiple pages that have the same friendly URL, which can produce unexpected results. To prevent potential confusion, ensure that all friendly URLs that you create are unique.

Use transaction processing with the XML configuration interface

Because pages are stored in the Portal Site library in Web Content Manager, each page has corresponding objects in the JCR database. You must be aware of this relation when you create, update, or delete pages with the XML configuration

interface. If **xmlaccess** processing is interrupted, it can result in a mismatch between the page state and database state.

WARNING: If you redeploy your site daily, your JCR size increases because of page versions. Periodically clean up your versions to reduce the JCR size. Go to "Clearing version history" on page 1194 for information.

To ensure that page and database information for a page remain synchronized, use the `transaction-level` attribute of the `request` element in the XML file. For more information about using the `transaction-level` attribute, go to *XML configuration reference.*

Example:

```
<request
    type="update"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    transaction-level="resource">
```

Troubleshooting pages

When you work with pages, you might encounter problems that are related to projects, access rights, or other issues.

User *A* cannot view project *X*

Ensure that User *A* has the following access rights:

- User on the project. Specify this access by editing the project and adding User *A* to the **User** list in the **Access** section.
- User on the WCM_REST_SERVICE virtual resource. Specify this access in the portal.Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**. From the list of Resource Types, select **Virtual Resources** by clicking it. On the Resource Permissions page, click on the **Assign Access** icon for the WCM_REST_SERVICE resource. Then, click on the **Edit Role** icon to specify the access for the user.

User *A* cannot modify a published or draft page

Check the following issues as potential causes:

- If the page is part of a workflow, ensure that User *A* has Editor access to the current workflow stage.
- Is access control inheritance enabled for the portal page site area? The setting is enabled by default but can be disabled as needed. Verify the setting by editing the portal page site area and viewing the **Access** section of the properties to determine whether the **Inheritance** setting is selected.

  If access control inheritance is disabled, ensure that User *A* has Editor access to the portal page site area.

Why does User *A* receive the message "You are customizing this page. Changes are only visible to you"?

This message is generated because User *A* has Privileged User access to the page. This access level is the default access for a newly created user, and changes that the user makes are visible only to this user.

If you want the changes that User *A* makes to be visible to all users of that page, User *A* requires Editor access on the page.

User *A* is in a project and receives a message rather than creating a draft

The message "You are customizing this page. Changes are only visible to you" is generated because User *A* has Privileged User access to the page. This access level is the default access for a newly created user, and changes that the user makes are visible only to this user.

To create a draft in a project, User *A* requires either of the following access:

- Editor or higher rights on the page.
- User access on the page and Draft creator or higher access on the corresponding web content page item.

User *A* cannot drag content from the site toolbar onto the page

When the user uses the site toolbar and attempts to add content from the **Content** category in the toolbar, the following access is required for User *A*:

- Editor rights on the page.
- User rights on the web content viewer portlet that User *A* wants to add.

Portal pages are not synchronized with portal page site areas in Portal Site library

Typically, the pages in the portal and their corresponding portal page site areas in the Portal Site library are automatically synchronized. However, in some cases, these artifacts can become unsynchronized. For example, this situation can occur when data is restored from a backup or from errors when the portal page site area is created after the portal page is created.

You can resynchronize the Portal Site library based on the current portal page structure that is stored in the portal database. When you do the synchronization, the portal database acts a master repository. Any portal page site areas in the Portal Site library that do not correspond with existing portal pages are removed from the Portal Site library. Any content site areas or content items within the affected portal page site areas are also moved to the lost and found section of the Portal Site library.

To do the resynchronization, run the `create-page-nodes` configuration task, as described in *Enabling managed pages*.

Important: This task also removes any draft pages that are not found in the Portal Site library.

Related tasks:

"Enabling vanity URL support" on page 2100
In a new WebSphere Portal Express Version 8.5 installation, vanity URL support is enabled. If you upgrade your WebSphere Portal Express from a previous version to Version 8.5, vanity URL support is disabled. You can enable and disable vanity URL support as required by using a portal configuration task.

"Synchronizing the vanity URL database" on page 2104
Vanity URLs are stored as part of the page in the JCR database in the portal page site area of Web Content Manager. For performance reasons, the data is also stored in the WebSphere Portal Express database. When the data is modified, the portal synchronizes the data between both sides. However, under certain circumstances it can happen that the data is not synchronized. For such cases, the portal provides a

configuration task that synchronizes the data.

Known issues for pages

You can review known issues for pages.

Remote portlet entities are not aware of projects

`PortletEntity` objects that are stored in the Release domain of the portal database are project-aware. Changes to such a portlet entity, such as setting and modifying preferences, are reflected as a change limited to the active project. Changes to a portlet made in the active project are not visible on the published site until the changes are syndicated.

This ability to modify a portlet in a project does not apply to remote portlets that are produced with WSRP. As the remote system, the WSRP Producer is responsible for managing the portlet entities. However, because the WSRP Producer is not project-aware, the Producer cannot differentiate between the following changes:

- Changes made to the remote portlet entity directly on the published site.
- Changes made to the remote portlet entity when viewing and interacting with a project.

Because of this limitation, changes made in a project are displayed immediately on the published site through the remote portlet entity.

Authoring portlet issues

Search results for page items in the authoring portlet
When you search in the authoring portlet with the **Titles** or **Descriptions** filter, no results are returned for page items.

Sorting order of pages
When displayed in the authoring portlet, pages are listed according to the page IDs rather than the page titles. If you attempt to sort pages by title, this behavior causes the pages to display in an unexpected order. This sorting behavior also applies to any window or view, such as the Manage Project window, that is based on the authoring portlet.

Changing the order of pages in the portal

You can modify the ordering and hierarchy of pages in the portal only with the site toolbar in the portal interface. If you move the portal page site area in the authoring portlet, the page order in the portal is not affected.

Personalization rules

- Personalization rules that you create by using the Personalization editor are not managed in Web Content Manager and so are not available for versioning or included in syndication. These rules must be published by using the **pznload** command or by publishing with Personalization.
- Personalization rules are not aware of projects and the status of items in a project. Because of this characteristic, rules operate only on published content and do not include draft items.

Limited support for derived pages

Explicitly derived pages that are in the release domain can be managed by Web Content Manager. However, if you modify an explicitly derived page, that change does not generate drafts for all of the derived pages. If you want the change to

occur for all of the derived pages, you must edit each derived page separately. For more information, see the documentation about derived pages.

Portlet configuration settings

Configure mode

If you change the configuration settings for a portlet in **Configure** mode, these changes are global and are not limited to the page. Because the changes are global, the changes cannot be managed in Web Content Manager and so cannot be syndicated to another server. To transfer these changes to another server, use the XML configuration interface (**xmlaccess** command).

Edit Shared Settings mode

If you change the configuration settings for a portlet in **Edit Shared Settings** mode, these changes are part of the page. Because the changes are part of the page, the changes are managed in Web Content Manager and are automatically syndicated to other servers.

Automatic publishing and deleted items

When you specify automatic publishing for a project, the project is published as soon as all the items in the project reach a state of "pending." Deletions do not go through an explicit approval stage and are available for publishing immediately. If your project consists of only deletions, automatic publishing of the project can occur prematurely.

To prevent this automatic publishing, you can complete the following steps:

- Ensure that the project contains new pages or changes to pages, which require approval before publishing.
- Set the project to use manual publishing.

Syndication and versioning

- The versioning feature of Web Content Manager also applies to pages and is used to run different tasks with page versions. Versioning tasks include saving, deleting, and restoring versions. The Page Properties window lists the versions of the page on the **Advanced** tab. However, if you create a page and syndicate the page for the first time, the version information is empty when you view the page properties on the delivery server. After subsequent syndication operations, the version information is listed.

Portlets

Portlets are small applications that are independently developed, deployed, managed, and displayed. After the portlet is deployed, you can use it multiple times on different pages.

Almost everything on a page is rendered through a portlet. The portlet can provide access to enterprise data, content that is stored in IBM Web Content Manager, and external content from third-party sources. In the following image, there are five portlets on the page, but only one is highlighted. The highlighted Member Login Portlet is providing access to the enterprise LDAP user registry to enable members to authenticate.

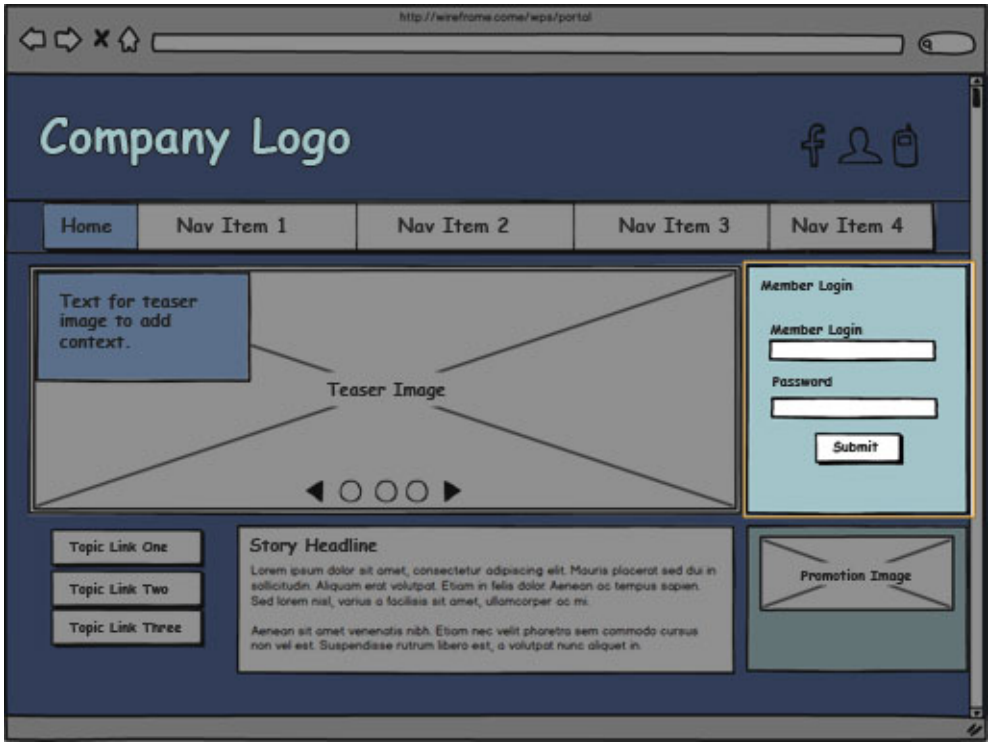

Figure 19. Wireframe of a website with portlet highlighted

Application palette

Content authors access portlets from the **Applications** palette (**Create** > **Applications**).

Content portlets

Specialized portlets are available to render content.

Web Content Viewer
: Renders content from Web Content Manager. When an author drags content from the **Content** palette onto a page, the content is rendered by using the Web Content Viewer Portlet.

Web Dock Portlet
: Renders content from third-party sources. And administrator must configure the content provider source and associate it with a Web Dock application. Then, content authors can add the Web Dock Portlet to a page.

Syndicated Feed Portlet
: Gets feeds from third-party feeds. The portlet is configured to retrieve weekly podcasts from IBM developerWorks.

Administration portlets

Use administrations portlets to configure portal. Administrations portlets are immediately available after you install the portal. To get to the administration portlets, click the **Administration menu** icon in the toolbar. Administration portlets are also available in the **Applications** palette.

Content

Rich content and elegant user experiences drive the success of websites. Each digital experience consists of many different types of content from many various sources.

In the example wireframe, content is highlighted. Depending on your point of view, all of the information in the page could be considered content. The highlighted article is the most obvious example of content. The content and associated presentation template is rendered through a portlet.

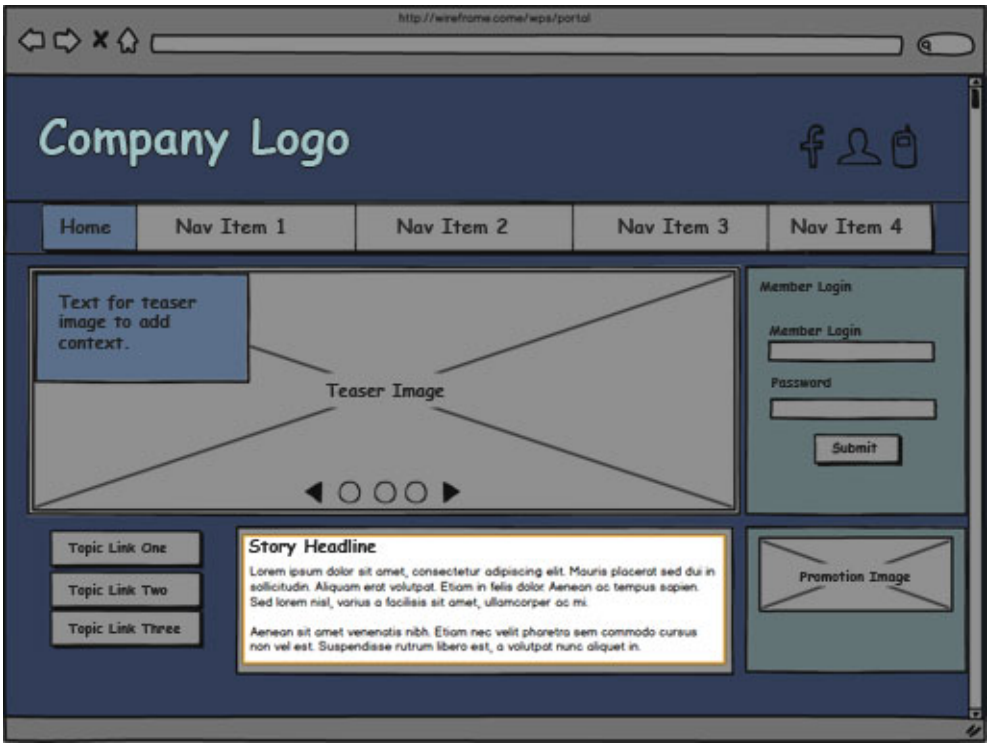

Figure 20. Wireframe with content highlighted

"Content stored in Web Content Manager" on page 1747
Use Web Content Manager to store and manage content. Web Content Manager separates the content from the presentation layer. Content authors enter information in authoring templates. The authoring template is then associated with a presentation template. The presentation template defines how the content is rendered and presented to the site visitor. As a result, you can rapidly change the look and feel of your content without editing the same elements repeatedly. Use the Web Content Viewer Portlet to render content from Web Content Manager.

"External content" on page 1747
Many capabilities are included to retrieve content from external sources. You can use Web Content Integrator, REST services for IBM Web Content Manager, IBM Digital Data Connector (DDC) for WebSphere Portal Express, specialized portlets, WSRP, and other mechanisms to retrieve and render content from sources outside your digital experience.

"Social Content" on page 1747
Integrating social content into your digital experiences adds to the rich user experience. Capabilities such as community pages and IBM Connections portlets make that integration possible.

Content stored in Web Content Manager

Use Web Content Manager to store and manage content. Web Content Manager separates the content from the presentation layer. Content authors enter information in authoring templates. The authoring template is then associated with a presentation template. The presentation template defines how the content is rendered and presented to the site visitor. As a result, you can rapidly change the look and feel of your content without editing the same elements repeatedly. Use the Web Content Viewer Portlet to render content from Web Content Manager.

External content

Many capabilities are included to retrieve content from external sources. You can use Web Content Integrator, REST services for IBM Web Content Manager, IBM Digital Data Connector (DDC) for WebSphere Portal Express, specialized portlets, WSRP, and other mechanisms to retrieve and render content from sources outside your digital experience.

IBM Web Content Integrator

The Web Content Integrator is a solution for integrating externally managed Web content with WebSphere Portal Express. Through the use of standard content syndication feed technologies based on RSS 2.0, the Web Content Integrator provides a loosely-coupled mechanism for transferring published content and metadata to the portal after they have been approved in the source system. Once the content and metadata have been transferred to the portal, it is possible to use the built-in content management features of WebSphere Portal Express to secure, personalize, and display the content to users.

REST service for Web Content Manager

The REST service for Web Content Manager is a collection of web services that are compliant with the Atom Publishing Protocol. They provide access to web content, including versions and workflow states, through HTTP. The service is designed according to the REST (REpresentational State Transfer) architectural style.

REST services make it easy to build interactive content, which can be modified directly by your site users. Responsive, integrated editing tools can be created by embedding HTML and JavaScript in web content components, which bind to the REST service to display or update content asynchronously. (Ajax)

Digital Data Connector

Use the IBM Digital Data Connector (DDC) for WebSphere Portal Express to integrate data from external data sources on portal pages by using IBM Web Content Manager presentation components. With Digital Data Connector, content authors and designers can use Web Content Manager presentation components to generate the web page markup for external data.

Social Content

Integrating social content into your digital experiences adds to the rich user experience. Capabilities such as community pages and IBM Connections portlets make that integration possible.

Integrate Connections into your site using community pages and Connections Portlets.

Community pages

Portlets on community pages are automatically scoped to the community membership and display content from the community in the portlets. For example, if your community contains a forum you can add the forum portlet to a community page. The portal site visitors can view and interact with the forum content from the portal site.

You can automatically create new communities for your pages during the page template instantiation.

Connections Portlets

Connection portlets are not installed with the portal but you can easily download them from IBM Lotus and WebSphere Portal Business Solutions Catalog.

The portlet includes activities, blogs, blog summary, bookmarks, bookmarks summary, profiles, profiles summary, wikis, forums, forums summary, community overview, and tags.

Planning a website

Before you build a website, take the time to analyze, plan, and design the entire system that supports the website. You must plan not only the website, but the web content system that manages the website and the infrastructure that is required for the system. You must also define in advance the roles and users that are involved in building the website and installing the infrastructure.

"Website objectives" on page 1749
It is important to have an understanding of the objectives, deliverables, and scope of a web content system. Your website definition outlines the "what, why, and who" of the project and can be used throughout the life of your website.

"Human resource planning" on page 1751
These roles are examples of the type of work performed by the people who create and manage a website. A single person can be responsible for more than one of the roles outlined in this section. The roles you implement in your organization to support your website are determined by the size and complexity of the system being deployed. Not all the following roles are required for every website, but all aspects of these roles must be considered during any system deployment.

"Plan your site with an analysis document" on page 1766
An analysis document is used to record the information that is gathered from stakeholders. It describes the design of the website, its content, and its features.

"How to design a prototype website by using HTML" on page 1768
Before you create a design document for your web content system, it can be useful to create a prototype of your site by using HTML. This prototype is based on the outline that is defined in your project plan and the data that is gathered in your analysis document. The site structure, design, and HTML code you develop for your prototype can be used as the basis for many of the items that are defined in your design document.

"The design document" on page 1769
When you have defined the project and created an analysis document, you then define the requirements of your web content system in a design document. The design document outlines what types of content is needed for your site, how they are structured, how content is authored, and what the final website looks like.

"Roadmap to building a web content system" on page 1781
To build a web content system you need to deploy hardware, configure servers,

design an authoring system, configure a delivery environment and enable syndication. Get an overview of the steps required to build your web content system. Keep in mind the analysis and design documents developed during the planning phase of a project as you review the roadmap.

Website objectives

It is important to have an understanding of the objectives, deliverables, and scope of a web content system. Your website definition outlines the "what, why, and who" of the project and can be used throughout the life of your website.

You define the following information in your project plan:

Background

Define the background information for the project. This information can include why the project is being undertaken and any history of previous and current related projects.

Mission

What is the mission of the project? Writing a mission statement can help in determining the requirements of the website.

Objectives

It is essential to determine the objectives of the project. These objectives can be provided by the project team, which is determined from meetings with the project stakeholders, and usability workshops with users. All stakeholders should agree on the final objectives of the site. Each objective must be clear and concise. There is no room for assumptions or varied interpretations.

Business objectives

These objectives define what the business wants to achieve. They focus on concerns such as profit and brand value.

The following are examples of business objectives for an internet site:

- Reduce costs of distributing press releases and sales materials
- Reduce the number of phone calls taken by the support team
- Strengthen existing customer loyalty
- Discover potential customers online

The following are examples of business objectives for an intranet:

- Provide specialized and tailored content to key groups within the company
- Ensure that employees feel valued
- Reduce business costs by making staff more productive by improving their core tasks

Operational objectives

Operational objectives can be grouped according to short-term and long-term objectives.

The following are examples of operational objectives:

- Provide information to company employees
- Provide information to customers

- Develop skills within the company to administer a website
- Develop single sign-on function

User objectives

These objectives define the needs of the user of the website and are crucial to developing the site objectives, structure, and function.

The following are examples of a user objective for an internet site:

- Make it easy for me to find what I want
- Make the information understandable and relevant
- Let me know where I am in the site
- Retain my privacy

The following are examples of a user objective for an intranet:

- Find up to date, relevant information as quickly as possible
- Keep me informed of latest news and updates
- Help me perform core business functions such as completing time-sheets and applying for leave
- Reduce my frustrations
- Let me publish information
- Help me feel connected, supported, and valued

Site objectives

Site objectives are derived from the business, operational, and user objectives. They might be the result of the intersection of the business, operational, and user objectives, or they might be extra objectives that result from analysis.

The following are examples of site objectives for an internet site:

- Provide clear and easy to understand navigation that enables users to find information quickly
- Provide a search feature
- Write content for the web so that it is easy to read and understand
- Provide an FAQ section that addresses the most frequently asked questions of the support team
- Provide a framework that structures content for the user and not the business division

The following are examples of site objectives for an intranet:

- Provide clear and easy to understand navigation that enables users to find information quickly
- Support key common tasks such as timesheet entry
- Provide a customized news section
- Provide an FAQ section that addresses the most frequently asked questions of the support team
- Provide a framework that structures content for the user and not the business division
- Enable staff to enter content that is then put through a workflow before it is published on the intranet

Project teams

Define the role of each of the teams that are involved in the project and the organization of the teams. The following are some project team examples:

Executive sponsors
The owners and drivers of the project.

Project team
Responsible for the day-to-day management, analysis, and construction of the new site.

Reference group
Business unit representatives that are consulted to ensure that their needs are addressed.

Focus group
User representatives that are consulted to ensure that the new site is user-focused.

Deliverables

Document all the deliverables of the project. Give a description of what the deliverables are and the expected time frame for delivery.

Human resource planning

These roles are examples of the type of work performed by the people who create and manage a website. A single person can be responsible for more than one of the roles outlined in this section. The roles you implement in your organization to support your website are determined by the size and complexity of the system being deployed. Not all the following roles are required for every website, but all aspects of these roles must be considered during any system deployment.

"The project manager" on page 1752
Large complex deployments require a project manager to ensure that there are sufficient resources available to deploy a system, that the correct users have been assigned to the project and that the tasks required to deploy the system occur at the correct time in the overall deployment process.

"The business analyst" on page 1753
A business analyst is responsible for developing an analysis document.

"The architecture and design team" on page 1753
Based on the data collected in the analysis document, the architecture and design team documents all the things required by the WebSphere Portal system. The design documents the team develops are used by the deployment and development teams to deploy and manage the WebSphere Portal system.

"The deployment team" on page 1757
Based on the design documents developed by the technical design team, the deployment team builds and manages the WebSphere Portal system.

"The development team" on page 1761
Based on the design documents developed by the technical design team, the development team is responsible for creating custom applications using the product API.

"The website creation team" on page 1762
Based on the design documents developed by the technical design team, the website creation team is responsible for creating the website and related systems.

"The content acquisition team" on page 1764
Based on the content identified in the analysis document, the content acquisition team is responsible for importing content from legacy systems into the new website. The team consists of a mixture of administrators and developers. Team members need to be experts in both legacy products and WebSphere Portal Express

"The maintenance team" on page 1765
Based on the maintenance architecture developed by the technical design team, the maintenance team is responsible for the ongoing monitoring and maintenance of the overall system.

The project manager

Large complex deployments require a project manager to ensure that there are sufficient resources available to deploy a system, that the correct users have been assigned to the project and that the tasks required to deploy the system occur at the correct time in the overall deployment process.

Defining the project:

It is important to have an understanding of the objectives, deliverables, and scope of a web content system. The project manager is responsible for creating a project plan to document the overall scope and goals of the project.

- "Website objectives" on page 1749

Overseeing the development of a site prototype and design documents:

After defining the project and creating an analysis document, the project manager is responsible for overseeing the development of a site prototype and design documents.

- "How to design a prototype website by using HTML" on page 1768
- "Plan your site with an analysis document" on page 1766

Ensuring that the project has the optimum level of human and physical recourses:

The project manager is responsible for ensuring that sufficient human and physical resources have been planned for the initial design, development, and ongoing maintenance of the website and related infrastructure.

Project managing the deployment and installation of the hardware and software used to manage and deliver the website:

The project manager is responsible for overseeing the deployment and installation of the hardware and software used to manage and deliver the website. The project manager monitors the progress of the overall deployment, and takes appropriate action to ensure that milestones are reached on time and on budget.

- Chapter 4, "Installing," on page 101

Project managing the ongoing maintenance and upkeep of the hardware and software used to manage and deliver the website:

The project manager also develops a plan for the ongoing monitoring and maintenance of the website and related infrastructure.

- "Web content administration tools" on page 1176

Planning to install WebSphere Portal

"Planning a website" on page 1748
Before you build a website, take the time to analyze, plan, and design the entire system that supports the website. You must plan not only the website, but the web content system that manages the website and the infrastructure that is required for the system. You must also define in advance the roles and users that are involved in building the website and installing the infrastructure.

The business analyst

A business analyst is responsible for developing an analysis document.

The business analyst is responsible for developing an analysis document. This document is used to record the information gathered from stakeholders that determine the design of the website, its content, and its features. The analysis document includes information on:

- The types of users that will use the system
- What features and applications will be required on the website
- What existing content will need to be imported into the new web content system, and what new content will need to be created

Related concepts:

"Plan your site with an analysis document" on page 1766
An analysis document is used to record the information that is gathered from stakeholders. It describes the design of the website, its content, and its features.

Related information:

"Planning a website" on page 1748
Before you build a website, take the time to analyze, plan, and design the entire system that supports the website. You must plan not only the website, but the web content system that manages the website and the infrastructure that is required for the system. You must also define in advance the roles and users that are involved in building the website and installing the infrastructure.

The architecture and design team

Based on the data collected in the analysis document, the architecture and design team documents all the things required by the WebSphere Portal system. The design documents the team develops are used by the deployment and development teams to deploy and manage the WebSphere Portal system.

"The technical architecture team" on page 1754
The technical architects are responsible for designing the overall server topology required for the entire system and the architecture of the servers that make up the system. The technical architecture team can include technical architects, database architects, security architects, performance engineers, and other resources as required.

"The information architect" on page 1755
The information architect determines the overall informational structure of the website based on requirements gathered in the analysis document.

"The website designer" on page 1756
A website designer is responsible for designing the layout and style of the web pages in a website. A graphic designer might also be employed to create graphics and color schemes for the website.

"The authoring system architect" on page 1756
The authoring system architect is responsible for determining the architecture of the authoring system used to create and manage web content.

The technical architecture team:

The technical architects are responsible for designing the overall server topology required for the entire system and the architecture of the servers that make up the system. The technical architecture team can include technical architects, database architects, security architects, performance engineers, and other resources as required.

Determining a server architecture:
The technical architect is responsible for designing a server architecture describing all the servers and related software required to deliver the website.

- "Server architecture" on page 1770

Determining a database architecture:
The database architect is responsible for designing a database architecture describing all the configuration settings required for the databases used in the system.

- "Server architecture" on page 1770
- "Database" on page 119
- "User registry considerations" on page 128

Determining syndication strategies:
The technical architect determines what syndication strategies are required between the different environments in the web content system.

- "Server architecture" on page 1770
- "Syndication relationships" on page 449

Determining a security architecture:
The security architect is responsible for designing a security architecture describing all groups and roles, and access levels required to ensure that different types of users have access only to the functions and content appropriate to their roles.

- "Security architecture" on page 1771
- "Users, Groups and Roles" on page 1557
- Managing users and groups
- "Controlling access" on page 1524

Determining a content acquisition architecture:
The technical architect is responsible for designing a content acquisition describing the technical details of the methods to use when importing existing content in the new web content system. The content to import is based on the information collected in the analysis document.

- "Content acquisition architecture" on page 1779
- "Plan your site with an analysis document" on page 1766
- "The IBM Web Content Manager API" on page 3154
- "IBM Web Content Integrator" on page 1936
- "WebDAV" on page 1986

Determining delivery strategies:
The technical architect is responsible for determining which delivery methods are best suited for the types of websites being delivered.

- "Delivery architecture" on page 1779
- "Types of websites" on page 45

- "Delivering web content" on page 2016

Determining system maintenance strategies:

The technical architecture team is also responsible for determining the ongoing maintenance strategies and procedures of the system.

- "Maintenance architecture" on page 1780

Installing WebSphere Portal

"Planning a website" on page 1748

Before you build a website, take the time to analyze, plan, and design the entire system that supports the website. You must plan not only the website, but the web content system that manages the website and the infrastructure that is required for the system. You must also define in advance the roles and users that are involved in building the website and installing the infrastructure.

The information architect:

The information architect determines the overall informational structure of the website based on requirements gathered in the analysis document.

Determining the website structure:

The web site structure designed by the information architect determines:

- What Portal pages will need to be created if using portlet delivery.
- What site areas will need to be created

Determining what content types are required:

The content types required for each section in the website structure determine:

- What authoring templates are required
- What presentation templates are required
- What template mappings are required

Determining a content profiling architecture:

The information architect determines what content profiling is required for features such as menus.

Related concepts:

Item management features

Web Content Manager includes a range of features that help you manage the web content items that are used in your system.

"Delivering web content" on page 2016

The type of delivery method you use to deliver web content to your viewers depend on the type of content that is being delivered, and the type of viewers your website is intended for.

The website designer:

A website designer is responsible for designing the layout and style of the web pages in a website. A graphic designer might also be employed to create graphics and color schemes for the website.

Determining what themes, style sheets, and templates are required:
The website designer determines what themes, style sheets, and presentation templates are required to deliver the website.

- "Design architecture" on page 1776
- "How to design a prototype website by using HTML" on page 1768
- Creating a presentation template

Determining what elements and components are required:
The page types and presentation templates required for your site determine:

- What components are required
- What elements are required for each authoring template
- What elements are required to be stored in site areas
- "Components" on page 1795

Determining personalization strategies:
The website designer determines what personalization strategies are required for the website.

- "Personalization" on page 2240

The authoring system architect:

The authoring system architect is responsible for determining the architecture of the authoring system used to create and manage web content.

Designing the library architecture:
The authoring system architect determines what libraries are required for the website.

Determining what authoring templates are required:
The authoring system architect documents the configuration of each authoring template used in the authoring system and what template mappings are required to link authoring templates and presentation templates.

- "An overview of authoring templates" on page 1787
- "Template mappings" on page 1792

Designing a folder architecture:
The authoring system architect determines what folders are required to store item-types within logical groupings.

- Web content folders

Design a change management model:
The authoring system architect determines what workflows are required to manage approval processes and what items require a workflow, and also design project templates.

- "Workflow and change management" on page 1929
- "Projects" on page 1923

Determine version control strategies:

The authoring system architect determines what version control strategies are applied to the web content system.

- How to manage versions of items

Related concepts:

Item management features
Web Content Manager includes a range of features that help you manage the web content items that are used in your system.

Related information:

Installing WebSphere Portal

The web content administrator:

A web content administrator is responsible for configuring the web content servers within a WebSphere Portal system.

Web content authoring environments

In a web content authoring environment, a web content administrator performs the following tasks:

Create new pages
An administrator might need to create new pages to display additional authoring portlets used by different users, or for displaying web content viewer portlets to preview sites within.

- "Pages" on page 1736
- "Custom portal pages for authoring" on page 1897

Configure an authoring portlet
Each authoring portlet in an authoring environment needs to be configured to ensure that it has been configured correctly for the users using each authoring portlet.

- "Authoring portlet settings" on page 1915

Configure a web content viewer portlet
Each web content viewer portlet in an authoring environment needs to be configured to display the content that is being previewed.

- "Web Content Viewers" on page 2017
- "Displaying content with Web Content Viewers" on page 2034

Create web content libraries
The web content administrator creates a set of web content libraries based on the recommendations of the web content architect.

Clone a web content repository
Before enabling syndication, a web content administrator, with a database administrator, clones a web content repository from the authoring environment to other environments.

- "How to clone a web content repository" on page 1214

Manage syndication
Syndication relationships are normally created on subscriber servers. As you typically syndicate only out from an authoring environment to other environments, you would not normally create a syndication relationship from an authoring environment, but a web content administrator might need to manage syndication settings and configurations from time to time.

- "Syndication relationships" on page 449
- How to manage syndicators and subscribers
- "Syndication tuning" on page 456

Create and manage feed configurations and jobs
Sometimes web content is stored and maintained in external systems. You use the Web Content Integrator to consume content from external systems using feeds.

- Web content feed management

Tune an authoring environment configuration settings
Authoring environment configuration settings can be tuned for specific features.

- "Configuring a web content authoring environment" on page 393

Web content delivery environments

In a web content delivery environment, a web content administrator performs the following tasks:

Create new pages
An administrator might need to create new pages when displaying content using web content viewer portlets.

- "Pages" on page 1736

Configure a web content viewer portlet
Each web content viewer portlet in a delivery environment needs to be configured to display the correct content.

- "Web Content Viewers" on page 2017
- "Displaying content with Web Content Viewers" on page 2034

Manage syndication
A web content administrator creates syndication relationships to the delivery environment from the web content staging and authoring environments.

- "Syndication relationships" on page 449
- How to manage syndicators and subscribers
- "Syndication tuning" on page 456

Tune a delivery environment configuration settings

Delivery environment configuration settings can be tuned for specific features.

- "Configuring a web content delivery environment" on page 411

User acceptance test environment

A user acceptance testing environment is set up like authoring and delivery environments depending on the type of user acceptance test being performed. The tasks required to set up the UAT environment are the same as those for the authoring and delivery environments.

Related concepts:

"Delivery architecture" on page 1779
Your technical architect and information architect need to define what delivery methods are most appropriate for the website you are delivering.

"Server architecture" on page 1770
Your technical architects define what web content environments are required for your system and the servers that are required for each environment. This information ensures that you have sufficient hardware to support your web content system

Developing

The theme developer:

A theme developer is responsible for creating new themes based on the designs developed by the information architect and the graphic designer.

The theme developer is primarily responsible for creating custom themes based on the Web site designs outlined in the design architecture and the HTML used in the website prototype. Themes are a set of JSPs, images, and style sheets packaged together in a common directory structure. They can either be packaged directly in the wps.war or inside a separate WAR file of their own, or with other themes, skins, and resources.

Related concepts:

The design architecture describes what your website looks like, and what components are needed to build your site. You need to define presentation templates, components, and themes.

The website creation team

Based on the design documents developed by the technical design team, the website creation team is responsible for creating the website and related systems.

"The website creator"
A website creator is responsible for building a website by creating presentation templates, authoring templates, site areas, components and categories. The web site creator is also responsible for creating content management items such as folders and workflows. The items created by a website creator are based on the designs created by the information architect and graphic designer.

"The web content author" on page 1764
A web content author is responsible for creating web content for the sites developed and managed using Web Content Manager.

"The web content manager" on page 1764
A web content manager is responsible for performing ongoing site maintenance activities.

The website creator:

A website creator is responsible for building a website by creating presentation templates, authoring templates, site areas, components and categories. The web site

creator is also responsible for creating content management items such as folders and workflows. The items created by a website creator are based on the designs created by the information architect and graphic designer.

Creating web content management items

Before creating a website, the web content creator begins by creating any required content management items:

Creating folders
Folders are used to store item-types within logical groupings.

- Working with folders

Creating workflows
Workflows are required to manage the approval processes of items.

- "Workflow and change management" on page 1929

Creating projects
Projects are used to manage the approval process of a collection of items.

- "Projects" on page 1923

Creating a website

To create a website the following Web Content Manager items will need to be created:

Site areas
Site areas are used to define the site framework of a site. Content items that form part of the site framework will be stored within the site framework.

- Creating site areas

Authoring templates
Authoring templates are required for the different types of pages in a website. Content items created by content authors will be based in the authoring templates created by the website creator.

- Creating authoring templates

Presentation templates
Presentation templates determine the layout of the pages in a website and are linked to authoring templates by the template maps defined in site areas.

- Creating a presentation template

Elements and components
Elements are added to authoring templates and site areas to store different types of content. Components are used to create single elements that can be reused across a website.

- "Elements" on page 1804

Categories
Categories are used to profile items that have been configured to allow content profiling.

- "Taxonomies, Categories, and keywords" on page 1847

Related concepts:

"Information architecture" on page 1774
The information architecture describes the information structure of the site and

how users browse through the site.

"Design architecture" on page 1776
The design architecture describes what your website looks like, and what components are needed to build your site. You need to define presentation templates, components, and themes.

The web content author:

A web content author is responsible for creating web content for the sites developed and managed using Web Content Manager.

Content authors create content either by accessing an authoring portlet, or by using a custom content authoring interface.

Creating content items
Presentation templates determine the layout of the pages in a website and are linked to authoring templates by the template mappings defined in site areas.

- "Content items" on page 1794

Working with elements and components
Elements are added to authoring templates and site areas to store different types of content. Components are used to create single elements that can be reused across a website.

- "Elements" on page 1804

The web content manager:

A web content manager is responsible for performing ongoing site maintenance activities.

Moving, linking and copying items:
From time to time a web content manager will need to redesign the structure of a website by moving or copying items.

Managing authoring templates:
From time to time a web content manager will need to reapply or change the authoring template used by content items and site areas.

Restoring items:
From time to time a web content manager will need to restore an item to a previously saved version.

Editing user profiles:
Profiling information specific to a web content system can be added to a user profile to allow you to personalize content for a specific set of users.

Managing access controls
From time to time a web content manager will need to reapply or change the access controls of a set of items.

The content acquisition team

Based on the content identified in the analysis document, the content acquisition team is responsible for importing content from legacy systems into the new website. The team consists of a mixture of administrators and developers. Team members need to be experts in both legacy products and WebSphere Portal Express

The Web Content Manager API:

You can use the Web Content Manager API to import content into Web Content Manager.

- "The IBM Web Content Manager API" on page 3154

Web content feeds

You use the Web Content Integrator to consume content from external systems using feeds.

- "IBM Web Content Integrator" on page 1936

Using WebDAV for web content:

With WebDAV for WebSphere Portal Express, you can use standard operating system tools to create, modify, and delete web content rather than the standard authoring portlet.

- "WebDAV" on page 1986

Related concepts:

"Content acquisition architecture" on page 1779
The content acquisition architecture is used to define what existing content will be imported into your web content system, how it is imported, and what content needs to be created.

The maintenance team

Based on the maintenance architecture developed by the technical design team, the maintenance team is responsible for the ongoing monitoring and maintenance of the overall system.

The database administrator

After all databases have been setup, the database administrator is then responsible for the ongoing monitoring and maintenance of all databases in the system.

The WebSphere Portal administrator

The WebSphere Portal administrator is responsible for ongoing maintenance of the WebSphere Portal servers in the system.

- Chapter 11, "Administering," on page 1041

The web content administrator

Manage syndication:

Syndication relationships are normally created on subscriber servers. As you typically syndicate only out from an authoring environment to other environments, you would not normally create a syndication relationship from an authoring environment, but a web content administrator might need to manage syndication settings and configurations from time to time.

- "Syndication relationships" on page 449
- Working with syndicators and subscribers
- "Syndication tuning" on page 456

Manage feed configurations and jobs:

Sometimes web content is stored and maintained in external systems. You use the Web Content Integrator to consume content from external systems using feeds.

- Web content feed management

Maintain an authoring system:
From time to time a web content administrator needs to perform some maintenance tasks.

- "Web content administration tools" on page 1176

The security administrator

Managing the user registry:
The security administrator maintains the security registry by running various update delete tasks.

- "Updating your user registry" on page 585

Managing the users and groups:
The security administrator maintains the users and groups stored in the user registry.

- Managing users and groups

Managing access control:
The security administrator manages access controls to pages, portlets, modules, and other applications.

- "Controlling access" on page 1524

Additional security tasks:
There are various other tasks carried out by the security administrator depending on the environment being used.

- "Enabling step-up authentication and the **Remember me** cookie" on page 1587

The performance engineer

The performance engineer is responsible for ensuring that all the hardware and software in the system are tuned for maximum performance and reliability.

- Chapter 17, "Troubleshooting," on page 3537

Related concepts:

"Maintenance architecture" on page 1780
You need to plan for the tasks that maintain the health and integrity of your web content system. Your technical architect and database architect need to define what maintenance procedures are required for your system, and when and how often they need to be run.

Plan your site with an analysis document

An analysis document is used to record the information that is gathered from stakeholders. It describes the design of the website, its content, and its features.

Here are some examples of the analysis that can be undertaken when you design a web content system.

User analysis

To design a website that supports the needs of the company and the users, you must know who your audience is. It is important to determine your users at this early stage of the project. Some of the things you want to discover are:

- Who they are?
- Who are the most important groups?
- What do they want to do on the site?

- What makes them return to the site?
- What is their level of experience with the web?

To help you understand your main user groups even further, you can develop personas and scenarios:

Personas

A persona is a fictional person who represents a major user group for your site. By using the information that is gathered about your users, create a person who represents each main user group. Give them:

- A name and picture
- Demographics, such as age, education, and family status
- Job role and responsibilities
- Their goals and tasks in relation to the site
- A background on their computer and web usage

Scenarios

A scenario is a story of how users might experience the site. They help you visualize the site and its users. They can help you view the navigation process as a whole. Scenarios are also useful in validating the website design after it is finished and can be used in usability testing. Use your personas, and give them a task to accomplish on the site. Write a story about how the character uses the site to finish the task. Be creative.

Competitive Analysis

If you are building a public website, it is useful to look at what the competition is doing. Generate a list of competitors and document things you like and dislike about their Internet sites. For intranet sites where you cannot compare your site with websites of competitors, you can instead ensure that your intranet meets current standards.

Website requirements

Website requirements describe the features and functions of a website. They document what the site must have and also what users can do. The requirements are not used to describe how to build the website, which is detailed in the design document.

For example:

General features:

- Search
- Contact details

Allow users to:

- Purchase a product
- Sign up for a newsletter
- Complete a timesheet online

Include the following content and site areas:

- Press releases
- Policies and guides
- Links to related articles

Content Inventory

It is useful to identify the types of content that make up the site. As your new website might be a redesign of an existing site, identify what content exists and what new content needs to be written. Create a content inventory, and add any existing web pages and potential types of content that you can think of. Types of content include:

- Static content such as copyright notices and privacy statements
- Dynamic content such as latest news and product campaigns
- Transactional content such as logon pages and registration pages for email newsletters

When you create a content inventory, you can collect the following information:

- A brief description
- Topic area or category
- Priority
- Format, such as a web page, a file, or on paper
- Intended audience
- Related content
- Created date
- Last modified date
- Owner
- Author
- Expiration date

How to design a prototype website by using HTML

Before you create a design document for your web content system, it can be useful to create a prototype of your site by using HTML. This prototype is based on the outline that is defined in your project plan and the data that is gathered in your analysis document. The site structure, design, and HTML code you develop for your prototype can be used as the basis for many of the items that are defined in your design document.

By creating a prototype website by using HTML, you get to see what your actual website looks like, plus you develop many of the features that are used by your web content system and website.

Building the prototype

- The prototype website includes example pages of each page type that is defined in your project plan and analysis document. It also includes the basic site structure of your proposed website.
- The prototype can be a functional website. It can include functioning navigational features so you can browse through the prototype. Examples of real content are used to populate the prototype.
- Take care to ensure that the HTML and other code you write to create the prototype meets coding best practices because much of the code you develop for the prototype is reused in your Web Content Manager site.

How to use HTML to plan the design of your site

A useful method to begin the design of your content management system is to use HTML to develop a prototype of your site. Do this task in consultation with the web content information architect.

The HTML site can include:

- The design for the main home pages of each section of your site
- The design for content pages that are stored in each section
- The navigation features of your site

The HTML site can then be used to help you determine what web content items need to be created for your web content management system.

For example, the design of each web page in the HTML mock-up can determine different parts of your Web Content Manager site:

- The layout of each HTML page determines the layout of your presentation templates.
- The design of the navigation features determines what menus and navigators you need to create.

The presentation template is used to combine elements from different parts of the web content system, such as site areas, content items, and components.

Other features of your design, such as images and style sheets, determine what components need to be created and whether you need to develop a new WebSphere Portal theme.

The design document

When you have defined the project and created an analysis document, you then define the requirements of your web content system in a design document. The design document outlines what types of content is needed for your site, how they are structured, how content is authored, and what the final website looks like.

"Server architecture" on page 1770
Your technical architects define what web content environments are required for your system and the servers that are required for each environment. This information ensures that you have sufficient hardware to support your web content system

"Security architecture" on page 1771
The security architecture describes what groups are required for your site and what access is required for different groups to the authoring portlet and rendered website.

"Information architecture" on page 1774
The information architecture describes the information structure of the site and how users browse through the site.

"Design architecture" on page 1776
The design architecture describes what your website looks like, and what components are needed to build your site. You need to define presentation templates, components, and themes.

"Authoring architecture" on page 1777
The authoring architecture describes what types of content are required for the site and what change management strategies are applied when you update content and design. You need to define what authoring templates are required

for your system, what workflows are used to manage changes and what folders are used to group items in the authoring portlet.

"Content acquisition architecture" on page 1779
The content acquisition architecture is used to define what existing content will be imported into your web content system, how it is imported, and what content needs to be created.

"Delivery architecture" on page 1779
Your technical architect and information architect need to define what delivery methods are most appropriate for the website you are delivering.

"Maintenance architecture" on page 1780
You need to plan for the tasks that maintain the health and integrity of your web content system. Your technical architect and database architect need to define what maintenance procedures are required for your system, and when and how often they need to be run.

Server architecture

Your technical architects define what web content environments are required for your system and the servers that are required for each environment. This information ensures that you have sufficient hardware to support your web content system

Environmental architecture

Every Web Content Manager system consists of at least one authoring environment and one delivery environment. The authoring environment is used to create and manage the individual items that make up your website. The delivery system is used to deliver the web content to your viewers. In addition to these environments, you might also require testing environments where you undertake user acceptance testing (UAT).

The technical architecture team documents the overall environmental architecture that is required for your Web Content Manager system including:

- What authoring, delivery and UAT environments are required
- What WebSphere Portal servers or clustered are required in each environment
- What database servers are required to store the data repositories that are used by each WebSphere Portal server or cluster
- What syndication relationships are required between each environment
- What user repositories, such as LDAP, are required

Server architectures

The technical architecture team also documents a server architecture for each server that is described in the environmental architecture. A server architecture describes the detailed setup of each server, including:

- What hardware is required for each server
- What operating system is required for each server
- What software is required
- Configuration settings for all hardware, software, and operating systems
- Other relationships such as remote data repositories, and user repositories

Security architecture

The security architecture describes what groups are required for your site and what access is required for different groups to the authoring portlet and rendered website.

Note: The following example describes the type of security architecture that is required for an authoring environment. In most cases, the security architecture for a staging or delivery environment would be much simpler with only the **All Portal User Groups** group assigned user access to the library. This strategy prevents users from being able to edit content and disables features like authoring tools from being displayed on the published site.

In this example, item type roles are applied to the following groups:

Table 248. Groups

Group	Details
WCMAdmins	Members of this group require access to all features of the authoring portlet.
SiteAdmins	Members of this group require access to all features of the authoring portlet except workflow.
SiteDesigners	Members of this group require access to content items, presentation templates, authoring templates, and components.
ContentAuthors	Members of this group require editor access to content items only.
ContentReviewers	Members of this group require Reviewer access to content items only.

Library access

The simplest method of setting library access is to grant contributor access to all your groups. This access gives all users and groups contributor access to the library and authoring portlet. Extra access is then granted to each group by using resource permissions. You can also grant the Anonymous Portal User group user access to ensure that all anonymous users can access the library if anonymous access is required for your website.

Table 249. Library access

Roles	Allow propagation	Allow inheritance	User or group
Administrator	Yes	Yes	
Manager	Yes	Yes	
Editor	Yes	Yes	
User	No	Yes	Anonymous Portal User
Contributor	Yes	Yes	WCMAdmins SiteAdmins SiteDesigners ContentAuthors ContentReviewers

Resource permissions

Set the following resource permissions for each role type:

- The WCMAdmins group is assigned the administrator role for all resources.
- The SiteAdmins group is assigned the manager role to all resources except workflow and workflow elements as they do not require access to these resources.
- The other groups are assigned roles for each resource according to the following tables.

Authoring templates

The SiteDesigners group is assigned editor access to authoring templates as they are required to create new authoring templates.

Table 250. Authoring templates

Roles	Allow propagation	Allow inheritance	User or group
Administrator	Yes	Yes	WCMAdmins
Manager	Yes	Yes	SiteAdmins
Editor	Yes	Yes	SiteDesigners
User	Yes	Yes	
Contributor	Yes	Yes	

Components

SiteDesigners are assigned editor access to components as they are required to create components.

Table 251. Components

Roles	Allow propagation	Allow inheritance	User or group
Administrator	Yes	Yes	WCMAdmins
Manager	Yes	Yes	SiteAdmins
Editor	Yes	Yes	SiteDesigners
User	Yes	Yes	
Contributor	Yes	Yes	

Content

Both the SiteDesigners and ContentAuthors groups are assigned editor access to content as they are required to create content items.

The ContentReviewers group is assigned Reviewer access only, because they are not required to create new content items, but need Reviewer access to content items during a workflow. You must also assign the ContentReviewers group approve access in the properties section of any workflow stages that ContentReviewers use to approve content items.

Table 252. Content

Roles	Allow propagation	Allow inheritance	User or group
Administrator	Yes	Yes	WCMAdmins
Manager	Yes	Yes	SiteAdmins

Table 252. Content (continued)

Roles	Allow propagation	Allow inheritance	User or group
Editor	Yes	Yes	SiteDesigners ContentAuthors
User	Yes	Yes	
Contributor	Yes	Yes	
Reviewer	Yes	Yes	ContentReviewers

Presentation Templates

The SiteDesigners group is assigned editor access to presentation templates as they are required to create new presentation templates.

Table 253. Presentation templates

Roles	Allow propagation	Allow inheritance	User or group
Administrator	Yes	Yes	WCMAdmins
Manager	Yes	Yes	SiteAdmins
Editor	Yes	Yes	SiteDesigners
User	Yes	Yes	
Contributor	Yes	Yes	

Site areas and pages

Only the WCMAdmins and SiteAdmins groups require access to site areas and pages as these are the only groups that build site frameworks.

Table 254. Site areas and pages

Roles	Allow propagation	Allow inheritance	User or group
Administrator	Yes	Yes	WCMAdmins
Manager	Yes	Yes	SiteAdmins
Editor	Yes	Yes	
User	Yes	Yes	
Contributor	Yes	Yes	

Taxonomy

Only the WCMAdmins and SiteAdmins groups require access to taxonomies as these are the only groups that build taxonomies.

Table 255. Taxonomy

Roles	Allow propagation	Allow inheritance	User or group
Administrator	Yes	Yes	WCMAdmins
Manager	Yes	Yes	SiteAdmins
Editor	Yes	Yes	
User	Yes	Yes	
Contributor	Yes	Yes	

Workflow Items

Only the WCMAdmins group requires access to workflow items as this is the only group that creates workflows. The groups that use workflows do not require access to the workflow items resource permissions.

Table 256. Workflow Items

Roles	Allow propagation	Allow inheritance	User or group
Administrator	Yes	Yes	WCMAdmins
Manager	Yes	Yes	
Editor	Yes	Yes	
User	Yes	Yes	
Contributor	Yes	Yes	

Item-level security inheritance

By default, each role's access is automatically inherited down to each item in a library. To prevent a user or group from automatically having inherited access to an item, you need to turn off inheritance on that item.

The permissions set for item type do not automatically give you access to individual items. They give you access only to specific tasks and views within the authoring portlet.

You can also assign specific access to individual groups or users on each item.

Related concepts:

"User registry considerations" on page 128
A user registry or repository authenticates a user and retrieves information about users and groups to do security-related functions, including authentication and authorization.

"Users, Groups and Roles" on page 1557
Your content management system requires different types of users. You need to create a different group for each type of user and then assign those groups different roles within your system.

Related tasks:

"Setting up access" on page 1801
Access controls allow you to assign access to who has the ability to view rendered constant and pages, and who has the ability to edit or administer content, pages, or features.

Information architecture

The information architecture describes the information structure of the site and how users browse through the site.

The site map

The website structure that is designed by the information architect determines what pages and site areas need to be created to give your site a hierarchical structure. The site map describes the structure of the site and determines what pages and site areas are required for your site. For example:

- Home page
  - News Page
  - Products Page

    - Product Site Area 1
    - Product Site Area 2
    - Product Site Area 3
  – Downloads Page
  – Support Page

Content types

The content types that are identified by the information architect determine what authoring templates are required for your authoring system. For example, your site might require the following content types:

- Section home pages
- News articles
- Employee profiles
- Product information
- Photo galleries
- Legal disclaimers

Content profiling and taxonomies

The information architect is responsible for determining what taxonomies are required to allow users to profile content. This information determines what content is displayed within menu components.

This is an example of a taxonomy for a financial services company:

- MetaBank taxonomy:
  – Financial
    - Banking Solutions
    - Interest Rates
      - Personal
      - Business
      - Corporate
  – News

Related concepts:

Site framework
A site framework is a hierarchical set of pages and site areas that are used to define the navigational structure of your website. You store content items within the site framework by saving them under different pages or site areas.

"An overview of authoring templates" on page 1787
Authoring templates are like forms that content authors can use to create new content. It defines default settings for the items that are created by using the authoring template. There are two types in authoring templates, site area and content.

"Presentation templates" on page 1789
You use a presentation template define the layout of your web content. Use tags to determine which properties, elements, or components are displayed.

"Taxonomy" on page 1801
Before creating a taxonomy, you should analyze how the taxonomy will be used in your site to determine the best structure for your taxonomy.

Design architecture

The design architecture describes what your website looks like, and what components are needed to build your site. You need to define presentation templates, components, and themes.

Themes and style-sheets

You list the themes, style-sheets, and styles in the design architecture. These designs can be based on the styles that are developed for your prototype website.

Page wireframes

Page wireframes can be used to describe the basic structure of each page-type in your site and the elements that are used on each page.

Presentation templates

You list each presentation template that is required for your website plus its HTML in the design architecture. The HTML you developed for the prototype website can be used as the basis for the HTML in the design document. The presentation template design includes:

- The HTML design of the presentation template
- Access settings
- Whether a workflow is required and, if so, which one

Components and elements

Each component and element that is required for your website is listed in the design architecture, and additional information such as:

- HTML design for any required component fields
- Parameter selections for any component parameters
- Access settings
- Whether a workflow is required and, if so, which one

Personalization strategies

The website designer also determines what content needs to be personalized for specific users. For example, you might want to display a personalized home page for each individual user based on the user profile. The personalization strategies that are documented in the design architecture determines what rules, content spots, and campaigns need to be created when the Personalization application is used.

Related concepts:

"Presentation templates" on page 1789
You use a presentation template define the layout of your web content. Use tags to determine which properties, elements, or components are displayed.

"Components" on page 1795
You use components to store elements that are used in more than one area of your website. For example, a company logo or a copyright notice.

"Personalization" on page 2240
Portal Personalization provides automatic customization of website content for individual users and user groups.

Authoring architecture

The authoring architecture describes what types of content are required for the site and what change management strategies are applied when you update content and design. You need to define what authoring templates are required for your system, what workflows are used to manage changes and what folders are used to group items in the authoring portlet.

Library architecture

The library architecture describes where you store your web content items. For example, you might split your site between the items that control the design of your site, such as presentation templates and components, from the content of your site. You might also separate your libraries into different team libraries such as "human resources" and "support".

Authoring templates

You need a separate authoring template for each type of content item and site area that is used by your site. The list of authoring templates that are defined in your authoring architecture is based on the different page types that are identified in the project plan, analysis document, and prototype website.

The information that is specified for each authoring template includes:

- Which content type to use. For example:
  - A site area for a parent item
  - A content item for the children of the parent item
  - A site area for a subsection of a parent item
- For the authoring template itself:
  - Name
  - Display title
  - Description
  - Template type
  - Access settings
- Default form settings including:
  - Default presentation template, if required
  - Default style sheet, if required
  - Form layout
  - Whether editors can manage elements
  - Actions to hide
  - Where to save items
  - Help text
  - Versioning strategy
- Default content and fields for the item:
  - Name and field display options
  - Display title and field display options
  - Description and field display options
  - Required elements
    - HTML design for any default element content
    - Default parameter selections for any component parameters

    - Field display options
- Default properties for each item:
  – Any default profiling and field display options
  – Any default workflow parameters and field display options
  – Any default access settings and field display options
  – Field display options for the History section

Workflows

You use workflows to control the access to, verification of, and eventual approval of items. Only if an item is approved at all stages up to a published stage can it be viewed on your website. You can use a workflow to:

- Review the accuracy of content.
- Review content for any legal implications.
- Review content to ensure that it meets accessibility guidelines.
- Ensure that no malicious code such as cross scripting attacks is added to content.

Each workflow, workflow stage, and workflow action that is required for your web content system is listed in the authoring architecture.

Folders

Folders are used to group sets of item types into logical groupings. This is useful when you have large numbers of items in your library and want to distinguish between different groups of items within each item type view. Each folder that is required for your web content system is listed in the authoring architecture.

For example, you might use a set of folders to groups different sets of image components:

- Logos
- Diagrams
- Staff photos
- Product photos

Version management strategies

You can configure your system to either automatically save a version of an item each time it is published, or allow users to select when to save a version of an item. The version management strategy for different item types is documented in the authoring architecture.

Related concepts:

"Content libraries" on page 1798
Content libraries store the assets for your website, including but not limited to pages, content, images, authoring and presentation templates, and workflows.

"Users, Groups and Roles" on page 1557
Your content management system requires different types of users. You need to create a different group for each type of user and then assign those groups different roles within your system.

Web content folders
You use folders to group sets of web content item types into logical groupings.

"Workflow and change management" on page 1929
You can manage changes to web content items either by creating drafts, by using workflows, or adding items to projects.

How to manage versions of items
You can configure your system to either automatically save a version of an item each time it is published, or allow users to select when to save a version of an item. You can restore items individually, or choose to restore a set of items within a library that either have the same label or were versioned at, or before, a specified date and time.

Content acquisition architecture

The content acquisition architecture is used to define what existing content will be imported into your web content system, how it is imported, and what content needs to be created.

The content acquisition architecture is based on the content inventory that was collected during the analysis phase of the project. For each piece of content that is identified in the content inventory you define the following information:

- Will this content be imported into the web content system, or will it be created afresh.
- If the content is to be imported, what tool will be used. For example, WebDAV or the Web Content Integrator.

Additionally, the type of items being created need to be identified. For example:

- Reusable pieces of content are best created as components
- Web page-specific content is best created as a content item
- Content specific to a particular section of a website is best saved within a site area

Related concepts:

"The IBM Web Content Manager API" on page 3154
You can use the Web Content Manager API to extend functions of Web Content Manager.

"IBM Web Content Integrator" on page 1936
The Web Content Integrator is a solution for integrating externally managed web content with WebSphere Portal Express. By using standard content syndication feed technologies based on RSS 2.0, the Web Content Integrator provides a loosely coupled mechanism for transferring published content and metadata to the portal after they are approved in the source system. When the content and metadata are transferred to the portal, it is possible to use the built-in content management features of Web Content Manager to secure, personalize, and display the content to users.

Related tasks:

"WebDAV" on page 1986
With WebDAV for IBM WebSphere Portal Express, you can use standard operating system tools to create, modify, and delete web content rather than the standard authoring portlet.

Delivery architecture

Your technical architect and information architect need to define what delivery methods are most appropriate for the website you are delivering.

The delivery architecture describes which delivery methods are required for your web content system.

Pre-rendered delivery

You can pre-render a complete website into HTML and save it to disk. The pre-rendered site can then be used as your live site and displayed to users by using either Web Content Manager or a web server. You deploy a pre-rendered site when you are not using any WebSphere Portal features, such as portlets, and your content is static and is updated only periodically.

Servlet delivery

Users can access content that is displayed by the Web Content Manager servlet. A servlet-delivered website is used when you don't need to use any WebSphere Portal based features such as authoring tools.

Local web content viewer delivery

Web content viewers are portlets that display content from a web content library as part of a portal page. If your presentation is simple, a single web content viewer can be sufficient, but you can also use multiple web content viewers to aggregate content from different libraries and provide a richer experience for your users. A local web content view portlet is used to display content within your web content delivery environment.

Remote web content viewer delivery

A remote web content view portlet is used to display content on a remote WebSphere Portal server or cluster.

Related information:

"Delivering web content" on page 2016
The type of delivery method you use to deliver web content to your viewers depend on the type of content that is being delivered, and the type of viewers your website is intended for.

Maintenance architecture

You need to plan for the tasks that maintain the health and integrity of your web content system. Your technical architect and database architect need to define what maintenance procedures are required for your system, and when and how often they need to be run.

Backup and restore strategies

Document backup and restore strategies for all the software and repositories in your web content system. This approach includes documenting procedures to back up and restore:

- Data repositories
- Themes
- Portlets
- Page structures
- Configuration settings
- Custom application

Applying updates

The process and timing of software updates are defined in the maintenance architecture. This document not only applies to Web Content Manager and WebSphere Portal, but to all software products in your web content system.

For example, you would document procedures to install fix packs for Web Content Manager regularly.

Running maintenance tools

You document the process and timing of running each maintenance tool. This documentation not only applies to Web Content Manager and WebSphere Portal, but to all software products in your web content system.

For example, you would document when and how often to run maintenance tools, such as the member fixer task, and when to clear item and version histories to maintain server performance.

Related concepts:

"Web content administration tools" on page 1176
IBM Web Content Manager includes tasks and tools to help maintain your content management system. For example, use the member fixer task to resolve renamed or deleted users and user groups. Use the workflow checker and updater tools to modify workflow security settings, reschedule pending actions, and add workflow to items. Web Content Manager also includes tools to assist with library and item management, and item and version history management.

Roadmap to building a web content system

To build a web content system you need to deploy hardware, configure servers, design an authoring system, configure a delivery environment and enable syndication. Get an overview of the steps required to build your web content system. Keep in mind the analysis and design documents developed during the planning phase of a project as you review the roadmap.

1. "Deploying the authoring environment" on page 1782
   The first environment to deploy is your authoring environment. This environment can initially be used by a small team as a development environment, but can eventually be used as the authoring environment for all your users. The authoring environment is deployed based on the technical architecture that is defined in the project design documents.
2. "Building the content authoring system" on page 1783
   Before you can start adding content to your web content system, you need to create all the items that are used to manage and deliver your web content.
3. "Importing and creating content" on page 1784
   When the authoring system is ready, you then import and create the default content for your system. This task is often managed by a separate team from the team that builds the web content authoring system.
4. "Deploying the delivery environment" on page 1784
   The delivery environment is used to deliver your website to your website viewers. The delivery environment is deployed based on the requirements that are defined in the project design document.
5. "Going live with your website" on page 1785
   When your environments are installed, the authoring system is completed, your default content is created, and fully tested the system, you are ready to go live.

Related tasks:

Installing WebSphere Portal Express and Web Content Manager
Installing the digital experience software includes preparing your operating system and using IBM Installation Manager to install IBM WebSphere Portal Express and Web Content Manager. Then, use the Configuration Wizard to complete the deployment configuration.

Deploying the authoring environment

The first environment to deploy is your authoring environment. This environment can initially be used by a small team as a development environment, but can eventually be used as the authoring environment for all your users. The authoring environment is deployed based on the technical architecture that is defined in the project design documents.

About this task

Procedure

1. Based on the database architecture that is defined in the project design document, the database administrator deploys a database server for the authoring environment.
   - "Database" on page 119
2. Based on the security architecture that is defined in the project design document, the LDAP administrator:
   a. Creates an LDAP server if one does not exist.
   b. Creates all the groups and users required for the web content system.

   "Security architecture" on page 1771
3. Based on the server architecture that is defined in the project design document, the WebSphere Portal administrator does the following:
   a. Installs a WebSphere Portal server or cluster of servers.
   b. Configures the WebSphere Portal server or cluster to use the database server setup by the database administrator.
   c. Configures WebSphere Portal to use the LDAP server as its user repository.
   d. Configures various WebSphere Application Server, WebSphere Portal and Web Content Manager configuration properties to ensure that the system is correctly setup for web content authoring and is tuned for optimal performance.
   - Chapter 4, "Installing," on page 101
   - Chapter 5, "Configuring," on page 231
   - "Web Content Manager" on page 392
4. Based on the information architecture and security architecture that is defined in the project design document, the WebSphere Portal administrator:
   a. Creates all the libraries that are required for the web content system.
   b. Assigns users and groups to the roles and access permissions.
   c. Create all pages that are required by the web content system.
   d. Adds all required authoring portlets to the appropriate pages and configures the authoring portlets for use by different teams to create and manage web content items.
   e. Adds all required web content viewer portlets to the required pages for use as preview pages.
   - "Users, Groups and Roles" on page 1557

- "Security architecture" on page 1771
- "Displaying content with Web Content Viewers" on page 2034

5. Final testing and tuning of the authoring environment is undertaken by all administrators.

Results

The authoring environment is now ready to use.

Building the content authoring system

Before you can start adding content to your web content system, you need to create all the items that are used to manage and deliver your web content.

Procedure

1. Based on the design architecture that is defined in the project design document, the web content developer creates plug-ins and JSP code in preparation for the creation of the content authoring system.
   - "The web content developer" on page 1762
   - "Design architecture" on page 1776
   - Developing
2. Based on the information architecture that is defined in the project design document, the website creator does the following:
   a. Creates site areas.
   b. Creates taxonomies and categories.
   - "The website creator" on page 1762
   - "Information architecture" on page 1774
3. Based on the content authoring architecture that is defined in the project design document, the website creator does the following:
   a. Creates workflow actions, stages, and defines workflows.
   b. Creates authoring templates.
   - "The website creator" on page 1762
   - "Authoring architecture" on page 1777
4. Based on the design architecture that is defined in the project design document, the website creator does the following:
   a. Creates components.
   b. Creates presentation templates.
   - "The website creator" on page 1762
   - "Design architecture" on page 1776
   - Creating components
   - Creating a presentation template
5. Based on the information architecture that is defined in the project design document, the website creator edits site areas and defines template mappings.
   - "The website creator" on page 1762
   - "Information architecture" on page 1774
   - "Template mappings" on page 1792
6. If needed, the web content developer also creates a custom content authoring interface based on the content authoring architecture that is defined in the project design document.
   - "The web content developer" on page 1762

- "Design architecture" on page 1776
- Developing

7. The website creator then creates some test content to test the content authoring system, and previews the test content. Any defects that are found in the content authoring system are addressed and further changes that are made to improve performance and usability.

Importing and creating content

When the authoring system is ready, you then import and create the default content for your system. This task is often managed by a separate team from the team that builds the web content authoring system.

Procedure

1. Based on data that is gathered during the analysis phase of the project, the content acquisition team identifies and prepares any existing content for import into the web content authoring system.
   - "The content acquisition team" on page 1764
   - "Content acquisition architecture" on page 1779
2. The content acquisition team then imports existing content into the web content authoring system by using features such as the Web Content Integrator, WebDAV, or the web content API.
   - "IBM Web Content Integrator" on page 1936
   - Developing
3. The content acquisition team then create new content based on the information architecture that is defined in the project design document.
   - "Information architecture" on page 1774
4. The content acquisition team then test the authoring system, and preview the default content. Any defects that are found in the authoring system are addressed and further changes that are made to improve performance and usability.

Deploying the delivery environment

The delivery environment is used to deliver your website to your website viewers. The delivery environment is deployed based on the requirements that are defined in the project design document.

Procedure

1. Based on the database architecture that is defined in the project design document, the database administrator does the following:
   a. Deploys a database server for the delivery environment.
   b. Clones the data that is stored on the authoring database onto the delivery database.
   - "Database" on page 119
   - "How to clone a web content repository" on page 1214
2. Based on the server architecture that is defined in the project design document, the WebSphere Portal administrator does the following:
   a. Installs a WebSphere Portal server or cluster of servers.
   b. Configures the WebSphere Portal server or cluster to use the database server setup by the database administrator.

c. Configures various WebSphere Application Server, WebSphere Portal and Web Content Manager configuration properties to ensure that the system is correctly setup for web content delivery and is tuned for optimal performance.

- Chapter 4, "Installing," on page 101
- Chapter 5, "Configuring," on page 231
- "Web Content Manager" on page 392

3. Based on the information architecture and security architecture that is defined in the project design document, the WebSphere Portal administrator:
   a. Create all pages that are required by the web content system.
   b. Adds all required web content viewer portlets to the appropriate pages.

      "Displaying content with Web Content Viewers" on page 2034
4. The WebSphere Portal administrator configures and enables syndication.

   "Syndication" on page 448
5. Final testing and tuning of the delivery environment is undertaken by all administrators.

Results

The delivery environment is now ready to use.

Going live with your website

When your environments are installed, the authoring system is completed, your default content is created, and fully tested the system, you are ready to go live.

Procedure

1. Ensure that your stakeholders are ready to use your website and authoring system:
   a. Ensure that your content authors are trained on how to use the new web content authoring system.
   b. Ensure that any legacy authoring or delivery systems are redirected to the new system.
   c. Start marketing campaigns to bring visitors to the new website.
2. Based on the maintenance architecture that is defined in the project design document, you run regular monitoring and maintenance tasks to ensure that your system is operating efficiently.
   - "Maintenance architecture" on page 1780
   - "Web content administration tools" on page 1176

Creating reusable assets

Use reusable assets to store or generate content that is used in more than one place in your website.

"Page templates" on page 1786
Content authors use the page templates to quickly create pages that are consistent with your site design. They do not have to waste time to configure settings that are probably consistent across your site, such as theme selection, page layout, and more.

"An overview of authoring templates" on page 1787
Authoring templates are like forms that content authors can use to create new

content. It defines default settings for the items that are created by using the authoring template. There are two types in authoring templates, site area and content.

"Presentation templates" on page 1789
You use a presentation template define the layout of your web content. Use tags to determine which properties, elements, or components are displayed.

"Template mappings" on page 1792
Template mappings are used to determine which presentation templates are used to display each site area or content item.

"Content items" on page 1794
Content items are created from authoring templates. A single content item can be used one time in the website or it can be reused in different areas of the website.

"Components" on page 1795
You use components to store elements that are used in more than one area of your website. For example, a company logo or a copyright notice.

Page templates

Content authors use the page templates to quickly create pages that are consistent with your site design. They do not have to waste time to configure settings that are probably consistent across your site, such as theme selection, page layout, and more.

Available page templates

Three templates are provided for immediate use: Articles, Basic, and Label. The Basic template is an empty page that you can add content to.

The Articles template has two portlets that display content, Articles and List of Articles. There is also a content association between the two portlets. The List of Articles portlet displays a list of the articles that are stored in the page site area. You can select an article from the list and it displays in the Article portlet. Both of the portlets were developed from the content viewer portlet.

The Label template is a simple label. Labels are navigation elements. The label displays in the navigation, but label type page does not include content. The content of the first child page displays when you click the label in the navigation.

Custom page templates

The provided page templates are probably not comprehensive enough for your website. Based on your html prototype or wireframe for your website, you can determine common page layouts and configurations. After you identify a few common page layouts from your design, then you can create templates for the content authors. For example, if each landing page in your site includes breadcrumbs, a carousel, and a three-column content area, then create a landing page template with those elements.

When you create a template you can include portlets and portlet preferences, page layout and style selections, theme and skin settings, portlet wires for communication with other portlets, page parameters, and page descriptions. Use the Manage Pages Portlet in the administration area to create new templates.

Page templates are created in a specific area of the portal hierarchy, called Page Templates. Pages that you add to this area automatically appear as an available page template in the site toolbar in the **Create** > **Page** area.

Note: When you create a new page based on a page template, you might see the following error message: `The page template could not be instantiated underneath the page PARENT_PAGE since this page has no default content association to a site area outside of the Portal Site library or the current user does not have access to the mapped site area.` To prevent this from happening, decide where to store the content that is copied from the template page to your new page:

- If you want to store the content outside of the Portal Site library, create a default content association to a site area outside of the Portal Site library for the parent page of the new page.
- If you want to store the content in the Portal Site library, transfer the content for the template page to the Portal Site library first. For more information, go to *Transferring content associations to the Portal Site library*.

Related tasks:

"Transferring content associations to the Portal Site library" on page 380
When you enable manage pages, any web content pages that you have are converted to managed pages and added to the Portal Site library. However, the content that is associated with the web content pages remains in the original libraries. You can transfer this associated content to the Portal Site library with the `internalize-content-mappings` task.

Related information:

Creating page templates

An overview of authoring templates

Authoring templates are like forms that content authors can use to create new content. It defines default settings for the items that are created by using the authoring template. There are two types in authoring templates, site area and content.

Create authoring templates for your content authors to use as they develop new content for the website. The authoring template is mapped to a presentation template. You can use one presentation template for multiple authoring templates. This removes presentation considerations and treatment from the content. The website design is updated by modifying the presentation template instead of modifying multiple pieces of content.

Authoring template types

Site area templates

Site area authoring templates are used to define the default settings of site areas.

Default site area template:

A default site area is installed with IBM Web Content Manager. This can be used to maintain the behavior of site areas that are migrated from previous releases. You can disable the creation of new site areas by using the default site area template by changing the following configuration parameter to "false" in the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console. If the setting does not exist, it can be added.

```
wcm.authoringui.defaultSiteAreaTemplateEnabled=false
```

Content templates

Content authoring templates are used to define the default settings for content items. You create render content in two different ways:

Content rendering.

If you configure a content authoring template to render as content, then the content items you create are standard content items. These content items are used to store elements that can be rendered within presentation templates.

Resource rendering.

If you configure a content authoring template to render as a resource, then the content items you create are based on a file that is stored in a file resource element. When a resource content item is rendered, the file that is stored in the selected file resource element is rendered on the web page. No presentation template is used when the file is rendered, only the content of the file itself. This strategy is useful when you want to store a file, such as a PDF file, and render it directly on a page but would also like to have the PDF file that is listed in navigational components such as menus and navigators.

Authoring template properties

Element selection

When you create an authoring template, you can add elements to the template to determine what types of content is stored within the item. When you construct the authoring template, you can select more than one element field of the same element type. For example, you might add three text element fields, two rich text element fields, and four image element fields to the same authoring template.

Default values

You can specify default values for each field and element in the authoring template to make it easier and more efficient for an author to create new items and streamline the item creation process.

Simplified form layout

The authoring template provides features that help you simplify the presentation of the authoring form.

Authoring form layout options.

You can control the general layout of the fields on the authoring form by specifying an authoring form layout option. Depending on the layout option, this selection can reduce the vertical space that is required to display the elements on the authoring form.

Hidden fields.

In addition to organizing an authoring form with a layout option for the fields, you can further simplify the form that is presented to the item author by using hidden fields. Except for those fields that are required for an authoring form, you can designate any other field in the authoring template to be hidden. A field marked to be hidden in the authoring template is not displayed on the authoring form, which streamlines the form's visual appearance. Note, however, that although a hidden field is not displayed on the authoring form, the information that is defined in the field is still associated with the authoring form and is processed with the form.

This is useful when used with a default value for a field because it means you can specify a setting for a field and then hide the field on the authoring form to ensure that the field's value cannot be changed by the item author. For example, you might want to set access control levels for item that is generated from the authoring template in the Access Control section of the template and then hide that section on the resulting authoring form. When an item is generated from the template, the access control levels for the item are derived from the default values in the template.

Custom help text

To further help tailor the content form for an item author, Web Content Manager provides the capability of adding customized help text to the authoring template.

- You can define help text for the entire authoring form that is generated from the authoring template. For example, this help text can be used to describe the purpose of the form. You must include whatever specific information you feel would be of use to the authors by using the form.
- In addition to the HTML text, you can also specify in-line help text that is displayed with each element on the form. This help text can provide targeted information for a particular field on the form, explaining possible values or noting special conditions that are related to the field.

Labeling elements

The names of element labels in different items must be the same if an element reference in a presentation template is to change depending on the current context. This is an important consideration if two authoring templates are using the same presentation template. The element types however, do not have to be consistent.

Table 257. Example: An element reference called Heading from Current Site Area

Site area	Element label	Element type
Business	Heading	Image
Personal	Heading	Rich Text
Features	Heading	Text
News	Heading	Text

Presentation templates

You use a presentation template define the layout of your web content. Use tags to determine which properties, elements, or components are displayed.

Defining presentation for Web Content Viewer portlets

When you display content with WebSphere Portal, the presentation template defines only the layout of content that is displayed in a Web Content Viewer portlet. The overall page design is determined by which page layout is selected, which portlets are added to the page, and the selected theme.

Defining presentation for servlet rendered content

When you display content in a servlet delivered site, the presentation template represents the entire page. The presentation template also defines the default properties of a web page such as the background and default font of a web page.

There is little difference between building a presentation template and using HTML to build a servlet delivered web page. It might even be helpful to build a "mock-up" of the page you are designing in HTML before creating a new presentation template. Then replace the different sections of your web page with references to elements and components by using web content tags.

"Page layout"
You use HTML to define the layout of a presentation template in the same way you use HTML to define the layout of a web page.

"Page style" on page 1792
You use HTML to define the default properties of a presentation template in the same way you use HTML to define the default properties of a web page.

Page layout

You use HTML to define the layout of a presentation template in the same way you use HTML to define the layout of a web page.

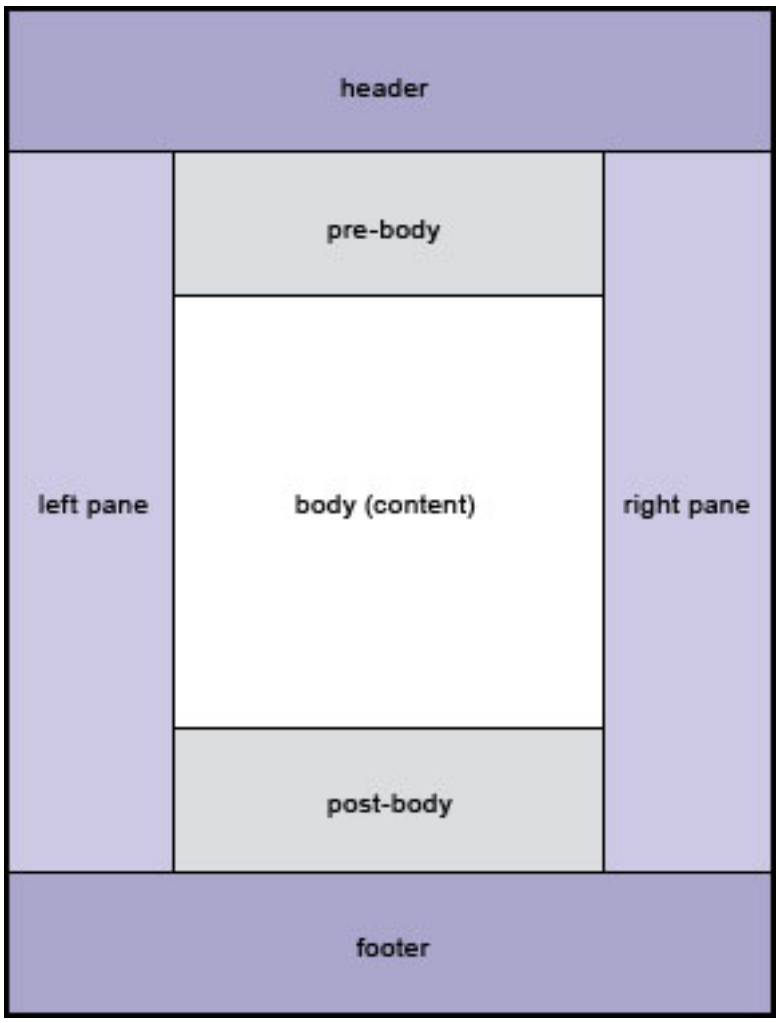
This is an example of a possible layout of a presentation template. Although it is recommended that HTML elements (such as tables) be used to specify the exact layout of a presentation template, you do not have to use them. You can lay out your page in any way you want.

When the layout of a page is defined, all you need to do is reference different components into the different sections of your HTML table. (You can reference more that one component within a single table cell.)

You can also enter text and HTML tags directly into a presentation template. This method is useful if you have an element that needs to appear on all pages that use a common presentation template. However, if that element is used on other presentation templates, it would be more efficient to save it as a component.

Example

This is an example of the HTML you might enter in a presentation template to set the layout of a presentation template.



```
<html>
<head></head>
<body>
<table width="100%" border="0"
cellspacing="0">
<tr><td colspan="3"></td></tr>
<tr><tdrowspan="3"></td><td></td><td
rowspan="3"></td></tr>
<tr><td></td></tr>
<tr><td></td></tr>
<tr><tdcolspan="3"></td></tr>
</table>
</body>
</html>
```

Text and IBM Web Content Manager tags are then added to the different table cells to create the finished web page.

Enabling Connect tags

Connect tags are advanced Web Content Manager tags that can be used to retrieve data from external sources and apply custom caching. **Process connect tags** must be selected in a presentation template form for connect tags to be processed.

Page style

You use HTML to define the default properties of a presentation template in the same way you use HTML to define the default properties of a web page.

Any valid HTML property can be set including:

- Margin sizes
- Text colors
- Background colors or images

Example

This is an example of the HTML you might enter in a presentation template to set default properties for a presentation template.

```
<html>
<head></head>
<body bgcolor="#CC0000" text="#000000" link="#6666FF"
vlink="#9999FF" alink="#FF33CC"leftmargin="5" topmargin="5">
</body>
</html>
```

Note: If the same page properties are used in more than one presentation template, they can be stored in a single text component that is itself referenced within the presentation template:

```
<body <component name="TextComponentName"/>>
```

This means that by editing a single text component, the page properties of multiple presentation templates can quickly be updated.

Cascading stylesheets

Default style properties cannot be set for components. The default page properties override any page properties set in a component.

Cascading stylesheets can be used to control the style of components. For example, You might make the links in a menu a different color to the links in a navigator by using cascading stylesheets to determine the style of different components.

Note: Where possible, use one cascading stylesheet for an entire site. A link to the stylesheet can be used, rather than embedding the stylesheet.

Template mappings

Template mappings are used to determine which presentation templates are used to display each site area or content item.

Template mapping strategies

The presentation template that is used by an item is determined by the relationship between the item's authoring template and a presentation template that is defined in the authoring template, or a template mapping that is defined in a site area in the path of the current item. Template mappings assigned in site areas override template mappings set in authoring templates.

This can result in the following relationships:

- A content item can be displayed by using two different presentation templates if linked to different site areas.

- Two items that use different authoring templates can be displayed by using the same presentation template if both authoring templates are mapped to the same presentation template.

Defined in authoring templates

If you select a default presentation template in an authoring template, it is used as the default presentation template for all items based on that authoring template. This ensures that all items based on that authoring template is rendered with the same presentation template, but it does not ensure design consistency between other items that are located in the same site area. If a different template mapping is specified in any site area in the item path, then the template mapping that is defined in the lowest part of the item path is used instead.

Defined in site areas

If you define a template mapping in a site area, this strategy ensures that all items based on the selected authoring template use the same presentation template in that site area. If a different template mapping is specified in any child site areas of the parent site area, then the template mapping that is defined in site area in the lowest part of the item path is used.

Template mapping examples

In these examples the following template mappings are used:

- *Authoring Template 1* uses *Presentation Template 1* as its default presentation template
- *Authoring Template 2* uses *Presentation Template 2* as its default presentation template
- *Authoring Template 3* also uses *Presentation Template 2* as its default presentation template
- *Authoring Template 4* has no default presentation template
- *Site Area 1* has no template mapping
- *Site Area 2* contains a mapping between *Authoring Template 1* and *Presentation Template 2*
- *Site Area 1* and *Site Area 2* are located under *Site Area A*.
- *Site Area A* contains a mapping between *Authoring Template 4* and *Presentation Template 3*

The presentation template that is used by each item is determined by the authoring template the item used, and the location of the item in the site framework.

Table 258. Template Map Results

Content and location	Result
Content 1 using *Authoring Template 1* located in *Site Area 1*	As *Site Area 1* contains no template mappings, *Content 1* is displayed by using *Presentation Template 1* that is the default presentation template of *Authoring Template 1*.
Content 1 using *Authoring Template 1* located in *Site Area 2*	As *Site Area 2* contains a mapping between *Authoring Template 1* and *Presentation Template 2*, *Content 1* is instead displayed by using *Presentation Template 2*.

Table 258. Template Map Results (continued)

Content and location	Result
Content 2 using *Authoring Template 2* located in *Site Area 1*	As *Site Area 1* contains no template mappings, *Content 2* is displayed by using *Presentation Template 2* that is the default presentation template of *Authoring Template 2*.
Content 3 using *Authoring Template 3* located in *Site Area 1*	As *Site Area 1* contains no template mappings, *Content 3* is also displayed by using *Presentation Template 2* that is the default presentation template of *Authoring Template 3*.
Content 4 using *Authoring Template 4* located in *Site Area 1*	As *Site Area 1* contains no template mappings, *Content 4* is displayed by using *Presentation Template 3* that is mapped to *Authoring Template 4* in *Site Area A*.

Element references

When referencing elements in a presentation, it is important to note the following:

- The elements a presentation template uses must be defined in the authoring template the content is based on.
- If the element being referenced does not exist in the current item, nothing is displayed in that section of the presentation template.

Although the template author can identify a number of elements that can be displayed on the item form, whether the elements are displayed depends on the presentation template that is used with the authoring template to render the content form. A presentation template might not include every element that is defined in an authoring template, but in order for an element or element type to be available to a presentation template, the element must be included in the authoring template that is used to create the content.

Content items

Content items are created from authoring templates. A single content item can be used one time in the website or it can be reused in different areas of the website.

If you have content that you want to appear on multi-pages, create a content item. Then link the content item to the different areas in the website where the content needs to appear. This approach ensures consistency and makes changing the content items easier.

The authoring template can determine what element types are included in a content item, whether a workflow is used or not and what workflow to use, and where the content item can be saved.

Each content item that you create is the equivalent to a web page in a traditional website. Unlike traditional websites, a single content item can be linked to different areas within your website, or linked to a different website altogether. The changes that you make to a single content item is visible in every place you link the content item to.

The look and feel of a content item when displayed in a website depends on what authoring template was used to create the content item, and what presentation

template is used to display the content. The presentation template that is used depends on the current context of the content item, and which template mapping applies to the current context of the content item.

Components

You use components to store elements that are used in more than one area of your website. For example, a company logo or a copyright notice.

Static components

Static components are used to store static content such as text, files, or images.

- component reference component
- date and time component
- file resource component
- HTML component
- image component
- JSP component
- link component
- number component
- rich text component
- short text component
- style sheet element
- text component
- user selection component

Dynamic components

Dynamic components are used to dynamically generate content based on the parameters set in the component properties.

- menu component
- navigator component
- Personalization component
- taxonomy component
- user name component

Tool components

Tool components are used to create tools that can be added to web pages for users to do tasks such as search, inline editing, and paging through pages of links.

- authoring tools component
- page navigation component
- search component

Building the website

Building a website includes creating libraries, pages, and web content. You also create links and navigation to your content, and assign access to different types of users, such as editors and viewers.

"Site Builder" on page 1797
Site Builder is an application that is used to create site templates and section

templates. You then use Site Builder to quickly roll out new websites, or add new sections to existing websites, using these site templates and section templates.

"Content Template Catalog" on page 1797
The Content Template Catalog (CTC) is a set of templates that accelerate the process of building a website. You should also install the Content Template Catalog with Site Builder so you can build sites based on Content Template Catalog components.

"Content libraries" on page 1798
Content libraries store the assets for your website, including but not limited to pages, content, images, authoring and presentation templates, and workflows.

"Setting up access" on page 1801
Access controls allow you to assign access to who has the ability to view rendered constant and pages, and who has the ability to edit or administer content, pages, or features.

"Taxonomy" on page 1801
Before creating a taxonomy, you should analyze how the taxonomy will be used in your site to determine the best structure for your taxonomy.

"Navigation" on page 1802
Navigation is defined by your page hierarchy and your site area hierarchy. Navigation elements include your page theme, menus, and navigators.

"Elements" on page 1804
Create a website by, building templates, and specifying other key components of the system. When these items are in place, you can begin adding elements to your templates and use them to create content items.

"Tags" on page 1833
Tags are used in your markup to reference content that is stored or generated by elements, or to display metadata from different items.

"Setting up search for site visitors" on page 1846
Learn about the initial considerations for setting up search for site visitors before you begin configuring and administering search on your website.

"Taxonomies, Categories, and keywords" on page 1847
The combination of taxonomy and categories enables control what displays in menus.

CF07 "How to store translated text in a content item or site area" on page 1848
Translated text can be stored in a content item or site area. The translated text can then be referenced in web content tags, or as localized text in web content authoring portlet forms.

"Hiding content" on page 1850
You can hide portlets and widgets on a page so they are present but not visible in the page layout.

"Static content" on page 1851
Static content is part of every website. In a portal site, static content can be rendered as static page or it can be added to specific content areas on a page.

"Dynamic content" on page 1880
Dynamic content is generated when a page is rendered and is based on a set of predefined criteria such as the current user, the metadata of the current page. It allows you to deliver content specifically customized for the current user, or to deliver content customized for a campaign or product in your organization.

CF05 "Content as a Service pages" on page 1881
Starting with version 8.5 CF05, IBM WebSphere Portal Express introduces the

concept of Content as a Service pages. The Content as a Service pages can be used to render content that is managed by your IBM Web Content Manager in different data formats.

"URLs" on page 1886
Portal URLs do not look like plain HTTP server URLs over a simple file system. Portal URLs have a complex structure and include a large compressed and encoded XML Navigation State document. The stream of random characters in a Portal URL is the Navigation State document. Full Portal function depends on correctly maintaining this Navigation State document during all the operations a user might do in Portal. Forcing Portal URLs to look like plain HTTP server URLs over a simple file system structure cripples the function of WebSphere Portal Express.

Site Builder

Site Builder is an application that is used to create site templates and section templates. You then use Site Builder to quickly roll out new websites, or add new sections to existing websites, using these site templates and section templates.

Installing Content Template Catalog and Site Builder together offers you the widest choice of website designs. After you install Site Builder and set up access for administrators and website creators, they can log in to IBM WebSphere Portal Express and go to the Site Builder page to access the features of Site Builder.

After you create a site with Site Builder, you can use IBM WebSphere Portal Express and IBM Web Content Manager to customize it further. For example, you can add pages and portlets, edit content, set up content targeting, and refine author and user access.

Related information:

Site Builder

Content Template Catalog

The Content Template Catalog (CTC) is a set of templates that accelerate the process of building a website. You should also install the Content Template Catalog with Site Builder so you can build sites based on Content Template Catalog components.

You can use Content Template Catalog to mock up a site quickly or to build the skeleton of a site as a basis for further development. By using the templating patterns that Content Template Catalog is built on, you can supply a customized system for your users that lets them build their own sites.

To get started, install Content Template Catalog on a development server and try customizing copies of the templates. Content Template Catalog templates are designed to allow your own templates, components, workflows, and other item types to slot into the framework easily so they can be used in conjunction with out-of-the-box Content Template Catalog assets. Experimenting with the templates will give you a good working knowledge of Content Template Catalog for your own site development. Building a prototype as you start using Content Template Catalog can drive the design process or be a starting point for development.

The Content Template Catalog templates cover many basic content types and design elements. Using these templates you can build a basic site very quickly

with little or no customization. For more complex sites, Content Template Catalog allows you to rapidly move past the initial build phase and proceed to delivering real value to your customer.

Related information:

Content Template Catalog

Content libraries

Content libraries store the assets for your website, including but not limited to pages, content, images, authoring and presentation templates, and workflows.

All pages are stored in a Portal Site library. The Portal Site library is immediately available and includes the welcome page, getting started page, and more. Create more libraries to store your website content and assets. You can create multiple libraries to organize your content or to reflect your companies structure. You might create a library for a specific department that requires different access control. In most cases you need to create a minimum of two libraries:

1. A design library where you store all the items that are required for the web content system itself
2. A content library that is used to store the content that is developed by your content creators

The access control and syndication configuration is unique for each library that you create.

Note: When you search through content libraries, you can search for items by their titles. However, if you sort items by title, the sorting option filters pages by the Unique name or Identifier of the page, and not by the title that you specified in the page settings.

New libraries and default items

When you create a new library, you can select to include default items. The default items are helpful if you are not familiar with standard library assets such as authoring templates, presentation templates, and workflows. Include the default items to see examples that you can customize and use.

To create a new library, Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.

Important: When you create a web content library, ensure that the name of the library does not match the URL context of any virtual portals on the same server. If the name of a library and the URL context of a virtual portal have the same value, incorrect rendering behavior can result.

When to use the Portal Site library with web content

You can store web content in the IBM WebSphere Portal Express site library or in a separate content library:

- For dedicated page content that is created and displayed on one single page, it is more convenient to store the web content in the Portal Site library.
- For web content that is reused in multiple places or not tied to the Portal Site hierarchy, it is more convenient to store the web content in a separate dedicated content library.

Storing web content in the Portal Site library

- This scenario is easy to set up, but means that the content cannot be syndicated, exported or imported separately.
- Managed pages must be enabled.
- The web content is moved or deleted when a page is moved or deleted.

Storing web content in dedicated content libraries

- This scenario is easy to deploy if the content associations are set up correctly. The content can be syndicated, and exported or imported separately.
- The web content is associated with a page.
- The web content is not moved or deleted when a page is moved or deleted.
- Web content can be stored in separate libraries. This way, you can logically organize your content, and setup separate syndication scenarios.

Note: When you store web content in dedicated content libraries, maintain the site area hierarchy so that it exactly matches the page hierarchy. For example, when you create a new page, also create a site area at the same point in the hierarchy, and associate it with the new page that you created. Similarly, when you rename, move, or delete pages, update, and synchronize the associated site areas accordingly.

"Creating libraries"
Web content libraries are used to store your web content and managed pages. Syndication is used to keep libraries in synch between your different server environments.

"Web content library default items" on page 1800
When you create a web content library, you can choose to include a set of default web content items in the new library. These items can be used as a starting point for your Web Content Manager system and website.

Related concepts:

"IBM Web Content Manager Multilingual Solution" on page 2442
The Web Content Manager Multilingual Solution is a set of tools that are used to manage translated versions of localized and regionalized websites.

Related information:

Create a content library

Creating libraries

Web content libraries are used to store your web content and managed pages. Syndication is used to keep libraries in synch between your different server environments.

About this task

When setting up a website, you should only create multiple libraries when:

- You need to manage the access and security of different types of content for different users and groups in different ways. For example, by creating different libraries for design elements and content elements, different groups could be assigned library level access in different ways on each library,
- You need to manage syndication strategies differently for different types of content. For example, by creating different libraries for design elements and content elements, different syndication strategies are applied to each library. The

content library could be assigned automatic syndication, whereas the design library could be manually syndicated only when it was appropriate to do so.

Procedure

1. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.
2. Click **Create new library**.

Web content library default items

When you create a web content library, you can choose to include a set of default web content items in the new library. These items can be used as a starting point for your Web Content Manager system and website.

Default items

The following items are created when you select **Include default items in the new library** when you create a library.

Workflow items:

- A workflow that is named **Express Workflow** with a single workflow stage named **Publish Stage** by using the publish action named **Publish**.
- A workflow that is named **Three Stage Workflow** by using the following workflow stages:
  - **Draft Stage**
  - **Publish Stage** by using the publish action named **Publish**.
  - **Expire Stage** by using the expire action that is named **Expire**.

Authoring template:

The authoring template is named **Article** and contains a single rich text element that is named **Body** and uses the **Express Workflow** as the default workflow for content items that are created by using this authoring template.

Presentation template:

The presentation template is named **Article Presentation**.

Site area and content items:

- The content items that are named **Sample Article** and **Sample Article 2** are stored in the site area named **Articles**.
- The site area that is named **Articles** contains a template map between the authoring template that is named **Article** and the presentation template named **Article Presentation**.

Components:

- The authoring tool that is named **Article Toolbar** is used to add **New** and **Edit** functions to the rendered page. It is referenced in the presentation template named **Article Presentation**.
- The menu that is named **Articles List** is used to display a list of content items on the rendered page. It is referenced in the presentation template named **Article Presentation**.

Access controls

As the web content library default items are configured to inherit their access settings from the library they are stored in, users are not able to access these items until you configure the access settings of the library.

Default items

The default items are best displayed by using a web content viewer portlet:

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. Select **New Page From**.
3. Under **Web Content Mappings**, select the site area that is named **Articles** from your web content library.
4. Complete the rest of the form and click OK.
5. Edit the page layout of the new page and add a **Web Content Viewer** portlet to the page.
6. The content item that is named **Sample Article** is displayed on the page.

Setting up access

Access controls allow you to assign access to who has the ability to view rendered constant and pages, and who has the ability to edit or administer content, pages, or features.

About this task

Setting up access is covered in more detail in the Administering and Securing sections of the documentation, but there are some things to consider when setting up access for a website.

- Create groups for each type of user of your site. For example, if you have a set of users who need edit access to a site, create an Editors group and assign your editors to this group.
- Use library inheritance so that access is automatically inherited down to each item in a library. Inheriting permissions, instead of explicitly defining access rights on individual items, simplifies access rights maintenance and improves overall system performance. Define role assignments as high as possible in the library so that they apply to the largest set of items. Explicitly defined permissions are a powerful and flexible way to control access to an item, but when the same user or group is being granted the same role on all items within an area, or across an entire library, then inherited permission is the best option.
- Use Workflow security to assign access to groups or users at different stages in a workflow cycle.

Taxonomy

Before creating a taxonomy, you should analyze how the taxonomy will be used in your site to determine the best structure for your taxonomy.

Creating a taxonomy

To create a taxonomy:

1. Open the applications menu and click **Content** > **Web Content Authoring**.
2. Create a top-level taxonomy item.
3. Create child categories for the taxonomy item.

You cannot use taxonomies in menu searches. If you need a menu to return results based on content that is profiled with any category in a taxonomy, create a single top-level category. Then, and base the menu on the top-level category.

Additional classification options

Classifying users

You can add classification information to users. This can be used as search parameters in menu elements.

Classifying rendering portlets

You can add classification information a Web Content Viewer Portlet. This can be used as search parameters in menu elements.

Classifying content versus access controls

By classifying content with categories or keywords, you can personalize a website for different users. This is different from using item access controls to limit what items a user can access. In a personalized site, although a user may not be able to access all the pages via personalized menus, they may still be able to access other pages by using navigators, or by searching for content. Using access controls limits a user to only view items that they have been granted access to.

Authoring portlet: Creating a taxonomy

Navigation

Navigation is defined by your page hierarchy and your site area hierarchy. Navigation elements include your page theme, menus, and navigators.

Hierarchical navigation

The hierarchical structure of your website is displayed to users in different ways.

Page navigation

The top levels of navigation are defined by your page hierarchy, and are automatically displayed by the default portal theme as links. The location of these links is determined by the page layout you select.

Site area navigation

If your website includes web content, extra navigational links are displayed with a navigator component. This component type displays a subsection of the hierarchical structure of the site areas and content items that are used by your website.

Criteria based navigation

Use menu components to display lists of links to your web content based on predefined or dynamic criteria. The parameters that are defined in a menu component can be based on set criteria, such as a category or authoring template, or they can be set with dynamic criteria that are based on the current content item, site area, or other variables.

"Creating links and navigation" on page 1803
Use navigators and menus to create links to content, and display content-level navigation.

"Adding page-level navigation" on page 1803
The default portal theme automatically adds page-level navigation to your site based on the page hierarchy of your site.

"Hiding and displaying pages in the navigation" on page 1803
By default, pages that you create are displayed in the navigation of the portal

site. If you do not want a page that you create to appear in the navigation, you can hide the page by setting the **com.ibm.portal.Hidden** page parameter to `true`. While this parameter does not affect your portal access control settings for the page, it is hidden from the navigation.

Creating links and navigation

Use navigators and menus to create links to content, and display content-level navigation.

About this task

Navigators

Navigators display links to different site areas in a website. They represent the logical arrangement of the content displayed within each page of your site.

A set of element designs is used to format the look of each branch of a navigator.

Menus

A menu displays metadata and content from content items that match the search criteria of the menu element. The search criteria of a menu can include matching site areas, authoring templates, categories, and keywords.

Adding page-level navigation

The default portal theme automatically adds page-level navigation to your site based on the page hierarchy of your site.

About this task

Page-level navigation is added to static pages using these portlets:

The Breadcrumb Trail portlet

The Breadcrumb Trail portlet allows you to add the navigation path to your static pages. The breadcrumb trail starts at the content root and goes down to the currently selected static page.

The Navigation portlet

The Navigation portlet allows you to add dynamic portal navigation to a static page. When writing a static portal page you can configure the starting point of the navigation and the number of navigation levels by using the initialization parameters.

Hiding and displaying pages in the navigation

By default, pages that you create are displayed in the navigation of the portal site. If you do not want a page that you create to appear in the navigation, you can hide the page by setting the **com.ibm.portal.Hidden** page parameter to `true`. While this parameter does not affect your portal access control settings for the page, it is hidden from the navigation.

About this task

As a page editor, you might want to access hidden pages by using the navigation. For example, to use the site toolbar to edit a page, you need to go to the page first. You can either use a direct URL to the hidden page or make hidden pages display as described in the following.

Procedure

- To hide hidden pages from the navigation, select **Menu** > **Hide Hidden Pages** from the site toolbar.
- To make hidden pages display in the navigation, select **Menu** > **Show Hidden Pages** from the site toolbar. Hidden pages are displayed in brackets in the navigation. For example, `[Hidden Page]`.

Related reference:

"Marking pages as hidden under the content root" on page 1107
By default, pages that you create under the content root display in the main menu. If you do not want a page that you create to appear in the main menu, you can hide the page.

Elements

Create a website by, building templates, and specifying other key components of the system. When these items are in place, you can begin adding elements to your templates and use them to create content items.

"Links and navigation" on page 1805
You use these elements to define or generate links between different pages in a website, or add navigational elements to a website.

"How to use a search element" on page 1807
A search element is used to display the results of a search query. A search element cannot be used in isolation, but must be used together with an HTML element that is used to define the search query form.

"How to store text and HTML" on page 1811
You use different types of elements to store text or HTML depending on the type of text or HTML being created.

"How to store files and images" on page 1814
You use these elements to store files or images.

"Selection elements" on page 1817
You use these elements to make selections from existing elements and data.

"Personalized content" on page 1819
You use these elements to create or reference personalized content.

"Page navigation element" on page 1826
A page navigation element provides navigation controls that are used to browse through a set of results that are generated by menus, navigators, personalization, and search elements.

"URL generation by using `PathCmpnt` and `URLCmpnt` tags" on page 1827
There are some special considerations to keep in mind when you use `URLCmpnt` and `PathCmpnt` tags to create URLs to other web content items from within your content.

"Personalizing federated documents" on page 1827
Portal Personalization provides the federated documents feature to retrieve metadata about documents that are stored in external content management systems or document repositories. Examples of these systems include IBM Content Manager, IBM FileNet Content Manager, and Microsoft Sharepoint. You can use a personalization component in IBM Web Content Manager to display metadata from federated documents and to create links to download or open the documents.

Related information:

How to work with elements

Element designs

Links and navigation

You use these elements to define or generate links between different pages in a website, or add navigational elements to a website.

"Link element"
A link element stores a link to a web content item, or to external content such as a web page.

"Menu element"
A menu element displays metadata and content from content items that match the search criteria of the menu element. The search criteria of a menu element can include matching site areas, authoring templates, categories, and keywords.

"Navigator elements" on page 1807
A navigator element displays metadata and content from a predefined section of a site framework, usually in the form of links.

Link element:

A link element stores a link to a web content item, or to external content such as a web page.

Most web pages contain links, either to other web pages, or to files. In a web content site, most links are generated by using navigator and menu elements. A link element stores a link that is not part of a site's navigation. For example, you can store a link to your "home" content item in a link element. You then add a reference to the link element in every presentation template that is used by your site to enable users to return to the "home" content item. If you want to change your "home" content, you change the selected item in the link element.

Creating a link element

To create a link element, you can either add a link element to an authoring template, site area or content item, or create a link component.

Menu element:

A menu element displays metadata and content from content items that match the search criteria of the menu element. The search criteria of a menu element can include matching site areas, authoring templates, categories, and keywords.

Creating a menu element

You can use a menu element only by creating a menu component. You cannot add a menu element to authoring templates, site areas, or content items.

Menu search options

Menu element search options are defined in the **Menu Component Query** section of the menu element form. These search options define which content items from your site are displayed in the menu element. Search options can include a combination of search parameters that include searches based on authoring templates, categories, and site areas.

Menus can search for the following content in a website:

- Content with matching authoring templates
- Content with matching site areas

- Content with matching categories
- Content with matching keywords

Between different criteria, menu searches are "and" searches, but within each search criteria, menu searches are "or" searches. For example, a menu element that searches for two different categories and an authoring template displays content items that are profiled with at least one of each profile type. Content that matches only one profile type is not displayed.

Menus do not display search results if you select a search criteria but do not enter any search parameters. For example, if the menu is configured to display results that are based on categories, but no categories are specified in the menu form, then no matches are displayed.

Menu sorting options

You can sort menu search results according to following criteria:

- Content document name
- Content document description
- Published date
- Expired date
- General date one
- General date two
- Last modified date

You can select a maximum of three sort options.

Menu paging options

IBM Web Content Manager provides flexible paging options that are used to display search results that are generated by the menu element.

- You can specify the number of results that are displayed in a menu page. For example, a menu that is defined to show five results per page would display only five records from the set of search results.
- You can indicate where in the results set you want to begin showing results by specifying which menu page to use as a starting point. As an example, if you are displaying five results per menu page and you want to show records 6–10, you would start showing search results with the second menu page instead of the first.
- To provide easier navigation of the search results in a menu, you can include a page navigation element in the header or the footer of the menu element. The page navigation element enables stepping forward or backward through multiple menu pages without the need for creating multiple menu elements to display the different pages.
- A large number of search results can cause a delay when the menu element is initially rendered. To prevent this delay, you can limit the maximum number of pages of results that are included in the menu. To further improve the efficiency of the menu, you can also specify how many pages of results must be read beyond the current page so that paging performance is not affected by rebuilding the menu.

While a page navigation element is a convenient way of displaying and browsing a menu's search results, you can use the menu's paging options to display search

results in other ways. For example, if you wanted to show the results in a 3-column table, you might create three menu elements with the same search criteria and then tailor the paging options of each menu to display different result sets:

Table 259. Example

Menu	Results per page	Start page	Records displayed
Menu element 1:	5	1	1 to 5
Menu element 2:	5	2	6 to 10
Menu element 3:	5	3	11 to 15

The three menus might then be referenced within three different cells of a table row in a presentation template.

Navigator elements:

A navigator element displays metadata and content from a predefined section of a site framework, usually in the form of links.

Navigators are not menus. Menus are a list of hyperlinks that take you to specific pages. Navigators can also be hyperlinks that can take you to specific pages but navigators are organized differently. Navigators present the logical arrangement of a website whereas menus are a list of related web pages in your website.

The navigator element is configured by selecting a start area and determining a child depth, a parent level, and a sibling value relative to the start area. Possible start areas are site areas, or content items.

There are also options to determine whether the start area is to be displayed, if content items are to be displayed, and if the hierarchy from the start area to the current site area is expanded.

A set of element designs is used to format the information for each branch of a navigator.

Navigators display links to different site areas in a website. As such, each site area in a website must have a default content item. Otherwise, some links in a navigator will not work.

Creating a navigator element

You can only use a navigator element by creating a navigator component. You cannot add a navigator element to authoring templates, site areas, or content items.

How to use a search element

A search element is used to display the results of a search query. A search element cannot be used in isolation, but must be used together with an HTML element that is used to define the search query form.

To create a search form, you must:

1. create a search query by using an HTML element
2. create a search results view by using a search component

You reference both the HTML element and search component in a single presentation template. The search component is only rendered after a search query is run by a user.

"Search query examples"
These are examples of search queries you can create by using an HTML element.

"Search result examples" on page 1810
These are examples of how to design your search results.

Search query examples:

These are examples of search queries you can create by using an HTML element.

The query parameters can be set in the request parameters. For instance, a search component that is displayed on a page whose URL contained a search query `?search_query=shoes` displays search results for shoes.

Simple search query

This is an example of a simple search query form:

Table 260. Simple search query

Code example	Description
`<form action='<PathCmpnt type="servlet" /> /library/sitearea/content' method="post">`	This is the form header where you specify the location of the content item containing the search element that is used to display the search result. This is typically the same content item that this HTML element is stored in.
`<table> <tr><td> <input type="text" name="search_query"/> </td></tr> <tr><td align="right"> <input type="submit" value="Search"/> </td></tr> </table>`	This is the body of the search form. Like any standard HTML form, it contains an input field and a submit button. In this example, a table has been used to format the search query form.
`</form>`	This closes the form.

Searching metadata

In this example, two more fields have been added allowing users to search both content title and author name:

Table 261. Searching metadata

Code example	Description
`<form action='<PathCmpnt type="servlet" /> /library/sitearea/content' method="post">`	This is the form header where you specify the location of the content item containing the search element that is used to display the search result. This is typically the same content item that this HTML element is stored in.
`<table> <tr> <td>Content Title</td> <td><input type="text" name="search_title"/></td> </tr> <tr> <td>Author's Name</td> <td><input type="text" name="search_authors"/></td> </tr> <tr> <td>Content Body</td> <td> <input type="text" name="search_query"/> </td></tr> <tr><td align="right"> <input type="submit" value="Search"/> </td></tr> </table>`	This is the body of the search form. Like any standard HTML form, it contains input fields and a submit button.
`</form>`	This closes the form.

Including hidden data

In this example, a hidden field has been added to restrict the search to content that use the authoring template called "Press Release":

Table 262. Including hidden data

Code examples	Description
`<form action='<PathCmpnt type="servlet" /> /library/sitearea/content' method="post">`	This is the form header where you specify the location of the content item containing the search element used to display the search result. This is typically the same content item that this HTML element is stored in.

Table 262. Including hidden data (continued)

Code examples	Description
`<input type="hidden"` `name="search_authoringtemplate"` `value="Press Release"/>`	Here a hidden input field has been added that searches for content that use the authoring template called "Press Release".
`<table>` `<tr>` `<td>Content Title</td>` `<td><input type="text" name="search_title"/></td>` `</tr>` `<tr>` `<td>Author's Name</td>` `<td><input type="text" name="search_authors"/></td>` `</tr>` `<tr>` `<td>Content Body</td>` `<td>` `<input type="text" name="search_query"/>` `</td></tr>` `<tr><td align="right">` `<input type="submit" value="Search"/>` `</td></tr>` `</table>`	This is the body of the search form. Like any standard HTML form, it contains input fields and a submit button.
`</form>`	This tag closes the form.

Setting the search query in the request attributes

The query parameters can also be set in the request attributes on the server. For instance, a search component that is displayed after the following tag is used: `[Plugin:RequestAttribute key="search_query" value="shoes" compute="once"]` displays search results for shoes.

Search result examples:

These are examples of how to design your search results.

Search element design example for use in a website

In this example, a table is used to lay out the search results.

Table 263. Search element design example for use in a website

Design field	Details	Code example
Header		`<table>`
Result	The attributes to display in each search result are defined here.	`<tr><td>` `<attributeResource attributeName="namelink"/> ` `<attributeResource attributeName="summary"/>` `</td></tr>`
Separator	A separator can be used to delineate each search result.	`<tr><td bgcolor="#FFFAA" colspan="2"/></tr>`

Table 263. Search element design example for use in a website (continued)

Design field	Details	Code example
Footer	A page navigation element that is stored in a component is referenced here to add page navigation to the search results.	`<tr><td>` `<component name="pagenavigationcomponent"/>` `</td></tr>` `</table>`
No results		There are no results for your query. Please refine your search and try again.

Search element design example for use in a rendering portlet

In this example, a table is used to lay out the search results.

Table 264. Search element design example for use in a rendering portlet

Design field	Details	Code example
Header		`<table>`
Result	The attributes to display in each search result are defined here. When displaying search results in a rendering portlet, you must specify the page that the linked content is displayed in when opened. A URL map to the portal page that contains the rendering portlet is required.	`<tr><td>` `<a href="/[PORTAL_CONTEXT_ROOT]/` `[PORTAL_PAGE_URL_MAPPING]/?WCM_GLOBAL_CONTEXT=` `<AttributeResource attributeName="url" />">` `<AttributeResource attributeName="title" /></a>` `<attributeResource attributeName="summary"/>` `</td></tr>`
Separator	A separator can be used to delineate each search result.	`<tr> <td bgcolor="#FFFAA" colspan="2"/> </tr>`
Footer	A page navigation element that is stored in a component is referenced here to add page navigation to the search results.	`<tr><td>` `[component name="pagenavigationcomponent"]` `</td></tr>` `</table>`
No results		There are no results for your query. Refine your search and try again.

How to store text and HTML

You use different types of elements to store text or HTML depending on the type of text or HTML being created.

Tip: Text that is common to all content that uses a single presentation template can be entered directly in the presentation template rather than separate elements.

Text, rich text and HTML elements:

You use the short text, text, rich text, and HTML elements to store blocks of text, but each has slightly different properties.

Creating an element

Short text, text, rich text, and HTML elements can be added to site areas, content items, and authoring templates or they can be created as individual components.

Short text element

A short text element is used to store small amounts of fixed-length text where the length is 250 bytes or less. Unlike the other text elements, short text elements can also be used as a search parameter in a Personalization rule.

Text element

You use a text element to store larger amounts of text than can be stored in a short text element. No special processing occurs for this element.

HTML element

An HTML element is used to store fragments of HTML that can be reused in presentation templates and other elements designs. You can enter HTML directly into the element or upload HTML from a previously created HTML file.

Rich text element

A rich text element is similar to the HTML element except that it includes a rich text editor. The rich text editor can be used to format text that is stored within a rich text element. The main purpose of the rich text element is to provide base-level content creators with an easy-to-use text editor. Advanced users who are required to produce more advanced code, including web content tags, or who need to store fragments of HTML must use an HTML element instead.

You must use rich text elements sparingly in authoring templates, site areas, and content items as adding multiple rich text elements to these items can reduce authoring performance.

The rich text editors that are used by Web Content Manager are supplied by other vendors. For information on using the rich text editor, see the user documentation that is supplied by the specific rich text editor vendor.

How to use web content tags in rich text and HTML elements

Table 265. How to use web content tags in rich text and HTML elements

Element type	Details
Short Text and Text elements	Web content tags cannot be used in short text and text elements.
HTML elements	Any combination of web content tags can be used in HTML elements with the following exceptions: 1. You cannot use single quotation marks around attribute values. • `[Component name='example']` • `[Component name='example' start='<a href="' end='">link</a>']` • `[Component name='example' start='<img src="' end='"/>']` 2. You cannot use double quotation marks inside attribute values. • `[Component name="example" start="<a href="" end="">link</a>"]` • `[Component name="example" start="<img src="" end=""/>"]`
Rich text elements	Basic Web Content Manager tags can be used in rich text elements. For example, the following tags can be used in Rich Text elements: • `[component name="test"]` • `[element type="content" context="current" key="body"]` The following tag formats are invalid: 1. The use of single quotation marks around attribute values. • `[Component name='example']` • `[Component name='example' start='<a href="' end='">link</a>']` • `[Component name='example' start='<img src="' end='"/>']` 2. The use of double quotation marks inside attribute values. • `[Component name="example" start="<a href="" end="">link</a>"]` • `[Component name="example" start="<img src="" end=""/>"]` 3. Embedding tags inside other HTML tags. • `<a href='[Component name="example"]'>link</a>` • `<img src='[Component name="example"]'/>`

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Number element:

You can store a numerical value in a number element.

Creating a number element

To create a number element, you can either add a number element to an authoring template, site area or content item, or create a number component.

How to store files and images

You use these elements to store files or images.

"File resource element"
You can store a file in a file resource element. You can then reference the file resource so that users can download the file by using a link or, for supported file types, convert the file directly to HTML and render it on the page.

"How to reference a file resource"
A file resource can be referenced within presentation templates and other element designs with either a component or element tag.

"Image element" on page 1815
You store an image in an image element.

"JSP elements" on page 1816
You use a JSP element to store a path to a JSP. When rendered within a presentation template or element design, a request to a JSP is generated and processed.

"How to use stylesheets in items" on page 1816
Stylesheets can be used to format the design of IBM Web Content Manager pages in the same way as normal web pages.

File resource element:

You can store a file in a file resource element. You can then reference the file resource so that users can download the file by using a link or, for supported file types, convert the file directly to HTML and render it on the page.

By storing a file in a file resource element:

- You can reference the file anywhere in your site regardless of the original file location or URL.
- The file is automatically transferred to other servers during syndication.

Creating a file resource element

To create a file resource element, you can either add a file resource element to an authoring template, site area or content item, or create a file resource component.

Using a resource content item versus using a file resource component:

If you configure an authoring template to be a resource template, the content items that are created by using that authoring template are known as resource content items. Like a file resource component, files that are stored within a resource content item can be directly rendered in a web page. The difference between using a resource content item instead of a file resource component is that a resource content item can be listed in navigational components such as menus and navigators.

How to reference a file resource:

A file resource can be referenced within presentation templates and other element designs with either a component or element tag.

Creating a link to a file resource

To create a link to a file resource in a presentation template or element design to enable users to download the file reference, use the following tag structures.

To create a link to a file resource component, you use a component tag:

```
<a href="[component name="FileResourceName"]">Link Text</a>
```

To create a link to a file resource element, you use an element tag. For example, to link to a file resource element in the current content item:

```
<a href="[element type="content" context="current" key="FileResourceName"]">Link Text</a>
```

Rendering a file resource on a page

If your file resource is a file type that can be converted to HTML, you can instead convert the file to HTML and render the converted HTML directly in your web content with the *format="HTML"* parameter in a component or element tag. For example:

```
[component name="FileResourceName" format="HTML"]
[element type="content" context="current" key="FileResourceName" format="HTML"]
```

Examples of supported file types include:

- word-processing documents (*.doc, *.odt)
- spreadsheets (*.xls) *
- HTML files (*.htm, *.html)
- Text files (*.txt)

Other file types might also work but you need to test them first.

Note: If you configure an authoring template to be a resource template, then the content items you create are resource content items. When a link to a resource content item is rendered, the file that is stored in the selected file resource element is rendered on the web page. In this case, you would not use an element tag. Instead, the file resource is rendered either with a placeholder tag in a navigator or menu design, or by writing a link directly to the resource content itself.

Image element:

You store an image in an image element.

When you store an image in an image element:

- You can reference the image anywhere in your site regardless of the original file location or URL.
- The image is automatically transferred to other servers during syndication.
- You can reference the image element within other items as required.

Creating an image element

To create an image element, you can either add an image element to an authoring template, site area or content item, or create an image component.

Note: Images with names that include non-ascii characters cannot be pre-rendered. If you are pre-rendering a site, you must rename the image before you add it to the image element.

Valid mime types

You can configure which mime types are valid for an image element by editing the `imageresourcecmpnt.allowedmimetypes` setting. See "Web content authoring

options" on page 396 for further information.

JSP elements:

You use a JSP element to store a path to a JSP. When rendered within a presentation template or element design, a request to a JSP is generated and processed.

Creating a JSP element

To create a JSP element, you can either add a JSP element to an authoring template, site area, or content item, or create a JSP component.

Syndication:

Syndication does not move the JSP page referred to in a JSP element. Only the item that contains the JSP element is moved. You need to store the JSP page in the same folders of both the subscribing and syndicating servers.

Note:

The JSP referenced within a JSP component must not include a reference, directly or indirectly, to the same JSP component. This restriction includes references within web content tags or the API. If it does, a loop is created and errors occur.

How to use stylesheets in items:

Stylesheets can be used to format the design of IBM Web Content Manager pages in the same way as normal web pages.

Creating and referencing stylesheet elements

Stylesheet elements can be stored only in stylesheet components.

To link a stylesheet component to a specific authoring template, you must select a stylesheet component as the default stylesheet in an authoring template.

To link a stylesheet component to a specific site area or content item, you must add a component reference element to a site area or content item and select a stylesheet component.

Referencing a stylesheet element in a presentation template

Stylesheet elements are referenced in the "header" section of a presentation template by using either a style element tag or component tag.

Table 266. Referencing a stylesheet element in a presentation template

Details	Code example
To use the stylesheet that is specified in the authoring template of the current content item, you must use a `<styleElement>` tag.	`<HTML>` `<HEAD>` `<styleElement source="template"/>` `</HEAD>` `<BODY></BODY>` `</HTML>`

Table 266. Referencing a stylesheet element in a presentation template (continued)

Details	Code example
To use the stylesheet that is selected in a component reference element that is stored in either the current site area or content item, you must use a <styleElement> tag.	<HTML> <HEAD> <styleElement source="path" name="component reference name"/> </HEAD> <BODY></BODY> </HTML>
To use a specific stylesheet, you must use a <component> tag.	<HTML> <HEAD> <component name="stylesheet component name"/> </HEAD> <BODY></BODY> </HTML>

When rendered in web content, references to stylesheet components are rendered as external stylesheet links:

```
<HTML>
<HEAD>
<link href="stylesheet" media="media-type" rel="styleheet-type" type="text">
</HEAD>
<BODY></BODY>
</HTML>
```

How to use styles in HTML tags

Styles that are used in HTML are stored in presentation templates and element designs in the same way as normal HTML. The style must exist in the stylesheet that is referenced in the presentation template that is used to render the HTML.

For example, to add a class that is called "wcm" to a heading tag:

```
<H1 class="wcm">Heading</H1>
```

How to use styles in web content tags

Stylesheets can be used to format the style of content that is retrieved by using Web Content Manager tags. The style must exist in the stylesheet that is referenced in the presentation template that is used to render the Web Content Manager tag.

For example, to format the links in a menu by using a stylesheet class called "wcm", the following placeholder tag would be used:

```
<a href="<placeholder tag="href" />" class="wcm"><placeholder tag="name" /></a>
```

Selection elements

You use these elements to make selections from existing elements and data.

"Component reference element" on page 1818
You use a component reference element to store a reference to a component.

"Date and time element" on page 1818
You use a date and time element to store a date or time to be displayed on a web page.

"Option selection element"
An option selection element is used to present a list of predefined options that your content creators can select from when you create a content item or site area. An option selection element can be added to an authoring template only.

"User selection element" on page 1819
A user selection element stores a selection of users or groups.

Component reference element:

You use a component reference element to store a reference to a component.

You can use component reference elements in two ways:

- A component-reference element can be added to an authoring template so that content creators can select an existing component from the component library rather than build the component themselves.
- By referencing a component-reference element in a presentation template or another element, the component that is being displayed can be changed without having to change the presentation template or element design.

  For example, if you referenced a component-reference element called "Featured Product" in more than one presentation template the element that is referenced within the component-reference element can be changed without having to edit the presentation templates.

Creating a component reference element

To create a component reference element, you can either add a component reference element to an authoring template, site area or content item, or create a component reference component.

Date and time element:

You use a date and time element to store a date or time to be displayed on a web page.

Creating a date and time element

To create a date and time element, you can either add a date and time element to an authoring template, site area or content item, or create a date and time component.

Option selection element:

An option selection element is used to present a list of predefined options that your content creators can select from when you create a content item or site area. An option selection element can be added to an authoring template only.

When you use an option selection element, you can either enter a custom set of options, or select a set of categories. Which option you use depends on how you want to use the option selection element.

Simplifying item profiling

If you select a set of categories in an option selection element, you can choose to have the categories that a user selects when you create an item added to the item's profile. You can use multiple option selection elements on an item form to simplify

the process of profiling an item. For example, if you used separate taxonomies for "product type", "team" and "campaign", you might use three separate option selection elements in an authoring template. This strategy makes it easier for your content creators to select categories from each taxonomy on the content form.

Displaying different text on a rendered page

A simple use-case for using option selection elements is when you want to enable content creators to select from a short list of text options that are rendered on a page. For example, if you wanted to indicate different document types such as a "procedure", "policy" or "news" on the rendered page.

How to add custom code

Option selection elements can also be used to allow content creators to select different options that can then be used as parameters in some custom code such as a custom workflow or a JSP component.

User selection element:

A user selection element stores a selection of users or groups.

Creating a user selection element

To create a user selection element, you can either add a user selection element to an authoring template, site area, or content item, or create a user selection component.

Using a user selection element

Click **Select Users** to select users and groups.

- Select either **Users** or **Groups**.
- Type text to search in the **Search** field and then click **Search**. Leave the **Search** field blank to display all users or groups.) Select the required users or groups and then click **OK**.
- To remove a user or group, select the users or groups you would like to remove and then click **Remove**.

Note: Virtual users cannot be selected in a user selection element.

Personalized content

You use these elements to create or reference personalized content.

"Personalization element" on page 1820
A personalization element stores a reference to a personalization rule or content spot that is generated by Portal Personalization. To use a personalization element, you must create a personalization component.

"Personalization element examples" on page 1821
The layout and design of a personalization element is created in a similar way to a menu element, with a header design, footer design, and a design to be repeated for each result.

"Taxonomy element" on page 1823
A taxonomy element defines the layout of a category selection form that enables users to select categories to display in a personalized menu.

"Creating category selection trees" on page 1823
You use category selection trees to allow users to personalize menus.
"Using a user name element" on page 1826
A user name element displays the name of the current user in a presentation template, component design, or element design. You can use a user name element only by creating a user name component. You cannot add a user name element to authoring templates, site areas, or content items.

Personalization element:

A personalization element stores a reference to a personalization rule or content spot that is generated by Portal Personalization. To use a personalization element, you must create a personalization component.

A personalization element can:

- Display personalization content within a presentation template or element design.
- Display a link to personalization content within a presentation template or element design.
- Display attributes of personalization content within a presentation template or element design.

Creating a personalization element

You can use a personalization element only by creating a personalization component. You cannot add a personalization element to authoring templates, site areas, or content items.

Note: A maximum of 100 items can be displayed in a single Personalization element.

Access controls

When you create a personalization element, a user can select only those personalization rules and content spots that they have access to in Portal Personalization.

The personalization rule or content spot that is selected in the personalization element is rendered only if the user that views the web content has access to the personalization rule or content spot in Portal Personalization.

Re-creating Personalization Rules and content spots

If you delete a Personalization Rule or content Spot that is referenced in a Personalization element and then create a new Personalization Rule or content spot with the same name, it is no longer displayed in the Personalization element. You need to edit the Personalization element and reselect the Personalization Rule or content spot.

Caching Personalization components

Web content caching can sometimes be used with Personalization components but depends on the conditions set in the personalization rule, or the resources that are used to determine the rule results. Cache testing is required to determine whether

the content returned by your personalization component can be cached by using web content caching.

Personalization element examples:

The layout and design of a personalization element is created in a similar way to a menu element, with a header design, footer design, and a design to be repeated for each result.

Creating a Personalized menu

1. Create a content spot or personalization rule in Portal Personalization based on some Web Content Manager content.
2. Create a personalization element in Web Content Manager.
   - Click **Search** and select the content spot or personalization rule you created before. Click **OK**.
   - Create an element design to display the results of the content spot or personalization rule. This method is similar to designing a menu element or navigator. For example, enter this text in the "**Design for each menu search result**" section:

     ```
     [placeholder tag="namelink"]
     <br>
     ```
3. Save the personalization element.
4. Reference the personalization element in a presentation template.

Displaying personalized content

To display a single piece of personalized Web Content Manager content for different users:

1. Create an authoring template that includes an element. For example, a text element called "body".
2. Create a set of content items that are based on this authoring template.
3. Create a content spot or personalization rule in Portal Personalization based on the authoring template and content. The content spot or personalization rule must return only a single piece of Web Content Manager Content for each user.
4. Create a personalization element in Web Content Manager.
   - Click **Search** and select the content spot or personalization rule you created before. Click **OK**.
   - Create an element design to display the results of the content spot or personalization rule. For example, enter this text in the **Design for each menu search result** section:

     ```
     [element type="Content" context="autofill" key="Body"]
     ```

     This displays the content of the text element called "Body" from the content item that is returned by the content spot or personalization rule.
5. Save the personalization element.
6. Reference the personalization element in a presentation template.

Displaying personalized web content components

A set of personalized web content components can be displayed by using a personalization element:

1. Create a content spot or personalization rule in Portal Personalization that searches for web content components.
2. Create a personalization element in Web Content Manager.
   - Click **Search** and select the content spot or personalization rule you created before. Click **OK**.
   - Create an element design to display the results of the content spot or personalization rule. For example, Enter this text in the **element design** section:

     Header:

     ```
     <div>
     ```

     Design for each menu search result:

     You must use a Component tag with a context of "autofill".

     ```
     <span>
     [Component context="autofill"]
     </span><br>
     ```

     Footer:

     ```
     </div>
     ```
3. Save the personalization element.
4. Reference the personalization element in a presentation template.

Displaying attributes of Personalized content

The attributes of personalized content can also be displayed by using a personalization element:

1. Create a content spot or personalization rule in Portal Personalization .
2. Create a personalization element in Web Content Manager.
   - Click **Search** and select the content spot or personalization rule you created before. Click **OK**.
   - Create an element design to display the results of the content spot or personalization rule. For example, Enter this text in the **element design** section:

     Header:

     ```
     <div>
     ```

     Design for each menu search result:

     You must use a "AttributeResource" tag for each attribute you want to display. For example:

     ```
     <span>
     [AttributeResource attributeName="ibmcm:title"]
     [AttributeResource attributeName="ibmcm:effectiveDate"]
     </span><br>
     ```

     Footer:

     ```
     </div>
     ```
3. Save the personalization element.
4. Reference the personalization element in a presentation template.

Notes:

Displaying keywords and categories:

To retrieve a list of categories or keywords, Use the Property tag.

Displaying authors and owners:

To retrieve a list of authors or owners, Use the Property tag.

Displaying the Site Path:

To display the site path to a personalized Web Content Manager element, use a placeholder tag.

Taxonomy element:

A taxonomy element defines the layout of a category selection form that enables users to select categories to display in a personalized menu.

You configure the element by selecting either a taxonomy or a category to be the start area of the category selection tree. You then select a child depth relative to the start area. Select "Include Start" if you would like the start area to display in the category selection tree. This option has no effect if the start area is a taxonomy.

There are two element design options available: one is rendered when the logged in user selects the category that is to be displayed, and the other is rendered if the user does not select the category. These element designs are rich text elements, and are used in a similar fashion to the navigator and menu elements.

Note: To use this feature, you must configure a property extension database to store user-specific data. See “Configuring a property extension database” on page 596 for further information.

Creating a taxonomy element

You can use a taxonomy element only by creating a taxonomy component. You cannot add a taxonomy element to authoring templates, site areas, or content items.

Creating category selection trees:

You use category selection trees to allow users to personalize menus.

Note:

- Ensure the `connect.businesslogic.module.ajpecatselect.class` property is defined in the `WCM WCMConfigService` service, using the IBM WebSphere Application Server administration console, with a value of `com.aptrix.pluto.CategoryProfileUpdaterModule`.
- You cannot use category selection trees in a local rendering portlet. Instead, you must render the tree directly. For example:

  `http://host:port/wps/wcm/myconnect/library/`*`sitearea`*`/`*`content`*

Taxonomy element form

The main function of the taxonomy element is to display a category selection tree that is used to allow a user to select categories for menu personalization.

- You configure the element by selecting either a taxonomy or a category as a start area.
- Select a child depth from the start area and a parent level relative to the start area.

- Select "Include Start" to display the start area. This option has no effect if the start area is a taxonomy.
- There are two element design options available
  - One is rendered when the logged in user has selected the category that is to be displayed.
  - The other is rendered if the user has not selected the category.

  These element designs are rich text elements, and are used in a similar fashion to the navigator and menu elements.

The taxonomy element form example creates a check box input form:

- The category identity number is assigned to the "value" attribute in the input fields.
- Check box input fields are created, assigning the "selectedCategories" value to the "name" attribute.
- Hidden input fields are created, assigning the "visibleCategories" value to the "name" attribute.

Element designs

The following code examples are used to develop a basic category selection tree:

Table 267. Header

Code	Details
`[PathCmpnt end="/[Library]/[SiteArea]/[Content]" type="servlet"]` `method=post>` `"start="` `<FORM action='" type="servlet"]`	This code calls the Category Profile Updater Module.
`<input type="hidden"` `value='[PathCmpnt type="servlet"]/[Library]/[SiteArea]/[Content]'` `name="redirectURL">`	This code points to the page to go to after the user request has been processed. The element does not render correctly if the path, "[Site area]/[Content]" is not valid.
`<input type="hidden"` `name="updateSourceProfile" value="true">`	This line determines how a user's category profile is updated. The "value" parameter is optional. **True** Permanently updates the user category profile. **False** Updates only the user's session profile. **Updating the user's session profile:** The user's selected categories are calculated by combining the categories that are in the user's session profile and the categories that are in the permanent user category profile. Therefore, if a category is in the user category profile and is removed from the user's session profile only, it will still be shown as selected.

Table 268. Unselected element design

Code	Details
<input type="checkbox" name="selectedCategories" value="[Placeholder tag="idnum"]"/> <IndentCmpnt offset="0" repeat=".."> [Placeholder tag="name"] <input type="hidden" name="visibleCategories" value="[Placeholder tag="idnum"]"/> 	This is used to display unselected items in the rendered category selection tree.

Table 269. Selected element design

Code	Details
<input type="checkbox" checked name="selectedCategories" value="[Placeholder tag="idnum"]"/> [IndentCmpnt offset="0" repeat=".."] [Placeholder tag="name"] <input type="hidden" name="visibleCategories" value="[Placeholder tag="idnum"]"/> 	This is used to display selected items in the rendered category selection tree.

Table 270. Footer

Code	Details
<input type="submit" value="Set User Categories"> </form>	This footer contains the submit button.

Indent element:

This example uses the indent element tag. This can be used in the navigator and taxonomy elements. This tag represents an HTML/text string that should be repeated depending on the depth of a tree node being rendered in these elements.

In the taxonomy element example, the indent element is used to render and repeat the "." string dependent on the depth of the node the element design is being applied to. It is possible to offset the repeat value by assigning an integer value to the "offset" attribute of the tag. For example, A current node depth of 5 and an offset value of -2 would render the repeat string three times. If the sum of the offset and the node depth is negative or 0, the repeat string is not rendered.

element designs:

The only difference between the unselected element design and the selected element design is that the check box input field in the selected element design has the "checked" attribute set.

User access:

If using a taxonomy element, users must be given "Edit" access to their own user item to enable them to update their selected categories.

Using a URL to update user categories:

You can use a URL as an alternative to using a category selection tree to update a user's selected categories:

```
http://host:port/wcm/connect/SiteArea/SelectPage?MOD=AJPECatSelect
&redirectURL=/wcm/connect/SiteArea/Content&updateSourceProfile=false
&selectedCategories=categoryID1,categoryID3
&visibleCategories=categoryID1,categoryID2,categoryID3,categoryID4
```

The "selectedCategories" and "visibleCategories" parameters have multiple values which are comma delimited. The categories specified in "selectCategories" should be a subset of "visibleCategories".

This URL could be used on a page in the form of a button to allow users to update their user categories. For example, You could create a button that would add the category "News" to a user's selected categories list.

Related tasks:

“Setting service configuration properties” on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Using a user name element:

A user name element displays the name of the current user in a presentation template, component design, or element design. You can use a user name element only by creating a user name component. You cannot add a user name element to authoring templates, site areas, or content items.

About this task

To create a user name component, open the applications menu and go to **Content** > **Web Content Management** and then click **New** > **Component** > **User Name**.

Page navigation element

A page navigation element provides navigation controls that are used to browse through a set of results that are generated by menus, navigators, personalization, and search elements.

A page navigation element can generate two kinds of page navigation controls:

- Shuttle controls provide navigation relative to the current page. This includes sequential linking to the previous or next page of results and quick linking to the first and last pages in the set.
- Paging controls provide navigation according to the page number of the result set. A list of page number links is displayed, along with a continuation link for access to the previous or next set of page numbers, if all page numbers are not displayed.

A page navigation element can combine both shuttle and paging controls, as in the following Navigation example.

Table 271. Page navigation layout example

Attribute	Example
First	<<
Previous	<
Continuation	...
Page Numbers	4,5,6

Table 271. Page navigation layout example (continued)

Attribute	Example
Continuation	...
Jump to page	Go to page:
Next	>
Last	>>
Page size	Items to display: 10 | 50 | All

Creating a page navigation element

You can only use a page navigation element by creating a page navigation component. You cannot add a page navigation element to authoring templates, site areas, or content items.

URL generation by using `PathCmpnt` and `URLCmpnt` tags

There are some special considerations to keep in mind when you use `URLCmpnt` and `PathCmpnt` tags to create URLs to other web content items from within your content.

The `URLCmpnt` tag

The URL component tag `URLCmpnt` can be used to create URLs to content items in a presentation template. If the attribute `mode="portal"` is set, the content item is displayed through a content viewer portlet.

The `PathCmpnt` tag

The path component is used to create the base part of a URL in web content. Typically, the base part is extended by some string that identifies the content to be displayed. If the path component is used inside the context of a web content viewer, the generated URL has the updated URL format and thus cannot be displayed with the traditional web content viewer.

Adding URL parameters

Adding URL parameters to a regular portal URL do not affect the web content viewer. For this purpose, you must use the `URLCmpnt` or `PathCmpnt` tag. Extra URL query parameters, like those parameters that are used with the traditional web content viewer, can be appended to the URLs generated by these tags.

Personalizing federated documents

Portal Personalization provides the federated documents feature to retrieve metadata about documents that are stored in external content management systems or document repositories. Examples of these systems include IBM Content Manager, IBM FileNet Content Manager, and Microsoft Sharepoint. You can use a personalization component in IBM Web Content Manager to display metadata from federated documents and to create links to download or open the documents.

About this task

The federated documents feature can acquire metadata from remote systems that support the following methods:

- Document Services remote interfaces, as supported by IBM Content Manager and FileNet Content Manager
- Content Management Interoperability Services 1.0 (CMIS 1.0), as supported by IBM Connections, IBM Content Manager, IBM FileNet Content Manager, Microsoft Sharepoint, and others.
- Atom feeds

"Creating a federated documents selection rule"
Create a selection rule that selects metadata of documents that are contained in a specific folder of a remote content management system or document repository.

"How to use a federated documents rule in a personalization component" on page 1829
To access the information from a federated documents rule in your web content system, create a personalization component, associate it with the rule, and specify the design for displaying document information that is retrieved by the rule.

Creating a federated documents selection rule:

Create a selection rule that selects metadata of documents that are contained in a specific folder of a remote content management system or document repository.

Before you begin

Before you create a rule to access federated documents information, ensure that you configure the feature as described in "Setting up support for federated documents" on page 405.

About this task

Procedure

1. Open the Personalization Navigator.
2. Browse to the folder where you want to create the rule, or create a folder for the new rule.
3. Click **New** > **Rule**.
4. Enter a name for the rule.
5. Optional: Enter a description for the rule to identify the data that the rule selects.
6. Click the link for the **Select** action in the rule editor (for example, **Web Content**), and select **Federated Documents**.
7. Specify the folder on the remote system either by entering the URL directly or by browsing the remote system. In addition to a folder on a remote system, you can enter the URL of any Atom feed available on the network. The Atom data that is created by those feeds is mapped to corresponding AttributeResource tags in IBM Web Content Manager.
   - To enter the URL for a folder directly, complete these steps:
     a. Click **value** *.
     b. Enter the URL of the folder.
     c. Click **Submit**.
   - To browse a Document Services server or CMIS server, click the > symbol on the **Feed URL** condition, and click **Select Document Folder** to start the wizard to select a folder.

To connect to a remote server, you identify the server and the authentication method that is used to access the server. You can either select a predefined server or enter the server URL directly. By default, no predefined servers are configured, but an administrator can add servers to the list. To authenticate with a server, there are several available methods:

- If single sign-on is configured between the remote server and the portal, you can connect with the current user.
- You can enter a user ID and password for the remote server.
- You can select a credential vault slot that is associated with the server. Credential vault slots are set up by an administrator and enable users to log in without credentials.

If you use a user ID and password or credential vault slot, the remote server must accept authentication requests that use HTTP basic authentication.

For details on how administrators can add servers and configure authentication, see *Configuring the federated documents feature.*

Note: To browse remote servers and select a folder, the page that contains the Personalization Editor requires a theme and module profile that support the wp_federated_documents_picker theme module. For example, you can use the Portal 8.0 theme and the full or deferred profile. If the page does not use this theme module, the wizard to select a folder is not available when you click **Select Document Folder**. You can still manually enter a feed URL to a remote folder by clicking **value** *. To enable the folder selection wizard, ensure that the wp_federated_documents_picker theme module is available to the page that contains the Personalization Editor.

8. Optional: Click **show all items**, and specify the maximum number of entries to be retrieved.
9. Click **Save**.

Results

You can now use this rule in a personalization component to render the selection result of this rule in web content.

Related concepts:

"Reserved authoring portlet" on page 430
When you use the web content viewer or web content pages, some scenarios involve web content authoring tasks that are accomplished with authoring tools components. Authoring tasks are run through a special instance of the authoring portlet that is reserved specifically for these tasks and is installed on page that is hidden from the page navigation available to typical users.

"The module framework" on page 2526
The module framework allows extensions to contribute to different areas of a page to provide flexibility, enhance the user experience, and maximize performance.

Related tasks:

"Configuring the federated documents feature" on page 407
Configure the federated documents feature to specify information about the source servers for the documents that are available to users.

How to use a federated documents rule in a personalization component:

To access the information from a federated documents rule in your web content system, create a personalization component, associate it with the rule, and specify the design for displaying document information that is retrieved by the rule.

About this task

Procedure

1. Open the authoring portlet, and click **New** > **Component** > **Personalization**.
2. Enter a name and description for the new component.
3. Click **Search** in the **Personalization Element** section, and select the federated documents selection rule.
4. Define the design for the headers, footers, and individual documents that are selected by the configured selection rule. Use the **AttributeResource** element to reference individual metadata fields from the selected documents.
5. Save the component.

Results

You can now preview your component and reference it from within presentation templates, other element designs, or a web content viewer.

"Sample designs for a federated documents selection rule"
When you render document metadata information retrieved with a federated documents selection rule, you can tailor the header, footer, and menu search result designs for simple or more elaborate presentations.

"`AttributeResource` values for federated documents" on page 1831
The `AttributeResource` tag is used as a placeholder to display attributes from a federated documents selection rule within a personalization element design. It cannot be used in a presentation template or other element types.

Sample designs for a federated documents selection rule:

When you render document metadata information retrieved with a federated documents selection rule, you can tailor the header, footer, and menu search result designs for simple or more elaborate presentations.

Bulleted list design

To render a simple bulleted list of links to the documents, you can use a design like that described here.

Header

```
<ul>
```

Design for each menu search result

```
<li>
  <a target="_blank" href="[AttributeResource attributeName="contentLink"]">
    [AttributeResource attributeName="title"]
  </a>
</li>
```

Footer

```
</ul>
```

Table list design

To render a complete list of information with a table, you can use a design like that described here.

Header

```
<table>
<tr>
<th>Title</th>
<th>Authors</th>
<th>Load</th>
<th>Load via Portal</th>
<th>Load via Portal with Authentication</th><th>Load</th>
<th>Edit</th>
<th>Content Type</th>
<th>Size</th>
<th>Updated</th>
<th>Published</th>
</tr>
```

Design for each menu search result

```
<tr>
<td><b>[AttributeResource attributeName="title"]</b></td>
<td>[AttributeResource attributeName="authors" separator=","]</td>
<td><a target="_blank" href=" [AttributeResource attributeName="rawContentLink"]">download</a></td>
<td><a target="_blank" href=" [AttributeResource attributeName="contentLink"]">download</a></td>
<td><a target="_blank" href=" [AttributeResource attributeName="contentLinkAuthenticated"]">download</a></td>
<td><a target="_blank" href="[AttributeResource attributeName="viewLink"]">open</a></td>
<td>[AttributeResource attributeName="contentType"]</td>
<td>[AttributeResource attributeName="size"]</td>
<td>[AttributeResource attributeName="updated"]</td>
<td>[AttributeResource attributeName="published"]</td>
</tr>
```

Footer

```
</table>
```

`AttributeResource` values for federated documents:

The `AttributeResource` tag is used as a placeholder to display attributes from a federated documents selection rule within a personalization element design. It cannot be used in a presentation template or other element types.

When used with a federated documents selection rule, the following values for the `attributeName` attribute of the `AttributeResource` tag are supported for each document in the result set:

`authors`
: This attribute displays the names of the authors of the document. The actual result depends on the corresponding attribute mapping that needs to exist at the remote content management system. If no such mapping exists, an empty value is displayed.

`contentLink`
: This attribute displays the absolute URL that can be used to download the document. Unlike the `rawContentLink` attribute, the `contentLink` attribute contains the URL that addresses the Ajax proxy with parameters used to download the document through the proxy. You can disable proxied URLs by editing the `wcm.pzn.ecm.enable.proxy.content.links` property in the `WCM` `WCMConfigService` configuration service and setting the value to `false`.

`contentLinkAuthenticated`
: This attribute displays the absolute URL that can be used to download the document, including authentication information when needed. Similar to the `contentLink` attribute, the `contentLinkAuthenticated` attribute contains the URL that addresses the Ajax proxy with parameters used to download the document through the proxy. However, depending on the personalization selection rule, the `contentLinkAuthenticated` attribute

might also include information about a shared credential vault that is used to authenticate the user. The credential vault authentication information is available only if the selection rule was created by using a credential vault.

contentType
This attribute displays the MIME type of the document. If this information is not served by the remote content management system, an empty value is displayed.

contributors
This attribute displays the names of the contributors of the document. The actual result depends on the corresponding attribute mapping that needs to exist at the remote content management system. If no such mapping exists, an empty value is displayed.

id This attribute displays the unique ID of the document.

published
This attribute indicates the point in time of the first availability of the document. The actual result depends on the corresponding attribute mapping that exists at the remote content management system. If no such mapping exists, an empty value is displayed.

rawContentLink
This attribute displays the raw absolute URL that can be used to download the document. Although similar to the `contentLink` attribute, the `rawContentLink` attribute contains the URL as it appears in the federated documents feed used by the federated document selection rule. This value does not include any additional proxy that is addressed in the URL.

size This attribute displays the size of the document in bytes. If this information is not served by the remote content management system, an empty value is displayed.

summary
This attribute displays the summary of the document. If this information is not returned by the remote content management system, an empty value is displayed.

Note: Because the value of the summary attribute can contain large character data, the amount of data that is returned by this attribute is limited. You can increase or decrease the amount of data that is returned by setting the `wcm.pzn.ecm.max.field.length` property in the **WCM WCMConfigService** configuration service.

title This attribute displays the title of the document. The actual result depends on the corresponding attribute mapping that needs to exist at the remote content management system. If no such mapping exists, the file name is displayed.

updated
This attribute indicates the point in time of the last update to the document. The actual result depends on the corresponding attribute mapping that exists at the remote content management system. If no such mapping exists, an empty value is displayed.

viewLink
This attribute displays the absolute URL that can be used to open the document in context of the remote content management user interface. If no such URL is returned by the remote content management system, an empty value is displayed.

Note: The `viewLink` attribute is not supported if you are connected to a IBM Content Manager repository or are using a CMIS server.

Here is an example of how to use these attribute values in a design:

```
<li>
  <a target="_blank" href="[AttributeResource attributeName="contentLink"]">
    [AttributeResource attributeName="title"]
  </a>
</li>
```

Tags

Tags are used in your markup to reference content that is stored or generated by elements, or to display metadata from different items.

"Web content tags"
You use tags to reference elements within presentation templates and element designs.

CF07 "Web content tag behavior and enhancements"
These features and enhancements can be used to simplify the process of creating and maintaining web content tags.

"Indenting element designs" on page 1835
You use an indent tag to format element designs that require results to be indented.

"Writing links to web content" on page 1836
Links to content items can be written as URLs.

"Contextual linking" on page 1840
Contextual linking is used in systems where content from one site is shared across multiple sites. When content is linked into a site, embedded links (link elements and links in HTML) reference the site the original content item is in. Contextual linking is used so that when content is linked from another site, the link is rendered relative to the current site if possible.

"Custom caching" on page 1840
You can overrule the default caching parameters of a site by using "cache" and "expire" parameters in URLs and IBM Web Content Manager tags.

Web content tags

You use tags to reference elements within presentation templates and element designs.

To create a web content tag, click **Insert a Tag** from a presentation template or element design field. The Tag Helper dialog opens.

Web content tag behavior and enhancements

These features and enhancements can be used to simplify the process of creating and maintaining web content tags.

CF07

Tag delimiter

Web content tags can be written by using square or angle brackets. For example:

- `[Property field="title"]`
- `<Property field="title">`

CF07

Parameter delimiter

A choice of attribute delimiters can be used when you write web content tags. For example, the field parameter in a property tag can be written with double quotation marks, single quotation marks, or no quotation marks:

- `[Property field="title"]`
- `[Property field='title']`
- `[Property field=title]`

Note: The anchor and image HTML tags are the only HTML tags that are processed within web content tags. An attribute delimiter tag must always be used with these HTML tags, and are added automatically if omitted.

CF07

Primary parameters

Tags can be shortened by using their primary parameter.

For example, the tag `[Property field="title"]` can be shortened to `[Property:title]`.

These primary parameters can be used to shorten a tag:

Field This parameter is the primary parameter of the Property and EditableProperty tags.

Key This parameter is the primary parameter of the Element, EditableElement, IfDefined, and IfNotDefined tags.

Restriction: A shortened tag cannot be used with elements that have a space in their name. For example, if you add a text element to an item named "First Text Element" you cannot shorten its tag to `[Element:First Text Element]`. You must instead use the full tag syntax: `[Element key="First Text Element"]`

Tag This parameter is the primary parameter of the Placeholder tag.

Type This parameter is the primary parameter of the Path Component tag.

CF07

Dynamic Parameter Tag

The dynamic parameter tag is used as a simple representation of a more complex web content tag. It is represented by using a $ symbol.

For example, the property tag `[Property field="title"]` can be written as `[$title]`.

When a dynamic parameter tag is used, the context of the tag is determined in this order: Property, then element, then parameter resource. So, if you used this tag, `[$yellow]`, a property named "yellow" would be used first. If this property does not exist, an element named "yellow" would be used. If neither of these tags exist, a tag that contains a resource parameter named "yellow" would set the context.

The parameters of a dynamic parameter tag always default to `context="autofill"`, and `type="auto"`.

CAUTION: If you use the dynamic parameter tag, errors will occur when using cross-version syndication to servers that are not upgraded to CF07 or higher. All data will be lost from any element on the older server that uses a dynamic parameter tag.

CAUTION: If you roll back to CF06 or earlier after using the dynamic parameter tag, you will need to change any tags using the dynamic parameter tag back to the pre-CF07 standards.

CF07

Simplified plug-in tags

This tag is an example of a plug-in tag: `[Plugin:Page paramKey1='id']`

You can simplify the plug-in tag to this: `[Page paramKey1='id']`

The simplified plug-in tag cannot replace an existing web content tag. For example, if you created a plug-in named "Property", you must use the full tag: `[Plugin:Property]`. The tag `[Property]` is treated as a property tag, not a plug-in tag.

CF07

Default undefined tag attributes

If not specified in a tag, the `context` and `type` tag parameters default to `context="autofill"` and `type="auto"`.

CF07

HTML image tag

The border tag that is used in HTML image tags that are generated by Web Content Manager are not rendered in the tag if the border specified in an image element is not specified, or is zero.

Indenting element designs

You use an indent tag to format element designs that require results to be indented.

About this task

This is an example of the format of an IndentCmpnt tag:

```
[indentcmpnt repeat=" " offset=" " start=" " end=" " ]
```

To create a IndentCmpnt tag:

Procedure

1. Click **Insert a Tag** from a presentation template, component, or element design field. The **Tag Helper** dialog opens.
2. Select **Indent** as the tag type.
3. Select an offset level. The offset is used to determine how many times the repeat string is used for each indent. The offsets that are used are based on the number of nodes of the hierarchical content that is displayed. For example, A current node depth of 5 and an offset value of -2 would render the repeat string three times. If the sum of the offset and the node depth is negative or 0, the repeat string is not rendered.

4. Click **OK** to add the tag to your navigator design.

What to do next

When you add the tag to your design, you can also add the following parameters to the tag:

Table 272. indent tag parameters

Tag parameter	Description
`repeat=" "`	Enter the text to repeat at the beginning of the indent.
`start=" "` `end=" "`	The start and end attributes are used to wrap the data that is returned by a tag within other tags, such as HTML. These attributes are not mandatory.

Double-byte character sets:

Not all double-byte character sets support extended ASCII. To use tags, such as "` `", you need to replace "`&`" with "`&`".

For example:

```
[indentcmpnt offset="0" repeat="&amp;nbsp;&amp;nbsp;"]
```

Writing links to web content

Links to content items can be written as URLs.

Linking to web content from other web content

The following examples show how to write links to web content that are to be used with the web content viewer or the Web Content Manager servlet.

To create a link from a piece of web content to another piece of web content, use the following URL format:

```
[URLCmpnt mode="current" context="Selected" type="Content"
name="library/site_area_path/content"]
```

library
The name of the web content library.

site_area_path
The path to the site area where the content is located.

content
The name of the content item.

Linking to web content from an external portlet or website

To create a link from an external portlet or website that displays web content, use the following URL format:

```
http://hostname/context_root/library/site_area_path/content
```

hostname
The name of the Web Content Manager host.

context_root
The Web Content Manager context root. For example: `wps/wcm/connect`

library
The name of the web content library.

site_area_path
The path to the site area where the content is located.

content
The name of the content item.

Linking to content displayed in a web content viewer from an external portlet or website

To create a link from an external portlet or website to content displayed in a web content viewer, use one of the following piece of content (POC) URIs:

wcm:path:*content_path*
Use this POC URI to link to the content with the specified path. For example: `/Web Content/Articles/Sample Article`.

wcm:oid:*content_id*
Use this POC URI to link to the content with the specified ID. For example: `fa2bfd32-7b2f-4394-a5ab-2e150c5ed8aa`.

Use one of the POC URIs to create a URL with the following format:

`http://`*`hostname`*`/`*`context_root`*`/mypoc/`*`virtual_portal_context?urile=poc_uri`*

Note: The POC URI needs to be URL encoded. For example:

```
http://myportal/wps/mypoc/myvp?urile=wcm%3Apath%3A/Web+Content/Articles/
Sample+Article
```

You can add query parameters to the URL to specify how the portal resolves the POC URI.

To address a specific portal page, use one of the following parameters. The parameters cannot be combined:

page To specify the unique name or the object ID of the target page, use this parameter. For example: `&page=my.content.page`

mapping
To specify the target page using a URL mapping, use this parameter. For example: `&mapping=myContentPage`

current
To specify that the current page is the target page, use this parameter. For example: `&current=true`

To use a specific presentation template to render the requested content, use the following parameter:

pagedesign
Specify the path to the presentation template in your web content library including the names of folders. For example: `&pagedesign=/Web+Content/My+Templates+Folder/My+Presentation+Template`

CF05 To specify a mime type for the Content as a Service feature described in topic *Content as a Service,* use the following parameter:

mime-type
Specify the MIME type that is used as response content type of a **Content as a Service** request. If you enable your content for different data formats based on the MIME type, this parameter specifies the content type produced by the design component that renders the requested content. You can either use an element from the content item or a presentation template to produce the output. For more information about enabling different data formats based on the mime-type parameter, go to section **Selecting data format based on MIME** type. For example: `&mime-type=application/json`

Dynamic page lookup: The `page` parameter is optional. You can use the link broadcasting feature of the web content viewer to dynamically look up pages by omitting the `page` parameter. For example, if you have a content item **News1**, stored in the library **Web Content** under the site area **News**, you can create a link to that content item with the following URL:

`http://`*`hostname`*`/`*`context_root_poc`*`?urile=wcm%3Apath%3A/Web+Content/News/News1`

hostname
The name of the Web Content Manager host.

context_root_poc
The portal context root. For example, **wps/poc** or **wps/mypoc**.

Alternatively you can also add a specific portal page by using a URL mapping by using the following format:

`http://`*`hostname`*`/`*`context_root`*`/portal_page_url_mapping/?current=true&urile=wcm%3Apath%3A`*`library/site_a`*

hostname
The name of the Web Content Manager host.

context_root
The portal context root. For example, anonymous sites can use **wps/portal**. Otherwise use **wps/myportal**.

portal_page_url_mapping
The compound name of the portal URL mapping to the portal page that contains the Web Content Manager portlet (URL mappings can be set up using the portal administration portlets).

library
The name of the web content library.

site_area_path
The path to the site area where the content is located.

content
The name of the content item.

Note: The web content viewer on the target page must be configured to receive links from **Other portlets and this portlet**.

Adding cache parameters to a URL

You can add web content "Cache parameters" on page 1841 and "Cache expire parameters" on page 1842 to a URL to custom caching strategies to individual items. For example:

`http://`*`hostname`*`/`*`context_root`*`/`*`library`*`/`*`site_area_path`*`/`*`content`*`?cache=site`
`&contentcache=session`

hostname
The name of the Web Content Manager host.

context_root
The Web Content Manager context root. For example: `wps/wcm/connect`

library
The name of the web content library.

site_area_path
The path to the site area where the content is located.

content
The name of the content item.

Adding a last modified parameter to a URL

You can add the last modified date of the current content item to the header of the rendered page. For example:

`http://`*`hostname`*`/`*`context_root`*`/`*`library`*`/`*`site_area_path`*`/`
`content``?returnLastModified=true`

hostname
The name of the Web Content Manager host.

context_root
The Web Content Manager context root. For example: `wps/wcm/connect`

library
The name of the web content library.

site_area_path
The path to the site area where the content is located.

content
The name of the content item.

Overriding the context mode

The **`urlModeOverride`** parameter is used to override the default URL context when linking to URL, Link, and Placeholder components. These are the accepted values:

`current`
Chooses the URL style based on the request.

`standalone`
Generates URLs that render outside a portal site, such as a servlet site.

`poc` Generates a stateful Portal URL that renders content against the mapped wcm rendering portlet, or a servlet URL if no mapping exists. Functions as 'static' when rendering outside a portal site.

`static` Generates a short stateless Portal URL, or a servlet URL if no mapping exists.

Other URL Parameters

`WCMRenderAbsoluteURLs`
Add this to a URL to generate an absolute URL of an item instead of the relative URL.

Related concepts:

"Content as a Service pages" on page 1881
Starting with version 8.5 CF05, IBM WebSphere Portal Express introduces the concept of Content as a Service pages. The Content as a Service pages can be used to render content that is managed by your IBM Web Content Manager in different data formats.

"Select data format based on MIME type" on page 1882
With Content as a Service pages, you can specify different representation of your web content for different MIME types. This way when you request Content as a Service pages, you can specify the preferred representation of your web content. There are different options to manage the presentation components that produce the output for the MIME types you like to support.

Contextual linking

Contextual linking is used in systems where content from one site is shared across multiple sites. When content is linked into a site, embedded links (link elements and links in HTML) reference the site the original content item is in. Contextual linking is used so that when content is linked from another site, the link is rendered relative to the current site if possible.

Contextual path links

Contextual path links attempt to resolve a link by using a relative path technique. Contextual path linking assumes that each site framework that the linked content is stored in has the same site structure.

Contextual path links can be applied to elements referenced by using the element tag. For example:

- `[Element type="content" context="current" key="body" link="path" ]`

It can be used only if *context=current* or *context=autofill*.

When contextual path linking is used, a compatible link is searched for using the same relative path. If no link is found, the original link is used.

Custom caching

You can overrule the default caching parameters of a site by using "cache" and "expire" parameters in URLs and IBM Web Content Manager tags.

Note: Custom caching can be used only when a server's default web content cache is set to none or advanced caching. If basic caching is used as your default web Content cache, Custom caching cannot be used.

There are two basic methods in which custom caching can be used with your default server caching settings:

Default Server Caching Enabled

In this scenario, some form of default server caching is enabled. Caching parameters within connect tags and URLs can be used to either:

- Disable caching for the data that is being requested.
- Apply different caching parameters to the data that is being requested.

This method is used with sites that are mostly static, but that contain a few dynamic elements that require a different caching strategy from the server's default caching strategy.

Default Server Caching Disabled

In this scenario, default server caching is disabled. Caching parameters within connect tags and URLs can be used to enable caching for the data that is being requested.

This scenario is used with sites that contain many elements that require different caching strategies.

"Cache parameters"
Use the **cache** parameters in IBM Web Content Manager tags and URLs to specify whether the retrieved data is cached or not. If it is cached, how it is cached. The **cache** parameter is not mandatory.

"Cache expire parameters" on page 1842
You use the "expires" parameter in IBM Web Content Manager tags and URLs to specify how long to maintain data in the cache before it is expired. When data expires from a cache, the next request for the data will be retrieved from the original server. The **expires** parameter is not mandatory.

"Caching IBM Web Content Manager elements" on page 1845
You can apply caching to elements by using "connect" tags to reference elements within presentation templates instead of the component or element tag.

Cache parameters:

Use the **cache** parameters in IBM Web Content Manager tags and URLs to specify whether the retrieved data is cached or not. If it is cached, how it is cached. The **cache** parameter is not mandatory.

Custom caching parameters can be used only when a server's default web content cache is set to none or advanced caching. If basic caching is used as your default web content cache, custom caching cannot be used. Custom caching can be used to set cache parameters for basic, advanced, and data caches. When custom caching is used in a connect tag, the caching applies to the data that is being retrieved with the connect tag. When custom caching is used in a URL request, the caching applies to the entire page that is being requested.

Table 273. Values for the CACHE parameter

Basic caching	Advanced Caching	Data caching
CACHE=SITE CACHE=SESSION CACHE=NONE	CONTENTCACHE=SITE CONTENTCACHE=SESSION CONTENTCACHE=USER CONTENTCACHE=SECURED CONTENTCACHE=PERSONALIZED CONTENTCACHE=NONE	CONNECTORCACHE=SITE CONNECTORCACHE=SESSION CONNECTORCACHE=NONE

Examples:

```
<CONNECT MOD=Web SRV=HTML ACTION=http://www.ibm.com CACHE=SITE >
```

```
http://host:port/wps/wcm/connect/library/sitearea/content?cache=site&contentcache=session
```

Custom caching strategies

- When you apply custom caching to static content, you would mostly use `CACHE=SITE`, `CACHE=SESSION` or `CONTENTCACHE=USER`.
- When User Groups are used in implementing site security, you can use the `SECURED` custom caching strategy: `CONTENTCACHE=SECURED`.

- When Categories and/or Keywords, along with User Groups, are used for customization of your site, you can use the `PERSONALIZED` custom caching strategy: `CONTENTCACHE=PERSONALIZED`.
- If your Server's default web Content Cache is set to Advanced, you must use `CONTENTCACHE=NONE` to disable caching.
- If you retrieve external data, you must use `CONNECTORCACHE=NONE` to disable caching.

CacheKey parameter

The *CacheKey* parameter is used when caching content with the basic cache. A CacheKey is used as a key instead of a URL. This strategy is useful if you have multiple URLs for the same page but want it cached only once. This reduces the amount of memory that is used by the cache.

Example:

The following URLs use the same web page called news.html.

```
<CONNECT MOD=Web SRV=HTML ACTION=http://www.ibm.com/news.html
CACHE=SITE CACHEKEY=news >

<CONNECT MOD=Web SRV=HTML ACTION=http://www.ibm.com.au/news.html
CACHE=SITE CACHEKEY=news >

<CONNECT MOD=Web SRV=HTML ACTION=http://www.lotus.com/news.html
CACHE=SITE CACHEKEY=news >
```

In this example, "news" is used as the CacheKey to store the value of the response from these connect tags. This means that news.html is cached only once instead of being cached three separate times.

Caching, content updates, and syndication

When an item is updated, either directly or as a result of syndication, no cache is updated. The rendered items are not updated until each configured cache is expired. It is important to choose cache timeout parameters that complement your syndication strategy.

Cache expire parameters:

You use the "expires" parameter in IBM Web Content Manager tags and URLs to specify how long to maintain data in the cache before it is expired. When data expires from a cache, the next request for the data will be retrieved from the original server. The **`expires`** parameter is not mandatory.

Custom expiring parameters can be used only when a server's default web content cache is set to none or advanced caching. If basic caching is used as your default web content cache, custom expiration cannot be used. Even though you cannot use custom expiration with basic caching enabled, you can still use custom expiration (when you use the advanced cache) to expire data in the basic cache.

Values for the **`expires`** parameter can represent either a relative period or an absolute date and time:

Basic cache

- `EXPIRES="ABS {date and time}"`
- `EXPIRES="REL {integer}{units}"`

Advanced Caching

- CONTENTCACHEEXPIRES="ABS {date and time}"
- CONTENTCACHEEXPIRES="REL {integer}{units}"

Data caching

- CONNECTORCACHEEXPIRES="ABS {date and time}"
- CONNECTORCACHEEXPIRES="REL {integer}{units}"

Examples:

```
<CONNECT MOD=Web SRV=HTML ACTION=http://www.ibm.com CACHE=SITE
EXPIRES="REL 9000s">
```

```
http://host:port/wps/wcm/connect/library/sitearea/content?cache=site&expires="REL 9000s"
```

Custom expiring strategies

- CONNECTORCACHEEXPIRY= must be used when you set custom expiry parameters to retrieving external data by using a connect tag or URL request.
- If your default cache is basic, or if you specify CACHE= in a connect tag or URL request, you must use EXPIRES=.
- If your default cache is advanced, or if you specify CONTENTCACHE= in a connect tag or URL request, you must use CONTENTCACHEEXPIRES=.
- If your default cache is none, and only CACHE=, or CONTENTCACHE= is specified in a connect tag or URL request, the connect.connector.httpconnector.defaultcacheexpires property in the WCM WCMConfigService service is used to expire the data.

Specifying an absolute time

An absolute date specifies the date and time the document expires.

To indicate a time, use the following format:

- ABS {date and time}

For example:

- ABS Mon, 29 May 2000 03:04:18 GMT

A request for this document after this exact time causes the document to be flushed from the cache and a new copy retrieved.

When you specify an absolute expiry date, the date must be prefixed with ABS, and the date must be in one of the following formats:

- Mon, 06 Nov 2000 09:00:00 GMT
- Monday, 06-Nov-00 09:00:00 GMT
- Mon Nov 6 09:00:00 2000.
- 6 Nov 2000 9:00 AM.

The first three date formats use the standard HTTP specification, while the last is a simple, short date format for convenience.

When you use absolute times and dates to expire data, cached items remain in the cache until they expire. When expired, the original item is retrieved on the next request and a copy is placed in the cache. Because the absolute time or date has already expired, the item will immediately be expired. Whn expired, an item is not

permanently cached again when you use absolute times and dates. All absolute time values are in GMT.

Specifying a relative period

Rather than specifying an absolute time, a relative time can be used to specify that the document will expire some time after the document is placed in the cache, for example a number of hours or days. The actual time the document expires is then calculated from the time the document is retrieved and added to the cache.

Rather than specifying a fixed time for the expiry of cached data, the expiry can be specified relative to the time that the data was added to the cache, for example, a number of hours or days.

To indicate a relative time use the following format:

- REL {integer}{units}

Note: The space after REL is required.

The integer specifies a whole number of time units. Decimal numbers are not supported. The units are specified by using a single case-insensitive character:

- S: Seconds
- H: Hours
- D: Days
- M: Months

Table 274. Formatting examples

In a connect tag	In a URL Request
• `EXPIRES="REL 2M"` • `EXPIRES="REL 9000s"`	• `EXPIRES=REL 2M` • `EXPIRES=REL 9000s`

The first example indicates an expiry of two months. The second indicates 9000 seconds (2.5 hours).

By design only seconds, hours, days, or months can be specified. Minutes are not supported to simplify the interface (M is used for months). Instead, a multiple of seconds can be used (for example, 300 seconds for 5 minutes).

Caching, content updates, and syndication

When an item is updated, either directly or as a result of syndication, no cache is updated. The rendered item is not updated until each configured cache is expired. It is important to choose cache timeout parameters that compliment your syndication strategy.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Caching IBM Web Content Manager elements:

You can apply caching to elements by using "connect" tags to reference elements within presentation templates instead of the component or element tag.

Example: Applying custom caching

An example of the type of tag that can be used to cache individual elements within a presentation template:

```
<connect
 SRV="cmpnt" PATH="/Library/SiteArea/Content"
 SOURCE="library" CMPNTNAME="TestNav" CONTENTCACHE="site" CONTENTCACHEEXPIRES="REL 9000s">
</connect>
```

Table 275. Connect tag details

Parameter	Details
`SRV="cmpnt"`	The Service for this Module is "cmpnt".
`PATH="/libraryname/SiteArea/Content"`	This parameter sets the context for the element. The "sitepath" and "name" placeholders can be used instead of "PATH=" when caching menus or navigators: `[placeholder tag="sitepath"]/[placeholder tag="name"]`
`SOURCE="library"`	Source is either "content", "sitearea" or "library". In this example it is "library" because the element being cached comes from a component.
`CMPNTNAME="TestNav"`	This parameter is the name of the element to be cached.
`CONTENTCACHE="site"`	This parameter is either "site or "session".
`CONTENTCACHEEXPIRES="REL 9000s"`	The time the component expires from the cache is set here.

The first time the presentation template is rendered, the element is added to the cache. The next time the presentation template is rendered, the element is displayed from the cache instead of being rendered afresh by the Web Content Manager application. The element is not rendered again by the Web Content Manager application until it is expired from the cache. For this reason, only elements that do not require to be freshly rendered every time that a page is accessed should be cached.

If you are caching a component that is used in more than one presentation template, save the connect tag as a HTML component and then reference that component in each presentation template. If you then need to change the cached component tags, you only need to change it in the HTML component rather than in multiple presentation templates.

If you have a set of cached components that use the same `ContentCacheExpires` parameter, save the `ContentCacheExpires` parameter as an HTML component and then reference that component in each connect tag that is used to cache components. If you then need to change the `ContentCacheExpires` parameter, you change it in the HTML component only, rather than in multiple connect tags. This also applies to any common cache tags.

Example: Disabling caching

You can also use this method to disable caching. In this example the property *CONTENTCACHE=NONE* is used to disable caching of this element.

```
<connect
 SRV="cmpnt" PATH="/SiteArea/Content"
 SOURCE="library" CMPNTNAME="TestNav" CONTENTCACHE="none" >
</connect>
```

Setting up search for site visitors

Learn about the initial considerations for setting up search for site visitors before you begin configuring and administering search on your website.

What is your portal environment?
If you are operating in a stand-alone environment, you can use the Default Search collection to start working immediately with Portal Search. If you are operating in a cluster environment, remote search service must be installed and configured before Portal Search can be used. Remote search service enables all nodes of the cluster to equally access the same search service.

What keywords, categories, and metadata do you want to specify for searching?
Predicting specific search terms and keywords to index is an important first step when you are setting up your site for search by site visitors. Oftentimes, the prediction of search terms, metadata, and keywords to be indexed depends upon current industry and marketing trends for your specific business. Content authors can set keywords and metadata terms for a specific page. You can also enable searching of the words that are used in the body of your content instead of keywords or metadata that is associated with content items.

How do you want to return search results when a site visitor runs a search?
The results of a search on WebSphere Portal collections are displayed in the Search Center by default. The Search Center is wired together with the search form in standard themes included with WebSphere Portal. However, you can use the Search Results page template to create a search landing page that displays a list of search results when a site visitor runs a search query. The search landing page that you create can be placed anywhere in your site. Search results are automatically displayed on the new search landing page instead of in the Search Center.

Do you need to index documents of various formats, such as PDFs?
If so, you must install and configure Document Conversion Services (DCS). This third-party software is included with WebSphere Portal. DCS converts various types of documents into a format that can be consumed and processed by the search engine. DCS is needed in order for attachments to be indexed and appear in search results.

Which search service suits your business and website needs?
Portal Search is available for immediate use, though you can also provide advanced search features on your website by using IBM Content Analytics with Enterprise Search. Additionally, you can integrate search on your website with third-party search engines if you have a license for that third-party search software. Your website's specific environment and search needs determine which search service your website requires.

Taxonomies, Categories, and keywords

The combination of taxonomy and categories enables control what displays in menus.

Taxonomies and categories

A Category refers to the subject matter of your content item. For example, your content item might be of the category *New Products* or *Latest News*. Sets of categories are grouped within different top-level taxonomies. List of links to content items that use the same category are displayed by using a menu component.

Keywords

Use Keywords to profile content. Unlike categories, which are chosen from a predefined list, you can enter any keywords that you like when you create content items. List of links to content items that use the same keyword are displayed by using a menu component.

Taxonomy example

In the example:

- "Financial" is the ancestor of "Interest Rates", "Personal", "Business", "Corporate" and "Banking Solutions".
- "Personal", "Business" and "Corporate" are the descendants of "Interest Rates" and "Financial".
- Financial
  - Banking Solutions
  - Interest Rates
    - Personal
    - Business
    - Corporate
- News

Category scenarios

When building a hierarchy of taxonomies and categories, it is important to consider how a menu uses your categories in a search, because menus search both upwards and downwards within groups of categories.

Table 276. Examples

Scenario	Example
If you base a menu on a top-level category, all content that is profiled with categories that belong to that top-level category and their descendants appear in the menu.	In the previous example, a menu based on Financial displays content that is profiled with any of the following: • Financial – Banking Solutions – Interest Rates - Personal - Business - Corporate

Table 276. Examples (continued)

Scenario	Example
If you base a menu on a mid-level category, all content that is profiled with the mid-level category or its descendants or its ancestors appear in the menu.	A menu based on Interest Rates displays content that is profiled with any of the following: • Financial – Interest Rates - Personal. - Business. - Corporate.
If you base a menu on a bottom-level category, all content that is profiled with the bottom-level category or its ancestors are returned by the menu.	A menu based on Business displays content that is profiled with any of the following: • Financial – Interest Rates - Business.

How to store translated text in a content item or site area

CF07

Translated text can be stored in a content item or site area. The translated text can then be referenced in web content tags, or as localized text in web content authoring portlet forms.

How to create the content item or site area to store the translated text

- Create a content item or site area.
- Add `ibm.wcm.TextProvider` as a keyword in the content item or site area's profile settings.
- Create a set of text elements for each language that is used by your site. Each text element must be named entering a language code for the language in the name field. See "Supported languages" on page 3622 for a list of codes. At render time, if the requested language does not exist in the list of elements, the first element is used as the default language.
- Type the translated text in each field by using this format: `keyname=translated-text`. You can add as many key names as you need into each text element. For example:

```
keyname1=translated text
keyname2=translated text
keyname3=translated text
```

- The key names must be consistent for each language.
- The list of key names and translated text uses the Java Properties File Format.

How to select the translated text in a web content authoring portlet form

Fields that support localized text have a **Localizations** link next to the field title. Click Localizations to select the content item or site area where your translated text is stored, and then select a key name.

How to select the translated text in a web content tag

You can render translated text by using a plug-in tag:

```
[Plugin:TextProvider key="" provider=""]
```

You specify the *name* path to the content item or site area in the `provider` parameter, and the name of the key to display in the `key` parameter. For example:

```
[Plugin:TextProvider key="keyname2" provider="library/sitearea/contentitem"]
```

Note: If you move or rename a content item or site area that is used to store text provider text, or its parent, you will break the text provider reference that is specified in a tag. To avoid this issue, you can instead specify the item ID instead of the name path.

For example:

```
[Plugin:TextProvider provider="[Element key='Text Provider Name' format='id']" key="keyname2"]
```

See Content plug-ins for further information about text provider plug-in tag.

Setting a default text provider in a web content tag

If you intend to use the TextProvider plug-in tag more than once in a component design or presentation template design using the same text provider, you can specify the default text provider item name path in one tag:

```
[Plugin:TextProvider defaultProvider="library/sitearea/contentitem"]
```

You can then leave out the provider parameter in the tags that follow the default provider tag:

```
[Plugin:TextProvider defaultProvider="library/sitearea/contentitem"]
[Plugin:TextProvider key="key1"]
[Plugin:TextProvider key="key2"]
[Plugin:TextProvider key="key3"]
```

The default provider is applied in all presentation template designs and component designs, including component designs that are included by using the tags, such as a component tag.

To remove the default provider, use:

```
[Plugin:TextProvider defaultProvider=""]
```

How to use replacement characters

You can use replacement characters with the text provider plug-in tag.

For example, to use `keyname_with_replacement=Welcome {0} to the website of {1}` in the content item that is located at `library/sitearea/contentitem`, use:

```
[Plugin:TextProvider key="keyname_with_replacement" provider="library/sitearea/contentitem" param.
```

This is rendered as:

```
Welcome Fred to the web site of Mary
```

Hiding a text provider item from the web content authoring interface

If you don't want a text provider item to appear in the list of text providers in the web content authoring interface, add a text element with the name of `isShownInAuthoringUI`. Then, type the word `false` in the text element field. You can still reference this text provider item in a plugin-in tag even though it is now hidden from the list of text providers in the web content authoring interface.

Hiding content

You can hide portlets and widgets on a page so they are present but not visible in the page layout.

About this task

Why Hide Content?

Sometimes you might want a portlet or widget on the page, but it does not have a user interface. In that case, it should be hidden. An example is if you have a data processing widget and a data viewer widget that are wired together. The data viewer widget is visible and the data processing widget would stay hidden.

In the portal theme, hide content by putting it into a special container in the layout that is hidden with CSS. All of the out of box layout templates have this hidden container.

Procedure

1. Viewing hidden content
   a. Click **Edit Mode**.
   b. Click **Menu** > **Show Hidden Content**.
2. How to hide content. There are two ways to hide a piece of content:
   Use the **Portlet Actions** menu:
   a. View the hidden content as described in step 1.
   b. Click the drop-down menu icon in the portlet or widget.
   c. Click **Hide**.
   d. Click **Save Draft** to save the page.

   Use drag and drop option:
   a. View the hidden content as described in step 1.
   b. Drag the portlet or widget into the hidden container that appeared in step a.
   c. Click **Save Draft** to save the page.
3. How to unhide content There are two ways to display a piece of content:
   Use the **Portlet Actions** menu:
   a. View the hidden content as described in step 1.
   b. Click the drop-down menu icon in the hidden portlet or widget.
   c. Click **Move Down**.
   d. Click **Save Draft** to save the page.

   Use drag and drop option:
   a. View the hidden content as described in step 1.

b. Drag the portlet or widget out of the hidden container.
c. Click **Save Draft** to save the page.

Static content

Static content is part of every website. In a portal site, static content can be rendered as static page or it can be added to specific content areas on a page.

To include, update, and administer your static content pages, you can use any of the portal administration tools, Manage Pages portlet, XML configuration interface, or the Portal Scripting Interface.

Working with static content pages has the following advantages:

- You or your web designers can create a portal page by using standard web authoring tools. This tool can be HTML editors or even simple text editors. Creating an HTML portal page requires no knowledge of JSP.
- You have more control over the layout of the page than by using the portal layout model.
- You can include portlets as dynamic elements and containers as placeholders for portlets in your pages. You can display these portlets by using server-side aggregation, Ajax, or iFrame techniques.
- You can update an existing static page by uploading a modified HTML file while you preserve the portlet customization on that page.
- Static pages can be rendered in the portal by the following two ways:
  - As stand-alone web pages that control the complete browser area.
  - As part of the portal content area. In this case, the portal still controls the banner and navigation area.
- You can deploy and manage your static content pages by using any of the portal administration tools.
- You can use portlet communication with static pages, for example by wires.

Compared to dynamic content pages based on the portal container model, static HTML pages also have the following characteristics:

- You create and administer static pages similarly as other portal pages. Some steps and options differ. For details, refer to the user interface and the portlet help of the Manage Pages portlet and its subportlets.
- To update a static page, you make the required changes in the HTML file. Then, you replace the portal page with the updated page by using the Manage Pages and Properties portlets or other portal administration tools. You can use the portal Page Customizer to update the static page layout if the static page contains portlet containers that are defined by the portlet container microformat.
- You provide national language support by bundling localized markup files into the compressed file, together with the HTML file that defines the static content. At rendering time, the portal globalization algorithms decide which locale is rendered, based on the request, on settings, and on the locals that are available.
- The portal defines a set of microformats for skins and portlet actions, such as configuring the portlet settings, portlet communication, and navigation for rendering. These microformats are styled by CSS that the static page author provides.
- Static pages can include drag actions. These actions are defined through a microformat. Users with the appropriate access rights can drag UI elements, such as portlets or pages.

- You provide JS, CSS, or image files for static pages by bundling them into a compressed file, together with the HTML file that defines the static content. These resources can then easily be referenced through relative links from the static page template.
- You can have static pages that are rendered by server-side aggregation or by client-side aggregation.
- Using skins and other graphic features with static content: When you write a static page and include it in your portal, the portal can render the page itself. But not with the visual features that you might configure for your portal. For example, you cannot encode skins within static pages. When the portal renders such a page, portlets on the page are rendered without a skin. To have portlets on static pages that are rendered with a skin, use CSS style sheets or JavaScript that use the microformats at rendering time.

The following topics describe how you create static pages in HTML, and what features you can use.

When you write the static page, you can include it in your portal by using the Manage Pages portlet.

Decision point: After you include a page in the portal, you cannot change the page from static content to standard portal layout or from standard portal layout to static content. If you want to change the page type after you create it, you need to delete the existing page and create a new page of the required type.

Note: When a static page uses the default Portal 8.5 theme, Portal 8.0 theme, or Portal 7.0.0.2 theme, users can change the style of the page, but they cannot change the layout of the page or add content to it.

"Creating a static page"
You can create a new portal page by starting with a static HTML file or an HTML fragment. If you revise the HTML, you can refresh the page to render the changes in the portal.

"Static resources" on page 1869
In addition to the HTML file that describes the page, static pages can contain resources such as images, scripts, and styles. Learn about the static resources that are available when you are using static pages.

"Dynamic page metadata" on page 1870
HTML defines some elements that refer to information that is managed as page metadata on portal pages. You can use the dynamic page metadata rewriting feature to place this information into the static HTML code automatically.

"Including static content pages in your portal" on page 1871
You can create a new portal page by starting with a static HTML file or an HTML fragment. If you revise the HTML, you can refresh the page to render the changes in the portal. To include, update, and administer your static content pages, you can use any of the portal administration tools, Manage Pages portlet, XML configuration interface, or the Portal Scripting Interface.

"Using WebDAV to manage pages and static content" on page 1877
WebDAV for IBM WebSphere Portal Express provides a simple and easy way to administer portal resources. Both administrators and users can use it.

Creating a static page

You can create a new portal page by starting with a static HTML file or an HTML fragment. If you revise the HTML, you can refresh the page to render the changes in the portal.

About this task

After you included a page in the portal, you cannot change the page from static content to standard portal layout or from standard portal layout to static content. If you want to change the page type after you created it, you must delete the existing page and create a new page of the required type.

When you use the Manage Pages and Page Properties portlets to create your static page in the portal, you select **Static Content** for the **Type of Page**. Then, select and complete the other options accordingly. For more information, see the portlet help.

Procedure

- The static HTML file can contain references to portlets, containers, and navigation. It defines the places in the portal page that host portlets or portlet containers. When the page is rendered, these places are filled by the server with the - possibly dynamic - content of portlet and with a microformat that defines metadata for these portlets. For example, portlet actions and the portlet title. For this purpose, the portal provides the following microformats:
  - The **portlet microformat** defines portlet windows and portlet actions, such as Edit default settings, Configure, Maximize, Minimize, Personalize, and Delete.
  - The **container microformat** defines portlet containers as placeholders for portlets.
  - For drag-and-drop actions, the portlet microformat can provide the drag source, and the container microformat provides the drop target.
  - The **navigation microformat** defines the navigation if your static page is rendered as a web page.

  The portlet window and portlet container microformats can contain object IDs. The server can handle these object IDs dynamically.

  When you write the static page, you can use CSS or JavaScript techniques that use the microformats to produce and render a user friendly user interface.
- You can define whether the static page is rendered as a web page or as part of a portal page:
  - To render the page as a stand-alone static page, include the `<html>` element as a root element in the markup file.
  - To render the page as part of a portal page, omit the `<html>` element.
- You can also include other resources as part of the page, such as cascading style sheets or graphic images. You must bundle all the files into a compressed file. This single compressed file is then used to create or update the static page.
- You can use portal frameworks such as Live Text with your static pages. To achieve this, include your static page as part of a dynamic portal page when you add the static page to your portal in a later step.
- To enable globalization, that is to represent your static page in different languages or locales, you bundle localized static markup files into a compressed file. For example, these can be HTML files, graphic files, such as JPGs, style sheets such as CSS or JS files. Observe the following naming convention for your localized files: For a base file *base_file_name.file_name_extension*, you must name the localized version of the file `base_file_name_`*locale*`.file_name_extension`. Example: For a base file named `my_page.html`, the English version of the file is `my_page_en.html`, and the US English version of the file is `my_page_en_us.html`. Although these files have different file names, they logically represent the same resource and are referenced by references to their base name. The portal serves the localized version of the resource when appropriate.

- To enable device support, which represents your static page for different device classes, bundle the static markup files that are device-class-specific into a compressed file. Observe the following naming conventions for your device-specific files:

  For a base file `base_file_name.file_name_extension`
  Name the device-specific version of the file `base_file_name_device.file_name_extension`. For example, for a base file named `my_page.html`, the smartphone-specific version of the file is `my_page_smartphone.html`, and the tablet-specific version of the file is `my_page_tablet.html`. Although these files have different file names, they logically represent the same resource and are referenced by references to their base name. The portal serves the device-specific version of the resource when appropriate.

  For localized, device-specific files
  For a base file named `my_page.html`, the smartphone-specific English version of the file is `my_page_smartphone_en.html`, and the smartphone-specific US English version of the file is `my_page_tablet_en_us.html`.

  These naming conventions also apply for the definition of static portal pages in HTML.

What to do next

To update a static page, you make the required changes in the HTML file, then you replace the portal page with the updated page by using the Manage Pages and Properties portlets or other portal administration tools. If the static page contains portlet containers that are defined by the portlet container microformat, you can use the portal Page Customizer to update static page layout .

Note: When you use only characters that can be encoded in ASCII in the names of the compressed file and the directories and files within the compressed file, you can use a compressed tool of your choice to create the file package. If you use characters that are not ASCII encoded, for example special characters or DBCS, in the names of the compressed file and the directories and files within the compressed file, you must create the compressed file by using the JRE tool `jar.exe`.

"Example HTML markup for defining a portal page" on page 1855
Use these code samples as examples of HTML markup to create a portal page.

"Class attributes for portlets on static pages" on page 1857
When you place a portlet on a static HTML page to be rendered by the portal, use a suitable CSS file to format the portlet. The CSS file makes use of the portlet microformat. You can make use of this microformat if you want to render portlets on your static HTML page with a skin of your choice. When you write the static page, you can use CSS or JavaScript techniques to convert the microformat into a friendly user interface. The portlet references in the static HTML page are replaced by the content of the portlet and the portlet microformat.

"Class attributes for a portlet container on static pages" on page 1859
To render a portlet container on a static page, you use a CSS file that makes use of the container microformat. One of the benefits is that users with the required access rights can later move the portlets by drag and drop.

"Class attributes for components on static pages" on page 1860
When you place a component on a static HTML page to be rendered by the

portal, use a suitable CSS file to format the portlet. The CSS file uses the component microformat. You can use this microformat if you want to render components on your static HTML page with a skin of your choice. When you write the static page, you can use CSS or JavaScript techniques to convert the microformat into a friendly user interface. The component references in the static HTML page are replaced by the content of the component and the component microformat.

"Navigation options for static pages" on page 1863
You can provide navigation for your static pages by using either the portal theme or by making use of the navigation microformat.

"Portlets for adding dynamic elements to static pages" on page 1866
If you want to add dynamic elements such as portal navigation to your static pages, you can use portlets that the portal provides.

Example HTML markup for defining a portal page:

Use these code samples as examples of HTML markup to create a portal page.

The HTML markup that you use to create a portal page has a direct effect on how the page is rendered in the portal. This topic provides examples of the HTML markup that you can use in a source file to produce various types of content in a portal page.

You can include portlets in a static HTML file by using the class attribute `portlet-window` on a `<div>` CF03 or an `<object>` element:

- Use a `<div>` element if the portlet is part of the `<body>` of the page.
- CF03 Use the `<object>` element if the portlet is part of the `<head>` element of the page.

The marked up element is replaced by the dynamic content of the portlet when the page is rendered. Unless the portlet is embedded in a container, it cannot be moved or deleted by the page customizer or other portal mechanisms. To delete such a portlet, you need to replace the static page with an updated HTML file that does not contain the portlet. In addition to the class attribute `portlet-window`, a portlet `<div>` CF03 or `<object>` element needs to contain the following information:

The parser decodes HTML documents and treats the following tags specifically:

Name attribute
This is the name of the portlet instance that is unique across the page. It is used to distinguish between different instances of the same type of portlet on the page. When a static page is updated, this instance name is used to determine if portlets need to be updated or deleted. This name is not the unique name in the portal.

Style attribute
The style attribute identifies the portlet definition, that is the type of the portlet. The attribute needs to contain the portlet definition style. The value of the style contains the object ID or the unique name of the portlet definition.

Example:

```
<div class="portlet-window" name="instancename"
     style="portlet-definition:definitionname"></div>
```

You can also parametrize portlet windows directly in the HTML document. These parameters are passed on as edit default preferences to the portlet instances at page creation or page update time. For a portlet included with a element, the parameters consist of name-value pairs that are formatted by using an HTML definition list. Example:

```
<div class="portlet-window" name="<instancename>"
     style="portlet-definition:<definitionname>">
   <dl>
      <dt>key1</dt>
      <dd>value1</dd>
      <dt>key2</dt>
      <dd>value2</dd>
   </dl>
</div>
```

CF03 For a portlet included by an <object> element, the parameters consist of name-value pairs that are formatted by using the <param> elements of the <object> element. Example:

CF03 <object class="portlet-window" name="<instancename>" style="portlet-definition:<definitionname>"> <param name="key1" value="value1"> <param name="key2" value="value2"> </object>

Portlet containers contain portlet windows that can be rearranged or deleted by a page editor, for example, the page customizer. In addition you can add new portlet windows after the page has been deployed. The portlet windows that you define in the static page as the content of the container are the portlets that are initially part of the container. Containers cannot be nested.

Similar to portlet windows, containers are marked up by using the class attribute portlet-container on a tag. In addition you need to specify the following:

Name attribute
This is the name of the container that is unique across the page. This is not the unique name in the portal.

Example:

```
<div class="portlet-container" name="holdername">
   <div class="portlet-window" name="instancename"
        style="portlet-definition:definitionname"></div>
</div>
```

Rendering a page from full HTML markup

When you include the beginning <html> and ending </html> markup in the source file, the resulting portal page is rendered without the portal theme, or surrounding navigation frame. The user sees only the layout that you code inside the HTML file. An example of the HTML markup looks like this:

```
<html>
   <head>
      <title>Sample Static Page</title>
   </head>
   <body>
      <p>This is a static page example.</p>
      <p>Welcome portlet</p>
      <div class="portlet-container" name="portletContainer1">
         <div class="portlet-window" name="portletWindow1"
              style="portlet-definition:wps.p.Welcome To WebSphere Portal">
```

```
        </div>
      </div>
   </body>
</html>
```

The values given for the name attributes must be unique in the scope of the page.

With this example, all information that the portal requires to render the page is well known at the time when you create and edit the static page.

Rendering a page from an HTML fragment

When the HTML source file is a fragment of HTML markup, and does not include the opening or closing `<html>` markup, then the page is rendered inside the portal navigation frame. An example of this HTML coding:

```
<p>This page has one Welcome Portlet.</p>
<p>Welcome portlet</p>
<div class="portlet-container" name="portletContainer1">
   <div class="portlet-window" name="portletWindow1"
        style="portlet-definition:wps.p.Welcome To WebSphere Portal">
   </div>
</div>
```

The values given for the name attributes must be unique in the scope of the page.

Class attributes for portlets on static pages:

When you place a portlet on a static HTML page to be rendered by the portal, use a suitable CSS file to format the portlet. The CSS file makes use of the portlet microformat. You can make use of this microformat if you want to render portlets on your static HTML page with a skin of your choice. When you write the static page, you can use CSS or JavaScript techniques to convert the microformat into a friendly user interface. The portlet references in the static HTML page are replaced by the content of the portlet and the portlet microformat.

Refer to the following list of class attributes for more information. An example of a portlet rendered from HTML is also provided.

portlet-window

This value of the `class` attribute identifies the containing `<div>` tag for the portlet window as it was defined by the Web designer when the static page was written. The style attribute and the name attribute contain the same information that was provided by the author of the page on the `<div>` element that referenced the portlet. The ID attribute contains the object ID of the window. Refer to the following example for rendering a page from full HTML markup:

```
<html>
   <head>
      <title>Sample Static Page</title>
   </head>
   <body>
      <p>This is a static page example.</p>
      <p>Welcome portlet</p>
      <div class="portlet-container" name="portletContainer1">
         <div class="portlet-window" name="portletWindow1"
              style="portlet-definition:wps.p.Welcome To WebSphere Portal">
         </div>
      </div>
   </body>
</html>
```

portlet-info
This value of the `class` attribute introduces the metadata section of the portlet. All metadata is encapsulated in this container so that it can be hidden it by CSS. The `xoxo` class denotes that this contains a list of items.

portlet-title
This value of the `class` attribute represents the localized title of the portlet. The `lang` attribute identifies the actual locale.

portlet-actions
This value of the `class` attribute lists the different portlet actions or operations that can be invoked in the portlet window.

Note: Such operations are not necessarily actions in the sense of HTTP. Instead, some actions are safe interactions, whereas others can be unsafe, as they modify the server. In the list of actions each interaction is either represented as a link to denote a safe interaction or as a `form` to denote an unsafe interaction.

portlet-action
This value of the `class` attribute describes the actual actions or operations. Those actions that would result in an idempotent operation are denoted by the selected attribute. In addition each action is classified by an action specific attribute to allow CSS to style these actions, for example, by adding action specific icons. The list of possible actions is computed on the server by making use of the Operations Feed. This feed is extensible, therefore new operations can be added over time.

portlet-window-body
This value of the `class` attribute denotes the body of the portlet.

iw-iWidiget
This value of the `class` attribute identifies the beginning of the microformat for placing an iWidget instance on a static page. Additional information about the iWidget microformat for including iWidgets into a broader set of markup, such as a portal page, provided by the iWidget specification and on the topic about Class attributes for iWidgets on static pages.

selected
This value of the `class` attribute identifies a selected item, either the portlet itself or an action. If it appears on the `<div>` tag for the portlet window, this means that the portlet was the target of the interaction that produced the page.

portal-drag-source
This is an optional class on the portlet window. It denotes that this portlet window can be dragged around on the screen by users. This attribute is only valid if the portlet window is part of a modifiable portlet container, and if the user has the rights to modify the page and the container is not locked. Refer to the Container Microformat to see how a drop target is represented and how the actual drag and drop operation can be performed.

Note: A drag and drop action is triggered from the client side, but is executed on the server.

xoxo This attribute denotes that the following is a list of items.

Example of rendering a portlet from HTML

The following is an example of a microformat representation for a portlet window on a page:

```
<div class='portlet-window' id='7_CGAH47L00OGRB02DA9LR6H1024' name='window2' >
   <ul class='xoxo portlet-info' >
      <li class='portlet-title' lang='en'>
         PetStorePortlet
      </li>
      <li class='portlet-actions' >
         Actions
         <ul class='xoxo portlet-action' >
            <li class='portletoperation-view selected' >
               <a href='?uri=wp.operations:onPortletModeView
                  (7_CGAH47L00OGRB02DA9LR6H1024)'
                  rel='view' >Back</a>
            </li>
            <li class='portletoperation-normal selected' >
               <a href='?uri=wp.operations:onWindowStateNormal
                  (7_CGAH47L00OGRB02DA9LR6H1024)'
                  rel='normal' >Restore</a>
            </li>
            <li class='portletoperation-minimized' >
               <a href='?uri=wp.operations:onWindowStateMinimized
                  (7_CGAH47L00OGRB02DA9LR6H1024)'
                  rel='minimized' >Minimize</a>
            </li>
            <li class='portletoperation-maximized' >
               <a href='?uri=wp.operations:onWindowStateMaximized
                  (7_CGAH47L00OGRB02DA9LR6H1024)'
                  rel='maximized' >Maximize</a>
            </li>
            <li class='portletoperation-delete_portlet' >
               <form method='POST' action='?uri=wp.operations:onDeletePortlet
                     (7_CGAH47L00OGRB02DA9LR6H1024)'
                     rel='delete_portlet' >Delete</form>
            </li>
         </ul>
      </li>
   </ul>
   <div class='portlet-window-body' >
   </div>
</div>
```

Class attributes for a portlet container on static pages:

To render a portlet container on a static page, you use a CSS file that makes use of the container microformat. One of the benefits is that users with the required access rights can later move the portlets by drag and drop.

To place a portlet container on a static page, use a style file that makes use of the container microformat. Refer to the following list of class attributes and the example of rendering a portlet container from HTML.

portlet-container

This value of the `class` attribute identifies the containing `<div>` tag for a portlet container as it was defined by the Web designer when the static page was written. The `ID` attribute contains the Object ID of the container, which is globally unique in the portal. The `name` attribute contains a name for the container that is unique only in the scope of the hosting page. In static page aggregation the HTML page designer determines this name.

portal-drop-target
This value of the `class` attribute identifies the container as a drop target of a drag and drop operation. Only modifiable containers use this class attribute.

drop-handler
This value of the `class` attribute identifies the `form` that represents the callback handler for drag and drop. The action contains a URL that uniquely identifies the drop target. You can add additional hints and the drag sources dynamically to the form by using Javascript.

For the drag source, use the attribute from the portlet microformat when defining the portlet:

portal-drag-source
This is an optional class on the portlet window. It denotes that this portlet window can be dragged around on the screen by users. This attribute is only valid if the portlet window is part of a modifiable portlet container, and if the user has the rights to modify the page and the container is not locked. Refer to the Container Microformat to see how a drop target is represented and how the actual drag and drop operation can be performed.

Note: A drag and drop action is triggered from the client side, but is executed on the server.

Example of rendering a portlet container from HTML

The following is an example of a microformat representation for a portlet container on a page:

```
<div id="content-area">
   <div class='portlet-container portal-drop-target'
        id='7_CGAH47L0008K402D2V3F7I2005' name='c1' >
      <form class='drop-handler' enctype='multipart/form-data' method='POST'
            action='/wps/mycontenthandler/!ut/p/dnd/lm:
                 oid:7_CGAH47L0008K402D2V3F7I2005@
                 oid:6_CGAH47L0008K402D2V3F7I2000?uri=dnd%3alm%3a
                 oid%3a7_CGAH47L0008K402D2V3F7I2005%40
                 oid%3a6_CGAH47L0008K402D2V3F7I2000'>
         <input type='hidden' name='_charset_'>
      </form>
   </div>

   ... the actual portlets come here

</div>
```

Class attributes for components on static pages:

When you place a component on a static HTML page to be rendered by the portal, use a suitable CSS file to format the portlet. The CSS file uses the component microformat. You can use this microformat if you want to render components on your static HTML page with a skin of your choice. When you write the static page, you can use CSS or JavaScript techniques to convert the microformat into a friendly user interface. The component references in the static HTML page are replaced by the content of the component and the component microformat.

For more information, see the following list of class attributes for portlet components. An example of a component that is rendered from HTML is also provided.

portlet-window / component-control
This value of the `class` attribute identifies the containing `<div>` tag for the component window as it was defined by the web designer when the static page was written. The style attribute and the name attribute contain the same information that was provided by the author of the page on the `<div>` element that referenced the component. The attribute `id-`*`ObjectID`* is the prefixed object ID of the component window, which is globally unique in the portal. Refer to the following example for rendering a page from full HTML markup:

```
<html>
   <head>
      <title>Sample Static Page</title>
   </head>
   <body>
      <p>This is a static page example.</p>
      <p>Welcome component</p>
      <div class="component-container" name="componentContainer1">
         <div class="portlet-window component-control" name="componentWindow1"
              id="Z7_2QC68B1A08A0B0IAUQ7VBO20G3"
              style="portlet-definition:wps.p.Welcome To WebSphere Portal">
         </div>
      </div>
   </body>
</html>
```

portlet-info
This value of the `class` attribute introduces the metadata section of the portlet. All metadata is encapsulated in this container so that it can be hidden by CSS. The `xoxo` class denotes that this contains a list of items.

portlet-title
This value of the `class` attribute represents the localized title of the portlet. The `lang` attribute identifies the actual locale.

portlet-actions
This value of the `class` attribute lists the different portlet actions or operations that can be started in the portlet window.

Note: Such operations are not necessarily actions in the sense of HTTP. Instead, some actions are safe interactions, whereas others can be unsafe, as they modify the server. In the list of actions each interaction is either represented as a link to denote a safe interaction or as a `form` to denote an unsafe interaction.

portlet-action
This value of the `class` attribute describes the actual actions or operations. Those actions that would result in an idempotent operation are denoted by the selected attribute. In addition, each action is classified by an action-specific attribute to allow CSS to style these actions, for example, by adding action-specific icons. The list of possible actions is computed on the server by using the Operations Feed. This feed is extensible, and therefore new operations can be added over time.

portlet-window-body
This value of the `class` attribute denotes the body of the portlet.

iw-iWidget
This value of the `class` attribute identifies the beginning of the

microformat for placing an iWidget instance on a static page. Additional information about the iWidget microformat for including iWidgets into a broader set of markup, such as a portal page, provided by the iWidget specification and on the topic about Including iWidgets in a static page.

selected
This value of the `class` attribute identifies a selected item, either the portlet itself or an action. If it appears on the `<div>` tag for the portlet window, this means that the portlet was the target of the interaction that produced the page.

portal-drag-source
This value is an optional class on the portlet window. It denotes that this portlet window can be dragged around on the screen by users. This attribute is valid only if the portlet window is part of a modifiable portlet container, and if the user has the rights to modify the page and the container is not locked. Refer to the Container Microformat to see how a drop target is represented and how the actual drag and drop operation can be done.

Note: A drag and drop action is triggered from the client side, but is run on the server.

xoxo This attribute denotes that the following is a list of items.

Example of rendering a component from HTML

The following is an example of a microformat representation for a portlet window on a page:

```
<div class='portlet-window' id='7_CGAH47L00OGRB02DA9LR6H1024' name='window2' >
   <ul class='xoxo portlet-info' >
      <li class='portlet-title' lang='en'>
         PetStorePortlet
      </li>
      <li class='portlet-actions' >
         Actions
         <ul class='xoxo portlet-action' >
            <li class='portletoperation-view selected' >
               <a href='?uri=wp.operations:onPortletModeView
                  (7_CGAH47L00OGRB02DA9LR6H1024)'
                  rel='view' >Back</a>
            </li>
            <li class='portletoperation-normal selected' >
               <a href='?uri=wp.operations:onWindowStateNormal
                  (7_CGAH47L00OGRB02DA9LR6H1024)'
                  rel='normal' >Restore</a>
            </li>
            <li class='portletoperation-minimized' >
               <a href='?uri=wp.operations:onWindowStateMinimized
                  (7_CGAH47L00OGRB02DA9LR6H1024)'
                  rel='minimized' >Minimize</a>
            </li>
            <li class='portletoperation-maximized' >
               <a href='?uri=wp.operations:onWindowStateMaximized
                  (7_CGAH47L00OGRB02DA9LR6H1024)'
                  rel='maximized' >Maximize</a>
            </li>
            <li class='portletoperation-delete_portlet' >
               <form method='POST' action='?uri=wp.operations:onDeletePortlet
                     (7_CGAH47L00OGRB02DA9LR6H1024)'
                     rel='delete_portlet' >Delete</form>
            </li>
         </ul>
```

```
      </li>
   </ul>
   <div class='portlet-window-body' >
   </div>
</div>
```

Navigation options for static pages:

You can provide navigation for your static pages by using either the portal theme or by making use of the navigation microformat.

Portal theme to provide navigation

To provide navigation for static pages by using the portal theme, remove the `<html>` and `<head>` tags from your static page content. If you do that, the portal renders the content as navigation.

Navigation microformat to provide navigation

If you have full static HTML pages with beginning and ending `<html>` tags in your portal, you might want to include links to other pages in the portal. In this case you write your HTML code so that it includes a navigation portlet in the page and makes use of the navigation microformat. Refer to the following list of class attributes and the example of the microformat navigation option.

first This attribute denotes the first child in a list. This is required for CSS styling.

last This attribute denotes the last child in a list. This is required for CSS styling.

expanded
This attribute denotes an expanded node. A node can only be expanded if it has children and its navigational state is set to **expanded**.

collapsed
This attribute denotes a collapsed node. A node can only be collapsed if it has children and its navigational state is set to **collapsed**.

page-actions
This attribute lists the actions that are available on the page. Typically, this list contains the actions used to expand or collapse the navigation nodes. For a page that is currently selected in the navigation, this list also contains the actions that are available for that page.

selected
This attribute denotes the page that is currently selected in the navigation.

pageoperation-expand
This attribute expands a collapsed node.

pageoperation-collapse
This attribute collapses an expanded node.

Example of the microformat navigation option

The following is an example of a microformat representation for a navigation for a page:

```
<div class="xoxo portal-navigation">
  <ul>
    <li class="first expanded">
      <a href='/wps/myportal/!ut/p/c5/ . . . . . '>Home</a>
```

```
  <ul>
    <li class="first">
      <a href='/wps/myportal/!ut/p/c5/ . . . . . /'>Web 2.0 Introduction</a>
    </li>
    <li>
      <a href='/wps/myportal/!ut/p/c5/e/'>Web 2.0 Portlets</a>
    </li>
    <li class="collapsed">
      <ul class="xoxo page-actions">
        <li class="pageoperation-expand">
          <a href='/wps/myportal/!ut/p/c5/e/'>Expand</a>
        </li>
      </ul>
      <a href='/wps/myportal/!ut/p/c5/ . . . . . /'>Static Page Aggregation</a>
    </li>
    <li>
      <a href='/wps/myportal/!ut/p/c5/ . . . . . /'>Navigation Page</a>
    </li>
    <li>
      <a href='/wps/myportal/!ut/p/c5/ . . . . . /'>Nav1</a>
    </li>
    <li>
      <a href='/wps/myportal/!ut/p/c5/ . . . . . /'>IBM</a>
    </li>
    <li>
      <a href='/wps/myportal/!ut/p/c5/ . . . . . /'>dnd</a>
    </li>
    <li>
      <a href='/wps/myportal/!ut/p/c5/ . . . . . /'>derivable</a>
    </li>
    <li>
      <a href='/wps/myportal/!ut/p/c5/ . . . . . /'>deriv1</a>
    </li>
    <li class="selected last">
      <a href='/wps/myportal/!ut/p/c5/ . . . . . /'>Container Test</a>
    </li>
  </ul>
</li>
<li class="collapsed">
  <ul class="xoxo page-actions">

    </li>
  </ul>
</div>
```

Inline navigation

The inline navigation feature can be enabled by setting the page metadata **spa.ex.anchor.enabled** to `true`. The default is `false`. With this feature, the markup of the static page can contain `<a>` links that point to different portal pages that use relative URLs. The **href** attribute is rewritten at rendering time and replaced by the portal URL that points to this page. The relative URLs in the source markup use the friendly path of the current page as the base URL. The relative reference is applied to this base URL and the resulting friendly path is used to address the target page. This feature works only if both the current page and the targeted page have a friendly path.

For example, if the current page has the friendly path `/home/mypage` and contains the following markup; `<a href="child">child_page</a>`, then this markup is rewritten to a portal URL that points to the page with the friendly name `/home/mypage/child`.

Notes:

- If the **href** attribute of an anchor link contains an absolute URL, no rewriting occurs and the link continues to point to the absolute URL.
- If the **href** attribute of an anchor link contains a URL that starts with `/`, then the rewriting logic resolves the URL as a friendly path. If no page for this path exists, the system assumes a link to another application on the same server and leaves the value of the **href** attribute untouched.
- If the **href** attribute of an anchor link starts with `?`, then the remainder is considered query parameters and no rewriting occurs.

Related tasks:

"Using friendly URLs" on page 1280
You can associate friendly URLs with portal pages and labels. You and your users can use these friendly URLs to access specific portal pages or labels by using a human readable path, which is easy to remember.

Portlets for adding dynamic elements to static pages:

If you want to add dynamic elements such as portal navigation to your static pages, you can use portlets that the portal provides.

WebSphere Portal Express provides the following portlets for static pages. These portlets are included in a default portal installation. You can address them by using their unique names.

Navigation portlet
: The Navigation portlet adds portal navigation to a page. When writing a static portal page you can configure the starting point of the navigation and the number of navigation levels by using the initialization parameters.

Breadcrumb Trail portlet
: The Breadcrumb Trail portlet adds the path from the content root down to the currently selected static page.

Page List portlet
: The Page List portlet adds an arbitrary list of links to pages to a static page.

For more details about these portlets and how you can use them refer to the following topics.

"The Navigation portlet"
The Navigation portlet allows you to add dynamic portal navigation to a static page. When writing a static portal page you can configure the starting point of the navigation and the number of navigation levels by using the initialization parameters.

"The Breadcrumb Trail portlet" on page 1868
The Breadcrumb Trail portlet allows you to add the navigation path to your static pages. The breadcrumb trail starts at the content root and goes down to the currently selected static page.

"The SPA Resource Addressability portlet" on page 1869
The SPA Resource Addressability portlet allows you to add a dynamically computed list of links to portal resources to a static page. This list is produced dynamically via a POCURI (Piece Of Content URI).

The Navigation portlet:

The Navigation portlet allows you to add dynamic portal navigation to a static page. When writing a static portal page you can configure the starting point of the navigation and the number of navigation levels by using the initialization parameters.

Unique name

You can address the Navigation Portlet by its unique name: `wps.p.SpaNavigation` .

Usage

You can embed the navigation portlet into a static page by using the semantic tag `portlet-window` described in the topic about class attributes for portlets on static pages. When rendering the page, the server replaces the semantic tag with the portlet microformat, and the portlet renders the navigation by using the navigation microformat. The portlet accepts the following configuration parameters that you can embed by coding a definition list (`<dl>`) in the static page:

root This identifies the node where the navigation starts that the portlet renders. This parameter accepts a path-like expression that is relative to the current selection. Path segments can include the OID or unique name of a node. The period character (**.**) or the double period (**..**) have the same meaning as in relative URLs. If you omit this parameter, the navigation starts at the current node.

levels The number of child levels that start at the node that is identified by the `root` parameter. A value of `-1` means all levels. This is also the default if you omit this parameter.

Example

The following example produces a single level navigation of the siblings of the current page:

```
<div class="portlet-window" name="main-navigation"
     style="portlet-definition:wps.p.SpaNavigation">
     <dl>
     <dt>root</dt>
     <dd>..</dd>
     <dt>levels</dt>
     <dd>1</dd>
     </dl>
</div>
```

The following example shows the quick link navigation:

```
<div class="portlet-window" name="quick-navigation"
     style="portlet-definition:wps.p.SpaNavigation">
     <dl>
     <dt>root</dt>
     <dd>ibm.portal.Quick Links</dd>
     </dl>
</div>
```

Related reference:

"Class attributes for portlets on static pages" on page 1857
When you place a portlet on a static HTML page to be rendered by the portal, use a suitable CSS file to format the portlet. The CSS file makes use of the portlet microformat. You can make use of this microformat if you want to render portlets on your static HTML page with a skin of your choice. When you write the static page, you can use CSS or JavaScript techniques to convert the microformat into a friendly user interface. The portlet references in the static HTML page are replaced by the content of the portlet and the portlet microformat.

The Breadcrumb Trail portlet:

The Breadcrumb Trail portlet allows you to add the navigation path to your static pages. The breadcrumb trail starts at the content root and goes down to the currently selected static page.

Unique name

You can address the Breadcrumb Trail portlet by its unique name: `wps.p.SpaBreadCrumbTrail` .

Usage

You can embed the Breadcrumb Trail portlet into a static page by using the semantic tag `portlet-window` described in the topic about class attributes for portlets on static pages. When rendering the page, the server replaces the tag with the portlet microformat, and the portlet renders the breadcrumb trail by using the navigation microformat.

Example

The following example produces a breadcrumb trail navigation for the current page:

```
<div class="portlet-window" name="breadcrumb"
     style="portlet-definition:wps.p.SpaBreadCrumbTrail">
</div>
```

When you place a portlet on a static HTML page to be rendered by the portal, use a suitable CSS file to format the portlet. The CSS file makes use of the portlet microformat. You can make use of this microformat if you want to render portlets on your static HTML page with a skin of your choice. When you write the static page, you can use CSS or JavaScript techniques to convert the microformat into a friendly user interface. The portlet references in the static HTML page are replaced by the content of the portlet and the portlet microformat.

The SPA Resource Addressability portlet:

The SPA Resource Addressability portlet allows you to add a dynamically computed list of links to portal resources to a static page. This list is produced dynamically via a POCURI (Piece Of Content URI).

Unique name

You can address the SPA Resource Addressability portlet by its unique name: `wps.p.SpaResourceList` .

Usage

You can embed the SPA Resource Addressability portlet into a static page by using the semantic tag `portlet-window` described in the topic about class attributes for portlets on static pages. When rendering the page, the server replaces the tag with the portlet microformat, and the portlet renders the list of page links by using the navigation microformat. The portlet accepts the following configuration parameters that you can embed by coding a definition list (`<dl>`) in the static page:

uri This is the POCURI to an ATOM feed. The list of resource links is the list of alternate links in this ATOM feed.

<any parameters>
All other parameters are taken as parameters for the POC (Piece Of Content) DataSource that produces the ATOM feed.

Static resources

In addition to the HTML file that describes the page, static pages can contain resources such as images, scripts, and styles. Learn about the static resources that are available when you are using static pages.

Linked resources

If the static page contains the `<html>` tag, a full page is represented. The `<head>` element of the page might contain `<link>` tags that point to static resources such as CSS style sheets and `<script>` tags that point to script resources. To efficiently point to resources embedded in the static page, enable the rewriting feature for these tags by modifying the following page metadata:

- Set **`spa.ex.link.enabled`** to `true`. The default is `false`.
- Set **`spa.ex.script.enabled`** to `true`. The default is `false`.

If the previous metadata is set to `true`, the `href` and `src` attributes are rewritten in the following ways:

- If the attribute contains an absolute URL, the URL is rewritten to point to the Ajax proxy server.

- If the attribute contains a relative URL, the URL is rewritten to point to an access point that serves the resource out of the static page container for the page.

In the following example, assume that the page contains the following resources:

- `index.html`
- `images/logo.gif`
- `css/styles.css`
- `script/script.js`

The following source code would enable the use of these resources:

```
<html>
<head>
 <link rel="shortcut icon" href="images/logo.gif">
 <link rel="stylesheet" href="css/style.css">
 <script src="script/script.js"></script>
</head>

...
</html>
```

The rewriting of the link occurs at rendering time. Therefore, the resulting URLs that point to the static resources provide an efficient way to serve them.

Images

To efficiently reference images from the static HTML source, enable the rewriting feature for image tags by modifying the following page metadata:

- Set **`spa.ex.image.enabled`** to `true`. The default is `false`.

If the previous metadata is set to `true`, the `src` attribute for `<img>` tags is rewritten in the following ways:

- If the attribute contains an absolute URL, the URL is rewritten to point to the Ajax proxy server.
- If the attribute contains a relative URL, the URL is rewritten to point to an access point that serves the resource out of the static page container for the page.

Resource sharing

Often, multiple static pages belong together in the form of an application. If so, multiple resources can be shared across the application. The mechanism that is used to rewrite resources searches across the parent page hierarchy, beginning with the current page. If a resource, for example, an image, cannot be found on one level, the fallback mechanism searches the next level. This mechanism enables the sharing of resources in a parent page that can be reused by child pages.

Note: Child pages do not have to have a special syntax to enable this sharing mechanism. The child pages contain a relative URL as if the resource were contained in the page itself.

Dynamic page metadata

HTML defines some elements that refer to information that is managed as page metadata on portal pages. You can use the dynamic page metadata rewriting feature to place this information into the static HTML code automatically.

The dynamic page metadata rewriting feature affects the HTML tags <base>, <title>, and <meta>. Enable the rewriting for each of these tags by modifying the following page metadata:

- Set **spa.ex.base.enabled** to true. The default is false.
- Set **spa.ex.title.enabled** to true. The default is false.
- Set **spa.ex.meta.enabled** to true. The default is false.

If you enable the previous settings, the following rewrites occur:

spa.ex.base.enabled
The href attribute of the <base> tag is replaced by the base URL to the current page.

spa.ex.title.enabled
The text value of the <title> tag is replaced by the page title that is using the currently requested location.

spa.ex.meta.enabled
If the <meta> tag contains an http-equiv attribute, the content attribute specifies the requested HTTP response header.

If the <meta> tag contains a name attribute, the rewriting depends on the value of the attribute. Depending upon the value of the name attribute, the content attribute is replaced by one of the following options:

description
The description of the portal page in the currently requested location.

csrf_param
The name of the **FORM** parameter for CSRF protection.

csrf_token
The CSRF token for the current request.

generator
The name or version of the IBM portal server that is hosting the page.

Including static content pages in your portal

You can create a new portal page by starting with a static HTML file or an HTML fragment. If you revise the HTML, you can refresh the page to render the changes in the portal. To include, update, and administer your static content pages, you can use any of the portal administration tools, Manage Pages portlet, XML configuration interface, or the Portal Scripting Interface.

About this task

After you have included a page in the portal, you cannot change the page from static content to standard portal layout or from standard portal layout to static content. If you want to change the page type after you have created it, you need to delete the existing page and create a new page of the required type.

When you use the Manage Pages and Page Properties portlets to create your static page in the portal, you select **Static Content** for the **Type of Page**. Then select and complete the other options accordingly. For more details refer to the portlet help.

To update a static page, you make the required changes in the HTML file, then you replace the portal page with the updated page by using the Manage Pages and Properties portlets or other portal administration tools. You can use the portal Page

Customizer to update static page layout if the static page contains portlet containers defined by the portlet container microformat.

"Exporting and importing static pages"
You can work with static portal pages by using the portal XML configuration interface. Learn about the tasks that you can perform and the XML elements for working with static pages.

"Scripting for static pages" on page 1875
You can work with static portal pages by using the Portal Scripting Interface, which enables you to use administration function through the Jacl scripting language. Get familiar with the scripting commands for working with static pages.

Exporting and importing static pages:

You can work with static portal pages by using the portal XML configuration interface. Learn about the tasks that you can perform and the XML elements for working with static pages.

Exporting a static content page

Exporting a static page by using the XML configuration interface works like exporting any other portal page. For details about how to do this refer to the topics about the XML configuration interface.

Importing a static content page

You can import a static content page into your portal by using one of the following three methods:

- Specify the static content page in binary content format
- Have the static content page in a archive or compressed file, and reference that file from the XML import script
- Create the content page from a layout template that is installed in the portal.

"Importing a static page in binary format" on page 1873
You can import a static content page in binary encoded content format by using the XML configuration interface.

"Importing a static page from an archive or compressed file" on page 1874
You can import a static content page from an archive or compressed file by using the XML configuration interface.

"Importing a static page from an installed template" on page 1874
You can import a static content page from an installed layout template by using the XML configuration interface.

Related tasks:

"Exporting pages or page hierarchies by using the Manage Pages portlet" on page 1063
You can do an XML export of a page or an entire page hierarchy by using the Manage Pages portlet.

"Importing pages or page hierarchies by using the XML Import portlet" on page 1063
You can import an XML configuration file by using the XML Import portlet.

Related reference:

"Importing static page content from archive or compressed files" on page 1107
You can import the content of static pages from an external archive or compressed file by using the XML configuration interface.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Importing a static page in binary format:

You can import a static content page in binary encoded content format by using the XML configuration interface.

You can adapt the following example and use it to import a static page. This example shows the following additional possibilities:

- It assumes that the portlet is already installed. Therefore it uses only the `locate` action for the Web module, and not the `update` action.
- It shows how you can specify the content of static page in binary format. To obtain the binary format content, export the page by using the XML configuration interface.
- You can export the result to generate a template for your XML scripts.

Sample file CreateStaticPage.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" update="true"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd" create-oids="true">
   <portal action="locate">
        <web-app action="locate" uid="ilwwcm-localrenderingportlet-jsr.war.webmod">
           <portlet-app action="locate" uid="ilwwcm-localrenderingportlet-jsr.war">
                <portlet action="locate" objectid="theExamplePortlet" name="Web Content Viewer (JSR 286)">
                </portlet>
            </portlet-app>
        </web-app>

        <content-node action="locate" objectid="parentPage" uniquename="ibm.portal.Home"/>
        <content-node action="update" active="true" allportletsallowed="true" content-parentref="parentPage"
                      create-type="explicit" domain="rel" ordinal="last" type="staticpage"
                      uniquename="ibm.portal.ssa.SamplePage.2">
            <localedata locale="en" prefix="page.sample">
               <title>Sample Page 1</title>
            </localedata>

            <pagecontents markup="html" display-option="inline">

    </portal>
</request>
```

Importing a static page from an archive or compressed file:

You can import a static content page from an archive or compressed file by using the XML configuration interface.

You can adapt the following example and use it to import a static page. This example shows the following additional possibilities:

- It assumes that the portlet is already installed. Therefore it uses only the `locate` action for the Web module, and not the `update` action.
- It shows how you can specify the content of static page from a compressed file of file type `.zip` .

Sample file CreatePageFromZip.xml

```
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" type="update"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd" create-oids="true">
    <portal action="locate">
        <web-app action="locate" uid="ilwwcm-localrenderingportlet-jsr.war.webmod">
           <portlet-app action="locate" uid="ilwwcm-localrenderingportlet-jsr.war">
                <portlet action="locate" objectid="theExamplePortlet" name="Web Content Viewer (JSR 286)">
                </portlet>
            </portlet-app>
        </web-app>

        <content-node action="locate" objectid="parentPage" uniquename="ibm.portal.Home"/>
        <content-node action="update" active="true" allportletsallowed="true" content-parentref="parentPage"
                      create-type="explicit" domain="rel" ordinal="last" type="staticpage"
                      uniquename="ibm.portal.ssa.SamplePage.2">
            <localedata locale="en" prefix="page.sample">
               <title>Sample Static Page 1</title>
            </localedata>

            <pagecontents markup="html" display-option="inline">
                <url>file:///$server_root$/base/wp.xml/doc/xml-samples/index1.zip</url>
            </pagecontents>

            <parameter name="com.ibm.portal.bookmarkable" type="string"
                       update="set"><![CDATA[Yes]]&gt;</parameter>
            <parameter name="com.ibm.portal.friendly.name" type="string"
                       update="set"><![CDATA[staticpage2]]&gt;</parameter>
            <parameter name="com.ibm.portal.static.page.file.name.html"
                       type="string" update="set"><![CDATA[index1.html]]&gt;</parameter>
            <access-control externalized="false" owner="uid=wpsadmin,o=defaultwimfilebasedrealm" private="false"/>
            <component action="update" active="true" domain="rel" ordinal="100" orientation="V" type="container">
                <component action="update" active="true" domain="rel" ordinal="100" orientation="V" type="container"/>
                <component action="update" active="true" domain="rel" ordinal="100" orientation="H" type="container">
                    <parameter name="com.ibm.portal.layoutnode.localname" type="string"
                               update="set"><![CDATA[portletContainer1]]&gt;</parameter>
                    <component action="update" active="true" domain="rel" ordinal="100" type="control">
                        <parameter name="com.ibm.portal.layoutnode.localname" type="string"
                                   update="set"><![CDATA[portletWindow1]]&gt;</parameter>
                        <portletinstance action="update" domain="rel" portletref="theExamplePortlet" />
                    </component>
                </component>
            </component>
        </content-node>
    </portal>
</request>
```

Importing a static page from an installed template:

You can import a static content page from an installed layout template by using the XML configuration interface.

You can adapt the following example and use it to import a static page. It assumes that the portlet is already installed. Therefore it uses only the `locate` action for the Web module, and not the `update` action. For more information about layout templates refer to the topic about Theme layout templates.

Sample file CreatePageFromTemplate.xml

```
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" type="update"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd" create-oids="true">
    <portal action="locate">
        <web-app action="locate" uid="ilwwcm-localrenderingportlet-jsr.war.webmod">
           <portlet-app action="locate" uid="ilwwcm-localrenderingportlet-jsr.war">
                <portlet action="locate" objectid="theExamplePortlet" name="Web Content Viewer (JSR 286)">
                </portlet>
            </portlet-app>
        </web-app>

        <content-node action="locate" objectid="parentPage" uniquename="ibm.portal.Home"/>
        <content-node action="update" active="true" allportletsallowed="true" content-parentref="parentPage"
                      create-type="explicit" domain="rel" ordinal="last" type="staticpage"
                      uniquename="ibm.portal.ssa.SamplePage.2">
            <localedata locale="en" prefix="page.sample">
                <title>Sample Static Page 1</title>
            </localedata>

     <pagecontents markup="html" display-option="inline"/>

            <parameter name="com.ibm.portal.bookmarkable" type="string"
                       update="set"><![CDATA[Yes]]&gt;</parameter>
            <parameter name="com.ibm.portal.friendly.name" type="string"
                       update="set"><![CDATA[staticpage2]]&gt;</parameter>
            <parameter name="com.ibm.portal.layout.template.ref" type="string"
                       update="set"><![CDATA[dav:fs-type1/layout-templates/2ColumnEqual]]&gt;</parameter>
     <access-control externalized="false" owner="uid=wpsadmin,o=defaultwimfilebasedrealm" private="false"/>
            <component action="update" active="true" domain="rel" ordinal="100" orientation="V" type="container">
                <component action="update" active="true" domain="rel" ordinal="100" orientation="V" type="container"/>
                <component action="update" active="true" domain="rel" ordinal="100" orientation="H" type="container">
                    <parameter name="com.ibm.portal.layoutnode.localname" type="string"
                               update="set"><![CDATA[portletContainer1]]&gt;</parameter>
                    <component action="update" active="true" domain="rel" ordinal="100" type="control">
                        <parameter name="com.ibm.portal.layoutnode.localname" type="string"
                                   update="set"><![CDATA[portletWindow1]]&gt;</parameter>
                        <portletinstance action="update" domain="rel" portletref="theExamplePortlet" />
                    </component>
                </component>
            </component>
        </content-node>
    </portal>
</request>
```

"Understanding the Portal Version 8.5 modularized theme" on page 2521
Modern websites and browsers enable incredible new capabilities that can greatly enhance your user's web experiences. However, these capabilities are not without cost in terms of large page sizes and more processing in the browser when each page is rendered. These capabilities are worth it when you need them, but removing them for an entire site or including them only on pages that take advantage of these capabilities provides for more flexibility.

Scripting for static pages:

You can work with static portal pages by using the Portal Scripting Interface, which enables you to use administration function through the Jacl scripting language. Get familiar with the scripting commands for working with static pages.

Including a static page in the portal

To include a static page in the portal, use the following command:

`$Content create staticpage title markup compressedfilename filename [displayoption] [select]`

Example: `$Content create staticpage MyStaticPageTitle html c:/tmp/StaticContentPage.zip index.html inline select`

This creates a static page underneath the currently selected content node for the html markup with the page title MyStaticPageTitle. The content of the page is read from the file `c:/tmp/StaticContentPage.zip`, and the entry point for the page display is read from the file `index.html`, which needs to be contained in the compressed file. To specify the display method, you can use the optional parameter `displayoption`. It takes one of the values `inline`, `iframe`, or `ajax`. The default value is `inline`. To make the newly created static page the currently selected content node, use the optional parameter `select`

Getting the static page content as a compressed file

To get a static page content in the format of a compressed file, use the following command:

`$Content pageget oid markup compressedfilename`

Example: `$Content pageget 6_CGAH47L00G2N802TJFV58Q3000 html c:/tmp/MyStaticContentPage.zip`

This writes the content of the specified static page to the compressed file `c:/tmp/MyStaticContentPage.zip`.

Setting the static page content by specifying a compressed filename

To set the static page content by specifying a compressed filename, use the following command:

`$Content pageset oid markup compressedfilename filename`

Example: `$Content pageset 6_CGAH47L00G2N802TJFV58Q3000 html c:/tmp/NewStaticContentPage.zip index.html`

This updates the specified static page content with the content of the compressed file `c:/tmp/NewStaticContentPage.zip`. The entry point for the page display is read from the file `index.html`. This file needs to be contained in the compressed file.

Getting attributes of a static page

To get attributes of a static page, use the following command:

`$Content get oid attribute markup`

Valid attributes are as follows:

filename
Use this attribute for getting the file name of the static page layout file in the compressed file.

displayoption
Use this attribute for the markup, for example HTML.

Example: `$Content get 6_CGAH47L00G2N802TJFV58Q3000 filename html`

This returns the filename of the entry point for the page display, that is `index.html` for the specified markup.

Setting attributes of a static page

To set attributes for a static page, use the following command:

`$Content set` *`oid attribute value markup`*

Valid attributes are as follows:

- `filename`. Use this attribute for getting the file name of the static page layout file in the compressed file.
- `displayoption`. Use this attribute for the markup, for example HTML.

Example 1: `$Content set 6_CGAH47L00G2N802TJFV58Q3000 filename anotherindex.html html`

This sets the entry point for the page display to `anotherindex.html` for the specified markup.

Example 2: `$Content set 6_CGAH47L00G2N802TJFV58Q3000 displayoption iframe html`

This sets the display option to `iframe` for the specified markup. Valid display option settings are `inline`, `iframe`, and `ajax`.

Deleting a static page

The command for deleting a static page is the same as for deleting a standard portal page. You can use the command: `$Content delete` *`oid`*

To delete a static page, use the following command:

Example: `$Content delete 6_CGAH47L00G2N802TJFV58Q3000`

Using WebDAV to manage pages and static content

WebDAV for IBM WebSphere Portal Express provides a simple and easy way to administer portal resources. Both administrators and users can use it.

About this task

WebDAV for WebSphere Portal Express allows users to administer portal pages and content of static pages of a portal by using standard operating system tools. This way client side administrators and users can browse, read, and write these resources by using file explorers or editors.

Portal pages are represented as folders. They can contain subfolders that represent child pages. Static pages are a special case: the content of a static page is located in a separate folder named `staticcontent` under the main folder of that page.

Users can work in the folders as usual, for example by performing drag-and-drop operations. The folders also hold property files that contain metadata for portal resources, such as the title and description. Users can edit the property files to update portal resources. When the user saves the updated file, the updates are transferred and applied to the portal directly.

Note: All the files shown in WebDAV are virtual files created from the page data in the portal database

You can use WebDAV to perform the following tasks:

- Browse through the page hierarchy. Each portal page is represented as a folder. The name of the folder is the unique name or the object ID of the page. Children pages in the topology are represented as subfolders.
- Change globalization information of pages. To do this, users edit and save properties files that contain the globalization information.
- Change metadata of pages. To do this, users edit and save properties files that contain the metadata information.
- Delete pages.
- For static pages only, you can browse, read, create, update, save, copy, move, and delete static content, such as HTML or image files. Users can access the content of static pages via the subfolder `staticcontent` of the page.

You cannot use WebDAV to perform any of the following tasks:

- Create new pages.
- Update portal content.
- Modify the unique name or `objectID` of pages.
- Move or copy pages.

WebSphere Portal Express contains the WebDAV service and enablement layer. Before using WebDAV for WebSphere Portal Express, users must set up their WebDAV client.

After setting up the WebDAV client, they can connect to WebDAV for WebSphere Portal Express and work with portal pages and content. To connect to WebDAV for WebSphere Portal Express, they enter the WebDAV entry URL.

Security: The WebDAV entry point requires user authentication via HTTP basic authentication. SSL access is not supported at this time. To use WebDAV, users log in to the portal with their portal user ID. Users can then access and work with portal pages according to their access permissions as set by Portal Access Control.

The WebDAV entry URL is as follows:

- For default portal installations:

  `http://`*`server_name`*`:`*`port_number`*`/wps/mycontenthandler/dav/contentmodel/wps.content.root/`
- For virtual portals:
  - If a host name was specified when the virtual portal was created, the WebDAV URL looks like this:

    `http://`*`virtual_portal_host_name`*`:`*`port_number`*`/wps/mycontenthandler/dav/contentmodel/wps.content.root/`
  - If the virtual portal was created with a URL context only and no host name was specified, the WebDAV URL looks like this:

`http://`*`server_name`*`:`*`port_number`*`/wps/mycontenthandler/`*`URL_context_of_the_virtual_portal`*`/!ut/p/dav/contentmodel/wps.content.root/`

For details about virtual portals and how to create them by host name or URL context refer to the topic about Multiple virtual portals and its subtopics.

"Connecting to WebDAV to work with portal pages and static content"
To connect to WebDav to work with portal pages and static content, you enter the WebDAV entry URL.

Connecting to WebDAV to work with portal pages and static content:

To connect to WebDav to work with portal pages and static content, you enter the WebDAV entry URL.

About this task

The WebDAV entry URL is as follows:

- For default portal installations:

  http://*server*:*port*/wps/mycontenthandler/dav/contentmodel/*page_unique_name*/

  or

  http://*server*:*port*/wps/mycontenthandler/dav/contentmodel/*page_object_id*/
- For virtual portals:
  - If a host name was specified when the virtual portal was created, the WebDAV URL is as follows:

    http://*virtual_portal_host_name*:*port*/wps/mycontenthandler/dav/contentmodel/*page_unique_name*/

    or

    http://*virtual_portal_host_name*:*port*/wps/mycontenthandler/dav/contentmodel/*page_object_id*/
  - If the virtual portal was created with a URL context only and no host name was specified, the WebDAV URL is as follows:

    http://*server*:*port*/wps/mycontenthandler/*URL_context_of_the_virtual_portal*/!ut/p/dav/contentmodel/*page_unique_name*/

    or

    http://*server*:*port*/wps/mycontenthandler/*URL_context_of_the_virtual_portal*/!ut/p/dav/contentmodel/*page_object_id*/

Where:

server Host name of the portal server.

port Port number of WebSphere Portal Express.

URL_context_of_the_virtual_portal
URL context of the target virtual portal, if the virtual portal URL context is configured to be encoded into the URL.

virtual_portal_host_name
Host name of the target virtual portal, if the virtual portal host name is configured to be encoded into the URL.

page_unique_name
Unique name for the portal page.

page_object_id
`objectID` for the portal page as it appears in the Manage Pages portlet.

Examples of entry URLs to all portal pages are as follows:

```
http://www.my_company.com:10039/wps/mycontenthandler/dav/contentmodel/wps.content.root/
```

For virtual portals examples of entry URLs to all portal pages are as follows:

- For a virtual portal created with the host name `vp.mycompany.com`:
  `http://vp.mycompany.com:10039/wps/mycontenthandler/dav/contentmodel/wps.content.root/`
- For a virtual portal created with the URL context `vp1` and without a host name:
  `http://localhost:10039/wps/mycontenthandler/vp1/!ut/p/dav/contentmodel/wps.content.root/`

For details about virtual portals and how to create them by host name or URL context refer to the topic about Multiple virtual portals and its subtopics.

View information on how you can scope your WebSphere Portal Express to have multiple virtual portals.

Dynamic content

Dynamic content is generated when a page is rendered and is based on a set of predefined criteria such as the current user, the metadata of the current page. It allows you to deliver content specifically customized for the current user, or to deliver content customized for a campaign or product in your organization.

Dynamic web content

Web content can be generated at render-time using dynamic element types:

Menus
: A menu displays metadata and content from content items that match the search criteria of the menu element. The search criteria of a menu can include matching site areas, authoring templates, categories, and keywords.

Personalization element
: A personalization element stores a reference to a personalization rule or content spot generated by Portal Personalization. To use a personalization element you must create a personalization component.

User name element
: This element will display different content for authenticated or anonymous users.

Targeted content and Portal Personalization

Personalization can recognize a specific user based on a profile or can determine characteristics of a user based on previous purchases, products or pages viewed, and so forth. Personalization then selects content that is appropriate for that profile. If a person has a high salary range, Personalization can be configured to retrieve information about a commercial website premium product. If an individual belongs to a particular geographic region, content specific to that region may be targeted to the individual. The page is assembled with the proper personalized information, and the user sees her personalized page.

Targeted content provides you with a way to deliver multiple pieces of content to different audiences. Targeted content matches the best content with the most appropriate group by using segments. Segments help you split your audience into meaningful groups with different interests or characteristics.

A targeted spot displays different content to different segments. You can create a target spot by defining content that is targeted to specific segments:

- Add content items to your content spot in a web content viewer.

- Add segments to each content item to display your content to the correct audience. Segments help you define your target audience. For example, you can define the audience by users, device class, or other attributes.

Content as a Service pages

Starting with version 8.5 CF05, IBM WebSphere Portal Express introduces the concept of Content as a Service pages. The Content as a Service pages can be used to render content that is managed by your IBM Web Content Manager in different data formats.

Individual representations of your web content can be generated by using the corresponding IBM Web Content Manager presentation components. Instead of generating HTML, the IBM Web Content Manager presentation components can be used to generate representations of your web content in formats of your choice for example, JSON, or XML. Content as a Service pages allow the content that is centrally authored and maintained on your website, to be accessed by the other data clients in raw data formats. Those data clients can generate their own client-specific visualization of the data. This approach of generating data is especially useful in mobile application that might want to present the content consistent with the other parts of the application.

CF05 "Technical concepts"
Before you use the Content as a Service pages in IBM WebSphere Portal Express, familiarize yourself with its building blocks.

CF05 "Select data format based on MIME type" on page 1882
With Content as a Service pages, you can specify different representation of your web content for different MIME types. This way when you request Content as a Service pages, you can specify the preferred representation of your web content. There are different options to manage the presentation components that produce the output for the MIME types you like to support.

CF05 "Setting up Content as a Service" on page 1884
To be able to work with Content as a Service pages in WebSphere Portal Express, you must enable it by using an IBM WebSphere Portal Express configuration task.

CF05 "Removing Content as a Service" on page 1884
To remove Content as a Service feature in WebSphere Portal Express, you must disable it by using an IBM WebSphere Portal Express configuration task.

CF05 "Access Content as a Service" on page 1885
To access your Content as a Service pages, you can write links to your content that specifies the CaaS page as target.

Technical concepts

Before you use the Content as a Service pages in IBM WebSphere Portal Express, familiarize yourself with its building blocks.

CaaS page

The CaaS page is the default Content as a Service page with the unique name `ibm.portal.caas.page`.

The CaaS page can be created by running the `install-caas-vp` task. The page uses the CaaS theme and a single Web Content Viewer portlet instance to generate the individual data representations for your content. The page can be addressed through its unique name or through the friendly name *caas*.

Important: Portal pages and web content libraries are virtual portal scoped resources. To use Content as a Service with content from a virtual portal, you must install the CaaS page to the virtual portal first.

CaaS theme
This theme with the unique name `wp.theme.caas` is referenced by the CaaS page. The theme ensures that no portal page aggregation-related markup gets added to the data representation strings generated by your Content as a Service presentation component.

Select data format based on MIME type

With Content as a Service pages, you can specify different representation of your web content for different MIME types. This way when you request Content as a Service pages, you can specify the preferred representation of your web content. There are different options to manage the presentation components that produce the output for the MIME types you like to support.

How to use well-defined element names in your content

The portal supports selecting different presentation components for the Content as a Service pages based on the requested MIME type. Depending on the MIME type parameter, different presentation components can be specified for generating the data format. For more information about the MIME type parameter, go to the section *Writing links to web content*.

You can use this MIME type-specific presentation component selection by adding component reference elements with well-defined names such as `ibm.design.json`, `ibm.design.xml`, and `ibm.design.html` to your content items. You can define the value for the component reference elements in your Authoring template that you use for creating your content items.

For example, specifying the parameter **`mime-type=application/json`** specifies the content element with the name `ibm.design.json` as the presentation component for representing your web content.

Important: If you choose this approach, there are implications that are related to how you manage your content. The presentation component elements are part of your content. Adding, removing, or updating one of these well-defined elements requires you to update all related content items individually. Restoring previous versions of content items can require you to update the presentation component again.

How to use presentation templates with the `pagedesign` query parameter

As an alternative to managing the well-defined elements in your content, you can also use alternate presentation templates based on the requested MIME type. If the portal does not find a content element for the requested MIME type, it renders the content using the presentation template specified by the `pagedesign` parameter from the web content link. (See “Writing links to web content” on page 1836). If the request does not include that parameter, the default presentation template of your content is used to produce the output.

The `pagedesign` parameter is another way of managing your presentation components for different MIME types to render your content. Furthermore, it also allows you to produce output for MIME types other than the ones supported by the well-defined content elements. For example, you can create a presentation

template that produces a "text/csv" (comma-separated values) representation of your content. You would then request your content with that MIME type with a URL like this:

```
http://hostname/context_root/virtual_portal_context/caas?current=true
&urile=wcm%3Apath%3Alibrary/site_area_path/content&mime-type=text/csv
&pagedesign=library/folder/presentation_template
```

Important: If you choose this approach, you must explicitly add the `pagedesign` parameter to the URLs when you request a representation of your content with a specific MIME type. If the output generated for a specific MIME type also includes web content links, the `pagedesign` parameter is not automatically added by the portal.

How to use presentation templates with a custom context processor

Instead of using the `pagedesign` query parameter, you can also implement a custom context processor that sets the presentation template dynamically based on the requested MIME type. This solution provides you with the full MIME type flexibility as the second option and does not require the `pagedesign` parameter in web content links. Your context processor can change the presentation template for a request based on the requested MIME type from the `mime-type`parameter. For more information on custom context processors, go to the topic "Creating a context processor class" on page 3230.

For example, you might use a naming convention to select the proper presentation template for a request: `authoring_template_name.mime_type`. Given this simple naming convention, requesting the JSON representation of the content item `Web Content/Articles/Sample Article` that is based on the authoring template `Web Content/Article` would mean that your context processor sets the alternative presentation for the request to `Web Content/Article.json`.

Important: You need to configure the instance of the Web Content Viewer portlet that is located on the CaaS page with the unique name `ibm.portal.caas.page` to use your context processor. To configure the context processor for the instance of the portlet, use the **Edit Shared Settings** mode of the portlet from the CaaS page. More information on configuring the Web Content Viewer portlet, go to the topic Advanced options. If you use Content as a Service pages with virtual portals, make sure to also configure the portlet instances on the CaaS pages in each virtual portal.

Limitations when using Content as a Service

- With Content as a Service, you always request web content items from a web content library. You cannot use this service to render components from a web content library.
- With Content as a Service, you cannot produce binary web content. For example, you cannot respond with the MIME type `image/jpg`. If you want to retrieve binary web content, such as images, from a web content library, include the URL to the web content in the Content as a Service response. The client can then use the URL to make a second request to load the binary web content.

Links to content items can be written as URLs.

Setting up Content as a Service

To be able to work with Content as a Service pages in WebSphere Portal Express, you must enable it by using an IBM WebSphere Portal Express configuration task.

Before you begin

For Content as a Service pages to work, you must have the new functions for WebSphere Portal Express and IBM Web Content Manager Version 8.5 CF05 enabled. For more information, see the *readme file for WebSphere Portal and Web Content Manager V8.5 CF05*.

About this task

The setup for Content as a Service pages comprises both resources that are shared across virtual portals and virtual portal scoped resources.

To set up Content as a Service pages, proceed with the following steps:

Procedure

1. Change the directory to the `wp_profile_root/ConfigEngine` directory. If you are using IBM z/OS, open a UNIX System Services command prompt to change directories.
2. Initiate the setup.
   - To initiate the setup of shared resources, run the configuration task `install-caas` as follows:`./ConfigEngine.sh install-caas -DPortalAdminID=user_id -DPortalAdminPwd=password -DWasUserid=user_id -DWasPassword=password`
   - To initiate the setup of virtual portal scoped resources in the default virtual portal, run the configuration task `install-caas-vp` as follows:`./ConfigEngine.sh install-caas-vp -DPortalAdminID=user_id -DPortalAdminPwd=password -DWasUserid=user_id -DWasPassword=password`
   - To initiate the setup of virtual portal scoped resources in a virtual portal, run the configuration task `install-caas-vp` as follows by adding the **`-DVirtualPortalContext`** or **`-DVirtualPortalHost`** as follows:`./ConfigEngine.sh install-caas-vp -DPortalAdminId=user_id -DPortalAdminPwd=password -DWasUserid=user_id -DWasPassword=password -DVirtualPortalContext=virtual_portal_context`
3. Restart your portal server.

Removing Content as a Service

To remove Content as a Service feature in WebSphere Portal Express, you must disable it by using an IBM WebSphere Portal Express configuration task.

Procedure

1. Change the directory to the `wp_profile_root/ConfigEngine` directory. If you are using IBM z/OS, open a UNIX System Services command prompt to change directories.
2. Initiate removal.
   - To initiate the removal of virtual portal scoped resources in the default virtual portal, run the configuration task `uninstall-caas-vp` as follows:`./ConfigEngine.sh uninstall-caas-vp -DPortalAdminID=user_id -DPortalAdminPwd=password DWasUserid=user_id -DWasPassword=password`

- To initiate the removal of virtual portal scoped resources in a virtual portal, run the configuration task `uninstall-caas-vp` by adding the **-DVirtualPortalContext** or **-DVirtualPortalHost**as follows:`./ConfigEngine.sh` *`uninstall-caas-vp`* `-DPortalAdminID=`*`user_id`* `-DPortalAdminPwd=`*`password`* `DWasUserid=`*`user_id`* `-DWasPassword=`*`password`* `-DVirtualPortalContext=`*`virtual_portal_context`*
- To initiate the removal of shared resources, run the configuration task `install-caas` as follows:`./ConfigEngine.sh` *`uninstall-caas`* `-DPortalAdminID=`*`user_id`* `_DPortalAdminPwd=`*`password`* `DWasUserid=`*`user_id`* `-DWasPassword=`*`passowrd`*

  Note: Uninstalling the shared resources while the virtual portal scoped installation is still present for other virtual portals leads Content as a Service feature to become dysfunctional for all virtual portals.

3. Restart your portal server.

Access Content as a Service

To access your Content as a Service pages, you can write links to your content that specifies the CaaS page as target.

When you construct the URLs for your links to web content, you can use the **`urile`** URL parameter to identify the content item. To access the content item by using the CaaS page, use one of the following methods:

- Include the friendly name of the CaaS page in the URL and add the URL parameter `current=true` to the URL.
- Specify the unique name of the CaaS page (`ibm.portal.caas.page`) in the URL by using the "*page*" URL parameter.

Generic URLs

Addressing the CaaS page from a virtual portal by using the page friendly name:

`http://`*`hostname`*`/`*`context_root`*`/`*`virtual_portal_context`*`/caas?current=true&urile=wcm:path:`*`libra`*

Addressing the CaaS page from a virtual portal by using the page parameter:

`http://`*`hostname`*`/`*`context_root_poc`*`/`*`virtual_portal_context`*`?page=ibm.portal.caas.page&urile=wc`

Example URLs

A URL to render the content item *Item1* that is stored in the site area *SiteArea1* of *Library1* by applying a JSON presentation template that is named *Presentation1* from the library that is named *Library2* looks like the following examples:

Addressing the CaaS page from a virtual portal by using the page friendly name:

`http://example.com/wps/myportal/vp1/caas?current=true&urile=wcm:path:Library1/SiteArea1/It`

Addressing the CaaS page from a virtual portal by using the page parameter:

`http://example.com/mypoc/vp1?page=ibm.portal.caas.page&urile=wcm:path:Library1/SiteArea1/I`

To render the content item that is found at location `Web Content/News/News1`, you can use a URL like the following example:

`http://example.com/wps/mypoc?urile=wcm:path:/Web+Content/News/News1&page=ibm.portal.caas.page`

If a JSON presentation component is associated to that content, you can request the JSON representation of this content item by using URL like the following example:

`http://example.com/wps/mypoc?urile=wcm:path:/Web+Content/News/News1&page=ibm.portal.caas.page&mime`

Related concepts:

CF05 "Writing links to web content" on page 1836
Links to content items can be written as URLs.

URLs

Portal URLs do not look like plain HTTP server URLs over a simple file system. Portal URLs have a complex structure and include a large compressed and encoded XML Navigation State document. The stream of random characters in a Portal URL is the Navigation State document. Full Portal function depends on correctly maintaining this Navigation State document during all the operations a user might do in Portal. Forcing Portal URLs to look like plain HTTP server URLs over a simple file system structure cripples the function of WebSphere Portal Express.

Some of the use cases that must be supported by Portal URLs include the following:

Backward and Forward button support
: The user can use the browser's back and forward buttons to switch between recent views.

Bookmark-ability
: The current view can be saved into a client-side bookmark and can be accessed at any time. The user might need to log on first before they can access the bookmark. The bookmark must remain valid across portal versions.

Crawl-ability
: Web-Crawlers such as Googlebot can crawl portal pages and index them.

Cacheability
: Views of pages must be cacheable.

Non-Functional requirements
: Non-functional requirements include RFC 1738 URL size limitations, URL generation performance, and markup size management when markup contains many Portal URLs.

A Portal URL can be self-contained, or can be a delta URL relative to a base. A Portal URL might contain human-readable tokens for URL Mappings, Friendly URLs, Vanity URLs, or Virtual Portal context, in addition to the encoded Navigational State document.

For users to find specific content in your website, you can provide friendly URLs or vanity URLs. These URLs are short URLs that people can easily remember. They are shorter than full WebSphere Portal Express URLs. These short URLs are sometimes also called marketing URLs. You can publish them for marketing campaigns through different channels, such as email or print. This way, you can use them to direct customers to a specific portal page or content item. Interested site visitors who want to view your campaign can then remember or copy the short URL and type it into the browser address field.

Friendly URLs
: Friendly URLs have human-readable strings in the URL that describe the path to a Portal page. These human-readable strings correspond to the Friendly URL Names that are associated with the pages or labels. In addition, there might also be Friendly Content Path tokens in the URL. The

Friendly Content Path tokens are human-readable strings that describe the site area path to Web Content Management library associated with the page.

Note: A friendly URL might also include an encoded Navigational State document. If it does not, it is a Stateless Friendly URL. There is a programming API specifically for working with Friendly URLs.

Vanity URLs
Vanity URLs are similar to Stateless Friendly URLs, in that they are human-readable and do not have an encoded Navigational State document. However, Vanity URLs are not tied to the Friendly URL Names associated with the Portal pages. Instead, Vanity URLs are intended to be aliases that are simple, easily remembered, and easily entered by hand if necessary. Vanity URLs are similar to Mapped URLs that were introduced in prior releases of WebSphere Portal. They are intended only as an initial entry point, and are not persistent in the browser address bar after interaction with the Portal site begins. There is a programming API specifically for working with Vanity URLs.

Deciding between vanity URLs and friendly URLs

Depending on your requirements, you can use vanity URLs, or friendly URLs:

- If you want to have a short URL as an entry point to a specific portal page or content item, use a vanity URL.
- If you want to have a friendly URL that your site visitors see when the portal shows the page, use a friendly name.
- If you want to be able to publish the page through the Web Content Manager workflow, use a vanity URL. For example, this URL can be useful for a marketing campaign.
- If you want to address a specific portal page through URL generation tags or APIs, use unique name IDs. For more information, see *URL generation in WebSphere Portal*.

You can create both vanity URLs and friendly URLs for the same portal page.

URL mappings

URL mappings were deprecated starting with WebSphere Portal Express Version 8.5. Instead, you can now use friendly URLs or Vanity URLs as an alternative to URL mappings.

Related concepts:

"URL generation in WebSphere Portal" on page 2835
Generating Portal URLs correctly is one of the most important tasks in programming a WebSphere Portal Express based application. There are several programming tools and techniques available for generating WebSphere Portal Express URLs in custom code. The following section introduces the programming tools available and discusses when it is most appropriate to use each of the tools.

Authoring tools

There are multiple ways to create and manage content including using the site toolbar, inline editing, and the authoring portlet.

"Site toolbar" on page 1888
The site toolbar is useful for managing and editing content day-to-day. It

provides convenient access to many capabilities directly from the website. Content authors can create pages, add content and application to pages, and manage page parameters.

"Edit mode" on page 1889
Edit mode is available from the site toolbar.

"Web content inline editing strategies" on page 1890
An inline editing system is used to deliver editable websites such as an intranet or a wiki. It combines the features of both an authoring system and a delivery system.

"Authoring portlet" on page 1897
The authoring portlet is another interface that can be used by content authors, site administrators, and site developers. From the authoring portlet, content authors use forms, called authoring templates, to add content to the website. You can use to customize the Web Content Manager user interface to simplify the content authoring process for your content creators.

Site toolbar

The site toolbar is useful for managing and editing content day-to-day. It provides convenient access to many capabilities directly from the website. Content authors can create pages, add content and application to pages, and manage page parameters.

The site toolbar is available for immediate use after you deploy the portal. The availability of the site toolbar is controlled by the theme. So you can disable it on your production server.

Figure 21. Screen capture of the site toolbar with annotations.

1 Menu options

There are three menu options: Site, Application, and Administration.

Use the **Site** menu to switch between the sites that are hosted on a single portal server.

Use the **Application** menu to access application such as Content, Collaboration, Messaging, Personalization, and Unified Task List.

Use the **Administration** menu to access the administration portlets.

2 Toolbar

The toolbar provides access to authoring tools such as **Projects**, **Create**, and **Page**.

From the Projects tab, the content authors can create new projects to manage multiple changes. The tab displays the content that has been created or changed in the website for that project. Each content item can be managed individually. The content author can also create project templates.

From the Create tab, content authors can create pages, add applications to a page, or add content to a page. The content shelf contains Web Content Viewer portlets that are preconfigured with content associations. When the content author drags content to the page, a copy of the associated content is added to the page. Then the content author can customize the content.

From the Page tab, content authors can view and modify page settings, such as layout, vanity URLs, and more.

3 Project indicator
The project indicator provides access to the project menu and displays the currently active project. If there is no active project, then the indicator shows "Published Site" and you are viewing the currently published website.

4 Edit Mode
Use the **Edit Mode** control to turn editing capability on and off.

5 Information Mode
Turns inline user assistance on and off. Inline assistance includes descriptions and examples that appear in the user interface and hover help.

Currently this mode is only implemented in the site toolbar.

6 Menu
Provides access to additional page and preview actions.

Page actions include: View Page Properties, Show Hidden Pages, Show Hidden Content, Move Page, and Delete Page.

Preview actions include: Preview as a specific user and preview as an unauthenticated user.

Site toolbar customization

The site toolbar is populated with the portlets that are immediately available after you deploy the portal. It includes a number of configured content viewers too. To customize your toolbar, you can:

- Add page templates to the Create Page tab
- Add new categories and applications to the Create Content tab
- Add configured content to the Create Content tab

Related concepts:

"Customizing the Content palette" on page 1904
The Content palette, which is accessed from the site toolbar, contains the content items a content author can add to a page.

"Customizing the Applications palette" on page 1909
WebSphere Portal Express includes ready to use portlets that you can browse through in the site toolbar. To ease browsing through this set of portlets, WebSphere Portal Express supports assigning portlets to one or more categories. As the site administrator, you can create, delete, and modify categories and assign portlets to them.

Edit mode

Edit mode is available from the site toolbar.

Edit mode and administration pages

Administration pages are not intended to be edited, those pages are excluded from the edit mode features provided by the site toolbar. The administration pages are not managed in the Web Content Manager. The edit mode features are suppressed by the page parameter **theme.disable.edit.mode** on the Administration page label (unique name wps.Administration). Setting the parameter on the top-level administration page also causes the child pages to be affected.

Disable edit mode

You can set the **theme.disable.edit.mode** parameter on any page where you want to disable edit mode in the site toolbar. Edit the properties of the page, and add the **theme.disable.edit.mode** parameter with a value of `true`.

Web content inline editing strategies

An inline editing system is used to deliver editable websites such as an intranet or a wiki. It combines the features of both an authoring system and a delivery system.

"Inline editing"
Inline editing enables users with edit access to a content item to edit that item from within the web page itself instead of using the authoring portlet. This feature is available when you display content with a web content viewer portlet.

"Creating an authoring tools element" on page 1892
The authoring tool element is used to add authoring portlet functions to web pages. When you create an authoring tool element, you need to define the layout of the authoring tool and any required actions, and select parameters for each action layout as required.

Inline editing

Inline editing enables users with edit access to a content item to edit that item from within the web page itself instead of using the authoring portlet. This feature is available when you display content with a web content viewer portlet.

The inline editing feature requires:

- WebSphere Portal version 8.0.0.1 or later, or Web Content Manager version 8.0.0.1 or later.
- A theme that supports Dojo. The themes that are included with WebSphere Portal are enabled for Dojo.

  If you create a custom theme, in addition to supporting Dojo, the new theme must reference the `wcm_inplaceEdit` theme module. For information about creating themes that support Dojo, see *Dojo and WebSphere Portal*.

Important: This feature can be enabled or disabled by enabling or disabling the content targeting feature and application objects. For more information, see *Installing content targeting features and application objects*.

Note: When a user tabs between inplace editing enabled fields, users need to click each field in turn to access inplace editing for each field.

"Updating sample template items for inline editing after an upgrade installation" on page 1891
IBM Web Content Manager includes sample content such as web content template pages and predefined portlets that you can add to pages to render content. If you upgrade, these sample web content template items continue to use the editing method of the earlier release. To use the inline editing method with the earlier template items, you must complete several manual steps.

"Enabling inline editing for content items" on page 1892
You can enable inline editing for content item fields in your site design.

Related information:

Creating an If Not Edit Mode tag

Updating sample template items for inline editing after an upgrade installation:

IBM Web Content Manager includes sample content such as web content template pages and predefined portlets that you can add to pages to render content. If you upgrade, these sample web content template items continue to use the editing method of the earlier release. To use the inline editing method with the earlier template items, you must complete several manual steps.

Procedure

1. Go to the *wp_profile_root*/ConfigEngine directory.
2. To redeploy the web content viewer portlets that are used with the template items, run the **action-deploy-templating-portlets** task.
   - Linux : `./ConfigEngine.sh action-deploy-templating-portlets -DPortalAdminPwd=password -DWasPassword=password`
   - Windows: `ConfigEngine.bat action-deploy-templating-portlets -DPortalAdminPwd=password -DWasPassword=password`
   - IBM i: `ConfigEngine.sh action-deploy-templating-portlets -DPortalAdminPwd=password -DWasPassword=password`
3. Log in to the portal as an administrator.
4. Go to the web content authoring portlet. For example, click **Applications** > **Content** > **Web Content Management**.
5. Edit the preferences for the authoring portlet, and ensure that the Portal Site library is listed with the libraries that are displayed in the portlet.
6. In the authoring portlet, click **Portal Site** > **Content** > **Content Root** > **Hidden Pages** > **Page Templates** > **Articles**.
7. Delete the following content items: **Article**, **No Items Found**, and **List of Articles**.
8. Log out of the portal.
9. Go to the *wp_profile_root*/ConfigEngine directory.
10. Run the **action-init-content-templating-pages** task.
    - Linux : `./ConfigEngine.sh action-init-content-templating-pages -DPortalAdminPwd=password -DWasPassword=password`
    - Windows: `ConfigEngine.bat action-init-content-templating-pages -DPortalAdminPwd=password -DWasPassword=password`
    - IBM i: `ConfigEngine.sh action-init-content-templating-pages -DPortalAdminPwd=password -DWasPassword=password`
11. Run the **action-internalize-content-mappings** task.
    - Linux : `./ConfigEngine.sh action-internalize-content-mappings -DPortalAdminPwd=password -DWasPassword=password`
    - Windows: `ConfigEngine.bat action-internalize-content-mappings -DPortalAdminPwd=password -DWasPassword=password`
    - IBM i: `ConfigEngine.sh action-internalize-content-mappings -DPortalAdminPwd=password -DWasPassword=password`

Results

After you complete these steps, the sample content items that are provided by default in the site toolbar are enabled for the updated inline editing feature.

- The following content items in the **Web Content** category of the **Content** tab are updated: **Article**, **Image**, **List of Articles**, **Rich Text**. These content items are modified to reference new versions of the items that are provided in the Template Page Content 3.0 library.
- The Articles page template is modified to reference a new version of the template that is provided in the Template Page Content 3.0 library.

Enabling inline editing for content items:

You can enable inline editing for content item fields in your site design.

About this task

Inline editing is enabled separately for each of the following content item fields:
- Name
- Title
- Description
- Author and owner
- Published date
- Expiry Date
- General Date 1
- General Date 2
- Each element that is stored in the content item.

You can enable inline editing in the design in two ways:
- Use editable element or editable property tags in presentation templates or component designs.
- Enable inline editing for new item creation with an authoring tool component.

Note to developers: When you create a custom theme, you must include a reference to the *wcm_inplaceEdit* module to enable inplace editing in the custom theme.

Creating an authoring tools element

The authoring tool element is used to add authoring portlet functions to web pages. When you create an authoring tool element, you need to define the layout of the authoring tool and any required actions, and select parameters for each action layout as required.

"The Authoring tools element" on page 1893
The authoring tool element is used to add authoring portlet functions to web pages.

"Inline item creation with authoring tool components" on page 1894
Inline item creation can be enabled for authoring tool components so that users can quickly create a new content item without having to access the authoring interface.

"How to use authoring tools components in a Web Content Viewer" on page 1895
When rendering authoring tool components in the Web Content Viewer, you must account for some changes in the way placeholder tags are specified and in the way users browse to pages that contain authoring tool components. Authoring tasks that are accessed through a Web Content Viewer, such as inline

editing, require the use of an instance of the IBM Web Content Manager authoring portlet that is reserved specifically for such tasks.

"How to reference an authoring tool" on page 1897
An authoring tool component can be referenced within presentation templates, menu element designs, and navigator element designs. When added to menus and navigators, the edit and delete functions are applied to each item displayed in a menu or navigator.

The Authoring tools element:

The authoring tool element is used to add authoring portlet functions to web pages.

You can add the following authoring portlet functions to a web page:

- Create a content item.
- Perform inline editing of a content item that is displayed in a web page.
- Delete the content item that is displayed in a web page.
- Approve or reject the current content that is being previewed. These options are visible to approvers only when they preview a draft item, or by opening the URL sent by an email action during a workflow.

Authoring tools can be referenced within presentation templates, menu element designs, and navigator element designs. When added to menus and navigators, the edit, delete, and approve functions are applied to each item displayed in a menu or navigator.

Creating an authoring tool element

You can use an authoring tool element only by creating an authoring tool component. You cannot add an authoring tool element to authoring templates, site areas, or content items.

How to use an authoring tool

When content is previewed, users with access to an authoring tool are able to run various authoring portlet functions.

Note: When content items that use a presentation template that includes an authoring tool are previewed, some functions are active and ready to use while other functions might not work as normal.

The authoring tool is also visible on the published site.

How to use an authoring tool on multiple servers

When an authoring tool is used on more than one server, you use two-way syndication to keep each server synchronized. This can lead to the occasional "save" conflict where an item updated on one server is overwritten with changes to the same item on another server when syndication occurs.

User access to an authoring tool

The authoring tools available to users on a web page are determined by:

- Whether a user has access to the authoring tool component.

- Which tools are enabled in the authoring tool element.
- The user's level of access to the content item displayed in a web page.
- Whether a user has access to the authoring portlet. Users are assigned at least contributor access to each web content library in a site to ensure that they have access to the authoring portlet.
- You grant "editor" access or higher to users who need to edit the authoring tool.
- You grant "user" access to users who also have access to the authoring server and who are using the authoring tool.
- In most cases, users who have access to the published site would not be granted access to an authoring tool as the tool is used as an authoring tool on an authoring server, not a published site.

Inline item creation with authoring tool components:

Inline item creation can be enabled for authoring tool components so that users can quickly create a new content item without having to access the authoring interface.

How to enable inline item creation with an authoring tool component

To enabled inline item creation with an authoring tool component, you select **Enable inline item creation** under the **New action properties** section of the authoring tools component form.

When enabled, when a user clicks the new action tool on the rendered web page, a small dialog is displayed where a user enters the name of the new item. No other fields are displayed.

For inline item creation with an authoring tool component to work:
- The authoring template must use a multiple stage workflow with the initial stage being a draft, or the authoring template has workflows disabled.
- The location for the new item must have been predefined in either the authoring template, or the authoring tool component.
- The portal page the authoring tool is displayed on must be in edit mode.

If any of these requirements are not met, the normal inline item creation dialog is displayed instead.

How to use inline item creation with an authoring tool component

Inline item creation with an authoring tool component works best when:
- The item created using the authoring tool has a valid page mapping so that the new item is automatically opened in the correct page.
- The authoring template used to create the content item contains some default content and metadata. For example, the **Title** field might be pre-filled with the sentence "Add your title here".
- The presentation template used by the new content item uses editable property and editable element tags so that the user can immediately update the new content item.
- If using a workflow, you should select **Allow templated items to be saved in the first draft stage even if the item fails field validation** when creating the workflow. This will allow users to create draft items that do not meet all field validation requirements.

- The new action properties section can use the tags `[Placeholder tag="titlelink"]`, `[Placeholder tag="namelink"]` or `<a href="javascript:;" onclick="[Placeholder tag="href"]">Create</a>` to create the link that opens the inline item creation dialog.

This ensures that the user is taken to an inline edit ready content item when they create a new item by using the inline authoring tool.

How to use authoring tools components in a Web Content Viewer:

When rendering authoring tool components in the Web Content Viewer, you must account for some changes in the way placeholder tags are specified and in the way users browse to pages that contain authoring tool components. Authoring tasks that are accessed through a Web Content Viewer, such as inline editing, require the use of an instance of the IBM Web Content Manager authoring portlet that is reserved specifically for such tasks.

"How to configure authoring tools components"
Authoring tools components that are rendered in a web content viewer allow you to create, read, edit, delete, approve, or reject content items directly in the web content viewer, instead of requiring you to browse to the IBM Web Content Manager authoring portlet to run the same action. The web content viewer either opens a window from the current page or redirects the user to another portal page that contains the authoring portlet.

How to configure authoring tools components:

Authoring tools components that are rendered in a web content viewer allow you to create, read, edit, delete, approve, or reject content items directly in the web content viewer, instead of requiring you to browse to the IBM Web Content Manager authoring portlet to run the same action. The web content viewer either opens a window from the current page or redirects the user to another portal page that contains the authoring portlet.

You can specify which behavior to use in the authoring tools element design. Typically placeholder tags are used to display authoring tools elements. The value of the `format` attribute of the placeholder tag determines what URL is created to run an authoring task:

`format="tag"`
The placeholder is rendered as a URL that opens a window that contains the authoring portlet.

`format="url"`
The placeholder is rendered as a URL that redirects the user to another portal page that is used by the web content viewer for inline editing.

Note: Authoring tasks that are run in the web content viewer are accomplished through a special instance of the authoring portlet that is reserved specifically for these tasks and is installed on a page that is hidden from the page navigation available to typical users. You can customize the authoring experience for these tasks by configuring the reserved authoring portlet and the page that is used to display it.

Authoring tools components that open in a window

When you use a window to display an authoring task, the window opens on the portal page and can be moved within the boundaries of the browser window while

still showing the portal page. After you complete the task that is triggered by the authoring tools element, the window closes automatically, and the portal page refreshes, updating the view in the web content viewer. You can cancel the authoring task by clicking the close icon in the window's title bar. When a task is canceled, no web content information is saved, unless you explicitly save changes before manually closing the window.

The default value of the `format` attribute for a placeholder tag is `tag`, so to use a window for inline editing, it is not necessary to specify a value for the `format` attribute. Either of the following design examples creates a URL that opens a window for authoring tasks:

```
<Placeholder tag="namelink"/>
<Placeholder tag="namelink" format="tag"/>

<a href="<Placeholder tag="href"/>">
  <Placeholder tag="name"/>
</a>
<a href="<Placeholder tag="href" format="tag"/>">
  <Placeholder tag="name"/>
</a>
```

Note: It is not possible to open the window in a separate browser window by adding `target="_blank"` to the HTML anchor tag in the design.

Authoring tools components that open on another page

Instead of running tasks from authoring tools elements in a window on the current page, you can open authoring tasks by browsing to a hidden portal page that contains a web content viewer that contains the reserved authoring portlet. Clicking a link for an authoring tools element automatically redirects you to the other page, but after you complete the authoring task, you must manually browse back to the original page. If the page with the reserved authoring portlet was opened in a new browser window or tab, you must close the window or tab and manually refresh the original page to see any changes.

To redirect users to another page for authoring tasks, specify a value of `url` for the `format` attribute in the placeholder tag in the authoring tools element design. Either of the following design examples creates a URL that redirects users to another portal page for authoring tasks:

```
<Placeholder tag="namelink" format="url"/>

<a href="<Placeholder tag="href" format="url"/>">
  <Placeholder tag="name"/>
</a>
<a href="<Placeholder tag="href" format="url"/>" target="_blank">
  <Placeholder tag="name"/>
</a>
```

Note: You can open the portal page in a separate browser window by adding `target="_blank"` to the HTML anchor tag in the design.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

How to reference an authoring tool:

An authoring tool component can be referenced within presentation templates, menu element designs, and navigator element designs. When added to menus and navigators, the edit and delete functions are applied to each item displayed in a menu or navigator.

Referencing an authoring tool component in a presentation template

An authoring tool element is referenced in a web content component tag:

```
[Component name="authoringtoolname" ]
```

Referencing an authoring tool element in a menu or navigator design

When you reference an authoring tool component in menu or navigator designs, you use a component tag with a parameter of `compute="always"`. For example:

```
[Component name="authoringtoolname" compute="always" ]
```

Authoring portlet

The authoring portlet is another interface that can be used by content authors, site administrators, and site developers. From the authoring portlet, content authors use forms, called authoring templates, to add content to the website. You can use to customize the Web Content Manager user interface to simplify the content authoring process for your content creators.

"Custom portal pages for authoring"
You do not have to use the default Web Content Manager page to create content. You can create a new portal page to act as the home page of your authoring system.

"Authoring system access strategies" on page 1898
The roles that you assign each library on your authoring system determines what views and features in an authoring portlet are accessible to your users.

"Custom authoring interfaces" on page 1898
You can use the Web Content Manager API and remote action parameters to create customized authoring interfaces specifically for your content creators.

Custom portal pages for authoring

You do not have to use the default Web Content Manager page to create content. You can create a new portal page to act as the home page of your authoring system.

You can create separate subpages under an authoring home page. For example:

- add an authoring portlet to one subpage
- add web content viewer portlets to other subpages to allow users to preview different parts of a website

You can also create pages specifically for different types of users. For example, you can create a separate page for your site designers and content creators. The authoring portlets that you add to each page can be configured specifically for each user type.

Creating new pages

When new pages are created that contain an authoring portlet, add the following metadata parameter to the advanced settings in the page properties:

- Parameter: **resourceaggregation.profile**
- Value: profiles/profile_wcmauthoring.json

Example authoring home page

In this example, you have two users groups; site designers and content creators. The website is split between a design library and a content library.

To create a shared authoring environment for both sets of users you would create a parent home page with separate subpages for each group, plus a third subpage that is used to preview the site:

Table 277. Example authoring subpages

Site designers page	Content creators page	Header
• Includes an authoring portlet that is configured to use both the design and content libraries. • Only site designers can access this page.	• Includes an authoring portlet that is configured to use only the content library. • Only content creators can access this page.	• Includes a web content viewer portlet that is used to preview the website. • Both site designers and content creators can access this page.

Authoring system access strategies

The roles that you assign each library on your authoring system determines what views and features in an authoring portlet are accessible to your users.

Grant each user or group access to roles and item types to match the kind of work they perform. For example:

- Assign website designers editor access to authoring templates and presentation templates as they are required to create new authoring templates.
- Assign both website designers and web content authors editor access to components if they are both required to create components.
- Content approvers are only assigned contributor access to content as they are not required to create new content items, but need approver access to content items during a workflow.

Custom authoring interfaces

You can use the Web Content Manager API and remote action parameters to create customized authoring interfaces specifically for your content creators.

You might not want to use an authoring portlet as the user interface for all your users. In some cases, it might be better to create a custom authoring interface by using the Web Content Manager API and remote action parameters. For example, you can create a simple content authoring interface for a specific content authoring team.

Custom launch pages

You can configure an authoring portlet to use a launch page of your own design instead of the default user interface. A custom launch page can either be a JSP or HTML file. You use remote actions to call different views and functions from the authoring portlet's user interface. You can also use the web content API to add other functions to your launch page. After you created a custom launch page, you then configure your authoring portlet to use the custom launch page instead of the default authoring portlet user interface.

Remote actions

Remote actions are used in the query string of a URL to trigger actions from the Web Content Manager application. You can use remote actions to add standard Web Content Manager functions to a custom user interface.

Related tasks:

Creating pages using the Manage Pages portlet
A page displays content, such as portlets and other pages, in a single area. By creating pages, you can organize your information and add new navigational elements to the site.

Preparing for content authors

Before content authors can create content you must prepare your site to be ready for content creation, including preparing the site toolbar, enabling inline editing, and creating templates.

"Creating project templates"
Projects help content authors group and manage changes across the website. As a site administrator, you can create templates for your authors to use.

"Enabling inline editing for content items" on page 1892
You can enable inline editing for content item fields in your site design.

"Preparing the site toolbar" on page 1900
The site toolbar enables content authors to work with content from the website instead of using the authoring portlet. Customize the site toolbars to improve the authoring experience for content authors.

"Customizing the Web Content Authoring portlet" on page 1915
To customize each Web Content Authoring portlet for the people who use that portlet, you can edit the shared settings of each Web Content Authoring portlet on your authoring system.

"Removing the site toolbar on a production server" on page 1920
The site toolbar provides access to editing features for managed pages, including adding and editing pages and web content. Although essential for an authoring server, it is recommended that you disable the site toolbar on a delivery server. You can disable the toolbar for an entire portal or for specific virtual portals.

Creating project templates

Projects help content authors group and manage changes across the website. As a site administrator, you can create templates for your authors to use.

About this task

Project templates include the recommended workflow and publish options. Selecting a predefined project saves the content author time as they work on the website. It also enables you to suggest or enforce workflow and approvers for content changes. To create a project template, access the Web Content Authoring portlet.

Content authors can create project templates from the Projects tab. Project templates that are created from the site toolbar are named by using the following convention: "Template from *project name*"

More information about creating the project templates is available in the help system.

Procedure

1. From the **Applications** menu, click **Content**.
2. Click **Web Content Authoring**.
3. Click **New** > **Project Template**.

Results

The project template appears in the list of available templates in the Projects tab of the toolbar.

Setting a default project template: CF07 To set a default project template to be used when new projects are created, select a project template in the library explorer view, and then click **More** > **Set as Default**. To clear the default template, click **More** > **Clear Default**. This setting is scoped to the virtual portal if managed pages are enabled.

Authoring portlet: Creating a project template (from the Web Content Authoring portlet as a site administrator)

Creating a project template (from the site toolbar as an author)

Enabling inline editing for content items

You can enable inline editing for content item fields in your site design.

About this task

Inline editing is enabled separately for each of the following content item fields:

- Name
- Title
- Description
- Author and owner
- Published date
- Expiry Date
- General Date 1
- General Date 2
- Each element that is stored in the content item.

You can enable inline editing in the design in two ways:

- Use editable element or editable property tags in presentation templates or component designs.
- Enable inline editing for new item creation with an authoring tool component.

Note to developers: When you create a custom theme, you must include a reference to the *wcm_inplaceEdit* module to enable inplace editing in the custom theme.

Preparing the site toolbar

The site toolbar enables content authors to work with content from the website instead of using the authoring portlet. Customize the site toolbars to improve the authoring experience for content authors.

In the authoring environment, content authors use the site toolbar to access and add content and applications to pages. Content authors can also create and manage pages using the site toolbar.

Site toolbar customization includes:

- Adding content
- Adding applications

The WebSphere Portal Express 8.5 site toolbar is built with portal pages and portlets. The available toolbar tabs are implemented as portal pages, which are content labels or content pages, that are grouped under the toolbar content root. All content pages and content labels that are children of the toolbar content root will show up in the toolbar navigation as toolbar tabs.

By default, the toolbar content root has the unique name `ibm.portal.toolbar.ContentRoot` and can be found under the hidden pages root unique name `ibm.portal.HiddenPages`.

The toolbar navigation supports two levels only. Content pages or labels that are appended to an existing toolbar sub tab will not show up in the toolbar navigation.

To extend the site toolbar with custom toolbar tabs, you can:

- Create a new toolbar first level tab by appending a content page or content label to the toolbar content root.
- Create a new toolbar sub tab by appending a content page to one of the existing first level tabs or to a custom first level tabs.

You can influence the order of the toolbar tabs by setting ordinals on the toolbar content nodes. Use the theme that is set on the toolbar content root. To enable intercommunication with the main page, you must set the page parameter `ibm.portal.toolbar.isToolbarPage = true` for your custom toolbar content pages and content labels.

To use the XML configuration interface for creating and managing your toolbar tabs, set this parameter as follows:

```
<parameter name="ibm.portal.toolbar.isToolbarPage" type="string"
update="set"><![CDATA[true]]&gt;</parameter>
```

For performance reasons, this parameter has to be set on every toolbar content node. If it is not set, the toolbar tab will not have access to the context of the main page.

You can now start to add content to your toolbar. Add a portlet to the content page representing your toolbar tab. For more information, see *Implementing portlets for the site toolbar*.

The feed that displays all portlets is cached after being viewed. If you deploy a portlet after viewing the portlets on the toolbar, the newly deployed portlet will not be visible until the cache expires, which is one hour, or you look up the portlet in **Manage Portlets** and then go back to the toolbar.

HTML 5 considerations

All of the drag-and-drop actions are based on the native HTML 5 drag-and-drop capability. The content items that are displayed in the toolbar, for example on the **Create** > **Applications** or **Create** > **Content** tab, are marked as draggable in terms of HTML 5.

The Search controls that are displayed on some toolbar tabs, exploit the auto-completion capability of HTML 5. Internally it is based on the HTML 5 `<datalist>` tag. As a consequence, you might see different search result suggestions depending on the browser that you are using. Internet Explorer version 9 does not support the HTML 5 auto completion feature.

"Configuring the behavior of toolbar tabs"
You can use page parameters to configure the height of your toolbar tabs, and how the toolbar tabs respond to resizing events in the browser.

"Implementing portlets for the site toolbar" on page 1903
The toolbar tabs of the Portal 8.5 site toolbar are represented as portal pages. The content of the toolbar tabs can be implemented by using portlets.

"Customizing the Content palette" on page 1904
The Content palette, which is accessed from the site toolbar, contains the content items a content author can add to a page.

"Customizing the Applications palette" on page 1909
WebSphere Portal Express includes ready to use portlets that you can browse through in the site toolbar. To ease browsing through this set of portlets, WebSphere Portal Express supports assigning portlets to one or more categories. As the site administrator, you can create, delete, and modify categories and assign portlets to them.

"Customizing the Page tab" on page 1912
As an administrator, you can customize the Page tab to include other layouts and styles that content authors can use when they are editing a page.

CF05 "Controlling the visibility of the site toolbar and toolbar tabs" on page 1914
You can control the visibility of the site toolbar and single toolbar tabs per virtual portal by using Portal Access Control.

Enabler ContextMenu API

Enabler API Quick Reference

Configuring the behavior of toolbar tabs

You can use page parameters to configure the height of your toolbar tabs, and how the toolbar tabs respond to resizing events in the browser.

You can set the page parameters for the site toolbar by selecting the **Edit Page Properties** icon for the hidden page Toolbar Content Root. Expand **Advanced options** and select **I want to set parameters**. Use the following parameters to control the size of your toolbar tabs.

`ibm.portal.toolbar.reloadOnResize = true | false`
Use this configuration parameter to indicate whether you want your toolbar tab to be reloaded automatically if a resize event occurs in the browser. Depending on how your content is rendered, it might be useful to set this parameter to true. Defaults to false. For example:

```
<parameter name="ibm.portal.toolbar.reloadOnResize" type="string"
update="set"><![CDATA[true]]&gt;</parameter>
```

ibm.portal.toolbar.minHeight = *floating point number*

Use this configuration parameter to specify the minimum height factor of your toolbar tab. The value must be greater (or equal) than 0.2 and less (or equal) than 0.9. The factor is relative to the available viewport height on the client. A value of "0.3" for example means that the toolbar tab must at least consume 30 percent of the available viewport height. This configuration parameter must be combined with the `ibm.portal.toolbar.maxHeight` parameter that is explained next. For example,

```
<parameter name="ibm.portal.toolbar.minHeight" type="string"
update="set"><![CDATA[0.35]]&gt;</parameter>
```

ibm.portal.toolbar.maxHeight = *floating point number*

Use this configuration parameter to specify the maximum height factor of your toolbar tab. The value must be greater than or equal to the value that is specified for the minimum height. It must not be greater (or equal) than 0.9. The factor is relative to the available viewport height on the client. A value of "0.75" for example means that the toolbar tab must not consume more than 75 percent of the available viewport height. This configuration parameter must be combined with the previous `ibm.portal.toolbar.minHeight` parameter. For example,

```
<parameter name="ibm.portal.toolbar.maxHeight" type="string"
update="set"><![CDATA[0.7]]&gt;</parameter>
```

If the values of the configuration parameters `ibm.portal.toolbar.minHeight` and `ibm.portal.toolbar.maxHeight` are equivalent, the toolbar framework enforces this height, regardless of the size of the tab content that is being loaded.

Implementing portlets for the site toolbar

The toolbar tabs of the Portal 8.5 site toolbar are represented as portal pages. The content of the toolbar tabs can be implemented by using portlets.

Use the Java Portlet API to implement these portlets. For more information, see Predefined public render parameters.

Accessing the main portal page running in the view area

If you want your toolbar portlet to access the main portal page that is currently displayed in the view area, you can use the following public render parameter. This parameter carries the serialized ObjectID of the main portal page, not the one of the toolbar content page. Use this ObjectID to locate the content page in the content model hierarchy of your portal using the public Model SPI or the Remote Model SPI if you want to query page information using REST. You can display properties of the main page in your toolbar portlet or even modify page properties by using the Controller SPIs.

```
{http://www.ibm.com/xmlns/prod/websphere/portal/publicparams}selection
```

Working with page edit mode and page view mode

You can configure your toolbar portlet to differentiate between page edit mode and page view mode. In page edit mode, your content authors, page editors and administrators can modify the main portal page that is currently displayed in the main view area. In page view mode, you can provide read-only information about the main portal page. You can use the following public render parameter to detect if page edit mode is active or inactive.

```
{http://www.ibm.com/xmlns/prod/websphere/portal/publicparams}editMode
```

Working with page information mode

Use the following public render parameter if you want your toolbar portlet to display additional help information for your content authors, page editors and administrators. Or, use it if page information is active.

`{http://www.ibm.com/xmlns/prod/websphere/portal/publicparams}infoMode`

Drag and Drop

If you want your toolbar tab to display a list of items that can be dragged to the portal page that is currently displayed in the main view area, you need to make these items draggable according to the Drag and Drop model of HTML 5. For more information, see *Customize drag and drop*.

Customizing the Content palette

The Content palette, which is accessed from the site toolbar, contains the content items a content author can add to a page.

These content items act as templates. When added to a page, the item is copied. Authors can adapt the item according to their needs. The top-level view of the Content palette contains categories. To find a certain content item, the content author can drill down in the category structure. You can use keywords or content associations to define the categories that are shown in the top-level view.

"Creating new categories for the Content palette by using Web Content Authoring Portlet"
For a site area, add a keyword to profiles to define categories in the Content palette. Content items in the site area appear in the new category of the site toolbar.

"Creating new categories for the Content palette by using the Manage Pages portlet" on page 1905
Associate content with the hidden Content page to define categories in the Content palette. Content items under the associated site area appear in the new category of the site toolbar.

"Creating Content Drag and Drop configurations" on page 1906
Configure the results that display when a content author searches for a portlet to add. You can also enable assistance for content authors by displaying supported markup in search results.

"Creating custom images for categories in the Content palette" on page 1906
You can assign a custom image to an item in the Content palette. You can either use a single image or a collection of images that are bundled into a `ZIP` file, called multi-scale icons. Supported image file formats are `PNG`, `JPG`, and `SVG`. If you are using multi-scale icons, the collection of images must be compressed into a `ZIP` file. No other format is supported. You can add custom images by either adding a file element directly into the content, or by creating a reference to a file component.

Creating new categories for the Content palette by using Web Content Authoring Portlet:

For a site area, add a keyword to profiles to define categories in the Content palette. Content items in the site area appear in the new category of the site toolbar.

About this task

You can create the site area and add the keyword at the same time. If you have a site area that contains content items that you want to add to the site toolbar, you can use the site area keywords to define the category in the toolbar. For example, you have a site area that is called, "Product Content". Add the keyword, `ibm.portal.toolbar.NewContent` to the Profile section of the site area to create a category that is called "Product Content" in the Content palette in the site toolbar.

Procedure

1. Click the **Applications** menu icon in the toolbar.
2. Click **Content** > **Web Content Authoring**.
3. Find or create the site area to use as the new category.
4. Expand the Profile section of the site area.
5. Add the keyword `ibm.portal.toolbar.NewContent`.
6. Save and close the dialog.

Related information:

Creating site areas

Creating new categories for the Content palette by using the Manage Pages portlet:

Associate content with the hidden Content page to define categories in the Content palette. Content items under the associated site area appear in the new category of the site toolbar.

Before you begin

The site area must exist.

About this task

The benefit to creating new categories for the Content palette by using the Manage Pages portlet is that you can view all libraries. You can therefore create a category from any of the libraries that are available.

Procedure

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. Select **Content Root** > **Hidden Pages** > **Toolbar Content Root** > **Create**.
3. Click **Edit Page Properties** of the Content palette.
4. Open **Advanced options**.
5. Select **I want to edit associations**.
6. Select **Add web content**.
7. Select the category that you want to show in the Content palette.
8. Click **OK**.

Related information:

Creating site areas

Creating Content Drag and Drop configurations:

Configure the results that display when a content author searches for a portlet to add. You can also enable assistance for content authors by displaying supported markup in search results.

About this task

When you drag an item from the Content palette to the page, the item is copied and a content viewer portlet that points to the new copy is added to the page. The Drag and Drop configurations are portal pages that contain a single portlet. The Drag and Drop configuration is defined by the preferences of the corresponding portlet entity. The Drag and Drop configuration pages can be found in **Content Root** > **Hidden Pages** > **DnD Configuration**. A Drag and Drop configuration can be set on categories or on single content items. When a configuration is set on a category, the configuration is applied to all child items, unless they have their own configuration. The available Drag and Drop configurations are listed on the configuration tab inside the Content palette.

To change the configuration for an item, Select the item so that the item details are shown. If you are in Advanced mode, open the **Configuration** tab. Select the configuration that you want to apply.

Procedure

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. Select **Content Root** > **Hidden Pages** > **DnD Configuration**.
3. Click **New Page** and give the page a name.
4. Click **OK**.
5. Click **Edit Page Layout** for the new page.
6. Click **Add Portlets**.
7. Select **Web Content Viewer** and click **OK**.
8. Click **Done**.
9. Click **Edit Page Layout** for the new page.
10. Open the context menu and click **Edit Shared Settings**.
11. Set the preferences for the new configuration.
12. Click **OK**.
13. Click **Done**.
14. Optional: To enter a description for your configuration, click **Edit Page Properties** for the new page.
    a. Open the **Advanced** options.
    b. Select **I want to set titles and descriptions**.
    c. Click **Edit** for the language you want to use.
    d. Enter the descriptions and click **OK**.

Creating custom images for categories in the Content palette:

You can assign a custom image to an item in the Content palette. You can either use a single image or a collection of images that are bundled into a `ZIP` file, called multi-scale icons. Supported image file formats are `PNG`, `JPG`, and `SVG`. If you are using multi-scale icons, the collection of images must be compressed into a `ZIP` file.

No other format is supported. You can add custom images by either adding a file element directly into the content, or by creating a reference to a file component.

Multi-scale icons

If you are using multi-scale icons, each individual image is a single entry in the ZIP file. Images with the same base name represent one logical icon. The variations of an image are size, device class, and locale. These variations are organized in the following structure:

```
<Width>x<Height>/<FileName>_<DeviceClass>_<Locale>_<TextDirection>.<Suffix>
```

Where <Width> and <Height> group the icons by size. These values are a mandatory top-level directory. <DeviceClass>, <Locale>, and <TextDirection> are optional identifiers. The variations are not a part of the base name. The base name of the image is formed by <FileName>.<Suffix>, for instance, Applications.png. The following example is a sample directory structure inside a compressed file. The sample directory structure defines one icon, Applications.png, in different variations:

```
32x32/
     Applications_ar.png
     Applications_he.png
     Applications_ltr.png
     Applications.png
64x64
     Applications_de_de.png
     Applications_de.png
     Applications_rtl.png
     Applications.png
     Applications_tablet_de.png
     Applications_tablet.png
```

Applications.png has two size variations, 32x32 and 64x64. The smaller variation (32x32) defines an icon for ar and he variations in addition to a generic fallback icon. The smaller variation also defines an icon for languages that are read left to right by including a <TextDirection> variation that specifies ltr. The large one (64x64) includes a variation for de_de that specifies the German language in the locale of Germany in addition to a fallback icon for de. The <TextDirection> variation that specifies rtl defines an icon for languages that are read right to left. <DeviceClass> variations are also included for tablet devices.

Note: The size subdirectory must be the top-level directory in the compressed file.

When the icon is rendered, the best match is found in the following way:

1. The size is specified based on the requested icon size, by using the Euclidean distance. If no size is requested, the largest available size is used.
2. For all variations of a specified size, the best matching device class is used.
3. For all variations of a specified size and device class, the best matching locale is used.

"Creating custom images for categories in the Content palette by adding a file element" on page 1908
You can create custom images for items in the Content palette by deploying the image file or multi-scale ZIP file directly into the item in the Content palette as an element.

"Creating custom images for categories in the Content palette by referencing a file component" on page 1908
You can create custom images for items in the Content palette by deploying the

image file or multi-scale ZIP file as a file component in a library. Then, put a component reference element into your item in the Content palette that refers to that file component.

Creating custom images for categories in the Content palette by adding a file element:

You can create custom images for items in the Content palette by deploying the image file or multi-scale ZIP file directly into the item in the Content palette as an element.

About this task

- Supported image file formats are PNG, JPG, and SVG.
- If you are using multi-scale icons, the collection of images must be compressed into a ZIP file.

Procedure

1. Click the **Applications** menu icon in the site toolbar.
2. Click **Content** > **Web Content Authoring**.
3. To assign a custom image to a content item or a site area, select the item and click **Edit**.
4. Click the **More** menu.
5. Click **Manage Elements**.
6. In the **Element type** dropdown menu, select **File**.
7. In the **Name** field, specify the name of the new element as `preview-image`.
8. Click **Add**.
9. Click **OK** to exit the Element Manager window.
10. Upload the compressed file or image file for the *my_icon* resource element.
11. Click **Save and Close**.
12. Clear your browser cache and refresh the page for the changes to take effect.

Creating custom images for categories in the Content palette by referencing a file component:

You can create custom images for items in the Content palette by deploying the image file or multi-scale ZIP file as a file component in a library. Then, put a component reference element into your item in the Content palette that refers to that file component.

About this task

- Supported image file formats are PNG, JPG, and SVG.
- If you are using multi-scale icons, the collection of images must be compressed into a ZIP file.

Procedure

1. Click the **Applications** menu icon in the site toolbar.
2. Click **Content** > **Web Content Authoring**.
3. Navigate to the library where you want to store the image as a file component.
4. Click **New** > **Component** > **File**.
5. Enter a unique name for the new component. For example, *my_icon*.
6. Upload the file and click **Save and Close**.

7. To assign a custom image to a content item or a site area, select the content item and click **Edit**.
8. Click the **More** menu.
9. Click **Manage Elements**.
10. In the **Element type** dropdown menu, select **Component Reference**.
11. In the **Name** field, specify the name of the new element as `preview-image`.
12. Click **Add**.
13. Click **OK** to exit the Element Manager window.
14. Click **Select Component** for the *my_icon* component reference. The Select a component window displays.
15. Navigate to the library where you saved the *my_icon* component reference.
16. Select the ***my_icon*** file component.
17. Click **OK**.
18. Click **Save and Close**.
19. Clear your browser cache and refresh the page for the changes to take effect.

Customizing the Applications palette

WebSphere Portal Express includes ready to use portlets that you can browse through in the site toolbar. To ease browsing through this set of portlets, WebSphere Portal Express supports assigning portlets to one or more categories. As the site administrator, you can create, delete, and modify categories and assign portlets to them.

Application categories

In WebSphere Portal Express, categories are represented as labels or external URLs and can be managed with the Manage Pages portlet. All categories are in the category root label that is identifiable by the unique name `com.ibm.portal.toolbar.applications.category.label.root`, which is a label in the hidden pages label.

Categories are shown by the toolbar's Applications palette where categories appear with said localized title.

The following categories are available for immediate use:

- All
- Administration
- Collaboration
- Web Content
- Tools

"Creating new applications and categories for the site toolbar" on page 1910
You can add new categories to the site toolbar to organize your applications. After you deploy portal, you can customize the **Create** > **Applications** user interface in the site toolbar. Add categories that reflect your business needs and website organization.

"Creating categories by using external URLs" on page 1910
You can also use external URLs to represent categories to organize your portlet entities. The advantage of representing labels, or external URLs, with categories is that administrators can easily add, delete, and modify categories by using the Manage Pages portlet as the administrative user interface. Since categories are

labels, or external URLs, they can be assigned localized titles and descriptions, which can be set with the Manage Pages portlet as well.

"Hiding portlets within Applications palette categories" on page 1911
If a portlet has been added to a category by adding it to a page that has been placed under a category label, remove the page it has been added to. Alternatively, if you do not want to delete the page, you can mark it as hidden.

"Modifying and deleting Applications palette categories" on page 1912
You can easily modify or delete Applications palette categories.

Creating new applications and categories for the site toolbar:

You can add new categories to the site toolbar to organize your applications. After you deploy portal, you can customize the **Create** > **Applications** user interface in the site toolbar. Add categories that reflect your business needs and website organization.

About this task

Portlets that are deployed on the portal server are automatically added to the All category.

The site toolbar structure is based on labels and pages. Create a label to add a category. Then, create a page for each application that you need to add to the site toolbar. The page title must match the name of the application.

Procedure

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. Locate the category root label. For example, search for a title that contains "Application" and then look for the unique name `com.ibm.portal.toolbar.applications.category.label.root` in the results.
3. Click **New Label**.
4. Enter the name of the category in the **Title** field. Click **OK**.
5. Click the new label.
6. Click **New Page** to add a child page.
7. Enter the name of the application that you want to add to the site toolbar in the **Title** field and click **OK**.
8. Click **Edit Page Layout** and add the portlet to the page. Click **Done**
9. Verify that the category and portlet appear on the Applications palette.

Results

If your content authors do not see the portlet that you added, the site toolbar might be cached. The feed that displays all portlets is cached after the content author views it. If you deploy a portlet and the site toolbar is already cached, the newly deployed portlet is not visible until the cache expires, which is 1 hour. To see the portlet sooner, look up the portlet in the **Manage Portlets** administration portlet and then go back to the site toolbar.

Creating categories by using external URLs:

You can also use external URLs to represent categories to organize your portlet entities. The advantage of representing labels, or external URLs, with categories is

that administrators can easily add, delete, and modify categories by using the Manage Pages portlet as the administrative user interface. Since categories are labels, or external URLs, they can be assigned localized titles and descriptions, which can be set with the Manage Pages portlet as well.

About this task

To assign portlets to these categories, you must point the external URL to a feed that returns either a list of portlet definitions or a list of portlet entities. These portlet definitions or portlet entities then represent the portlets that are shown as being part of the Applications palette.

Procedure

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. Locate the category root label. For example, search for the label with the unique name `com.ibm.portal.toolbar.applications.category.label.root`.
3. Click **New URL** to add a new label.
4. Add a title and description for the new category. Click **OK**.
5. In the **Advanced Options** section, select **HTML** as supported markup. Specify a URL pointing to a feed that returns a list of portlet definitions or portlet entities.
6. Click **OK**.
7. Verify that the category and portlet entities appear on the Applications palette.

Hiding portlets within Applications palette categories:

If a portlet has been added to a category by adding it to a page that has been placed under a category label, remove the page it has been added to. Alternatively, if you do not want to delete the page, you can mark it as hidden.

The following XMLAccess example marks a page as hidden.

```
<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" type="update" xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
    <portal action="locate">

        <content-node action="locate" domain="rel" uniquename="wps.content.root"/>
        <content-node action="locate" domain="rel" uniquename="ibm.portal.HiddenPages"/>
        <content-node action="locate" domain="rel" uniquename="com.ibm.portal.toolbar.applications.category.label.root"/>

        <content-node action="update" active="true" content-parentref="com.ibm.portal.toolbar.applications.category.label.root" domain="rel" ordinal="700"
type="label" uniquename="com.ibm.portal.toolbar.applications.category.label.administration">
            <supported-markup markup="html" update="set"/>
            <localedata locale="en">
                <title>Administration</title>
            </localedata>
            <parameter name="com.ibm.portal.Hidden" type="string" update="set"><![CDATA[true]]&gt;</parameter>
            <parameter name="com.ibm.portal.IgnoreAccessControlInCaches" type="string" update="set"><![CDATA[false]]&gt;</parameter>
            <parameter name="com.ibm.portal.remote-cache-expiry" type="string" update="set"><![CDATA[86400]]&gt;</parameter>
            <parameter name="com.ibm.portal.remote-cache-scope" type="string" update="set"><![CDATA[NON-SHARED]]&gt;</parameter>
            <parameter name="param.sharing.scope.{http://www.ibm.com/xmlns/prod/datatype/content/resource-collections}" type="string" update="set">
<![CDATA[ibm.portal.sharing.scope.page]]&gt;</parameter>
            <parameter name="param.sharing.scope.{http://www.ibm.com/xmlns/prod/datatype/content}" type="string" update="set"><![CDATA[ibm.portal.
sharing.scope.page]]&gt;</parameter>
            <parameter name="param.sharing.scope.{http://www.ibm.com/xmlns/prod/websphere/portal/publicparams}path-info" type="string" update="set">
<![CDATA[ibm.portal.sharing.scope.page]]&gt;</parameter>
            <access-control externalized="false" owner="undefined" private="false">
                <role actionset="User" update="set">
                    <mapping subjectid="all authenticated portal users" subjecttype="user_group" update="set"/>
                </role>
            </access-control>
        </content-node>
    </portal>
</request>
```

If a portlet becomes part of a category because the category label points to a feed returning portlet definitions (which contains the portlet), you can force the portlet

to not appear by marking the portlet hidden. You can only mark the portlet hidden as long as the feed exposes portlet preferences, like the PortletDefinitionList feed does.

The following example marks a portlet as hidden.

```
<?xml version="1.0" encoding="UTF-8"?>
<request require-defined-oids="true" type="update" version="8.5.0" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
    <portal action="locate">
        <web-app action="update" active="true" objectid="Z1_00000000000000AGU4RF6L0004" uid="sample.webmod">
            <url>file:///sample.war</url>
            <servlet action="update" name="Sample" objectid="ZV_00000000000000AGU4RF6L0002"/>
            <servlet action="update" name="Sample" objectid="ZV_00000000000000AGU4RF6L0000"/>
            <portlet-app action="update" name="sample" objectid="Z2_00000000000000AGU4RF6L0006" uid="sample">
                <access-control externalized="false" owner="undefined" private="false">
                    <role actionset="User" update="set">
                        <mapping subjectid="all authenticated portal users" subjecttype="user_group" update="set"/>
                    </role>
                </access-control>
                <portlet action="update" name="Sample" objectid="Z3_00000000000000AGU4RF6L0001"
servletref="ZV_00000000000000AGU4RF6L0000" uniquename="wps.p.Sample">
                 <preferences name="com.ibm.portal.Hidden" update="set">
                     <value><![CDATA[true]]&gt;</value>
                 </preferences>
                </portlet>
            </portlet-app>
        </web-app>
    </portal>
</request>
```

Modifying and deleting Applications palette categories:

You can easily modify or delete Applications palette categories.

About this task

To delete a category, delete the label or external URL of the category's root label. To modify a category, edit the label or external URL of the category's root label.

Customizing the Page tab

As an administrator, you can customize the Page tab to include other layouts and styles that content authors can use when they are editing a page.

The styles and layouts that are available in the Page tab are included as a part of the theme. However, other styles and layouts can be added without modifying the existing theme.

"Creating new styles or layouts by using a JSON file"
You can add new styles or layouts to the site toolbar with a JSON file. Sometimes components outside of the theme want to contribute a new style or layout, without editing existing theme files. Components can easily be added to the theme through a catalog deliverable by using scripting and the Solutions Installer.

Creating new styles or layouts by using a JSON file:

You can add new styles or layouts to the site toolbar with a JSON file. Sometimes components outside of the theme want to contribute a new style or layout, without editing existing theme files. Components can easily be added to the theme through a catalog deliverable by using scripting and the Solutions Installer.

Procedure

1. Create new styles and layouts.

2. Upload the styles or layouts to the portal. The out of box style and layout examples are in WebDAV at `dav:fs-type1/themes/Portal8.5/css/` and `dav:fs-type1/themes/Portal8.5/layout-templates`.
3. Create a JSON file to list and define the new styles and layouts. Base the style JSON file on the format in the topic *Creating a theme style*. The default JSON files can be used as examples and are in WebDAV at `dav:fs-type1/themes/Portal8.5/system/`.
4. Add the new JSON files to the portal.
5. Add theme metadata for each JSON file. The metadata keys are `ibm.portal.shelf.style.json.`*component* and `ibm.portal.shelf.layout.json.`*component*, for the style JSON files and layout JSON files, where *component* can be any string that uniquely identifies the contribution. The metadata values are URLs pointing to the JSON file location. Values that start with a forward slash (/) are treated as absolute URLs, and all other values are read relative to the theme root folder. By default, the theme root folder is in WebDAV at `dav:fs-type1/themes/Portal8.5/` The following example shows style and layout theme metadata for a component called **myAdditions**:

```
<parameter name="ibm.portal.shelf.style.json.myAdditions" type="string" update="set">

     <![CDATA[system/myNewStyles.json]]&gt;</parameter>

     <!-- This URL will be read relative to the theme root folder -->

<parameter name="ibm.portal.shelf.layout.json.myAdditions" type="string" update="set">

     <![CDATA[/myContextRoot/layouts/myNewLayouts.json]]&gt;</parameter>

     <!-- This is an absolute URL to a custom war file -->
```

   a. To create and run an XML access script, use the following example as a model.

```
<?xml version="1.0" encoding="UTF-8"?>
<request build="wp85" type="update" version="8.5"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
 <portal action="locate">
  <theme action="update" active="true"
   default="true" domain="rel"
   resourceroot="dynamicSpots" uniquename="ibm.portal.85Theme">
   <parameter name="ibm.portal.shelf.style.json.myAdditions"
type="string" update="set">
       <![CDATA[system/myNewStyles.json]]&gt;</parameter>
       <!-- This URL will be read relative to the theme root folder -->
    <parameter name="ibm.portal.shelf.layout.json.myAdditions" type="string" update="set">
       <![CDATA[/myContextRoot/layouts/myNewLayouts.json]]&gt;</parameter>
       <!-- This is an absolute URL to a custom war file -->
  </theme>
 </portal>
</request>
```

   b. Copy the script to *PortalServer_root*`/bin`.
   c. Run the XML Access command: `xmlaccess -user` *user* `-password` *password* `-url localhost:`*port*`/wps/config -in AddCategories.xml -out AddCategoriesOutput`
6. Log in to the portal and click **Edit Mode**.
7. Verify that the new styles and layouts are present:
   - If you have portal with combined cumulative fix 7 or earlier, proceed as follows:
     a. Select the **Page** tab.

b. Then, select the **Style** or **Layout** tab.

Related information:

How to add a layout and style to the toolbar

Controlling the visibility of the site toolbar and toolbar tabs

You can control the visibility of the site toolbar and single toolbar tabs per virtual portal by using Portal Access Control.

The visibility of the action bar that contains the **Edit Mode** switch and the global menus can be controlled by assigning resource permissions to the toolbar master page. The toolbar master page has the unique name `ibm.portal.Toolbar` and is located within the Hidden Pages Root in the portal page hierarchy. By default the toolbar master page is accessible for anonymous portal users and authenticated portal users.

The visibility of the toolbar tabs can be controlled by assigning resource permissions to the toolbar content root or one of its sub pages. The toolbar content root has the unique name `ibm.portal.toolbar.ContentRoot` and is located within the Hidden Pages Root in the portal page hierarchy. By default the toolbar tabs are accessible to all authenticated portal users but not to anonymous portal users.

You can change the resource permissions for certain users or user groups. You can use the Resource Permissions portlet or the XML configuration interface to change the resource permissions.

You can completely disable the site toolbar along with the toolbar tabs for the entire system or for a certain virtual portal. To disable the site toolbar, follow the configuration settings that are documented in *Removing the site toolbar on a production server.*

CF05 "Limiting toolbar visibility to administrators only"
You can limit toolbar visibility to administrators only.

Related tasks:

CF05 "Removing the site toolbar on a production server" on page 1920
The site toolbar provides access to editing features for managed pages, including adding and editing pages and web content. Although essential for an authoring server, it is recommended that you disable the site toolbar on a delivery server. You can disable the toolbar for an entire portal or for specific virtual portals.

Limiting toolbar visibility to administrators only:

You can limit toolbar visibility to administrators only.

Procedure

1. Click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage pages**.
2. Select **Unique name contains** and search `ibm.portal.Toolbar`.
3. Select **Set Page Permission** for Toolbar.
4. From the Resource Permission Portlet, click **Edit Role** for User.
5. Click **Delete Member from Role**.
6. Click **OK**.
7. Click **Toolbar**to return to the toolbar menu.
8. Clear the check box for **Privileged User**.

9. Click **Apply**.
10. Click **OK**.

Customizing the Web Content Authoring portlet

To customize each Web Content Authoring portlet for the people who use that portlet, you can edit the shared settings of each Web Content Authoring portlet on your authoring system.

About this task

For example, you can configure authoring portlets in the following ways:

- Select only the libraries that your users use. For example, if you configure an authoring portlet that you want to be used only by content creators, select only libraries that are used to store content items.
- Edit the preview options to best suit your users and the type of website they are creating. You can choose to preview pages on a standard website, on a local web content viewer on the same server as the authoring portlet, or on a web content viewer portlet on a different server.
- Customize the appearance of the authoring portlet by defining various user interface settings. You can use these settings to change some of the default settings of an authoring portlet, or to select a custom launch page to use in place of the default user interface.
- Select an appropriate rich text editor for your users.

In IBM WebSphere Portal Express, the Web Content Authoring portlet is on a hidden page. If you want to configure the portlet to use only a subset of the available site libraries, proceed as follows:

Procedure

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. Search for a page with the unique name `com.ibm.wps.hiddenpage.wcm.Authoring_Portlet`.
3. Select **Edit Page Layout**.
4. From the portlet menu, select **Edit shared settings**. The portal shows a dialog window.
5. In the window, click **Library Selection**.
6. Configure which libraries you want to use for the authoring portlet.
7. Click **OK** in the dialog window.
8. Click **Done** in the main window.

Results

You successfully configured the libraries for the Web Content Authoring portlet.

"Authoring portlet settings"
An authoring portlet is used to create and manage web content. You can edit the settings of an authoring portlet from within the **Preferences** section of the authoring portlet.

Authoring portlet settings

An authoring portlet is used to create and manage web content. You can edit the settings of an authoring portlet from within the **Preferences** section of the authoring portlet.

Use the **Configure** mode to specify settings for all users of all instances of the authoring portlet, regardless of the page on which the portlet instance appears.

Use the **Shared Settings** mode to specify settings for the current instance of an authoring portlet.

"Selecting web content libraries"
You can select which libraries are displayed by default in the authoring portlet.

"Defining preview options" on page 1917
The preview options determine how content can be previewed. Preview options are defined within the **Previewing Options** section.

"Defining user interface options" on page 1917
You use the **User Interface Options** section to define the user interface options of an authoring portlet.

"Editor options" on page 1919
You can configure IBM Web Content Manager to use different editors for rich text and HTML fields.

Selecting web content libraries:

You can select which libraries are displayed by default in the authoring portlet.

Procedure

1. Select **Show selected libraries** to select the libraries you want to make visible in the authoring portlet.
   a. To add a library, select a library from the list of available libraries, then click **Add**.
   b. To remove a library, select a library from the list of selected libraries, and then click **Remove**.
   c. Use the arrows to change the order of the selected libraries. This selection determines the order that the libraries appear in the authoring portlet.
2. Select **Show new libraries in the library explorer** if you want any newly created libraries to automatically be shown in the library explorer.
3. Alternately, to make all libraries visible in the authoring portlet, select **Show all libraries**. You can then select individual libraries to hide in the authoring portlet.
   a. To hide a library, select a library from the list of available libraries, and then click **Add**.
   b. To remove a library from the list, select a library from the list of selected libraries, and then click **Remove**.

What to do next

Configuring or editing shared settings of an authoring portlet:

Libraries that are selected by using the "configure" view are available on all instances of the authoring portlet, regardless of the page on which the portlet appears. Libraries that are selected with the "edit shared settings" view are only available for the current instance of an authoring portlet.

The libraries available in the "insert links" and "insert images" dialogs are based on the libraries that are selected in the "configure" view. If you select a library that is not selected in the "configure" view, you cannot select items from this library in the "insert links" and "insert images" dialogs.

You can select libraries specifically for the "insert links" and "insert images" dialogs by following these steps:

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. Search for the page with the unique name of *com.ibm.wps.hiddenpage.wcm.Authoring_Portlet*.
3. Edit the page layout.
4. Edit the shared settings of the web Content Authoring portlet.
5. Select the required libraries and click **OK**.
6. Click **Done**.

Note:

If you syndicate or import a library, it is not automatically added to the list of configured libraries for an authoring portlet on the target server. You must add the syndicated or imported library to each authoring portlet on each server.

Defining preview options:

The preview options determine how content can be previewed. Preview options are defined within the **Previewing Options** section.

Procedure

1. Select **Allow authors to preview content in a Web page** to allow users to preview pages with the Web Content Manager servlet.
2. To allow users to preview content in portal pages, you must select specific portal pages from the list that is located under **Allow authors to preview content in the local portal pages selected**. The portal pages that are displayed here are the pages available on the same instance of the portal where your Web Content Manager application is installed. The selected pages must contain a web content viewer to display the content.
3. To allow users to preview content in a portlet that is on a different portal server, you must enter the URL to the remote portal page in the **Allow authors to preview content using the following URLs** field. The portal pages that are entered here must contain a web content viewer to display the content.

What to do next

Note: When you use a web content viewer to preview content, ensure that the web content viewer is configured to receive links from **Other portlets and this portlet**.

Defining user interface options:

You use the **User Interface Options** section to define the user interface options of an authoring portlet.

Procedure

1. Select a visibility option for the navigation bar. This section is the part of the authoring portlet that displays navigational links to the item views, group by views, and personal views.

   Show If this option is selected, the navigation bar is visible when the home page, launch page, or item forms are displayed.

Hide If this option is selected, the navigation bar is hidden when the home page, launch page, or item forms are displayed. This selection is for users who need to work on basic web content management tasks only.

Hide when home page or launch page is open
If this option is selected, the navigation bar is hidden when the home page or launch page is displayed, but is visible when the item forms are displayed. The initial interface is made simpler, while still having the navigation bar available in other views. This option is for users who need to work on more complex web content management tasks.

Note: The navigation bar is always displayed when you use the library explorer.

2. Select a default view:

Basic home page
If selected, the basic home page is displayed when you first access the authoring portlet. The basic home page is designed for content authors who need to create content items and other simple item types only. They would not usually need access to the more advanced library explorer. The basic home page allows the creation of content with up to six different authoring templates. The authoring templates that are displayed are the favorites of the current user, and the most recently used by the current user.

You can define a set of authoring templates to display on the home page when a user does not have any favorites or recently used items. Add the *wcm.authoringui.homePageTemplates* parameter to the authoring options in the `WCM WCMConfigService` service from the IBM WebSphere Application Server administration console. The paths of the templates must be specified, separated by colons. For example:

```
Library 1/Template Name:Library 2/folder/Template Name 2:Library 3/Template Name 3
```

Home page
If selected, the standard home page is displayed when you first access the authoring portlet. One section of the home page is used to create items and open their favorite locations. Another section of the home page is used to view recent activity. This interface is designed for content authors who need to complete tasks such as creating content, editing their draft content and approving and declining content. They would not usually need access to the more advanced library explorer.

Launch page
If you created a custom launch page to use in place of the default user interface, select **Launch Page**. For example, `file.jsp`.

A custom launch page is a JSP file and must be stored in the WAR file directory for the Authoring portlet. *AppServer_root*`/installedApps/`*cellname*`/PA_WCM_Authoring_UI.ear/ilwwcm-authoring.war/jsp/html`, where *cellname* is unique to your installation. Enter the name of the JSP file in the custom launch page field.

Library Explorer
To use the default user interface, select **Library Explorer**.

3. Select **Hide the open item and view lists** to hide these functions from users in the authoring portlet.
4. To improve performance, you can limit the number of tasks a user can open at the same time in the authoring portlet by entering a number in the **Maximum open tasks per Authoring Portlet instance** field.

5. To improve performance, you can limit the number of items a user can select in an index at the same time in the authoring portlet by entering a number in the **Maximum selected items per action before warning** and **Maximum selected items per action before denying the action** fields.
6. The number of rows that appear in an index is defined in the **Maximum rows per table** field. If blank, this setting defaults to 10. A maximum of 500 rows can set.
7. To enable People Awareness, select **Enable people awareness**. People Awareness helps users to select user names that appear in views and forms within the Authoring Portlet, and send those users an email or Sametime message.
8. Select the default display mode of the library explorer.

   List view mode:
   This mode displays lists of items only as you browse a library.

   Tree view mode:
   This mode displays both lists of items plus a navigational tree as you browse a library.

Editor options:

You can configure IBM Web Content Manager to use different editors for rich text and HTML fields.

Rich text editor

Default
Select this option to use the default JavaScript editor. This editor does not require a working Java runtime environment on the client computer.

EditLive! JavaScript Editor
Select this option to use the EditLive! JavaScript editor. This editor does not require a working Java runtime environment on the client computer. Browser pop-up windows must be enabled to use this editor.

EditLive! Java Editor
Select this option to use the EditLive! Java Editor. This editor requires a working Java runtime environment on the client computer. Browser pop-up windows must be enabled to use this editor.

Custom

Select **Custom** to use a third-party rich text editor as your default editor. Before you enable a compatible third-party rich text editor, read the installation and configuration instructions of the third-party rich text editor. These instructions should include steps for enabling the third-party rich text editor to be used in a Web Content Manager solution.

When you configure a third-party rich text editor, you need to copy a JSP file that is supplied by the third-party rich text editor. This file is used to start the third-party rich text editor. You enter the name of this JSP file in the Rich Text Options section of the authoring portlet configuration.

If the third-party rich text editor is not available, the standard rich text editor is used.

HTML editor

Default
Select this option to use the default HTML editor.

Custom

Select **Custom** to use a third-party HTML editor as your default editor. Before you enable a compatible third-party HTML editor, read the installation and configuration instructions of the third-party HTML editor. These instructions should include steps for enabling the third-party HTML editor to be used in a Web Content Manager solution.

When you configure a third-party HTML editor, you need to copy a JSP file that is supplied by the third-party HTML editor. This file is used to start the third-party HTML editor. You enter the name of this JSP file in the HTML Options section of the authoring portlet configuration.

If the third-party HTML editor is not available, the default HTML editor is used.

Storing JSP files: JSP files are stored within a web application that runs on the portal. To reference a JSP file in another web application, use the following path: `contextPath;jspPath`. For example: `/wps/customapplication;/jsp/jspFilename.jsp`.

A dynamic context path value can be defined by adding a token to the context path that corresponds to a key and value pair to the Web Content Manager configuration service environment provider. When this key is used as the token in the jsp value field, it is replaced dynamically at render time. For example: `mycustomkey;myfile`, where *mycustomkey* is a constant within the Web Content Manager configuration service.

Removing the site toolbar on a production server

The site toolbar provides access to editing features for managed pages, including adding and editing pages and web content. Although essential for an authoring server, it is recommended that you disable the site toolbar on a delivery server. You can disable the toolbar for an entire portal or for specific virtual portals.

About this task

The site toolbar function is not typically needed on a delivery server, and disabling the site toolbar can improve performance on the delivery server.

Procedure

1. Log in to the WebSphere Integrated Solutions Console as an administrator.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP VirtualPortalConfigService**.
4. Update the appropriate configuration properties, depending on whether you want to affect the entire portal or a specific virtual portal.
   - To affect the entire portal, complete the following steps:
     a. Click **Custom properties**.
     b. Edit the **global.toolbar.enabled** property, and set the value to `false`.

     This setting disables the site toolbar for all virtual portals.
   - To affect a specific virtual portal, complete the following steps:

a. Click **Custom properties**.
b. To disable the site toolbar for the default virtual portal, edit the **default.toolbar.enabled** property, and set the value to `false`.
c. For each virtual portal other than the default where you want to disable the site toolbar, specify the following properties.

context.*virtual_portal_context***.property.toolbar.enabled**
Set the value to `false`. Replace *virtual_portal_context* with the context of the target virtual portal (for example, `context.vp1.property.toolbar`.

hostname.*virtual_portal_hostname***.property.toolbar.enabled**
Set the value to `false`. Replace *virtual_portal_hostname* with the host name of the target virtual portal (for example, `hostname.vp.example.com.property.toolbar.enabled`.

If defined, the **global.toolbar.enabled** property acts as a fallback setting for virtual portals that have no values defined.

For more information about prefixes, placeholders, and the order in which properties are evaluated, see *Virtual Portal Configuration Service*

Developing and managing content

Use these tools and processes to develop and manage your website.

"Previewing as another user" on page 1922
You can preview changes to your website without logging out and logging on again as another user. This preview capability is used to quickly verify that users with different access levels see only content that they are authorized to see. You can preview changes as a specific user or as an unauthenticated user.

"Projects" on page 1923
Projects are used to change a set of items on your site and ensure that they are published together at the same time. A new project has a default workflow that allows content to be reviewed and approved before it is published.

"Workflow and change management" on page 1929
You can manage changes to web content items either by creating drafts, by using workflows, or adding items to projects.

"IBM Web Content Integrator" on page 1936
The Web Content Integrator is a solution for integrating externally managed web content with WebSphere Portal Express. By using standard content syndication feed technologies based on RSS 2.0, the Web Content Integrator provides a loosely coupled mechanism for transferring published content and metadata to the portal after they are approved in the source system. When the content and metadata are transferred to the portal, it is possible to use the built-in content management features of Web Content Manager to secure, personalize, and display the content to users.

"WebDAV" on page 1986
With WebDAV for IBM WebSphere Portal Express, you can use standard operating system tools to create, modify, and delete web content rather than the standard authoring portlet.

"Blogs" on page 1999
Use blogs and blog libraries to provide news and commentary on a variety of subjects pertinent to your intranet and extranet sites. Blogs and blog libraries

typically combine text with graphics and links to other blogs and web sites. Entries that you create and post are arranged in reverse-chronological order, with the newest entry displayed first. Readers can post comments about your entries, fostering discussions and online networking. You can manage your own blog entries and comment on other blog entries. You can also incorporate tagging and rating as you would with other WebSphere Portal content.

"Wikis" on page 2005
Use wikis to share community content on a variety of subjects pertinent to your intranet and extranet sites. Wikis typically combine text with graphics and links to other wikis and web sites. You can monitor and manage your own wiki articles.

"Installed portlets" on page 2009
Learn about the portlets that are provided with WebSphere Portal Express.

CF04 "Renditions" on page 2013
Renditions are different versions of an image component or element. Renditions can be thumbnails or smaller versions of an image formatted for mobile devices.

CF04 "Video start and end points" on page 2015
File components or elements that have a video file that is stored in an HTML5 video format, which includes MP4, webM, or ogg, are stored in Brightcove and have a Brightcove ID.

Previewing as another user

You can preview changes to your website without logging out and logging on again as another user. This preview capability is used to quickly verify that users with different access levels see only content that they are authorized to see. You can preview changes as a specific user or as an unauthenticated user.

About this task

While in edit mode, click **More**, and then click either **As User** or **As Unauthenticated User**. The page is updated according to the user that you are impersonating.

To stop previewing, click **Stop Previewing**.

You can modify the preview function to tailor preview behavior in the following scenario:

- User1 creates a project and a page within the project. The new page contains a portlet.
- User1 then attempts to preview the page as User2. In this case, User2 has the permissions to view the page but does not have the permissions to view the portlet that is on the page.
- User1 receives the following message: `You are not authorized to use this portlet`. This message displays to make it clear that a portlet is rendered here, if the user has the required permissions.

You can suppress the message in this scenario.

For more information about the access permissions that are required for previewing as another user, see *Access control for managed pages.*

Procedure

1. Log on to the WebSphere Integrated Solutions Console as an administrator.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP ConfigService**, and then click **Custom properties**.
4. Locate and click the property `portlets.unauthorized.visible.project`. If the property is not listed yet, create it new.
5. Set the value of the property to `false` to suppress the message. The default value is `true`.

Related concepts:

"Access control for managed pages" on page 1256
Access control for managed pages provides more capabilities than access control for standard portal pages. In addition to the access control features available for pages through portal administration, you can also apply IBM Web Content Manager features, like workflow and syndication, to access control.

Projects

Projects are used to change a set of items on your site and ensure that they are published together at the same time. A new project has a default workflow that allows content to be reviewed and approved before it is published.

"Project review state" on page 1924
If you select at least one approver for a project, the project must be submitted for review before it can be published.

"Project States" on page 1924
When you use a project, the project progresses through a series of states.

"Ways to publish a project" on page 1924
Publishing a project refreshes the live website with your changes.

CF05 CF05 "Project Publishing" on page 1925
An outline of the process of publishing a project.

"Drafts and projects" on page 1925
You can create, update, and approve pages in a draft state, without affecting the published site. When you work with pages, you can edit pages as drafts, manage drafts with approval workflow, and then syndicate to publish changes.

"Scope of edits" on page 1926
When you edit pages in a project, you use workflow for approving changes before you publish them until they are approved. If you edit pages without selecting a project, your changes are published immediately.

CF05 CF05 "Project Validation" on page 1927
An outline of the validation process.

"Projects and syndication" on page 1927
Projects are included in syndication, the method that is used by IBM Web Content Manager to replicate data from a web content library on a syndicator server to a web content library on a subscriber server. Although projects are syndicated with other items in a library that is being syndicated, you cannot use the subscriber copy of the project to update or publish your project. Work with projects on the syndicator server only.

"Projects and custom workflow actions" on page 1928
Each workflow stage contains default actions, but you can also create custom workflow actions by creating a custom workflow plug-in.

"Best practices for projects" on page 1928
Use these tips and guidelines to develop and publish projects more effectively.

Project review state

If you select at least one approver for a project, the project must be submitted for review before it can be published.

To enforce a review, a user with editor access or higher clicks **Submit for Review** from the toolbar when all the items in the project are "pending". A project can either require the approval of only a single approver or all approvers. Only when the project is approved will the project itself become pending. The project is then either automatically or manually published depending on how the project is configured.

When a project is in the review state:

- Users with editor access or higher can return a project to an active state by clicking **Withdraw from Review**.
- Approvers can approve a project by clicking **Approve Project** . A project can either require the approval of only a single approver or all approvers.
- Approvers can decline a project by clicking **Reject Project**. The project is returned to the active state.
- If joint approval is specified, approvers can withdraw an approval while the project is still in review by clicking **Withdraw Approval**. The users's approval is withdrawn, but the project remains in a state of review.

Project States

When you use a project, the project progresses through a series of states.

Active A project that has draft items in it is considered "active". These items can be individually approved until they reach a state of "pending".

Syndicating
If "All items" or "Live and project" syndication is enabled for a library, a status of "Syndicating" is displayed on the project until all items on both the syndicator and subscriber reaches a state of pending.

Review
If any approvers are assigned to a project, the project can be submitted for review when all items in the project are in a pending state. If approved, the project then progresses to pending.

Pending
A project that contains only items in a "pending" state, or is approved, is itself considered "pending". If the project publish option is set to automatic this state is skipped. When the project is published manually or when the publish date is reached, the project moves to the "publishing" state.

Publishing
This state is the state where all items in the project move from pending to published.

Publish Failed
Indicates that one or more project items failed to publish.

Published
When all items are published, the project achieves a state of "published".

Ways to publish a project

Publishing a project refreshes the live website with your changes.

These publishing methods are used by projects:

Date When **Date** is selected, all items are published as soon as all the items in the project reach a state of "pending" and the publish date that is selected in the project is reached. You can also click **Publish** in the project form before the date is reached when all items in the project reach a state of "pending".

Manual
When **Manual** is selected, all items remain in a state of "pending" until the project is manually published by clicking **Publish** in the project form. The **Publish** function is not activated until all items in the project reach a state of "pending". Only users with editor access or higher to a project can publish a project.

Automatic
When **Automatic** is selected, all items are published as soon as all the items in the project reach a state of "pending".

When the project is published, you can continue to review the status and version history of the items in the project by opening the project form.

Note: You and other users can update the same items in multiple projects. Messages are displayed when you move an item to the publish state to warn you when this event occurs.

Project Publishing

An outline of the process of publishing a project.

- When a project publish action is initiated, all the project items are validated one by one until all items are processed.
- If any project item fails the validation, no attempt is made to publish any of the items in the project. The project state updates to "Publish Failed".
- The failed item is displayed in a table with the reason for failure. The user then modifies their content in preparation for the next validation or publish attempt.
- When all items pass the pre-publish validation, all project items are eligible to be published. The publishing process then starts, and each project item is attempted to be published one at a time.
- Any item that fails is displayed in a table with the reason for failure. The next item will then be published.
- If any items fail to validate or publish, the project state is "Publish Failed".
- If all items in the project are successfully published, the project state is "Published".

Drafts and projects

You can create, update, and approve pages in a draft state, without affecting the published site. When you work with pages, you can edit pages as drafts, manage drafts with approval workflow, and then syndicate to publish changes.

The page structure is replicated in the site structure of a web content library. Due to this integration, you can add web content directly underneath a page with the authoring portlet and use the portal page as a site area for organizing your content. Syndication then publishes the page, ensuring that changes to the page and to its associated web content are published at the same time. Update pages in a draft state first. Drafts are organized within projects in Web Content Manager. When you publish draft changes to the published site, a project coordinates the updates and ensures that all drafts are published at the same time.

The following changes inside of the scope of a project to a page managed with Web Content Manager result in a draft that is not visible on the published site and is only visible within the project:

- Any action that is run by using the toolbar, such as adding content to page, changing the page style, or changing the page layout.
- Changing the access control that is granted to a page.
- Changing the page properties.
- Creating a child page.
- Moving a page.
- Deleting a page.
- Changing the community or web content associations for a page.
- Creating or modifying portlet wires for communication between portlets on the same page or on different pages.
- Changing the portlet configuration with the **Shared Settings** mode of the portlet.

Changes to page draft elements result in either a new draft or an update to an existing draft. A page draft consists of the following elements:

- The page item itself, including title, description, metadata, and properties.
- The access control of the page.
- The page layout.
- Any public page wires that are connected to portlets on the same page or on another page.
- Any portlet preferences that are defined in **Edit Shared Settings** mode.
- The web content mappings of the current page.
- The Vanity URLs of the current page.

Scope of edits

When you edit pages in a project, you use workflow for approving changes before you publish them until they are approved. If you edit pages without selecting a project, your changes are published immediately.

When you edit pages, it is good practice to work within a project. When you are working in a project, any changes that you make to a page affect only the view within the project. After the project is approved and published, the changes are then available to all users.

Note: Changes to private pages and community pages are not part of a project. When you are working in a project, actions that personalize or create a private page are not visible.

When no project is selected, you are modifying the published site. Changes to public pages affect all users and are available immediately. While you work on the published site, changes that other users are making within active projects are not visible.

Related tasks:

"Adding workflow to managed pages" on page 1935
The default workflow that is used for published pages has only a draft and approved state. However, if the default workflow is not sufficient, you can define custom workflows and use them with published pages.

Default workflow for pages in projects: To make the page changes available on the published site, you must submit the page for review and approval. The steps for the workflow depend on what is defined for the page. By default, a simple workflow is assigned to page or URL mapping drafts. The default workflow (Express Workflow) has only two states: draft and published. For pages that use this workflow, submitting the draft moves the page to the publish pending state. When all other changes in the project are published, the pending draft page is also published. After all items in the project reach the pending state before publishing, you can publish the project by clicking **Publish** in the project menu.

Note: If you use the authoring portlet to edit the access settings for a page that is part of a workflow, you cannot modify the approvers. To change the approvers for the page, you must set the approvers on the workflow stage that currently contains the page.
However, you can change the assigned workflow in the user interface to include more review and approval stages on the project level in Web Content Manager. After the draft changes in the project are approved and published, the updated pages are visible to all users. For details on using a custom workflow, see *Adding workflow to managed pages.*

Project Validation

An outline of the validation process.

- Validating a project enables the user to check all items in a project for potential problems before the project is published. The project validation is the same validation process that is part of project publishing.
- If any item fails the project validation, they are added to a table that displays a list of items that have failed a project validation or publishing with the reason for failure.
- The user must modify their content to correct the problem before another project validation or project publishing action is initiated.
- When a validation completes, the project displays the list of items that failed the validation, the list of draft items in the project, the time that the validation was completed, and the number of items that failed.
- A validation can be initiated on a project only when it is in Pending, Publish Failed, Review, or Active State.
- A validation can be initiated by using the Authoring Portlet when a project is in read-mode.
- Only one validation per project can be initiated or running at any one time.
- A project publish action cancels any project validation for that project that is in progress because validation is part of publishing a project.

Projects and syndication

Projects are included in syndication, the method that is used by IBM Web Content Manager to replicate data from a web content library on a syndicator server to a web content library on a subscriber server. Although projects are syndicated with other items in a library that is being syndicated, you cannot use the subscriber copy of the project to update or publish your project. Work with projects on the syndicator server only.

Deferred to Syndication

When a project is syndicated, the publish method on the subscriber is automatically changed to "Deferred to Syndication", and the following actions are not enabled on the subscriber:

- CF05 Validate project
- Publish project
- Add to project
- Remove from project
- Mark for deletion
- Cancel deletion

This means that the project on the subscriber cannot be updated or published unless it receives updates from the syndicator.

When projects syndicate

Projects are not associated with a library. As syndication is library-based, a project is only syndicated when it contains unpublished items. Empty projects or previously published projects are not syndicated. Therefore, you might encounter some unexpected behavior. For example:

- If you delete a project on the syndicator and that project is empty on the subscriber, then the project deletion does not syndicate to the subscriber, because empty projects are not syndicated.
- However, if you remove all items from a project on a syndicator and then delete the project before syndication, then the project deletion is syndicated because there are still items in the subscriber version of the project.

Projects and custom workflow actions

Each workflow stage contains default actions, but you can also create custom workflow actions by creating a custom workflow plug-in.

You can assign custom workflow actions to run when a project enters a specific state in a project. For example, you might a create custom workflow action that can:

- verify web standards compliance for all assets within the project that includes items that are not traditionally workflowed, such as components and presentation templates.
- automatically reject a project if it is in review for a certain period.
- automatically delete a project when it is successfully published.

Best practices for projects

Use these tips and guidelines to develop and publish projects more effectively.

Use separate projects for different parts of the site structure

Coordinating projects is an important part of ensuring that changes to your website are published as expected. For example, you might have two authors working on the same part of the site structure but with each author editing pages in a different project. Because the authors are working in different projects, they cannot see draft changes that the other author makes until the projects are published. If both authors insert a new page between the same two published pages, the resulting page order might not be what was intended.

To prevent these situations, avoid editing the same part of the site structure with multiple projects at the same time. Instead, when multiple projects are used at the same time, ensure that you use each project for a different part of the site structure.

Coordinate changes to a project across users

When multiple users are working in the same project, one user might not be aware of the changes that another user makes. If you change the state of the project, such as deleting it or publishing it, any outstanding updates from other users are not saved. To ensure that you do not inadvertently discard changes from other users, coordinate with users of the project before the state of the project is changed.

Coordinate unique names across projects

When multiple projects are used for the same site, similar unique names might be introduced in different projects. For example, you might have two authors working on the same site but with each author editing in a different project. Because the authors are working in different projects, they cannot see draft unique names that the other author uses until the projects are published. If both authors insert a similar unique name, the result might not be what was intended.

To prevent these situations, avoid introducing new unique names with multiple projects at the same time. Instead, when using multiple projects at the same time, ensure that you use different unique names within each project.

Workflow and change management

You can manage changes to web content items either by creating drafts, by using workflows, or adding items to projects.

"Item status"
There are three major status levels that an item can be in at any one time; **Draft**, **Published**, or **Expired**. The current state of an item indicates where the item exists within a change management process, and where that item can be viewed and accessed.

"Workflow stages and actions" on page 1930
You use workflows to control the access to, verification and eventual approval of items. Only if an item is approved at all stages up to a published stage can it be viewed on your website.

"Adding workflow to managed pages" on page 1935
The default workflow that is used for published pages has only a draft and approved state. However, if the default workflow is not sufficient, you can define custom workflows and use them with published pages.

Item status

There are three major status levels that an item can be in at any one time; **Draft**, **Published**, or **Expired**. The current state of an item indicates where the item exists within a change management process, and where that item can be viewed and accessed.

Status types

Draft This indicates that the item is being updated.

Pending published
An item that uses a workflow can appear in a state of pending published. This indicates that the item has entered a workflow stage that includes a publish action but the action has yet to be processed.

Published
A published status indicates that an item is ready to be rendered in the live site.

Pending expired
An item that uses a workflow can appear in a state of pending expired. This indicates that the item has entered a workflow stage that includes an expire action but the action has yet to be processed.

Expired
An expired status indicates that an item is ready to be expired from the live site.

Changing status

The status of an item can change only in a linear fashion:

- **Draft** to **Published**.
- **Published** to **Expired**.
- **Expired** to **Published**.
- **Published** to **Draft**.

You cannot change an item's status from **Expired** to **Draft**.

The process of publishing and expiring items

When the status of an item changes to published or expired, this change does not mean that the item has been added or removed from the rendered site. A status of published or expired means that the process of publishing or expiring an item has begun.

The actual time a published item appears on a website, or the time an expired item is removed from a website, also depends on:

- how long it takes to syndicate updates to the delivery server
- how long it takes for the current cache to expire

Workflow stages and actions

You use workflows to control the access to, verification and eventual approval of items. Only if an item is approved at all stages up to a published stage can it be viewed on your website.

A workflow must have at least one stage, but typically has more, and it always flows in a linear pattern. You can use a workflow to:

- Review the accuracy of content.
- Review content for any legal implications.
- Review content to ensure that it meets accessibility guidelines.
- Ensure that no malicious code such as cross scripting attacks are added to content.

A reject stage can be specified, which is a stage that is run when a document is declined, before the document is moved it to the first stage of the workflow. If the item is rejected at any stage, someone with editor access needs to correct or amend the item and resubmit it into the selected workflow (for approval). All items that are rejected (regardless of the stage they are at in the approval process) are sent back to the first (creation) stage of the workflow.

You can also specify that a comment must be entered on every move a document makes in the workflow or only on specific stages. This comment is added to the document's history section.

Workflow stages:

Workflow stages are the building blocks of a workflow. You need to create at least one stage before you can create a workflow.

Workflow stages

Stages determine:

- What actions to run when an item enters or exits a workflow stage
- The access levels of users or groups within that stage.

In most cases, actions are run when an item enters a stage. For example, you add a scheduled move action to run on entering a stage so that it is enabled as soon as an item enters that stage. However, if you set a scheduled move action to run on leaving a stage, it is never run. The most common type of actions to run on leaving a stage are email actions, when you want to notify users that an item has exited a workflow stage.

Note: Some actions need to be run in a specific order. For example:

- A scheduled move action must always be the final action in a workflow stage, because any actions scheduled after a scheduled move action is not run.
- You cannot run a version action before a publish action because you cannot save versions of draft items.
- If you use a custom action, you can run the custom action before the email action is run, so that the draft content item is in a state ready to be reviewed by an approver.

Note: The access settings that are defined in the properties section of the workflow stage form are the security settings that are applied to items during a workflow, not the Security section of a workflow stage. The Security section defines who has access to the workflow stage item itself.

Reject stages

In addition to the workflow stages that make up a workflow, workflow stages are also used as part of rejecting an item. When an item is rejected, a reject stage can be triggered that runs pre-defined actions. When the actions are run, the item is returned to the first stage of the workflow.

Workflow actions:

Each workflow stage contains sets of actions; actions that are run when an item enters the stage, and actions run when an item exits the stage. The exit actions are restricted to non-scheduled actions, since they must be run immediately.

The following table describes the actions that you can choose for workflow stages.

Table 278. Workflow stage actions

Action	Details
Publish	Changes an item's Status from **Draft** to **Published**. The item is available on the rendered site. An item is published when it enters a workflow stage that contains a publish action, and when the selected published date and time are reached.
Expire	Changes an item's Status from **Published** to **Expired**. The document is no longer available on the site. An item is expired when it enters a workflow stage that contains an expire action, and when the selected expire date and time are reached.
Email	This action sends emails when run. You can create new email actions and specify who the recipients are. You can select to email approvers, authors, and owners. You can also create a list of other users or groups to email. A link to the Item to be reviewed is included in the email.
Scheduled Move	Runs a scheduled move to the next stage on a specified date. A list-box allows users to select one of four date types that are entered on each individual document, or you can specify a static date.
Version	This action creates a version of an item when run.
Custom	You can also create custom workflow actions by creating a custom workflow plug-in. These actions can be used and scheduled within a workflow like other workflow actions.

Access to items during a workflow:

If an item is participating in a workflow, the creator is given manager access to the item only in the first workflow stage. As the item progresses through a workflow, the item access is determined by the combined workflow and system defined access levels.

Table 279. Security matrix

Security level	First workflow stage	Other workflow stages
User **Contributor** **Editor** **Manager** **Reviewer** **Draft Creator**	• Administrator defined • Workflow defined	• Administrator defined • Workflow defined
Administrator	If you are assigned the administrator role to a library, you automatically inherit all administration access down to the item-level. It cannot be turned off.	If you are assigned the administrator role to a library, you automatically inherit all administration access down to the item-level. It cannot be turned off.

Joint approval:

Joint approval is used in cases where approval from multiple users is required before an item is moved to the next stage.

- You specify which stages you want to be jointly approved.
- If joint approval is active, then all the approvers that are specified for this stage must approve the document.
- The exception is an administrator, who can force a document to the next stage.
- If a group is specified as an approver, only one user per group is required to approve the document.
- If that user is a member of more than one Group that has Approve access, then all the groups are considered to have approved the document.

Workflow example:

This example describes the steps that are required to create a four stage Workflow.

Actions

The actions that are required for this workflow are:

Table 280. Actions

Action	Description
Publish	Makes a document visible as a published document on the website.
Scheduled Move	This scheduled move action detects when a document passes its expire date and moves the document into the Expired stage.
Expire	Stops a document from being visible on the website.
Email	Sends emails to selected users. In this example, you select "Email Stage Approvers".

Stages

The following stages make up the Workflow:

Table 281. Stages

Workflow Stage	Actions on Entering	Description
Stage 1, Draft		All content begins the Workflow in this Stage. All content authors are authorized to use the Draft stage.
Stage 2, Review	**Email**	Content requires a review stage before it is published. A small group of people are authorized to approve content in this stage and move it to the Publish stage. The email action sends an email to each approver.
Stage 3, Publish	**Publish** **Scheduled Move**	This is the stage where content from the workflow is published. The **Publish** action is triggered when the **Publish Date** is reached. At this point, the content is visible on the website. The **Scheduled Move** action is triggered when the **Expire Date** is reached.
Stage 4, Expired	**Expire**	The **Scheduled Move** action moves the content into this stage, where the **Expire** action stops the document from being visible on the website.

Progressing through the workflow

Table 282. Progressing through the workflow

Process	Stage	Status
An item is first created and saved:	**Stage 1, Draft**	**Draft**
When the Item Creator is ready, they move it to the next stage.	**Stage 2, Review**	**Draft**

Table 282. Progressing through the workflow (continued)

Process	Stage	Status
An Approver would then access the document and review it. If Approved, the item would be moved to the next stage. The Status is **Draft** pending **Published**. This is because the time specified in the **Publish Date** field of the item has not yet been reached.	**Stage 3, Publish**	**Draft** pending **Published**
Once the **Publish Date** is reached, the item's Status changes to **Published**. The item is still in **Stage 3, Publish**, but the Status has changed.	**Stage 3, Publish**	**Published**
Once the **Expire Date** is reached, the document is moved to the final stage. As both the **Scheduled Move** and **Expire** actions are using the **Expired** date in this example, the item's Status immediately changes to **Expired**. If the **Scheduled Moved** Action used a **General Date** prior to the **Expire Date**, then the item's Status would remain as **Published** pending **Expire** until the **Expire Date** was reached even though it had entered **Stage 4, Expire**.	**Stage 4, Expire**	**Expired**

Using workflows and access to workflow items:

Users do not require access to a workflow's actions or stages to participate in a workflow. Actions are performed using system access and are not determined by the access of the user who approved/rejected the item.

Adding workflow to managed pages

The default workflow that is used for published pages has only a draft and approved state. However, if the default workflow is not sufficient, you can define custom workflows and use them with published pages.

Before you begin

Before you do this task, ensure that you add the **Portal Site** library to the list of libraries that you can edit in the **Web Content Authoring** tab. In the **Web Content**

Authoring tab, click **Preferences**, and then click **Configure** or **Edit Shared Settings**.

About this task

To use a custom workflow with a published page, you must create a page template and specify the custom workflow on the template. When you create a page that is based on the template, the custom workflow is used for the page.

Important: Users with Privileged User access can personalize a page by adding content or by making other customizations to the page. Because Privileged User access is inherited by pages by default, your custom workflow can be bypassed by users with this access. If you want to ensure that users can update the page only through the workflow, disable the inheritance of Privileged User access for the page.

Procedure

1. In the **Web Content Authoring** tab, create any workflow stages that you require and then create the custom workflow.
2. Create a project to use for creating the page template.

   Note: Because you can set a workflow only on draft items, you must create the template as a draft in the context of a project. After you add your custom workflow to the draft, publish the draft to make the page template available.
3. In the **Web Content Authoring** tab, select **Project Views** > **All Projects** and select the new project as the current context.
4. Click the **Administration menu** icon . Then, click **Portal User Interface** > **Page Templates**.
5. Select **Create** from the site toolbar and create the page template.
6. Add the workflow to the template.
   a. In the site toolbar, select **Menu** > **Edit Page Properties** to display the Manage Page Properties window.
   b. Select the **Security** tab.
   c. In the **Workflow** section, click **Select** in the **Workflow** field.
   d. Select the custom workflow, and click **OK**.
   e. Exit out of the Manage Page Properties window.
7. Approve and publish the project to make the page template available for use.
   a. In the **Projects** menu of the site toolbar, select **Manage Project**.
   b. Select the page template in the list of project items, and click **More** > **Approve**.
   c. Click **Publish Project**.

What to do next

After you complete this task, you can select the new page template when you create a page in a project, and the custom workflow is automatically used.

IBM Web Content Integrator

The Web Content Integrator is a solution for integrating externally managed web content with WebSphere Portal Express. By using standard content syndication feed technologies based on RSS 2.0, the Web Content Integrator provides a loosely coupled mechanism for transferring published content and metadata to the portal

after they are approved in the source system. When the content and metadata are transferred to the portal, it is possible to use the built-in content management features of Web Content Manager to secure, personalize, and display the content to users.

To use the Web Content Integrator you must:

1. Create a feed on your source system by using the Web Content Integrator feed format specification.
2. Configure WebSphere Portal to consume the feed.

Feed format specification

RSS, or Really Simple Syndication, is an XML-based format that is widely used for syndicating content from sources such as websites and blogs to readers who are subscribed to the feeds. The input to the Web Content Integrator is a content feed that complies with the RSS 2.0 format. The core feed format is relatively simple, with only a limited number of elements that need to be specified for each item in the feed. However, the RSS 2.0 specification allows the base format to be extended by using XML namespaces to support extra functions. To enable a deeper level of control over how items are created in Web Content Manager, an RSS extension is defined which contains elements that map to many of the attributes of the Web Content Manager object model.

"Feed format overview"
RSS 2.0 is a dialect of XML, and all RSS files must comply with the XML 1.0 specification as published by the World Wide Web Consortium (W3C). RSS feed files typically have file extensions of either .rss or .xml. The Web Content Integrator does not impose any file naming conventions on the feed producer.

"RSS Namespace Extension for web content" on page 1940
Web Content Manager items contain a set of controls that are used to store information for various purposes. The elements in this namespace roughly map to the fields that are available on those controls. Depending on the type of the item, it can or can not contain certain controls so some of the elements in the namespace are only relevant to specific item types. All of the elements in this namespace are sub-elements of `<item>`, none are used at the `<channel>` level.

"How to handle embedded links" on page 1971
From time to time, the content that is being retrieved by the Web Content Integrator contains embedded links to images, files, and other content within the feed. You can use the link tag in your feed to represent embedded links so that they are converted into links to other Web Content Manager items that are created when the feed is processed.

"Processing images" on page 1976
The Web Content Integrator has an image-processing feature, which allows images that are referenced within HTML and rich text elements to be created as image components while processing a feed.

"Example feeds" on page 1979
View some example feeds that illustrate how to represent the various item types within a feed.

"RSS Namespace Extension for the Feed Service" on page 1982
The RSS namespace extension is used to exchange control information between the feed producer and consumer applications.

Feed format overview

RSS 2.0 is a dialect of XML, and all RSS files must comply with the XML 1.0 specification as published by the World Wide Web Consortium (W3C). RSS feed

files typically have file extensions of either .rss or .xml. The Web Content Integrator does not impose any file naming conventions on the feed producer.

RSS 2.0 feed file format

The most commonly used media type options are "text/xml" and "application/rss+xml". The choice of media type does impact how the Web Content Integrator is able to determine the character encoding of the feed. If the character encoding cannot be determined correctly, the Web Content Integrator will produce errors when parsing the feed. Therefore it is important to choose an appropriate media type for your environment.

Following the XML prolog, an RSS 2.0 file begins with a single <rss> element. This element has one required attribute, "version", which must be set to "2.0". The file must also contain a single <channel> element which contains a number of sub-elements that provide some metadata about the feed as a whole. The <channel> element must contain one or more <item> elements. The <item> elements in turn contain sub-elements which provide information about the content that is being syndicated. For example:

```
<?xml version="1.0"?>
<rss version="2.0">
 <channel>
  <title>Sample Feed</title>
  <link>http://www.ibm.com/feeds/sample.rss</link>
  <description>An example RSS Feed</description>
  <lastBuildDate>Tue, 31 Oct 2006 10:31:00 EST</lastBuildDate>
  <item>
   <title>News Item Two</title>
   <link>http://www.ibm.com/news/two.htm</link>
   <description>
   This is a summary of the second news article
   </description>
   <pubDate> Tue, 31 Oct 2006 10:31:00 EST</pubDate>
  </item>
  <item>
   <title>News Item One</title>
   <link>http://www.ibm.com/news/one.htm</link>
   <description>
   This is a summary of the first news article.
   </description>
   <pubDate> Tue, 31 Oct 2006 10:30:00 EST</pubDate>
  </item>
  </channel>
 </rss>
```

Note: If non-ascii data is used in a feed, then encoding="UTF-8" must be specified in the feed: `<?xml version="1.0" encoding="UTF-8"?>`

Channel-level Elements

Each RSS feed file must contain only one channel element. There are a number of allowable sub-elements of the channel that provide some metadata about the channel itself. The following elements are either required or used by the Web Content Integrator.

`title` This element is used to provide the name of the feed. This element is required by the RSS 2.0 specification but is not used by the Web Content Integrator.

link This element contains a URL that points to the Web page containing the feed. This element is required by the RSS 2.0 specification but is not used by the Web Content Integrator.

description
This element contains a brief description of the content of the channel. This element is required by the RSS 2.0 specification but is not used by the Web Content Integrator.

lastBuildDate
This element contains a date and time stamp representing the last time the content of the feed was changed. This date, as well as any others in the feed, must conform to the RFC 822 format. This is an optional element according to the RSS 2.0 specification, however some feed reader applications may depend on it. In certain cases the Web Content Integrator will store the value in the lastBuildDate element and then pass it back to the feed producer on the next request as a way of indicating which version of the feed it has already syndicated.

Item-level Elements

For the purposes of the Web Content Integrator, each item in the feed represents an item type. The following item types can be created or updated via the feed:

- Content items
- Site Areas
- Taxonomies
- Categories
- Component

The following sub-elements are either required or used by the Web Content Integrator:

title The value of this element is stored in the Name field of Web content items. For content items this becomes part of the URL to the content page. As this is used in the Name field of Web content items, the title can contain only alphanumeric characters (a-z, A-Z, 0-9), spaces, and the following characters: $ - _ . ! ( ) , This is a required sub-element.

link This is the URL to the source content. In some cases it will be used as the base URL from which any relative links embedded in the content are resolved.

description
The value of this element will be stored in the Description field of Web content items. Although the RSS specification allows entity-encoded or escaped HTML to be placed in this element, the Description field in Web content items is not designed to store HTML. For the purposes of the Web Content Integrator this element must only contain plain text.

pubDate
The value of this element must be an RFC 822 time and date stamp representing the time that the item was added to, or updated in, the feed. The Web Content Integrator will use this date in combination with the <guid> element to determine whether or not it has already processed the item. Each time an item is updated via the feed the value of the <pubDate> in the feed entry will be updated as well to indicate that something has changed. This is a required sub-element.

guid The <guid> element must contain an ID to uniquely identify the item. This will often be a unique ID from the source content management system. The Web Content Integrator will maintain a mapping of this ID to the item's internal Web Content Manager ID. This is necessary in order to be able to correctly update or delete items that already exist in Web Content Manager. This field is case sensitive and can contain any string of characters up to a maximum 256 characters in length. The isPermaLink attribute will be ignored. This is a required element.

category
Each <category> element will contain a hierarchical meta data tag that describes the content. The value of this element will be translated into taxonomy and category items in Web Content Manager. If the category tree specified in the <category> element does not already exist in Web Content Manager it will be created automatically by the Web Content Integrator when the feed entry is processed. The RSS 2.0 specification defines an optional domain attribute for the category element. Feed producers can use this attribute to store the name of the Web content library where the category tree is to be created. This element only applies to content items. A single <item> may contain multiple category elements. As this will be used in the Name field of Web content taxonomy and category items, the title can contain only alphanumeric characters (a-z, A-Z, 0-9), spaces, and the following characters: $ - _ . ! ( ) , This is a required sub-element.

author According to the RSS 2.0 specification this element contains the author's e-mail address. The specification only allows a single <author> element per item. Generally this will be the author of the content item in the source content management system. The Web Content Integrator will attempt to resolve the e-mail address into the common name of a portal user and then store the name of that user in the author field the Web Content Manager item. If this element is not present in the feed, or if the e-mail address cannot be resolved, then the name of the system user will stored in the author field of the Web Content Manager item instead.

RSS Namespace Extension for web content

Web Content Manager items contain a set of controls that are used to store information for various purposes. The elements in this namespace roughly map to the fields that are available on those controls. Depending on the type of the item, it can or can not contain certain controls so some of the elements in the namespace are only relevant to specific item types. All of the elements in this namespace are sub-elements of `<item>`, none are used at the `<channel>` level.

"Adding the custom namespace definition to the feed" on page 1941
The first requirement is to add the namespace reference to the `<rss>` element at the beginning of the feed.

"Process Control Elements" on page 1942
These elements are used to provide the Web Content Integrator with some information about how to handle the data that is contained within the `<item>`.

"Location Control Elements" on page 1943
These elements are used to provide the Web Content Integrator with some information about an item's relative location.

"Identity control elements" on page 1948
Most identification fields in Web Content Manager items map directly to core RSS elements; `<title>` maps to the name field, `<description>` maps to the description field, and `<author>` maps to the authors field. Other identification fields can be populated by using the following identity control elements.

"Profile Control Elements" on page 1949
Taxonomies and category fields are populated by using the RSS <category> element. To populate the **Keywords** field, a keywords element is required.

"The authoringTemplate element" on page 1950
The authoringTemplate element is used to specify the authoring template that is applied to a content item or site area. The value of this element must be the name of an existing authoring template.

"Element control element" on page 1951
The element control element is used to populate elements that are stored in components, site areas, and content items.

"Workflow control elements" on page 1966
Workflow elements is used to specify workflow-related parameters when content items are created that use a workflow.

"Security control elements" on page 1969
The security control element is used to set access controls on the item that is being created.

"Association control element" on page 1970
The association element is used to create an association between two or more separate content items. It is used to support some content item relationships that are not native to Web Content Manager but that are found in some other web content management systems. One example would be a technical journal article that needs to include some data from one or more author biography content items.

Adding the custom namespace definition to the feed:

The first requirement is to add the namespace reference to the <rss> element at the beginning of the feed.

About this task

The URL of the namespace is specified by using the following tag:

```
<rss version="2.0" xmlns:ibmwcm="http://purl.org/net/ibmfeedsvc/wcm/1.0" >
```

This is a fixed property value that the feed parser uses as the key to identify elements that belong to the custom Web Content Integrator namespace.

Example

For example:

```
<?xml version="1.0"?>
 <rss version="2.0" xmlns:ibmwcm="http://purl.org/net/ibmfeedsvc/wcm/1.0" >
 <channel>
  <title>Sample Feed</title>
  <link>http://www.ibm.com/feeds/sample.rss</link>
  <description>An example RSS Feed</description>
  <lastBuildDate>Tue, 31 Oct 2006 10:31:00 EST</lastBuildDate>
  <item>
   <title>News Item Two</title>
   <link>http://www.ibm.com/news/two.htm</link>
   <description>
   This is a summary of the second news article
   </description>
   <pubDate> Tue, 31 Oct 2006 10:31:00 EST</pubDate>
```

```
   <ibmwcm:itemType>Content</ibmwcm:itemType>
  </item>
 </channel>
</rss>
```

The namespace label "**ibmwcm**" can be changed if the label specified in the namespace declaration matches the label that is used on the extended elements in the feed.

Process Control Elements:

These elements are used to provide the Web Content Integrator with some information about how to handle the data that is contained within the <item>.

action

This element indicates the action to be run on the item that is represented by the <item>.

Table 283. action element

Element parameters:	Details for this element:
Applies to item types	All
Required for item types	All
Allowable Values	"add", "update", or "delete".
Required Attributes	None
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Example:

```
<ibmwcm:action>update</ibmwcm:action>
```

itemType

The itemType element indicates the type of item that is represented by the feed entry. These correspond to the Web Content Manager item types that can be created or updated via the feed. In some cases, the value of this element is combined with the value in the <ibmwcm:path> element to determine which Web Content Manager item type to create.

Table 284. itemType element

Element parameters:	Details for this element:
Applies to item types	All
Required for item types	All
Allowable Values	"siteArea" for site areas. "content" for content items. "component" for components. "category" for taxonomies and categories.
Required Attributes	None

Table 284. itemType element (continued)

Element parameters:	Details for this element:
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Example:

Site Area

```
<ibmwcm:itemType>siteArea</ibmwcm:itemType> + any other value for <ibmwcm:path>
or the lack of an <ibmwcm:path> element.
```

Taxonomy

```
<ibmwcm:itemType>category</ibmwcm:itemType> + <ibmwcm:path>/</ibmwcm:path>
```

Category

```
<ibmwcm:itemType>category</ibmwcm:itemType> + any other value for <ibmwcm:path>
or the lack of an <ibmwcm:path> element.
```

Component

```
<ibmwcm:itemType>component</ibmwcm:itemType>
```

Content

```
<ibmwcm:itemType>content</ibmwcm:itemType>
```

Location Control Elements:

These elements are used to provide the Web Content Integrator with some information about an item's relative location.

`library`

You must specify a default web content library name when configuring a task to consume an input feed. The Web Content Integrator performs all operations within that library including creating new Web Content Manager items, searching for existing versions of items, and searching for any associated design artifacts such as authoring templates and workflows. You can also override this setting so that a single feed can be used to create content in multiple libraries.

There are three ways that Web Content Integrator will check if a value was specified in this element:

- If the library specified in the library element matches an existing web content library, all operations during the processing of this feed entry is processed within the context of the library specified in the library element.
- If no library element is present in the feed entry, or if the library element is present but no value was specified then the default library from the task configuration is used.
- If a value is specified in the library element but no matching web content library is found, then an error message is logged and the feed entry will not be processed.

Table 285. `library` element

Element parameters:	Details for this element:
Applies to item types	All
Required for item types	None

Table 285. **library** *element (continued)*

Element parameters:	Details for this element:
Allowable Values	The name of an existing web content library.
Required Attributes	None
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Example:

```
<ibmwcm:library>LibraryName</ibmwcm:library>
```

path

The **path** element is used to indicate the hierarchical path to the web content item. For site areas and content items, this element contains the parent site area path. For categories, the value is the parent category path.

Site areas and categories can only have a single path element. If more than one path element is specified, only the first is used. Content items can have multiple parents, so multiple path elements can be used. The first path element is used as the main content item and the following path elements are treated as content links. An optional "library" parameter can be specified for path elements referring to linked content in a different library from the main content item.

New items are added to the end of the current list of items within Web Content Manager.

The path element cannot be used with components. Components can only be created under the "Components" preset folder.

Table 286. **path** *element*

Element parameters:	Details for this element:
Applies to item types	siteArea, Category, Content
Required for item types	Site Areas and Taxonomies.
Allowable Values	All values should start with a leading forward slash "/" character. For site area and taxonomy items the value should be just a single forward slash "/".
Required Attributes	None
Optional Attributes	"library" Contains the name of a library where the site path resides. This attribute is used where linked content resides on a different library from the main content. This attribute is ignored on the first path element that is listed in the feed entry.
Required sub-elements	None
Optional sub-elements	None

Examples:

```
<ibmwcm:path>/</ibmwcm:path>

<ibmwcm:path>/IBM/Products</ibmwcm:path>

<ibmwcm:path library="en_US">/Intranet/Home/News</ibmwcm:path>
```

createLinks

This is used to specify which parent items to link to when creating content items.

Table 287. **createLinks** *element*

Element parameters:	Details for this element:
Applies to item types	Content
Required for item types	None
Allowable Values	The **createLinks** element is a container for readability and has no attributes or expected values.
Required Attributes	None
Optional Attributes	None
Required sub-elements	**parentGuid** The **parentGuid** element should contain the unique ID of another item in the feed that describes the parent item.
Optional sub-elements	None

Examples:

```
<ibmwcm:createLinks>
 <ibmwcm:parentGuid>8234ad23fb29</ibmwcm:parentGuid>
</ibmwcm:createLinks>
```

The Orphan Container

If no valid parents or paths are specified in the feed, then the item is placed into an orphan container until it is able to be updated with a valid path. The Web Content Integrator will automatically create an orphans container in each Web content library as it is needed. For site areas and content items, the orphan container is a site area path name `WCI/Orphans`. For categories, the orphan container is a taxonomy and category path with the name `WCI/Orphans`. The name of the orphan containers can be controlled through a setting in the `WCMConsumerPlugin.properties` file.

children

The **children** element is used to specify the children of the current item. The value of this element should be the GUID of another entry in the feed that describes a child of the current item.

The referenced child item must be of an appropriate type. For site areas, the children must be site areas or content items. For taxonomies and categories, the children must be categories. If the type is not valid, the parent item will still be added or updated, but the child reference will not be created.

Multiple childGuid sub-elements can be contained within the children element. If multiple children are specified, they are added in the order in which they are listed in the feed. This allows the feed producer to control the order in which site areas and content items are linked to their parent site area which can be useful for setting up navigation displays.

There are two attributes of the children element that control how the children specified in the feed get combined with any children that may already be contained by the parent item. The action attribute controls whether the child list in the feed replaces the existing list of children. If the value of that attribute is set to "add", then the children that are specified in the feed is combined with the existing list of children. Any other value, including an empty string or the absence of this attribute, causes the list of children that are specified in the feed to completely replace the pre-existing list.

The position attribute is only relevant when the action attribute is set to "add". This attribute controls whether the children specified in the feed are added to the start or to the end of the pre-existing child list. If this attribute is not specified, the children will be added to the end of the pre-existing list. If the children element is not present in the feed, then the pre-existing child list remains intact.

Site areas and categories can only have one immediate parent. Any pre-existing parent relationships will be removed before adding them as a child of this item. As content items can have multiple parents, adding a content item as a child of this item does not remove it from any of its other parents

Table 288. **`children`** *element*

Element parameters:	**Details for this element:**
Applies to item types	siteArea, Category.
Required for item types	None
Allowable Values	The children element is just a container for readability. It has no expected values.
Required Attributes	None
Optional Attributes	**`action`** The action attribute can have a value of "add" or "replace". These values indicate whether to replace children that are existing or to add to them. **`position`** This attribute can have the value "start" or "end". These values indicate where the children are placed in sibling order as they are processed.
Required sub-elements	**`childGuid`** The childGuid element should contain the unique ID of another item in the feed that describes the child item.
Optional sub-elements	None

Examples:

```
<ibmwcm:children action="add" position="start">
 <ibmwcm:childGuid>8234cb51df43</ibmwcm:childGuid>
</ibmwcm:children>
```

defaultContent

The defaultContent element only applies to site areas. It allows the feed producer to specify which content item is used as the default content for a site area. If this element is missing, has a blank value, or cannot be resolved, then the default content of the site area is cleared.

Table 289. **defaultContent** *element*

Element parameters:	Details for this element:
Applies to item types	siteArea.
Required for item types	None
Allowable Values	Value should be the GUID of another item in the feed that describes a content item.
Required Attributes	None
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Examples:

```
<ibmwcm:defaultContent>8234cb5</ibmwcm:defaultContent>
```

templateMap

The **templateMap** element only applies to site areas. It allows the feed producer to specify the template maps to be used when rendering content that is contained within the designated site area. Use multiple instances of the **templateMap** element to create multiple template mappings on a site area.

When performing an update of an existing site area, the following steps are executed for each `<ibmwcm:templateMap />` element that is specified in the feed:

1. Get the names of the authoring and presentation templates specified in the **templateMap** element.
2. Attempt to locate an authoring template that matches the name that is specified in the feed.
3. If a matching authoring template item cannot be located, log an error and start processing the next **templateMap** element.
4. Attempt to locate a presentation template that matches the name that is specified in the feed.
5. If a matching presentation template cannot be located, log an error and start processing the next **templateMap** element.
6. Check if the site area already contains a mapping for the specified authoring template:
   a. If so, check whether it maps to the same presentation template as specified in the feed;
      1) If so, go to the next **templateMap** element.
      2) If not, remove the mapping and replace it with one to the specified presentation template.

b. If not, create a new mapping of the specified authoring template to the specified presentation template.

7. Process the next **templateMap** element

The WCM APIs don't provide a mechanism to get a complete list of template mappings that exist for a given site area. As a result, it is not possible to remove a template mapping via the feed. Once a mapping has been set on a site area, it can be updated via the feed but can only be removed manually through the WCM authoring portlet.

Table 290. **templateMap** *element*

Element parameters:	**Details for this element:**
Applies to item types	siteArea.
Required for item types	None
Allowable Values	This element does not take any values. The data is specified in the attributes.
Required Attributes	**authoring** The value of this attribute must be a string that exactly matches the name of an existing authoring template. **presentation** The value of this attribute must be a string that exactly matches the name of an existing presentation template.
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Examples:

```
<ibmwcm:templateMap authoring="AT News" presentation="PT News" />
<ibmwcm:templateMap authoring="AT Announcement" presentation="PT Announcement" />
```

Identity control elements:

Most identification fields in Web Content Manager items map directly to core RSS elements; `<title>` maps to the name field, `<description>` maps to the description field, and `<author>` maps to the authors field. Other identification fields can be populated by using the following identity control elements.

displayTitle

The displayTitle element allows the feed producer to specify a separate value for the **Display Title** field in Web Content Manager. If this element is not present in the feed entry, Web Content Manager sets the value of the **Display Title** field to match the **Name** field when the item is saved.

Table 291. displayTitle element

Element parameters:	**Details for this element:**
Applies to item types	All
Required for item types	None

Table 291. displayTitle element (continued)

Element parameters:	Details for this element:
Allowable Values	A string to be used as the **Display Title** in Web Content Manager. Unlike the **Name** field, this field can contain double-byte and non-ASCII characters.
Required Attributes	None
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Example:

```
<ibmwcm:displayTitle>
 Fourth Quarter Results Press Release
</ibmwcm:displayTitle>
```

owner

The owner element provides a mechanism to set the value of the **Owners** field by using the feed. Multiple owner elements can be specified. Each owner element must contain the common name of a single WebSphere Portal user or group. If the Web Content Integrator is unable to resolve a specified name to an actual user or group then that user or group is not added to the **Owners** field but all other processing continues as normal.

Table 292. owner element

Element parameters:	Details for this element:
Applies to item types	All
Required for item types	None
Allowable Values	[all users] [all authenticated portal users] The common name of any valid WebSphere Portal user or group
Required Attributes	None
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Example:

```
<ibmwcm:owner>[all authenticated portal users]</ibmwcm:owner>
<ibmwcm:owner>jsmith</ibmwcm:owner>
```

Profile Control Elements:

Taxonomies and category fields are populated by using the RSS `<category>` element. To populate the **Keywords** field, a keywords element is required.

keywords

The keywords element must contain a comma-delimited list of metadata tags that describe the content. The list is stored in the **Keywords** field of content items.

Table 293. keywords element

Element parameters:	Details for this element:
Applies to item types	Content
Required for item types	None
Allowable Values	A comma-delimited list of keywords in plain text format.
Required Attributes	None
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Example:

```
<ibmwcm:keywords>software,testing</ibmwcm:keywords>
```

The authoringTemplate element:

The authoringTemplate element is used to specify the authoring template that is applied to a content item or site area. The value of this element must be the name of an existing authoring template.

authoringTemplate

If the authoring template is in a different library from the item, you can specify the library name as well. If no library is specified, the Web Content Integrator searches the library that was specified in the `<ibmwcm:library>` element. If no `<ibmwcm:library>` element is present, the Web Content Integrator searches the default library that is specified in the task configuration.

Note: When an item is created, it is not possible to change its authoring template. When an update is processed, if the authoring template specified in the feed entry does not match the name of the authoring template that was originally used to create the item the Web Content Integrator generates an error message.

Table 294. authoringTemplate element

Element parameters:	Details for this element:
Applies to item types	Content, site area
Required for item types	None
Allowable Values	The name of an existing authoring template, or the name of an existing library and authoring template that is separated by a forward slash. For example: • News-AT • TmpltLib/News-AT
Required Attributes	None
Optional Attributes	None

Table 294. authoringTemplate element (continued)

Element parameters:	Details for this element:
Required sub-elements	None
Optional sub-elements	None

Example:

```
<ibmwcm:authoringTemplate>News</ibmwcm:authoringTemplate>
<ibmwcm:authoringTemplate>TmpltLib/News</ibmwcm:authoringTemplate>
```

Element control element:

The element control element is used to populate elements that are stored in components, site areas, and content items.

Element overview

The Web Content Integrator uses the following business logic to process each component element in the feed entry:

1. It checks whether the component site area or content item contains a field whose name matches the value in the feed element's name attribute. This is a case-sensitive comparison so the names must match exactly.
2. If a matching field is found, it checks whether the data type matches what was specified in the feed element's sub-element.
3. If both the name and data type match, the element in the site area or content item is updated to match the data contained the feed element.
4. If an element is found which matches the feed element's name, but not its data type, the Web Content Integrator removes the old field from the site area or content item and attempt to replace it with a new field that matches the data type specified in the feed.
5. If no matching field can be found on the content, the Web Content Integrator attempts to create a new element.

Note: When creating elements in Web Content Manager using an authoring portlet, it is possible to specify a number of field validation criteria such as the maximum size of a text field or the allowable range of a date field. These are validated during the save operation. If the data in the field does not meet the validation criteria the entire save operation fails, meaning that none of the changes in the feed entry is applied. The Web Content Integrator does not have the ability to check that the data in the feed element is valid before attempting the save operation. Therefore, if you elect to implement validations on your authoring templates, it is important for the feed producer to ensure that the content is valid during the generation of the feed.

Text element

Table 295. text element

Element parameters:	Details for this element:
Applies to item types	Site areas and content items
Required for item types	None.
Allowable Values	A text component must contain a plain text value.

Table 295. text element (continued)

Element parameters:	Details for this element:
Required Attributes	**name** The value of this attribute must match the name of an existing text element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "text". This value is not case-sensitive. **value** The value of this sub-element must be plain text.
Optional sub-elements	None

Short Text element

Table 296. short text element

Element parameters:	Details for this element:
Applies to item types	Site areas and content items
Required for item types	None.
Allowable Values	A short text component must contain a plain text value.
Required Attributes	**name** The value of this attribute must match the name of an existing short text element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "shorttext". This value is not case-sensitive. **value** The value of this sub-element must be plain text.
Optional sub-elements	None

Example:

```
<ibmwcm:element name="Headline">
 <ibmwcm:type>shorttext</ibmwcm:type>
 <ibmwcm:value>New Product Released</ibmwcm:value>
</ibmwcm:element>
```

HTML element

Table 297. html element

Element parameters:	Details for this element:
Applies to item types	HTML components, site areas, and content items
Required for item types	HTML components.

Table 297. html element (continued)

Element parameters:	**Details for this element:**
Allowable Values	The value of the value sub-element must be HTML that is stored in the corresponding HTML element. The HTML can either be entity-encoded or contained within a CDATA element. Alternatively, the feed producer can provide a URL to an HTML file whose contents are retrieved by the Web Content Integrator
Required Attributes	**name** The value of this attribute must match the name of an existing HTML element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "html". **value** Used when adding HTML markup that is either entity-encoded or contained within a CDATA element. **source** Used with a fully qualified URL to an HTML file. When the Web Content Integrator processes the feed it retrieves the file and store its contents in the HTML element in the site area or content item.
Optional sub-elements	None

Examples:

```
<ibmwcm:element name="footer">
 <ibmwcm:type>html</ibmwcm:type>
 <ibmwcm:value>
  &lt;strong&gt;Copyright 2006&lt;/strong&gt;
 </ibmwcm:value>
</ibmwcm:element>

<ibmwcm:element name="footer">
 <ibmwcm:type>html</ibmwcm:type>
 <ibmwcm:value>
  <![CDATA[<strong>Copyright 2006</strong>]]>
 </ibmwcm:value>
</ibmwcm:element>

<ibmwcm:element name="footer">
 <ibmwcm:type>html</ibmwcm:type>
 <ibmwcm:source>
  http://sourcecms.yourco.com/pages/footer.htm
 </ibmwcm:source>
</ibmwcm:element>
```

Rich text element

Table 298. Rich text element

Element parameters:	Details for this element:
Applies to item types	Site areas and content items
Required for item types	None
Allowable Values	The value of the value sub-element must be HTML that is stored in the corresponding rich text element. The HTML can either be entity-encoded or contained within a CDATA element.
Required Attributes	**name** The value of this attribute must match the name of an existing rich text element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "rich text". These values are not case-sensitive. **value** The value of this sub-element must be HTML markup that is either entity-encoded or contained within a CDATA element.
Optional sub-elements	None

Examples:

```
<ibmwcm:element name="body">
 <ibmwcm:type>rich text</ibmwcm:type>
 <ibmwcm:value>
  &ltp&gt;This is the content&ltp/p&gt;
 </ibmwcm:value>
</ibmwcm:element>
```

```
<ibmwcm:element name="body">
 <ibmwcm:type>rich text</ibmwcm:type>
 <ibmwcm:value>
  <![CDATA[<p>This is the content</p>]]>
 </ibmwcm:value>
</ibmwcm:element>
```

File resource element

Table 299. File resource element

Element parameters:	Details for this element:
Applies to item types	File resource components, site areas, and content items
Required for item types	File resource components.
Allowable Values	The value must be a fully qualified URL that points to the binary file that is to be uploaded into file resource element.

Table 299. File resource element (continued)

Element parameters:	Details for this element:
Required Attributes	**name** The value of this attribute must match the name of an existing file resource element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "file". These values are not case-sensitive. **source** The value must be a fully qualified URL that points to the binary file that is to be uploaded into a file resource element. **Note:** If the URL contains non-ascii characters, the non-ascii characters must be encoded. For example: http://server:port/wps/wcm/%E4%B8%AD%E6%96%87/%E7%BB%84%E4%BB%B6.pdf
Optional sub-elements	**fileName** The value of this sub-element must be the file name and extension to be applied to the file attachment when added to the file resource element. If this sub-element is present in the feed entry, then its value is used as the file name of the attachment in Web Content Manager regardless of what the name of the file was on the source server. This is useful if the URL to the binary file does not include the file name as is the case with some content management systems. If the fileName sub-element is not present in the feed, then the Web Content Integrator attempts to determine the file name from the URL in the value sub-element by taking all of the characters following the last forward slash in the URL.

Examples:

```
<ibmwcm:element name="attachment">
 <ibmwcm:type>file</ibmwcm:type>
 <ibmwcm:source>
  http://sourcecms.yourco.com/files/plan.doc
 </ibmwcm:source>
</ibmwcm:element>

<ibmwcm:element name="attachment">
 <ibmwcm:type>file</ibmwcm:type>
 <ibmwcm:source>
```

```
  http://sourcecms.yourco.com/files/plan.doc
 </ibmwcm:source>
 <ibmwcm:fileName>MktgPlan.doc</ibmwcm:fileName>
</ibmwcm:element>
```

Image element

Table 300. Image element

Element parameters:	Details for this element:
Applies to item types	Image components, site areas, and content items
Required for item types	Image components.
Allowable Values	The value must be a fully qualified URL that points to the binary file that is to be uploaded into image element.
Required Attributes	**name** The value of this attribute must match the name of an existing image element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "image". These values are not case-sensitive. **source** The value must be a fully qualified URL that points to the binary file that is to be uploaded into an image element. **Note:** If the URL contains non-ascii characters, the non-ascii characters must be encoded. For example: http://server:port/wps/wcm/%E4%B8%AD%E6%96%87/%E7%BB%84%E4%BB%B6.jpg

Table 300. Image element (continued)

Element parameters:	Details for this element:
Optional sub-elements	**fileName** The value of this sub-element must be the file name and extension to be applied to the file attachment when added to the image element. If this sub-element is present in the feed entry, then its value is used as the file name of the attachment in Web Content Manager regardless of what the name of the file was on the source server. This is useful if the URL to the binary file does not include the file name as is the case with some content management systems. If the fileName sub-element is not present in the feed, then the Web Content Integrator attempts to determine the file name from the URL in the value sub-element by taking all of the characters following the last forward slash in the URL. **htmlName** The HTML tag name for the image. **altText** The alternative text describing the image. **height** The height of the image. The value must be a number (for pixels) or a percentage. **width** The width of the image. The value must be a number (for pixels) or a percentage. **border** The width of a border around the image. The value must be a number (for pixels).

Examples:

```
<ibmwcm:element name="image">
 <ibmwcm:type>image</ibmwcm:type>
 <ibmwcm:source>
  http://sourcecms.yourco.com/images/logo.gif
 </ibmwcm:source>
</ibmwcm:element>

<ibmwcm:element name="image">
 <ibmwcm:type>image</ibmwcm:type>
 <ibmwcm:source>
  http://sourcecms.yourco.com/images/logo.gif
 </ibmwcm:source>
 <ibmwcm:fileName>yourco_logo.doc</ibmwcm:fileName>
</ibmwcm:element>
```

Date element

Table 301. date element

Element parameters:	Details for this element:
Applies to item types	Date and time components, site areas, and content items
Required for item types	Date and time components.
Allowable Values	A date or time value to be stored in a date and time element.
Required Attributes	**name** The value of this attribute must match the name of an existing date and time element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "date". This value is not case-sensitive. **value** The value of this sub-element must be a date and time value in the RFC 822 format.
Optional sub-elements	**format** This allows the feed producer to specify the format of the date or time. A value of "date" causes the date and time element to be set to display only the date portion of the data. Likewise, a value of "time" displays only the time portion of the data. Any other value, or the absence of this sub-element, results in both portions of the data being displayed. The values for this sub-element are not case-sensitive.

Example:

```
<ibmwcm:element name="StartDate">
 <ibmwcm:type>date</ibmwcm:type>
 <ibmwcm:value>
  Thu, 14 Apr 1966 15:15:00 EDT
 </ibmwcm:value>
 <ibmwcm:format>date</ibmwcm:format>
</ibmwcm:element>
```

Link element

Table 302. link element

Element parameters:	Details for this element:
Applies to item types	Link components, site areas, and content items
Required for item types	Link components.

Table 302. link element (continued)

Element parameters:	**Details for this element:**
Allowable Values	This component contains the information that is required to configure a link element. There are a number of optional sub-elements that can be used to set the various parameters of the Link field.
Required Attributes	**name** The value of this attribute must match the name of an existing link element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "link". This value is not case-sensitive. **format** • ExternalLink: creates a link to a URL external to your Web Content Manager system. • ManagedContent: creates a link to another Web Content Manager item. • ExistingLink: creates a link to a pre-existing link component **value** The value of this sub-element depends on what was specified in the "format" sub-element: • ExternalLink: a URL. • ManagedContent: the GUID of an existing Web Content Manager item. • ExistingLink: the GUID of an existing link component.

Table 302. link element (continued)

Element parameters:	Details for this element:
Optional sub-elements	**linkText** This sub-element allows the feed producer to specify what is rendered between the `<a href="">` and `</a>` portions of the anchor tag. Possible values include: • A plain text string • A string of HTML markup that is either entity-encoded or enclosed in a CDATA tag • The GUID of a feed entry that describes an image component A required type attribute indicates which of the previous value types to use. It can be set to "text", "html", or "imageGuid". If the linkText sub-element is not included in the feed, the link text default to the value set in either "ExternalLink", "ManagedContent" or "ExistingLink". **linkDescription** This sub-element provides a mechanism to specify a description for the link element. If this sub-element is not present, the description on the link element defaults to the value of the description of the site area or content item. **linkTarget** The sub-element is used to set the target browser window where the link is displayed when it is clicked. Allowable values are: "none", "_blank", "_top", "_self", "_parent", and "{NEW_WINDOW_NAME}". If this element is not present in the feed the link target defaults to "none" meaning that the link will open in the same browser window as the page containing it. **queryString** If present, the value of this sub-element is appended to the generated HREF of the link. This value must be encapsulated in a CDATA tag to prevent parsing problems. **additionalAttributes** The value of this sub-element is inserted into the `<a>` tag as extra HTML attributes. **allowClear** This sub-element controls whether the value in the link element can be deleted. It must be set to either "true" or "false". It defaults to "true"

Simple Link to external URL for IBM.com

```
<ibmwcm:element name="Link">
 <ibmwcm:type>link</ibmwcm:type>
 <ibmwcm:value>http://www.ibm.com</ibmwcm:value>
 <ibmwcm:format>ExternalLink</ibmwcm:format>
 <ibmwcm:linkText type="text">IBM</ibmwcm:linkText>
</ibmwcm:element>
```

Expanded link to external URL for IBM.com

```
<ibmwcm:element name="Link">
 <ibmwcm:type>link</ibmwcm:type>
 <ibmwcm:value>http://www.ibm.com/search</ibmwcm:value>
 <ibmwcm:format>ExternalLink</ibmwcm:format>
 <ibmwcm:linkText type="text">RSS Feed Format Resources</ibmwcm:linkText>
 <ibmwcm:linkDescription>Search for RSS Feed Format</ibmwcm:linkDescription>
 <ibmwcm:queryString><![CDATA[?q=rss+feed+format]]></ibmwcm:queryString>]]>
 <ibmwcm:linkTarget>_blank</ibmwcm:linkTarget>
 <ibmwcm:additionalAttributes>class="extLink"</ibmwcm:additionalAttributes>
</ibmwcm:element>
```

Simple link to a file resource component

```
<ibmwcm:element name="Link">
 <ibmwcm:type>link</ibmwcm:type>
 <ibmwcm:value>63000001</ibmwcm:value>
 <ibmwcm:format>ManagedContent</ibmwcm:format>
 <ibmwcm:linkText type="imageGuid">290df293e20a</ibmwcm:linkText>
 <ibmwcm:allowClear>true</ibmwcm:allowClear>
</ibmwcm:element>
```

Simple Link to another content item

```
<ibmwcm:element name="Link">
 <ibmwcm:type>link</ibmwcm:type>
 <ibmwcm:value>80220102</ibmwcm:value>
 <ibmwcm:format>ManagedContent</ibmwcm:format>
 <ibmwcm:linkText type="html"><![CDATA[<b>Marketing Plan</b></ibmwcm:linkText>]]>

</ibmwcm:element>
```

Number element

Table 303. number element

Element parameters:	**Details for this element:**
Applies to item types	Number components, site areas, and content items
Required for item types	Number components.
Allowable Values	A numerical value to be stored in a number element.
Required Attributes	**name** The value of this attribute must match the name of an existing number element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "number". This value is not case-sensitive. **value** A numerical value to be stored in a number element.

Table 303. number element (continued)

Element parameters:	Details for this element:
Optional sub-elements	**format** This allows the feed producer to specify the format for the number element. For example, if a value of "integer" is specified, then only data in the format of whole numbers are imported.

Example:

```
<ibmwcm:element name="FileSize">
 <ibmwcm:type>number</ibmwcm:type>
 <ibmwcm:value>34082</ibmwcm:value>
 <ibmwcm:format>integer</ibmwcm:format>
</ibmwcm:element>
```

Option selection element

Table 304. option selection element

Element parameters:	Details for this element:
Applies to item types	Site areas and content items
Required for item types	None
Allowable Values	This component contains a list of values that are set as the selected options in an option selection element.
Required Attributes	**name** The value of this attribute must match the name of an existing option selection element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "option". This value is not case-sensitive.

Table 304. option selection element (continued)

Element parameters:	Details for this element:
Optional sub-elements	**optionType** This is used to define the type of option selection element. • Specify `user` when referencing from a list of user-defined options. • Specify `taxonomy` when referencing options from an existing taxonomy. You can only specify 1 option type per option selection element. If no option type is defined, "user" will be used by default. **selectedCategory** This is used with the option type of "taxonomy" and is used to specify the path to a category you want to use in the option selection element. You can use as many selectedCategory elements as you require. If the taxonomy exists in a different library from the option selection element, you can also specify the library name. For example: `<ibmwcm:selectedCategory library="shared">Days/Monday</ibmwcm:selectedCategory>` You must specify the name of each category and taxonomy you want to reference. If they do not exist, they are created when the feed is processed. **selectedOption** This is used with the option type of "user" and is used to specify a list of user-defined options. You can use as many selectedOption elements as you require.

Example 1:

Selecting a single category where the category is in the same library as the item. In this example "Days" is the name of a taxonomy and "Monday" is the name of a category.

```
<ibmwcm:element name="DayOfTheWeek">
 <ibmwcm:type>option</ibmwcm:type >
    <ibmwcm:optionType>taxonomy</ibmwcm:optionType>
    <ibmwcm:selectedCategory>Days/Monday</ibmwcm:selectedCategory>
< /ibmwcm:element>
```

Example 2:

Selecting multiple categories where the categories are in the same library as the item.

```
<ibmwcm:element name="DayOfTheWeek">
  <ibmwcm:type>option</ibmwcm:type >
    <ibmwcm:optionType>taxonomy</ibmwcm:optionType>
    <ibmwcm:selectedCategory>Days/Monday</ibmwcm:selectedCategory>
  <ibmwcm:selectedCategory>Days/Tuesday</ibmwcm:selectedCategory>
< ;/ibmwcm:element>
```

Example 3:

Selecting a single category where the category is in a different library to the item.

```
<ibmwcm:element name="DayOfTheWeek">
  <ibmwcm:type>option</ibmwcm:type >
    <ibmwcm:optionType>taxonomy</ibmwcm:optionType>
    <ibmwcm:selectedCategory library="shared">Days/Monday</ibmwcm:selectedCategory>
</ibmwcm:element>
```

Example 4:

Selecting a user-defined option. In this example "False" is an option that is defined by a user on the Authoring Template for an item.

```
<ibmwcm:element name="Enable">
    <ibmwcm:type>option</ibmwcm:type >
    <ibmwcm:optionType>user</ibmwcm:optionType>
    <ibmwcm:selectedOption>False</ibmwcm:selectedOption>
</ibmwcm:element>
```

Component reference element

Table 305. component reference element

Element parameters:	Details for this element:
Applies to item types	Site areas and content items
Required for item types	None
Allowable Values	This component contains the GUID of a component.
Required Attributes	**name** The value of this attribute must match the name of an existing component reference element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "reference". This value is not case-sensitive. **value** This component contains the GUID of a component.
Optional sub-elements	None

Example:

```
<ibmwcm:element name="Footer">
 <ibmwcm:type>reference</ibmwcm:type>
 <ibmwcm:value>29bc2daf3289</ibmwcm:value>
</ibmwcm:element>
```

User selection element

Table 306. user selection element

Element parameters:	Details for this element:
Applies to item types	User selection components, site areas, and content items
Required for item types	User selection components.
Allowable Values	A list of names of users to be selected in a user selection element.
Required Attributes	**name** The value of this attribute must match the name of an existing user selection element in a site area or content item.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "userSelect". This value is not case-sensitive. **value** The value of this sub-element must be a comma-separated list of user names. When processed the Web Content Integrator attempts to resolve each name to a valid portal user. If a name cannot be resolved, it is skipped.
Optional sub-elements	None

Example:

```
<ibmwcm:element name="Users">
 <ibmwcm:type>userSelect</ibmwcm:type>
 <ibmwcm:value>wpsadmin,John Smith</ibmwcm:value>
</ibmwcm:element>
```

Style sheet element

Table 307. style sheet element

Element parameters:	Details for this element:
Applies to item types	Stylesheet components
Required for item types	Stylesheet components
Allowable Values	A URL that points to a CSS file that is uploaded into a stylesheet component.
Required Attributes	None
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "styleSheet". This value is not case-sensitive. **source** A URL that points to a CSS file that is uploaded into the stylesheet component.

Table 307. style sheet element (continued)

Element parameters:	Details for this element:
Optional sub-elements	**format** This sub-element is used to specify the type of the stylesheet. Valid options are: "preferred", "alternate", and "persistent". If this sub-element is not present in the feed, or if any value other than the previous values is specified, the type will default to "preferred". **mediaType** This sub-element specifies the media type of the stylesheet. Valid values are: "all", "aural", "braille", "handheld", "print", "projection", "screen", "tty", "tv", and "unspecified". If the mediaType sub-element is not present in the feed, or if any value other than the previous values is specified, the media type defaults to "unspecified". **cssTitle** The value of this sub-element must be a string that is set as the value of the title attribute when the link to the CSS file is rendered.

Example:

```
<ibmwcm:element name="cssFile">
 <ibmwcm:type>styleSheet</ibmwcm:type>
 <ibmwcm:source>http://www.yourco.com/styles/news.css</ibmwcm:source>
 <ibmwcm:format>alternate</ibmwcm:format>
 <ibmwcm:mediaType>print</ibmwcm:mediaType>
</ibmwcm:element>
```

Workflow control elements:

Workflow elements is used to specify workflow-related parameters when content items are created that use a workflow.

workflow element

This element specifies the workflow name and stage in which a content item is created. The value in the name attribute must match that of an existing workflow.

If the workflow is in a different library from the content item, you can specify the library name as well. If no library is specified, the Web Content Integrator searches the library that was specified in the `<ibmwcm:library>` element. If no `<ibmwcm:library>` element is present, the Web Content Integrator searches the default library that is specified in the task configuration.

Table 308. workflow element

Element parameters:	Details for this element:
Applies to item types	Content items

Table 308. workflow element (continued)

Element parameters:	Details for this element:
Required for item types	None
Allowable Values	Workflow name and related workflow stage.
Required Attributes	The name of an existing workflow, or the library and name of an existing library and workflow that is separated by a forward slash. For example: • 3-Stage-Workflow • Library1/3-Stage-Workflow
Optional Attributes	None
Required sub-elements	**workflowStage** The value of this sub-element must be the name of a workflow stage that is included in the named workflow.
Optional sub-elements	None

Examples:

```
<ibmwcm:workflow name="StdWorkflow">
 <ibmwcm:workflowStage>Live</ibmwcm:workflowStage>
</ibmwcm:workflow>

<ibmwcm:workflow name="DesignLib/StdWorkflow">
 <ibmwcm:workflowStage>Live</ibmwcm:workflowStage>
</ibmwcm:workflow>
```

date elements

This element is used to specify an RFC 822 formatted date that is used as the date of one of the date fields in the content item.

Table 309. date elements

Element parameters:	Details for this element:
Applies to item types	Content items
Required for item types	None

Table 309. date elements (continued)

Element parameters:	Details for this element:
Allowable Values	**publishDate** Used to set the published date of an item. If this element is not present in the <item>, the value in the <pubDate> element is used to set the publish date of the content item. This requires a publish action to be included in a workflow stage in the specified workflow. **expirationDate** Used to set the expiry date of an item. This requires an expire action to be included in a workflow stage in the specified workflow. **genDateOne and genDateTwo** Used to populate the general date fields of an item.
Required Attributes	An RFC 822 formatted date.
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Examples:

```
<ibmwcm:publishDate>
 Fri, 31 Oct 2008 15:32:00 EST
</ibmwcm:publishDate>

<ibmwcm:expirationDate>
 Sun, 1 Nov 2009 12:00:00 EST
</ibmwcm:expirationDate>

<ibmwcm:genDateOne>
 Wed, 1 Nov 2006 09:30:00 EST
</ibmwcm:genDateOne>

<ibmwcm:genDateTwo>
 Thu, 2 Nov 2006 09:30:00 EST
</ibmwcm:genDateTwo>
```

additionalViewer element

This element allows the additional viewers field to be populated via the feed. It should contain the common name of a single user or group that is to be added to the field. To specify multiple users and groups, use multiple additionalViewer elements.

Table 310. additionalViewer element

Element parameters:	Details for this element:
Applies to item types	Content items
Required for item types	None
Allowable Values	• [all users] • [all authenticated portal users] • The common name of any valid portal user or group.
Required Attributes	None
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Examples:

```
<ibmwcm:additionalViewer>[all users]</ibmwcm:additionalViewer>

<ibmwcm:additionalViewer>Sales</ibmwcm:additionalViewer>

<ibmwcm:additionalViewer>jsmith</ibmwcm:additionalViewer>
```

Security control elements:

The security control element is used to set access controls on the item that is being created.

access element

The access element provides a mechanism to set the access controls on Web Content Manager items via the feed. A feed entry can contain multiple access sub-elements. Each access element should contain the common name of a single, valid, portal user or group. The users and groups specified in the access element are added to the system defined security fields on the Web Content Manager items.

Table 311. access element

Element parameters:	Details for this element:
Applies to item types	Content
Required for item types	None
Allowable Values	• [all users] • [all authenticated portal users] • The common name of any valid portal user or group.
Required Attributes	None

Table 311. access element (continued)

Element parameters:	Details for this element:
Optional Attributes	**type** This attribute allows the feed producer to specify the exact access level that should be granted to the user or group. The allowable values for the type attribute correspond to the access levels available in Web Content Manager: "user", "contributor", "editor" and "manager". If the type attribute is not specified, "user" access is applied. **inheritance** You can specify whether inheritance is enabled or by adding either `inheritance="enabled"` or `inheritance="disabled"`. If not specified, the default or current inheritance setting for an item is used.
Required sub-elements	None
Optional sub-elements	

Examples:

```
<ibmwcm:access type="user">
 [all users]
</ibmwcm:access>

<ibmwcm:access type="editor" inheritance="enabled">
 Sales
</ibmwcm:access>
```

Association control element:

The association element is used to create an association between two or more separate content items. It is used to support some content item relationships that are not native to Web Content Manager but that are found in some other web content management systems. One example would be a technical journal article that needs to include some data from one or more author biography content items.

An association element is tied to a text element. The value of the element in the feed is a comma-delimited list of GUIDs that represent the other external content items that are to be associated with the text element. When the Web Content Integrator processes the feed, it attempts to resolve the GUIDs with the corresponding Web Content Manager items. A custom JSP component is then used in the presentation template to locate the linked content items at render time and display them in the context of the container content item.

Since this type of linkage is not a natural feature of Web Content Manager it relies on a custom JSP component for its implementation and there are some restrictions that are related to using an association element:

- As Web Content Manager DocumentIds are used to create the association to the other content items, the format of the DocumentId is not guaranteed to be

constant from version to version so there is some risk that the linkages might break following a Web Content Manager upgrade or migration

- The referential integrity of Web Content Manager does not apply to association element links.

Table 312. association element

Element parameters:	**Details for this element:**
Applies to item types	Content
Required for item types	None
Allowable Values	A list of GUIDs that map to other feed entries that are linked to associated content items.
Required Attributes	**name** The value of this attribute must match the name of an existing text element.
Optional Attributes	None
Required sub-elements	**type** The value of this sub-element must be "association". It is not case-sensitive. **value** The value of this sub-element must be a comma-delimited list of GUIDs that point to the feed entries that are linked to associated content items.
Optional sub-elements	None

Example:

```
<ibmwcm:element name="authors">
 <ibmwcm:type>association</ibmwcm:type>
  <ibmwcm:value>234ed298cf,7023bc23f1e</ibmwcm:value>
</ibmwcm:element>
```

How to handle embedded links

From time to time, the content that is being retrieved by the Web Content Integrator contains embedded links to images, files, and other content within the feed. You can use the link tag in your feed to represent embedded links so that they are converted into links to other Web Content Manager items that are created when the feed is processed.

Three types of embedded links can be processed: images, files, and content. In all cases, the link tag must include a GUID that points to another item in the feed, which describes the target item.

Content links

In this example, the following feed content contains a link to another web page:

```
<p>
<a href="http://cmsserver.ibm.com/news/one.htm">Press Release</a>
</p>
```

To ensure that the embedded link is converted into a link to a related content item that is being created when the feed is processed, you add the following code to your feed. It contains a GUID to the HTML file also being processed by the Web Content Integrator:

```
<![CDATA[<p>
<a href='<link type="content" guid="80000002"/>'>Press Release</a>
This is some text.
</p>]]>
```

When the content of the feed is saved within Web Content Manager, a link to a content item is added to the content.

```
<p>
<a href="wps/wcm/myconnect/Portal/Press/Announcement1?contentIDR=29e04295034efb">Press Release</a>
This is some text.
</p>
```

<ibmwcm:path>/Portal/News</ibmwcm:path>
<ibmwcm:workflow name="Std Workflow">
<ibmwcm:workflowStage>Live</ibmwcm:workflowStage>
</ibmwcm:workflow>
<ibmwcm:component name="BODY">
<ibmwcm:type>rich text</ibmwcm:type>
<ibmwcm:value>
<![CDATA[<p>
<a href='<link type="content" guid="80000002" />'>some content link</a>
This is some text.
</p>]]>
</ibmwcm:value>
</ibmwcm:component>
</item>
<item>
<title>Announcment1</title>
<link>http://cmsserver.ibm.com/news/one.htm</link>
<description>This is an announcment press release.</description>
<pubDate>Tue, 31 Oct 2006 10:11:00 EST</pubDate>
<guid>80000002</guid>
<ibmwcm:action>add</ibmwcm:action>
<ibmwcm:itemType>Content</ibmwcm:itemType>
<ibmwcm:authoringTemplate>Press Release</ibmwcm:authoringTemplate>
<ibmwcm:path>/Portal/Press</ibmwcm:path>
<ibmwcm:workflow name="Std Workflow">
<ibmwcm:workflowStage>Live</ibmwcm:workflowStage>
</ibmwcm:workflow>
<ibmwcm:component name="BODY">
<ibmwcm:type>rich text</ibmwcm:type>
<ibmwcm:value>This is some more text.</ibmwcm:value>
```

```
</ibmwcm:component>
</item>
</channel>
</rss>
```

File links

In this example, the following feed content contains a link to a PDF file:

```
<p>
<a href="http://cmsserver.ibm.com/files/spec.pdf">Product Spec</a>
This is some text.
</p>
```

To ensure that the embedded link is converted into a link to a related file resource component that is being created when the feed is processed, you add the following code to your feed. It contains a GUID to the PDF file also being processed by the Web Content Integrator:

```
<![CDATA[<p>
<a href='<link type="file" guid="50000002"/>'>Product Spec</a>
This is some text.
</p>]]>
```

When the content of the feed is saved within Web Content Manager, a component tag is added to the content.

```
<p>
<a href="<Component name="ProductSpec" />">Product Spec</a>
This is some text.
</p>
```

Example feed

         </ibmwcm:component>
      </item>
   </channel>
</rss>
```

Image links

In this example, the following feed content contains a link to an image file:

```
<p>
<img src="http://cmsserver.ibm.com/images/mylogo.gif" />
This is some text.
</p>
```

To ensure that the embedded image link is converted into a link to a related image component that is being created when the feed is processed, you add the following code to your feed. It contains a GUID to the image file also being processed by the Web Content Integrator:

```
<![CDATA[<p>
<link type="image" guid="50000001" />
This is some text.
</p>]]>
```

When the content of the feed is saved within Web Content Manager, a component tag is added to the content.

```
<p>
<Component name="My Logo" />
This is some text.
</p>
```

Example feed

```

         </ibmwcm:component>
      </item>
   </channel>
</rss>
```

Automatic image tag processing

The Web Content Integrator has an optional feature, which can be used in place of the `<link type="image" />` tag. If enabled, the Web Content Integrator automatically parses the values of any html or rich text elements and search for HTML `<img/>` tags that are embedded within the content. If any are found, the Web Content Integrator attempts to retrieve the referenced image file, create an image component, and then rewrite the reference so that it points to the new image component.

This feature can be enabled by editing the `disable.img.proc` setting in the `WCMConsumerPlugin.properties` file and setting it to "false". Automatic image tag processing is disabled by default.

If enabled:

- Only the content that is imported into HTML elements and components or Rich Text elements and components are processed.
- All image references matching the pattern "`<img src= ...`" are processed. Image references that are included within JavaScript code or CSS styles are not processed.
- The URLs specified in the "src" attributes of those image tags are converted to fully qualified URLs by using other information about the content item in the feed. Relative links must be relative to the URL in the <link> element of the feed that follows the standard rules for relative links.
- The image files are stored as shared image components. The access controls on the image component are set to match that of the content item, which references it. The name of the image component is based on the server-relative path to the image. For example, an image that is at `http://<host_name>/resources/images/sm_logo.gif` is named `resources.images.sm_logo.gif`.

- The URLs specified in the "src" attributes of the image tags must not contain a query string because everything after a question mark is ignored when the image component is created.

  For example, For example, `<img src="http://<host_name>/program/path?param1=hello&param2=a.jpg"....>` and `<img src="http://<host_name>/program/path?param1=world&param2=b.jpg" ...>` both creates or updates the same image component named "program.path".

Processing images

The Web Content Integrator has an image-processing feature, which allows images that are referenced within HTML and rich text elements to be created as image components while processing a feed.

Image-processing configuration

The following parameters can be set in the `WCMConsumerPlugin.properties` file:

Enable and disable image processing

By default, image processing is enabled. To disable image processing set the property: *disable.img.processing=true*

If image processing is enabled, then the URLs specified in the "src" attributes of the image tags must not contain a query string because everything after a question mark is ignored when the image component is created.

For example, `<img src="http://<host_name>/program/path?param1=hello&param2=a.jpg" ...>` and `<img src="http://<host_name>/program/path?param1=world&param2=b.jpg" ...>` both creates or updates the same image component named "program.path".

Enable and disable embedded rich text images

Images can be embedded directly into the rich text elements instead of first creating an image component. This function makes images within rich text elements that are consumed by the Web Content Integrator be processed identically to images added to rich text elements in the authoring UI. By default embedded rich text images are disabled. To enable them, set the properties:

- *disable.img.processing=false*
- *richtext.embedded.images.enabled=true*

Absolute image source URLs

Images within HTML and rich text elements can be specified by using absolute HTTP URLs within the image source attribute. The Web Content Integrator processes absolute image source URLs as specified in the feed.

Example feed item:

```
<item>
    <title>RichText Component With Image 1</title>
    <pubDate>Thu, 30 Mar 2011 16:00:00 EDT</pubDate>
    <guid>Image_Example_1</guid>
    <ibmwcm:action>add</ibmwcm:action>
    <ibmwcm:itemType>Component</ibmwcm:itemType>
    <ibmwcm:element>
      <ibmwcm:type>rich text</ibmwcm:type>
      <ibmwcm:value>
         <![CDATA[
```

```
        <p>Image 1:</p><img src="http://wci-feed-server/img/f/flower.jpg"/>
        <p>Image 2:</p><img src="http://wci-feed-server/img/g/guitar.jpg"/>
        ]]>
      </ibmwcm:value>
    </ibmwcm:element>
  </item>
```

Relative image source URLs

Images within HTML and rich text elements can be specified by using relative HTTP URLs within the image source attribute and a base URL from the link element of the item. The Web Content Integrator processes relative image source URLs as a concatenation of the item's link element and image source attributes in the HTML.

Example feed item:

```
<item>
    <title>RichText Component With Image 2</title>
    <pubDate>Thu, 30 Mar 2011 16:00:00 EDT</pubDate>
    <guid>Image_Example_2</guid>
    <link>http://wci-feed-server</link>
    <ibmwcm:action>add</ibmwcm:action>
    <ibmwcm:itemType>Component</ibmwcm:itemType>
    <ibmwcm:element>
      <ibmwcm:type>rich text</ibmwcm:type>
      <ibmwcm:value>
         <![CDATA[
         <p>Image 1:</p><img src="/img/p/penguin.jpg"/>
         <p>Image 2:</p><img src="/img/s/sunset.jpg"/>
         ]]>
      </ibmwcm:value>
    </ibmwcm:element>
  </item>
```

How to use both absolute and relative image source URLs

Images within HTML and rich text elements can be specified by using a combination of relative and absolute HTTP URLs within the image source attributes. The Web Content Integrator processes relative image source URLs as a concatenation of the item's link element and image source attributes in the HTML. The Web Content Integrator processes absolute image source URLs as specified in the feed.

Example feed item:

```
<item>
    <title>RichText Component With Image 3</title>
    <pubDate>Thu, 30 Mar 2011 16:00:00 EDT</pubDate>
    <guid>Image_Example_3</guid>
    <link>http://wci-feed-server</link>
    <ibmwcm:action>add</ibmwcm:action>
    <ibmwcm:itemType>Component</ibmwcm:itemType>
    <ibmwcm:element>
      <ibmwcm:type>rich text</ibmwcm:type>
      <ibmwcm:value>
         <![CDATA[
         <p>Image 1:</p><img src="http://www.ibm.com/favicon.ico"/>
         <p>Image 2:</p><img src="/img/f/fish.jpg"/>
         <p>Image 3:</p><img src="/img/g/grapes.jpg"/>
         ]]>
      </ibmwcm:value>
    </ibmwcm:element>
  </item>
```

Expected results for a rich text component

Example rich text component feed item:

```
<item>
    <title>RichText Component With Image 4</title>
    <pubDate>Thu, 30 Mar 2011 16:00:00 EDT</pubDate>
    <guid>Image_Example_4</guid>
    <ibmwcm:action>add</ibmwcm:action>
    <ibmwcm:itemType>Component</ibmwcm:itemType>
    <ibmwcm:element>
      <ibmwcm:type>rich text</ibmwcm:type>
      <ibmwcm:value>
         <![CDATA[
         <p>Image 1:</p><img src="http://wci-feed-server/img/l/leaf.jpg"/>
         ]]>
      </ibmwcm:value>
    </ibmwcm:element>
  </item>
```

Rich text component with image processing disabled:

- A rich text component named: "RichText Component With Image 4" is created in the feed library.
- HTML Source of the rich text Component: `<p>Image 1:</p><img src="http://wci-feed-server/img/l/leaf.jpg">`
- The rich text HTML is not modified.
- The image source is unmanaged because Web Content Manager cannot detect a broken image source.

Rich text component with image processing enabled:

- A rich text component named: "RichText Component With Image 4" is created in the feed library.
- An Image Component that is named `"img.l.leaf.jpg"` is created in the feed library
- HTML Source of the rich text Component: `<p>Image 1:</p><img src="/wps/wcm/myconnect/[IMAGE COMPONENT ID]/leaf.jpg?MOD=AJPERES">`
- The image source is replaced with a URL pointing to the newly created image.
- The image source is managed by Web Content Manager and is updated as the image component is updated.

Rich text component with embedded images enabled:

- A rich text component named: "RichText Component With Image 4" is created in the feed library.
- HTML Source of the rich text Component: `<p>Image 1:</p><img src="/wps/wcm/myconnect/[RT COMPONENT UUID]/1/img.l.leaf.jpg?MOD=AJPERES">`
- The rich text HTML is modified replacing the image source with a URL for the image that is embedded within the rich text Component.
- The image source is managed by Web Content Manager and is updated as the rich text changes.

Expected results for a HTML component

Example feed item:

```
<item>
    <title>HTML Component With Image 1</title>
    <pubDate>Thu, 30 Mar 2011 16:00:00 EDT</pubDate>
    <guid>Image_Example_5</guid>
    <ibmwcm:action>add</ibmwcm:action>
    <ibmwcm:itemType>Component</ibmwcm:itemType>
    <ibmwcm:element>
      <ibmwcm:type>html</ibmwcm:type>
      <ibmwcm:value>
         <![CDATA[
         <p>Image 1:</p><img src="http://wci-feed-server/img/l/leaf.jpg"/>
         ]]>
      </ibmwcm:value>
    </ibmwcm:element>
  </item>
```

HTML element with image processing disabled

- HTML Component that is named "HTML Component With Image 1" is created in the feed library.
- HTML Source of the HTML Component: `<p>Image 1:</p><img src="http://wci-feed-server/img/l/leaf.jpg"/>`
- The HTML is not modified.
- The image source is unmanaged because Web Content Manager cannot detect a broken image source.

HTML element with image processing enabled

- HTML Component that is named "HTML Component With Image 1" is created in the feed library.
- Image Component that is named `"img.l.leaf.jpg"` is created in the feed library
- HTML Source of the HTML Component: `<p>Image 1:</p><img src="<Component id="[IMAGE COMPONENT ID]" name="img test 1/img.l.leaf.jpg" format="url"/>"/>`
- The image source is replaced with a component tag that points to the newly created image.
- The image source is managed by Web Content Manager and is updated as the image component is updated.

Example feeds

View some example feeds that illustrate how to represent the various item types within a feed.

Note: If non-ascii data is used in a feed, then encoding="UTF-8" must be specified in the feed: `<?xml version="1.0" encoding="UTF-8"?>`

RSS Namespace Extension for the Feed Service

The RSS namespace extension is used to exchange control information between the feed producer and consumer applications.

To implement this namespace, specify the <rss> element as follows:

```
<rss version="2.0" xmlns:ibmwcm="http://purl.org/net/ibmfeedsvc/wcm/1.0"
xmlns:ibmfs="http://purl.org/net/ibmfeedsvc/feedsvc/1.0" />
```

The input feeds need to include this namespace only in certain scenarios where control information is going to be passed in the feed itself rather than in the HTTP headers.

"The Handshake Protocol" on page 1983
In many Web Content Integrator implementations the input content feeds are produced by an application that generates them dynamically in response to requests from the feed consumer application. In those cases, it is useful for the consumer to be able to indicate to the producer application which versions of a feed the Consumer has already seen so that the producer can make some intelligent decisions about what to include in the next feed.

"Results Feeds" on page 1984
When feed processing is initiated by using a call to the feed service servlet, the Web Content Integrator responds with an output feed. The first entry in this feed contains status information for the feed as a whole. Each of the subsequent entries in the output feed corresponds to an item that was in the input feed.

These latter entries contain status information about the results of processing each item. Feed producers might use this information to attempt to automatically recover from certain types of errors.

"Channel-level Elements" on page 1984
The following element must be a direct child of the feed's <channel /> element since it applies to the feed as a whole rather than to an individual item in the feed.

"Item-level Elements" on page 1985
The following elements are applied at the <item /> level since they contain information that is specific to each individual feed entry. These elements are only used in the output feed. They have no meaning in the context of an input feed.

The Handshake Protocol:

In many Web Content Integrator implementations the input content feeds are produced by an application that generates them dynamically in response to requests from the feed consumer application. In those cases, it is useful for the consumer to be able to indicate to the producer application which versions of a feed the Consumer has already seen so that the producer can make some intelligent decisions about what to include in the next feed.

The handshake protocol consists of the exchange of two feed attributes: a Last Modified Date, and an arbitrary Entity Tag. The values of both of these attributes are managed exclusively by the producer. The consumer receives the values from the producer, stores them, and passes them back unchanged on the next request. These attributes can be passed in one of two ways:

1. As HTTP header fields:
   - Requests from the consumer contain:

     ```
     If-Modified-Since : {last-modified_value}
     If-None-Match: {etag_value}
     ```

   - Responses from the producer contain:

     ```
     ETag: {etag_value}
     Last-Modified: {last-modified_value}
     ```

2. As elements in the feed and query string parameters:
   - Requests from the consumer are in the form:

     ```
     http://cmsserver.example.org/ProducerApp?etag={etag_value}&lastMod={last-modified_value}
     ```

   - Feeds sent back from the producer contain the following channel-level elements:

     ```
     <lastBuildDate>{last-modified_value}</lastBuildDate>
     <ibmfs:etag>{etag_value}</ibmfs:etag>
     ```

How the handshake works

1. The consumer makes its first request to the producer. This request does not contain any special header fields.
2. The producer receives the request, and since there were no special headers, it responds with a feed that contains items which represent all transactions that have occurred up to that point. Before sending the response it sets the Last-Modified header to the current time and the ETag header to a value that enables the producer identify this specific instance of the feed.

   ```
   Last-Modified: Thu, 7 Sep 2006 12:00:00 GMT
   ETag: ABC0011
   ```

3. The consumer receives the response, processes the feed, and stores the Last-Modified and ETag values only if the feed was processed successfully.
4. The next time the consumer is triggered, it again makes a request to the producer for the transaction feed. This time it sets the If-Modified-Since header to the Last-Modified date it received on the last request and the If-None-Match field to the value of the ETag it received on the last request.

   ```
   If-Modified-Since: Thu, 7 Sep 2006 12:00:00 GMT
   If-None-Match: ABC0011
   ```

5. The producer receives the request, and checks the values of the header fields. It then uses its own internal logic to generate a new feed which only contains changes that occurred since the last feed it sent to this consumer. It sends back a feed with the following header values:

   ```
   Last-Modified: Thu, 7 Sep 2006 13:00:00 GMT
   ETag: ABC0032
   ```

6. The consumer receives the response, processes the feed, and updates its stored values for the Last-Modified date and ETag.

Ideally, if no changes have occurred since the last time the consumer requested the feed, the producer should respond with an HTTP 304 (Not Modified) response code. This will signal the consumer that there are no changes and thus that it does not need to attemp to parse the feed and do the subsequent processing. However, if the producer is unable to implement this feature it won't affect any of the other processing.

The consumer will always send a request containing the Etag label of the last transaction feed it successfully received. In this case the producer application will be responsible for re-sending any entries that might have been missed due to a communication failure between the servers.

Results Feeds:

When feed processing is initiated by using a call to the feed service servlet, the Web Content Integrator responds with an output feed. The first entry in this feed contains status information for the feed as a whole. Each of the subsequent entries in the output feed corresponds to an item that was in the input feed. These latter entries contain status information about the results of processing each item. Feed producers might use this information to attempt to automatically recover from certain types of errors.

Each entry in the output feed has the following general format:

```
<item>
   <title>Results for: [INPUT_TITLE]</title>
   <link>[INPUT_LINK]</link>
   <pubDate>[CREATION_TIME_OF_OUTPUT_FEED_ENTRY]</pubDate>
   <guid permalink="false">[INPUT_GUID]</guid>
   <ibmfs:resultCode>[ OK | WARN | ERROR | FAIL ]</ibmfs:resultCode>
   <!-- 0 .. n resultMsg elements -->
   <ibmfs:resultMsg level="[ WARN | ERROR ]" code="[ERR_CODE]">[MESSAGE_TEXT]</ibmfs:resultMsg>
   <ibmfs:resultMsg level="[ WARN | ERROR ]" code="[ERR_CODE]">[MESSAGE_TEXT]</ibmfs:resultMsg>
   <ibmfs:documentId>[WCM_DOCUMENT_ID]</ibmfs:documentId>
   <description>[LIST_OF_PROGRESS_MESSAGES]</description>
</item>
```

Channel-level Elements:

The following element must be a direct child of the feed's `<channel />` element since it applies to the feed as a whole rather than to an individual item in the feed.

etag

Some producer applications are not able to manipulate the HTTP headers to set the handshake data. To support those applications, there is an alternative method that entails passing the same information directly in the feed by using the RSS `<lastBuildDate>` element and a custom namespace element, `<ibmfs:etag>`.

Table 313. etag element

Element parameters:	**Details for this element:**
Allowable Values	A string value that represents some meaningful label for the specific instance of the feed.
Required Attributes	None
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Example:

```
<ibmfs:etag>ABC0012</ibmfs:etag>
```

Item-level Elements:

The following elements are applied at the `<item />` level since they contain information that is specific to each individual feed entry. These elements are only used in the output feed. They have no meaning in the context of an input feed.

resultCode

Table 314. resultCode element

Element parameters:	**Details for this element:**
Allowable Values	This element has one of the following values depending on what happened when the input feed entry was processed: **OK** The entry was processed completely with no warnings or errors. **WARN** The entry was processed completely but one or more warnings were logged. **ERROR** One or more error messages were logged. The entry might not have been saved in Web Content Manager. **FAIL** The content item could not be saved or updated.
Required Attributes	None
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Example:

```
<ibmfs:resultCode>OK</ibmfs:resultCode>
<ibmfs:resultCode>WARN</ibmfs:resultCode>
```

resultMsg

Table 315. resultMsg element

Element parameters:	Details for this element:
Allowable Values	Each instance of this element contains the details of a warning or error message.
Required Attributes	**level** The value of this attribute indicates the severity of the message. Allowable values are: "WARN" and "ERROR". **code** This attribute should hold the error code that is associated with the message.
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Examples:

```
<ibmfs:resultMsg level="WARN" code="WCM0014">
Default Content GUID does not point to a content item. Default content set to null.
</ibmfs:resultMsg>

<ibmfs:resultMsg level="ERROR" code="WCM0030">
A WCMException was thrown when attempting to move the content.
</ibmfs:resultMsg>
```

documentId

Table 316. documentId element

Element parameters:	Details for this element:
Allowable Values	This element contains the ID that was generated by Web Content Manager.
Required Attributes	None
Optional Attributes	None
Required sub-elements	None
Optional sub-elements	None

Example:

```
<ibmfs:documentId>
com.ibm.workplace.wcm.api.WCM_Content/Connections Announcement/f6f60a00498c0d759ee9ffe695695374/PUBL
</ibmfs:documentId>
```

WebDAV

With WebDAV for IBM WebSphere Portal Express, you can use standard operating system tools to create, modify, and delete web content rather than the standard authoring portlet.

Before you begin

Before you can use WebDAV with web content, you need to set up a WebDAV client. After your client is set up, you can access the web content libraries with WebDAV with the following URL:

`http://server:port/portal_context_root/mycontenthandler/dav/content/libraries/`

For example:

`http://www.example.com:10027/wps/mycontenthandler/dav/content/libraries/`

About this task

By using tools like file system explorers, WebDAV is used to work with your web content items through familiar, everyday actions. Here are a few examples:

- You can create components or presentation templates by dragging a file into a corresponding folder.
- You can run actions on several items at the same time. For example, you can create five images at the same time by dragging five image files into the image component folder. This creates five separate image components, and for each image component the file name is used for the component's name and title.
- Modifying items is also straightforward through a WebDAV client. For example, you can open a presentation template by using your preferred HTML editor, make changes, and then save the changes. The WebDAV client takes care of accessing the web content library, downloading the template, and then uploading the changes.

In addition to modifying the actual content of an item, you can also modify any item's metadata or access control settings by modifying XML files that define the item's metadata and access control characteristics. You can also drag an existing XML file into the appropriate folder, enabling you to easily set the same data for different items.

You can create, modify, or delete the following items: libraries, taxonomies, categories, site areas, folders, components, and presentation templates.

Note: Be aware that the following features are not supported when using WebDAV with web content:

- Content items, except for managing metadata and access control
- Authoring templates, except for managing metadata and access control
- Nested items within site areas
- Server-side copy and move
- Unauthenticated users
- Exporting of web content libraries with WebDAV to be imported into another web content server

When using WebDAV with web content, be aware of the following considerations.

Locked item support

Locking or unlocking an item through WebDAV locks or unlocks the item in Web Content Manager and the JCR database. Because some items are represented by multiple files and folders, locking or unlocking one of these files causes locking or unlocking of the other associated files at the same time. If you lock an item, folders and files that are related to the content of the item, its metadata, and its access control settings are also locked.

Workflow support

There is no representation of a workflow itself in the WebDAV tree, but if a file is part of a workflow and the workflow indicates that the file is in a state that allows users to modify it, WebDAV will allow you to modify the file as well.

File names and file type suffixes

Files representing data items are always named exactly like the corresponding content item. For example if you have an image component that is named `myImage`, the corresponding image file is also named `myImage`, without any suffix indicating the file type, such as `.gif` or `.jpg`. This can sometimes cause a problem when opening the file through WebDAV because the appropriate application for editing the file cannot be chosen automatically. To account for this, you can either rename the component itself to include the file type (for example, `myImage.gif`), or you can manually start the editing application and open the file from within the client.

Missing items

If an item no longer displays or can no longer be modified, this could be due to a changed state for the item in the web content server where the item is stored. For example creating or modifying an item on the server could lead to a changed state that prevents you from accessing this item with WebDAV, depending on how workflow is set up. Expiration is another reason an item's state might change and so affect whether you can access the item with WebDAV.

Configuring a HTTP server front end

When you use an HTTP server front end to work with WebDAV, you need to set **Accept content for all requests** to `true` for the Web server plugin in the WebSphere Integrated Solutions Console under **Web servers** > **webserver1** > **Plug-in properties** > **Request and response**.

"Web content items in the WebDAV tree" on page 1989
The WebDAV tree that contains your web content items begins at the WebDAV root `/libraries/`, which displays all libraries to which you have access. All web content items within the libraries are organized with folders and files.

"Metadata and access control for web content items in WebDAV" on page 1991
WebDAV uses XML files to represent metadata and access control information for a web content item. You can change an item's metadata and access control settings by modifying these files, and you can specify settings for multiple files by copying the XML files to their appropriate locations in the WebDAV tree.

"Creating taxonomies and categories with WebDAV" on page 1993
Taxonomies and categories are profiling methods that are used to group content items, and you can work with taxonomies and categories directly through WebDAV. Taxonomies and categories are represented in WebDAV as folders, and you can set up your taxonomy by creating and nesting folders.

"Managing content with site areas in WebDAV" on page 1994
Site areas are used to organize content items in your web content system. In WebDAV site areas are represented as folders, and you can set up your site structure by creating and nesting folders. A content item within a site area is represented as a folder that contains the metadata and access control settings for the content item.

"Creating components with WebDAV" on page 1995
Components are used to store elements in your web content system, and you can use WebDAV to create and manage components. Each component type is

represented as a folder in WebDAV, with individual components represented as files in the appropriate component folder.

"Creating presentation templates in WebDAV" on page 1997
With WebDAV, you can create and maintain presentation templates to define the layout and appearance characteristics of web pages that are used to display content. You can also create nested image components for use with the presentation templates. Presentation templates are stored in a folder with nested image components in an associated folder.

Related tasks:

"Working with WebDAV clients" on page 1358
WebDAV is an HTTP extension framework with a plug point for the access and management of hierarchical data, for example, in content management systems. WebDAV stores the data in collections and allows you to work with the data in a user interface view that is similar to that of a file system. Various tools are available for integrating WebDAV resources into the client file system, known as WebDAV clients. To use WebDAV for WebSphere Portal Express, you must first set up your WebDAV clients.

Web content items in the WebDAV tree

The WebDAV tree that contains your web content items begins at the WebDAV root `/libraries/`, which displays all libraries to which you have access. All web content items within the libraries are organized with folders and files.

Items that do not pertain to content, such as site areas or categories, are represented as folders that contain only the item's metadata folder and any child items like other site areas or categories. No data files are present.

- sites
  - wcm.siteArea.siteArea1
    - meta-data
    - wcm.siteArea.siteArea1.1
      - meta-data
      - wcm.siteArea.siteArea1.1.1
        - meta-data
      - wcm.siteArea.siteArea1.1.2
        - meta-data
    - wcm.siteArea.siteArea2
      - meta-data

Data-oriented items like image components or presentation templates are represented as files so you can manipulate them with drag and drop operations. The corresponding metadata for the item is managed the same way as for the non-data items but in separate subfolders within the metadata folder.

- wcm.comps.image
  - image1.jpg
  - image2.jpg
  - meta-data
    - wcm.comp.image1.jpg

- wcm.comp.image2.jpg

In addition to folders that represent actual web content items, there are folders in the WebDAV tree to structure the data or to allow for better scalability. Each library contains folders for components, presentation templates, sites, and taxonomies.

- libraries
  - wcm.library.my_library
    - authoringTemplates
    - components
    - presentationTemplates
    - sites
    - taxonomies
  - wcm.library.contentlibrary
    - components
    - presentationTemplates
    - sites
    - taxonomies

Within the components folder, there are subfolders for the component types for better scalability and management of the different types of components.

- libraries
  - wcm.library.my_library
    - components
      - wcm.comps.authoring.tools
      - wcm.comps.component.references
      - wcm.comps.data.and.time
      - wcm.comps.federated.content
      - wcm.comps.file
      - wcm.comps.html
      - wcm.comps.image
      - wcm.comps.jsp
      - wcm.comps.link
      - wcm.comps.menu
      - wcm.comps.navigator
      - wcm.comps.number
      - wcm.comps.page.navigation
      - wcm.comps.personalization
      - wcm.comps.richt.text
      - wcm.comps.search
      - wcm.comps.short.text
      - wcm.comps.style.sheet
      - wcm.comps.taxonomy
      - wcm.comps.text
      - wcm.comps.user.name
      - wcm.comps.user.selection

To organize your authoring templates, presentation templates, and components, you can create custom web content folders. These web content folders are represented as folders in WebDAV and contain a set of component types that are structured in the same way as the root `components` folder. Here an example of a component folder structure:

- `CustomComponentFolder1`
  - `wcm.comps.authoring.tools`
  - `wcm.comps.component.references`
  - `wcm.comps.data.and.time`
  - `wcm.comps.federated.content`
  - `wcm.comps.file`
  - `.`
  - `.`
  - `.`
  - `wcm.comps.user.selection`
- `CustomComponentFolder2`
  - `wcm.comps.authoring.tools`
  - `wcm.comps.component.references`
  - `wcm.comps.data.and.time`
  - `wcm.comps.federated.content`
  - `wcm.comps.file`
  - `.`
  - `.`
  - `.`
  - `wcm.comps.user.selection`
- `wcm.comps.authoring.tools`
- `wcm.comps.component.references`
- `wcm.comps.data.and.time`
- `wcm.comps.federated.content`
- `wcm.comps.file`
- `.`
- `.`
- `.`
- `wcm.comps.user.selection`

Metadata and access control for web content items in WebDAV

WebDAV uses XML files to represent metadata and access control information for a web content item. You can change an item's metadata and access control settings by modifying these files, and you can specify settings for multiple files by copying the XML files to their appropriate locations in the WebDAV tree.

Metadata

An item's metadata is represented by the `meta-data.xml` file, which describes identification information for the item, including the name and title for the item and the list of authors and owners that are associated with the item.

Here is a sample `meta-data.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<meta-data>
  <item>
    <title lang="en" value="test1.JPG"/>
    <description lang="en" value="description"/>
    <wcm-group id="authors">
      <member DN="all_auth_portal_users" type="group"/>
      <member DN="uid=wpsadmin,o=defaultWIMFileBasedRealm" type="user"/>
    </wcm-group>
    <wcm-group id="owners">
      <member DN="uid=wpsadmin,o=defaultWIMFileBasedRealm" type="user"/>
      <member DN="all_users" type="group"/>
    </wcm-group>
  </item>
</meta-data>
```

Access control

An item's access control information is represented by the following files:

- `access-control-system.xml`: Contains access control settings for the system that are specified by the administrator.
- `access-control-user.xml`: Contains access control settings that are defined by the user.

In addition to these item-specific files, the `access-control.xml` file is provided for folders that represent resource types, like the `components` folder, and contains access control settings for the resource type.

Here is a sample `access-control.xml` file for resource access control settings:

```
<?xml version="1.0" encoding="UTF-8"?>
<access-control>
  <resource-config>
    <role-block role-type="Editor" type="inheritance"/>
    <role-block role-type="User" type="inheritance"/>
    <role-block role-type="Editor" type="propagation"/>
    <role-block role-type="User" type="propagation"/>
  </resource-config>
  <role-list>
    <role type="Administrator">
      <member DN="uid=wpsadmin,o=defaultWIMFileBasedRealm" type="user"/>
    </role>
    <role type="Contributor">
      <member DN="all_auth_portal_users" type="group"/>
    </role>
    <role type="Manager">
      <member DN="all_auth_portal_users" type="group"/>
    </role>
  </role-list>
</access-control>
```

Here is a sample `access-control-system.xml` file for an item's administrator-defined access control settings:

```
<?xml version="1.0" encoding="UTF-8"?>
<access-control>
  <resource-config>
    <role-block role-type="Contributor" type="inheritance"/>
    <role-block role-type="Manager" type="inheritance"/>
  </resource-config>
  <role-list>
    <role type="Editor">
      <member DN="authors" type="virtual"/>
    </role>
```

```
    <role type="User">
      <member DN="all_auth_portal_users" type="group"/>
    </role>
  </role-list>
</access-control>
```

Here is a sample `access-control-user.xml` file for an item's user-defined access control settings:

```
<?xml version="1.0" encoding="UTF-8"?>
<access-control>
  <role-list>
    <role type="Contributor">
      <member DN="owners" type="virtual"/>
    </role>
    <role type="Editor">
      <member DN="all_auth_portal_users" type="group"/>
    </role>
    <role type="Manager">
      <member DN="uid=wpsadmin,o=defaultWIMFileBasedRealm" type="user"/>
    </role>
  </role-list>
</access-control>
```

Related tasks:

"Managing metadata and access control settings for authoring templates with WebDAV" on page 1999
With WebDAV, you can change the metadata information for an authoring portlet or update the template's access control settings.

Creating taxonomies and categories with WebDAV

Taxonomies and categories are profiling methods that are used to group content items, and you can work with taxonomies and categories directly through WebDAV. Taxonomies and categories are represented in WebDAV as folders, and you can set up your taxonomy by creating and nesting folders.

About this task

All taxonomies and categories for a library are listed under the `taxonomies` folder for that library.

```
taxonomies
   - wcm.taxonomy.taxonomy1
       - meta-data
           access-control-system.xml
           access-control-user.xml
           meta-data.xml
       - wcm.category.category1
           - meta-data
               access-control-system.xml
               access-control-user.xml
               meta-data.xml
           - wcm.category.category1.1
               - meta-data
                   access-control-system.xml
                   access-control-user.xml
                   meta-data.xml
           - wcm.category.category1.2
               - meta-data
                   access-control-system.xml
                   access-control-user.xml
                   meta-data.xml
   - wcm.taxonomy.taxonomy2
       - meta-data
```

```
          access-control-system.xml
          access-control-user.xml
          meta-data.xml
   access-control.xml
```

Procedure

To create a new taxonomy or category for your library, create a new folder with the `wcm.taxonomy` prefix or the `wcm.category` prefix. Taxonomies can be created under the generic `taxonomies` folder only, while categories can be created in either a `wcm.taxonomy.*` folder or a `wcm.category.*` folder.

Important: Some WebDAV clients create a folder with a default name, such as `New Folder`, and as soon as you enter the name of the new folder, the client sends a request to rename the already created folder. Because taxonomy and category folders require a corresponding prefix for creation, this client behavior does not work. If your WebDAV client uses this method to create new folders, you can first create the new taxonomy or category folder locally and then copy it into the WebDAV tree.

Deleting taxonomies and categories: To delete taxonomies or categories delete the corresponding folder. Taxonomies or categories that contain categories cannot be deleted until you have also first deleted the child items. Also if a category is still being referenced by another item, it cannot be deleted until you have first removed the corresponding references by using the authoring portlet.

Managing content with site areas in WebDAV

Site areas are used to organize content items in your web content system. In WebDAV site areas are represented as folders, and you can set up your site structure by creating and nesting folders. A content item within a site area is represented as a folder that contains the metadata and access control settings for the content item.

About this task

All site areas and content items for a library are listed under the `sites` folder for that library.

```
sites
  - wcm.siteArea.siteArea1
      - meta-data
          access-control-system.xml
          access-control-user.xml
          meta-data.xml
      - wcm.siteArea.siteArea1.1
          - meta-data
              access-control-system.xml
              access-control-user.xml
              meta-data.xml
          - wcm.content.content1.1.1
              - meta-data
                  access-control-system.xml
                  access-control-user.xml
                  meta-data.xml
      - wcm.siteArea.siteArea1.2
          - meta-data
              access-control-system.xml
              access-control-user.xml
              meta-data.xml
   access-control.xml
```

Note: Support for content items is limited to modifying the metadata and access control settings. You cannot create or delete content items by using WebDAV.

Procedure

To create a new site area for your library, create a new folder with the `wcm.siteArea` prefix.

Important: Some WebDAV clients create a folder with a default name, such as `New Folder`, and as soon as you enter the name of the new folder, the client sends a request to rename the already created folder. Because site area folders require a corresponding prefix for creation, this client behavior does not work. If your WebDAV client uses this method to create new folders, you can first create the new site area folder locally and then copy it into the WebDAV tree.

Deleting site areas: To delete site areas delete the corresponding folder. Parent site areas containing site areas or content items cannot be deleted until you have also first deleted the child items. To delete child content items before deleting a site area, you must use the authoring portlet rather than WebDAV.

Creating components with WebDAV

Components are used to store elements in your web content system, and you can use WebDAV to create and manage components. Each component type is represented as a folder in WebDAV, with individual components represented as files in the appropriate component folder.

About this task

All components for a library are listed as folders under the `components` folder for that library. Within the `components` folder, you can also create custom folders that you can use to organize your components. Like the root `components` folder, custom folders contain folders for each type of component.

```
libraries
  - wcm.library.my_library
      - components
          - CustomComponentFolder1
              - wcm.comps.authoring.tools
              - wcm.comps.component.references
              - wcm.comps.data.and.time
              .
              .
              .
              - wcm.comps.user.selection
          - CustomComponentFolder2
              - wcm.comps.authoring.tools
              - wcm.comps.component.references
              - wcm.comps.data.and.time
              .
              .
              .
              - wcm.comps.user.selection
          - wcm.comps.authoring.tools
          - wcm.comps.component.references
          - wcm.comps.data.and.time
          - wcm.comps.federated.content
          - wcm.comps.file
          - wcm.comps.html
          - wcm.comps.image
          - wcm.comps.jsp
          - wcm.comps.link
          - wcm.comps.menu
```

```
        - wcm.comps.navigator
        - wcm.comps.number
        - wcm.comps.page.navigation
        - wcm.comps.personalization
        - wcm.comps.rich.text
        - wcm.comps.search
        - wcm.comps.short.text
        - wcm.comps.style.sheet
        - wcm.comps.taxonomy
        - wcm.comps.text
        - wcm.comps.user.name
        - wcm.comps.user.selection
        access-control.xml
```

Components are data-oriented items and represented as files and metadata folders.

```
libraries
  - wcm.library.my_library
      - components
        - wcm.comps.authoring.tools
        - wcm.comps.component.references
        - wcm.comps.data.and.time
        - wcm.comps.federated.content
        - wcm.comps.file
        - wcm.comps.html
        - wcm.comps.image
            image1.jpg
            image2.jpg
            - meta-data
              - wcm.comp.image1.jpg
                    access-control-system.xml
                    access-control-user.xml
                    meta-data.xml
              - wcm.comp.image2.jpg
                    access-control-system.xml
                    access-control-user.xml
                    meta-data.xml
        - wcm.comps.jsp
        - wcm.comps.link
        - wcm.comps.menu
        - wcm.comps.navigator
        .
        .
        .
         - wcm.comps.user.selection
        access-control.xml
```

Important: Although displayed in WebDAV, the following components cannot be created or modified through WebDAV and are represented by empty files:

- Authoring tools
- Component references
- Federated content
- JSP
- Menu
- Navigator
- Page navigation
- Personalization
- Search
- Taxonomy
- User name
- User selection

To change these components, you must use the authoring portlet.

Link component limitation: Currently, link components are not fully supported by WebDAV. The WebDAV file that represents the link component contains only the URL of the link itself but no other information, such as the link text. For example, if you use WebDAV to modify a link component that contains an HTML representation of `<a href='www.lotus.com'>lotus software</a>` and change the URL to`www.ibm.com`, the link text is rendered as `lotus software`, because that information cannot be modified with WebDAV.

Procedure

To create components for your library, drag one or more files into the appropriate component type folder. When you create a new component in this way, the object's file name is used as the name and title of the new component, and the file's content is stored as the component's data. In addition, the user who is authenticated with the WebDAV client is specified as the author and owner of the new component.
For example, you might drag an HTML file into the `wcm.comps.html` folder for a new HTML component or into the `wcm.comps.rich.text` folder for a new rich text element.

Important: Placing an incompatible file into a component type folder (for example, putting a JPEG file into the `wcm.comps.html` folder) can cause errors during component creation and might result in an unusable component.

Updating components: To update an existing component, you can replace the corresponding file in the WebDAV tree with a new file that has the same name. For example you can place `myCoolPic.jpg` into the image components folder that already contains `myCoolPic.jpg`, and the component is automatically updated with the new file's content. If you place a file with a different name, a new component with that name is created.

Creating presentation templates in WebDAV

With WebDAV, you can create and maintain presentation templates to define the layout and appearance characteristics of web pages that are used to display content. You can also create nested image components for use with the presentation templates. Presentation templates are stored in a folder with nested image components in an associated folder.

About this task

All presentation templates for a library are listed under the `presentationTemplates` folder for that library. Because they are data-oriented items, presentation templates are represented as files and `meta-data` folders. Nested image components are stored in a folder that is named after its associated presentation template–for example, *`template_name`*`_files`.

```
libraries
  - wcm.library.my_library
      - presentationTemplates
         template1.html
         myTemplate.html
         - meta-data
             - wcm.presentationTemplate.template1.html
                   access-control-system.xml
                   access-control-user.xml
                   meta-data.xml
             - wcm.presentationTemplate.myTemplate.html
```

```
            access-control-system.xml
            access-control-user.xml
            meta-data.xml
        access-control.xml
    - template1.html_files
        nested_image.jpg
    - myTemplate.html_files
```

Procedure

1. To create presentation templates for your library, drag one or more files into the `presentationTemplates` folder. When you create a new presentation template in this way, the object's file name is used as the name and title of the new template, and the file's content is stored as the template's data. In addition, the user who is authenticated with the WebDAV client is specified as the author and owner of the new template.

   Important: Placing an incompatible file into the `presentationTemplates` folder (for example, a JPEG file) can cause errors during template creation and might result in an unusable presentation template.

   Deleting presentation templates: To delete a presentation template delete the corresponding file. If the presentation template is being referenced by another item, such as a site area, it cannot be deleted until you have first removed the corresponding references by using the authoring portlet.

   Updating presentation templates: To update an existing presentation template, you can replace the corresponding file in the WebDAV tree with a new file that has the same name. For example, you can place `myTemplate.html` into the `presentationTemplates` folder, replacing the `myTemplate.html` file that is already there, and the presentation template will automatically be updated with the new file's content. If you place a file with a different name, a new template with that name is created.
2. Create any nested image components for your presentation template by adding the image files to the *`template_name`*`_files` folder for your template. For example, if your template is `template1.html`, you would add the image files to the `template1.html_files` folder.

   Note: When you add an image to the nested components folder, a temporary image is created initially, and the image is only permanently added to the list of nested components when a reference to that image is added to the presentation template's HTML code. This is done to prevent orphaned components within the presentation template.
3. If you have added a nested image component, update the presentation template's HTML code to reference the component according to the relative WebDAV path to the component.

   For example, to reference a nested image component, you would update the `template1.html` file with the following code:

   ```
   <img src="./template1.html_files/nestedImage.jpg" border="0"
   title="my nested image"/>
   ```

   To reference a standard image component, you would use HTML code similar to the following example:

   ```
   <img src="../components/wcm.comps.image/test2.jpg" border="0"
   title="my test image"/>
   ```

Managing metadata and access control settings for authoring templates with WebDAV

With WebDAV, you can change the metadata information for an authoring portlet or update the template's access control settings.

About this task

All authoring templates for a library are listed under the `authoringTemplates` folder for that library. Because they are data-oriented items, authoring templates are represented as files and `meta-data` folders.

```
libraries
  - wcm.library.my_library
      - authoringTemplates
         auth_template1.html
         myAuthTemplate.html
         - meta-data
             - wcm.presentationTemplate.auth_template1.html
                   access-control-system.xml
                   access-control-user.xml
                   meta-data.xml
             - wcm.presentationTemplate.myAuthTemplate.html
                   access-control-system.xml
                   access-control-user.xml
                   meta-data.xml
             access-control.xml
```

Note: You cannot modify the authoring template itself in WebDAV. To edit the authoring template, use the authoring portlet.

Procedure

1. To change the access control settings for an authoring template, edit the `access-control-system.xml` file for administrator settings or the `access-control-user.xml` file for user-defined settings.
2. To change the metadata for an authoring template, edit the `meta-data.xml` file for the authoring template.

Related concepts:

"Metadata and access control for web content items in WebDAV" on page 1991
WebDAV uses XML files to represent metadata and access control information for a web content item. You can change an item's metadata and access control settings by modifying these files, and you can specify settings for multiple files by copying the XML files to their appropriate locations in the WebDAV tree.

Blogs

Use blogs and blog libraries to provide news and commentary on a variety of subjects pertinent to your intranet and extranet sites. Blogs and blog libraries typically combine text with graphics and links to other blogs and web sites. Entries that you create and post are arranged in reverse-chronological order, with the newest entry displayed first. Readers can post comments about your entries, fostering discussions and online networking. You can manage your own blog entries and comment on other blog entries. You can also incorporate tagging and rating as you would with other WebSphere Portal content.

About this task

Tip: Use a blog for sharing information on a single subject. Use a blog library to share information on multiple discussions.

"Learn about the template libraries used by blogs and blog libraries"
Blogs and blog libraries use the template libraries provided by IBM Web Content Manager. Blog libraries use Web Resources v70 library and Blog v70 library. Blogs use the Web Resources v70 and Blog Solo v70 library. The page hierarchy that is provided for these components is the common one defined by the Web Content Manager template libraries.

"Adding a blog or blog library to a page" on page 2001
With Editor access to the portal or the portal page, you can add a blog or blog library to a page. Choose a blog to collaborate with your team on a single topic. Choose a blog library to collaborate with your team on multiple topics in a centralized view.

"Adding existing blogs or blog libraries to a page" on page 2002
If you created a blog or blog library for another page and now want to use it again, add a web content viewer to the new page and edit its settings to point to the existing blog or blog library.

"Assigning blog access to users" on page 2003
The Portal administrator can assign Editor access to you if you need to create and manage blogs within the site. If you are given Editor access to a blog, you can create or modify posts in that blog. If you are given Editor rights to a blog library, you can create and modify blogs and you can create and modify posts in that blog library. If you have Manager rights to a blog, you can create, modify, and delete posts and delete comments in that blog. If you are given Manager rights to a blog library, you can create, modify, and delete blogs. You can also create, modify, and delete posts and delete comments within the blogs.

"Viewing blogs and blog posts" on page 2004
You can view the blogs that are created in a specific library and you can view the posts in a blog by descending order. If you are a contributor, you can view blog pages. By default, all portal users can view content in a blog or blog post once it has been created.

"Deleting blogs or blog libraries" on page 2004
If you are the owner of a blog site, you have Manager access and can delete any blog, pages, comments, or posts on that site.

Related concepts:

"Tagging and rating portal content" on page 34
Users can tag or rate portal content and view the tags and ratings. Tagging and rating allow users to better organize, categorize, and find portal content. This task includes Web Content Manager, Connections, and custom content. For example, users can tag or rate books in an online bookstore.

Learn about the template libraries used by blogs and blog libraries

Blogs and blog libraries use the template libraries provided by IBM Web Content Manager. Blog libraries use Web Resources v70 library and Blog v70 library. Blogs use the Web Resources v70 and Blog Solo v70 library. The page hierarchy that is provided for these components is the common one defined by the Web Content Manager template libraries.

Note: The Web Content Manager libraries described in this topic only work with the theme customizer used in the default theme. Customization to these libraries will affect all blogs and blog libraries on the site.

Web Resources v70 library

The Web Resources v70 library provides the authoring and presentation templates for blogs and blog libraries. All blogs on the site use this single shared library. Changes to the main shared library affects all blogs.

Blog Solo v70 library

When you add a blog to a page, a copy of the Blog Solo v70 library is created using the name that you provided when adding a blog to a page. This copy of the Blog Solo v70 library is used to store posts and comments.

Blog v70 library

When you add a blog library to a page, a copy of the Blog v70 library is created using the name that you provided when adding the blog library to a page. The copy of the Blog v70 library is used to store posts and comments when new pages are added to the blog library.

Adding a blog or blog library to a page

With Editor access to the portal or the portal page, you can add a blog or blog library to a page. Choose a blog to collaborate with your team on a single topic. Choose a blog library to collaborate with your team on multiple topics in a centralized view.

Before you begin

Refer to the WebSphere Portal family Wiki for an example of how you can modify your custom theme to enable the capability of adding blogs and wikis to a page.

Procedure

1. Create a project or access an existing project, and open the project in edit mode.
2. If you did not already, create a page for the existing blog or blog library or open an existing page.

   Note: Blog and Blog Library require a certain amount of horizontal screen space to render properly, and are not supported on mobile devices. For desktop applications with limited horizontal screen space, use the portlets in a one-column layout.
3. Click the **Content** tab, then click **Communications**.
4. Click **Blog Library** to add a team blog or click **Blog** to create a single-topic blog.
5. Click **Add to page**.
6. Provide a name. Then, click **Add**.

   The name is used for the portlet title, library display title, and library name. It can contain alphanumeric characters, spaces, and the following characters: `$ - _ . ! ( ) ,`. If you use other characters, they are replaced by characters that are supported by the Web Content Manager library.
7. Click **Save Draft**.

   This action copies the appropriate IBM Web Content Manager blog template library and places an instance of the web content viewer on the page.

What to do next

After you publish the site with a blog library, click **Create Blog** and **Create Post** to add content. Click **Edit** to modify content. To delete a post, click **Delete**.

After you publish the site with a blog, click **Create Post** to add content. Click **Edit** to modify content. To delete a post, click **Delete**.

Note: Tagged web content that is displayed in the web content viewer is only available when there is a single instance of this portlet on the page. When you click a tag result, the Tag Center broadcasts the information on what content displays in the viewer with a public render parameter. If you have multiple instances of web content displayed in the web content viewer, then these instances display the content that you tagged rather than display the original content of these instances.

Adding existing blogs or blog libraries to a page

If you created a blog or blog library for another page and now want to use it again, add a web content viewer to the new page and edit its settings to point to the existing blog or blog library.

Procedure

1. Create a project or access an existing project, and open the project in edit mode.
2. If you did not already, create a page for the existing blog or blog library or open an existing page.

   Note: Blog and Blog Library require a certain amount of horizontal screen space to render properly, and are therefore not intended for small mobile devices such as smartphones. For some tablet and desktop situations with limited horizontal screen space, use the portlets in a one-column layout.
3. Click the **Content** tab.
4. Click **All** in the list of categories, and search for the portlet **Web Content Viewer**.
5. Add the web content viewer to your page by clicking the plus sign (+) or dragging the viewer onto the page.
6. Click **Save**.
7. Click the drop-down menu that is in the web content viewer title bar, and select **Edit Shared Settings**.
8. Under Content Type, select **Content Item**.
9. Under Content, click **Edit**.
10. Click **Libraries**.
11. Click the library that contains the blog or blog library you want to add.
12. Expand the selected library to see the blog or blog library you want to use.
13. Select the blog or blog library and click **OK**.
14. Click **Apply** to save your changes to the web content viewer.
15. Click **Advanced Options**.
16. Ensure the **Broadcast links to** option is set to **None** or **This Portal page**.
17. Ensure the **Receive links from** option is set to **This portlet only** or **Other portlets and this portlet**.
18. Click **OK**.

What to do next

Note: Tagged web content that is displayed in the web content viewer is only available when there is a single instance of this portlet on the page. When you click a tag result, the Tag Center broadcasts the information on what content displays in the viewer with a public render parameter. If you have multiple instances of web content that is displayed in the web content viewer, then these instances display the content that you tagged rather than display the original content of these instances.

Assigning blog access to users

The Portal administrator can assign Editor access to you if you need to create and manage blogs within the site. If you are given Editor access to a blog, you can create or modify posts in that blog. If you are given Editor rights to a blog library, you can create and modify blogs and you can create and modify posts in that blog library. If you have Manager rights to a blog, you can create, modify, and delete posts and delete comments in that blog. If you are given Manager rights to a blog library, you can create, modify, and delete blogs. You can also create, modify, and delete posts and delete comments within the blogs.

About this task

For an example of assigning access to users, refer to the following instructions for adding users to the Editor role:

Procedure

1. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.
2. Go to the library that contains the blog you want to manage and click **Set permissions**.
3. Click **Edit Role** for the Editor role.
4. Click **Add** to assign users or groups to the Editor role. Search for the users or groups that belong to this role.

Example

For example, the settings in the following table allow all authenticated users to create new blogs, but restricts them to posting only in blogs they created. Use the **Set Permissions** and **Library Resources** options from the Web Content Library page to assign the following settings:

Table 317. An example of access settings for a blog

Access settings	Group	Access level	Other settings
Presentation Templates	All Authenticated Portal Users	Contributor	Do not select "Allow propagation"
Presentation Templates	All Authenticated Portal Users	User	
Content	All Authenticated Portal Users	Editor	

Viewing blogs and blog posts

You can view the blogs that are created in a specific library and you can view the posts in a blog by descending order. If you are a contributor, you can view blog pages. By default, all portal users can view content in a blog or blog post once it has been created.

Procedure

1. Navigate to the page that contains the blog or blog library.
2. **(Blog library only)** click **List of Blogs** to view all of the blogs that were created in a specific library. Blogs are listed in descending order from first to last and display the name of the person who created the blog (Editor) and the date and time when the blog was created.
   a. Move through the list of blogs by using the page controls.
   b. Specify how many blogs to list on a page by choosing to **Show** *10*, *20*, *50* *100*.
   c. If you have Editor access, you can click **Create Blog**.
   d. Click the title of a blog to open the blog.
3. **(Blog or Blog Library)** View the posts, which are listed in descending order from first to last and display the name of the person who created the post (User) and the date and time when the post was created.
   a. Click **Latest Blog Posts** to view the most recent blog content.
   b. Move through the list of posts by using the page controls.
   c. Specify how many posts to list on a page by choosing to **Show** *10*, *20*, *50*, or *100*.
   d. If you have Editor access, you can **Create Post**. You can edit and delete posts that you own.
   e. If you have User access, you can comment on a post.

What to do next

After you view posts, you can add comments to share your thoughts. To add a comment, click **Add a Comment**.

Deleting blogs or blog libraries

If you are the owner of a blog site, you have Manager access and can delete any blog, pages, comments, or posts on that site.

About this task

To delete an individual blog, open the project that contains the blog library in a project. To delete an entire blog library, use the Portal Administration page.

Procedure

1. To delete one blog from a library, go to the page that contains the blog library.
2. Click **List of Blogs**.
3. Go to the blog library that contains the blog you want to delete.
4. Click **Delete** and **OK**.
5. You can delete an entire blog library. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.
6. Go to the library you want to delete and click **Delete library** and **OK**.

Wikis

Use wikis to share community content on a variety of subjects pertinent to your intranet and extranet sites. Wikis typically combine text with graphics and links to other wikis and web sites. You can monitor and manage your own wiki articles.

About this task

"Learn about the template libraries used by wikis"
Wikis use the template libraries provided by IBM Web Content Manager. Wikis use the Web Resources v70 library and the Wiki v70 library. The page hierarchy that is provided for wikis is the common one defined by the Web Content Manager template libraries.

"Adding a wiki to a page" on page 2006
With Editor access to the portal or the portal page, you can add a wiki to a page to quickly create and edit content in-line.

"Adding existing wikis to a page" on page 2007
If you created a wiki for another page and now want to use it again, add a web content viewer to the new page and edit its settings to point to the existing wiki.

"Assigning wiki access to users" on page 2008
If you are the administrator, you have Manager access and can assign Editor access to other users who need to create and manage wikis within the site. If you are the owner of a wiki site, you have Manager access. As wiki site Manager, you can also delete any wiki page or wiki. If you have Editor access, you can create and edit any wiki site and wiki pages. All wiki editors can modify all pages of a wiki site.

"Deleting wikis" on page 2008
If you are the owner of a wiki site, you have Manager access and can delete any wiki or wiki pages on that site.

"Purging deleted wiki pages" on page 2008
When you delete a wiki post, it is removed from the site, but remains in the delete view in IBM Web Content Manager. Users with Administrator access to libraries can purge these deleted wiki pages, which optimizes performance of the wiki library. Purging the deleted wiki pages removes all occurrences, including all versions. You cannot restore deleted items after you purge them.

Related concepts:

"Tagging and rating portal content" on page 34
Users can tag or rate portal content and view the tags and ratings. Tagging and rating allow users to better organize, categorize, and find portal content. This task includes Web Content Manager, Connections, and custom content. For example, users can tag or rate books in an online bookstore.

Adding existing wikis to a page

If you created a wiki for another page and now want to use it again, add a web content viewer to the new page and edit its settings to point to the existing wiki.

About this task

Refer to the following steps only when you are adding a web content viewer portlet from the **Page Properties** menu and configuring this web content viewer to point to an existing wiki. To create a new wiki, use the Customize link to add a wiki to a page.

Procedure

1. Create a project or access an existing project, and open the project in edit mode.
2. If you did not already, create a page for the wiki or open an existing page.

   Note: Wiki requires a certain amount of horizontal screen space to render properly, and is not intended for small mobile devices such as smartphones. For some tablet and desktop situations with limited horizontal screen space, use the portlet in a one-column layout.
3. Click the **Content** tab.
4. Click **All** in the list of categories, and search for the portlet **Web Content Viewer**.
5. Add the web content viewer to your page by clicking the plus sign (+) or dragging the viewer onto the page.
6. Click **Save**.
7. Click the drop-down menu that is in the web content viewer title bar, and select **Edit Shared Settings**.
8. Under Content Type, select **Content Item**.
9. Under Content, click **Edit**.
10. Click **Libraries**.
11. Click the library that contains the wiki you want to add.
12. Expand the selected library to find the wiki you want to use.
13. Select the wiki and click **OK**.
14. Click **Apply** to save your changes to the web content viewer.
15. Click **Advanced Options**.
16. Ensure the **Broadcast links to** option is set to **None** or **This Portal page**.
17. Ensure the **Receive links from** option is set to **This portlet only** or **Other portlets and this portlet**.
18. Click **OK**.

What to do next

Note: Tagged web content that is displayed in the web content viewer is only available when there is a single instance of this portlet on the page. When you click a tag result, the Tag Center broadcasts the information on what content displays in the viewer with a public render parameter. If you have multiple

instances of web content that is displayed in the web content viewer, then these instances display the content that you tagged rather than display the original content of these instances.

Assigning wiki access to users

If you are the administrator, you have Manager access and can assign Editor access to other users who need to create and manage wikis within the site. If you are the owner of a wiki site, you have Manager access. As wiki site Manager, you can also delete any wiki page or wiki. If you have Editor access, you can create and edit any wiki site and wiki pages. All wiki editors can modify all pages of a wiki site.

About this task

If you are a contributor, you can view wiki pages. By default, all portal users can view content in a wiki after it is created.

For an example of assigning access to users, refer to the following instructions for adding users to the Editor role:

Procedure

1. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.
2. Go to the library that contains the wiki you want to manage and click **Set Permissions**.
3. Click **Edit Role** for the **Editor** role.
4. Click **Add** to assign users or groups to the Editor role. Search for the users or groups that belong to this role.

Deleting wikis

If you are the owner of a wiki site, you have Manager access and can delete any wiki or wiki pages on that site.

About this task

You can delete a wiki and all its pages by deleting the wiki from a project.

Procedure

1. Create a project or access an existing project, and open the project in edit mode.
2. Open the page that contains the wiki.
3. From the site toolbar, click **More** > **Delete Page**.
4. Click **OK**.
5. Publish the project.

Purging deleted wiki pages

When you delete a wiki post, it is removed from the site, but remains in the delete view in IBM Web Content Manager. Users with Administrator access to libraries can purge these deleted wiki pages, which optimizes performance of the wiki library. Purging the deleted wiki pages removes all occurrences, including all versions. You cannot restore deleted items after you purge them.

Procedure

1. Select **Applications** > **Content** > **Web Content Management**.
2. In the Library Explorer, select the wiki library that contains the pages that you want to purge.

   Tip: If you do not see your library, click **Preferences** > **Configure** > **Library Selection** to add the library to the selection list.
3. Select **Item Views** > **Deleted Items**.
4. Select the appropriate wiki page and click **Purge**. Click **OK**.

Installed portlets

Learn about the portlets that are provided with WebSphere Portal Express.

You find all portlets that are provided with the portal under the directory *PortalServer_root*. Portlets that are already deployed by the WebSphere Portal Express installation are in the directory *wp_profile_root*/installedApps directory.

In addition to the portlets listed here, WebSphere Portal Express also provides several portlets that are used for administering the portal server. You find these portlets with the Administration portlets.

For the most up-to-date information on portlets, including the portlets available for download, go to the IBM Collaboration Solutions Catalog.

"Business portlets"
Business portlets are automatically installed during the WebSphere Portal Express installation. You can place and display them on a page after you install and start the portal.

Related information:

IBM WebSphere Portal Business Solutions Catalog

Business portlets

Business portlets are automatically installed during the WebSphere Portal Express installation. You can place and display them on a page after you install and start the portal.

All business portlets that are provided with WebSphere Portal Express are in the following directory: *PortalServer_root*/bp. To make the portlets available, click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.

Most of the business portlets are also available on the IBM Collaboration Solutions Catalog.

IBM i: Use the **Install and Configure** option of the remote GUI installation to install the portlets.

Table 318. Business portlets available for immediate use

Application	Description
Welcome	Shows version and copyright for WebSphere Portal Express installed.

Table 318. Business portlets available for immediate use (continued)

Application	Description
Banner Ad	Banner Ad enables users to insert and view an image on a portal page. This image can be hyperlinked to a web page. This web page can be specified to open either in the same or a new browser window. **Note:** The Banner Ad portlet verifies that you entered a URL for a particular image. It does not verify the validity of the URL.
Microsoft Exchange 2010 portlet application	The Microsoft Exchange 2010 portlet application connects to an Exchange server. This portlet application contains the following portlets: • MS Exchange 2010 Mail Portlet • MS Exchange 2010 Calendar Portlet
IBM Syndicated Feed Portlet for WebSphere Portal	Use this portlet to integrate, view, and manage RSS and Atom feeds from your portal pages. You can organize the feeds into new and existing feed categories and extensively customize the presentation style for these feeds. The portlet is supported in a proxied environment and enables dynamic modification of the portlet window title. As an Administrator, you can configure several administrative settings from within the portlet interface and apply selective locks on a user's ability to customize the portlet. The portlet complies with the Outline Processor Markup Language (OPML) standards for subscription management. It supports the export of feeds to an OPML-compliant file. It supports the import of multiple feeds into the portlet from an OPML URL.

Note: RSS portlet and IBM Feed Reader portlet are no longer included with WebSphere Portal Express. If you used these portlets, use IBM Syndicated Feed Portlet for WebSphere Portal. The Web2Bookmarks portlet is no longer available for immediate use. You can download the RSS, IBM Feed Reader, and Web2Bookmarks portlets from the IBM WebSphere Portal Business Solutions Catalog.

"Emailing with the Microsoft Exchange 2010 portlet application" on page 2011
By using the IBM portlet application for Microsoft Exchange 2010, users can perform routine mail-related tasks, such as composing, reading, and deleting emails. This application enables users to view, edit, and delete items in their mail and other personal Information Management applications. Administration users set up the portlets and the users who are registered with Exchange can personalize them.

Related information:

IBM WebSphere Portal Business Solutions Catalog

Catalog documentation for IBM Portlet Application for Microsoft Exchange

Emailing with the Microsoft Exchange 2010 portlet application:

By using the IBM portlet application for Microsoft Exchange 2010, users can perform routine mail-related tasks, such as composing, reading, and deleting emails. This application enables users to view, edit, and delete items in their mail and other personal Information Management applications. Administration users set up the portlets and the users who are registered with Exchange can personalize them.

About this task

The IBM portlet application for Microsoft Exchange connects to an Exchange 2010 server via Exchange Web Services.

The following portlets are provided in the portlet application that works with Microsoft Exchange 2010 server:

The IBM Microsoft Exchange Mail 2010 portlet
With Microsoft Exchange2010 Mail, you can connect to an Exchange 2010 Server. You can perform standard mail functions, such as compose, reply, forward, and delete mail.

The IBM Microsoft Exchange Calendar 2010 portlet
With Microsoft Exchange2010 Calendar, you can retrieve calendar information from the Exchange 2010 server and display it on your page. You can perform standard calendar functions, such as creating, editing, deleting, and viewing appointments.

Integration with Exchange OWA mode is not supported for the Exchange 2010 version.

"Setting the credential slot for the Microsoft Exchange 2010 portlet application"
For users to be able to use the IBM portlet application for Microsoft Exchange 2010 in WebSphere Portal Express, administrators must set up a vault slot for the portlets to use.

"Configuring your portal to accept the Exchange server SSL certificate" on page 2012
To use the secure socket layer (SSL) features, you must configure the JVM for the WebSphere Portal Express server to accept the SSL certificate of the Exchange server.

"Customizing the Exchange 2010 portlet" on page 2012
Each user that is registered with Exchange can customize an Exchange 2010 portlet by using the **Personalize** menu. Use the following list to set the appropriate configuration parameters.

Setting the credential slot for the Microsoft Exchange 2010 portlet application:

For users to be able to use the IBM portlet application for Microsoft Exchange 2010 in WebSphere Portal Express, administrators must set up a vault slot for the portlets to use.

Procedure

1. Go to the Credential Vault administration portlet.
2. Create a slot for use by the IBM portlet application for Microsoft Exchange 2010. This slot might not be a shared system credential.

3. Configure each portlet in the web module by placing the portlets on a page and click the configure icon. The configuration window shows a list of possible credential vault slots that you can use.

   Note: The **Configure** icon is only available to users who have Manage permission for the portlet.
4. Select the vault slot that you created for the Microsoft Exchange 2010 portlet application.
5. Click **OK**.
6. Repeat these steps for each portlet. If you select the same slot for each portlet, the users have the same credentials for each portlet.

Configuring your portal to accept the Exchange server SSL certificate:

To use the secure socket layer (SSL) features, you must configure the JVM for the WebSphere Portal Express server to accept the SSL certificate of the Exchange server.

About this task

You must obtain the certificate from the Exchange server. There are different methods to obtain the certificate. The best way is to ask the Exchange administrator to send it to you.

To make the Exchange Server SSL certificate available to the portal server, add the base 64-encoded ASCII data certificate by using the WebSphere Integrated Solutions Console.

Procedure

1. Open the WebSphere Integrated Solutions Console.
2. Click **Security** > **SSL certificates and key management**.
3. Under Related Items, click **Key Stores and Certificates**.
4. Click **NodeDefaultTrustStore**.
5. Under Additional Properties, click **Signer Certificates**.
6. Click **Add**.
7. In the **Alias** field, enter a name.
8. In the **File name** field, enter the path and name of the certificate file.
9. For the **Data type**, select **Bas64-encoded ASCII data** from the pull-down list.
10. Click **Apply**, then **OK**.
11. Restart server1 and your WebSphere Portal Express.

Customizing the Exchange 2010 portlet:

Each user that is registered with Exchange can customize an Exchange 2010 portlet by using the **Personalize** menu. Use the following list to set the appropriate configuration parameters.

About this task

Select version
Select the version of Exchange 2010 that you want to use with Microsoft Mail.

Select your time zone
From the drop-down menu, select the time zone in which you are located.

Server name
Enter the name of the Exchange 2010 Server.

Use a Secure Connection
Select this option to enable a secure connection.

User name
Enter the user name for Exchange 2010. For example, enter `jsmith`.

Password
Enter the password for the Exchange 2010 user name.

Mailbox alias
Enter your primary email address. For example, enter `jsmith@example.com`.

Domain
Enter the domain of your Exchange 2010 account that you received from your Exchange 2010 administrator.

Exchange Email address
Enter your Exchange 2010 email address.

Enter displayed date format
Enter the format in which you want to have the date display.

Number of attachments per message
From the drop-down menu, select the maximum number of attachments that a user can add to a message.

Messages per page
Set the number of messages you want to display.

Renditions

Renditions are different versions of an image component or element. Renditions can be thumbnails or smaller versions of an image formatted for mobile devices.

Renditions make it easy to reformat an image for publishing different sizes on different platforms. Users can choose the size of image they want with the user interface.

The image rendition exists in addition to the original image that is stored in the image component or element as binary code. The image rendition is part of the encapsulating image, which has the same UUID, but can be addressed by a unique URL.

The user interface supports uploading three renditions in addition to the original image. The renditions are named `Desktop`, `Tablet`, and `Smartphone`. You can expose the renditions through the user interface, or through a public API.

CF04 "Setting rendition properties on images" on page 2014
Renditions automatically render a version of your image that is best suited for the device connecting to the site.

CF04 "Disabling renditions" on page 2014
Renditions are enabled by default. If you want to disable them, you must run a ConfigEngine task.

CF04 "Enabling renditions" on page 2015
Renditions are enabled by default. If you disable them, you must run a ConfigEngine task to enable them.

Setting rendition properties on images

Renditions automatically render a version of your image that is best suited for the device connecting to the site.

Procedure

1. Select an image and open the rendition section in the image form.
2. To upload a version of the image that is sized for your purpose, select the rendition, such as **desktop**. You can choose from **desktop**, **tablet**, **smartphone**, or **none**. You can upload a main image, but it is not required if you have an image that is uploaded into the default rendition spot.
3. You can replace a rendition to scale and crop the image for each device size.
4. In the authoring template for image elements, you can disable renditions for an element or set preferred pixel or file sizes in the properties section.
5. When you are finished, click **Place Rendition**.

Results

For component and element tags that reference an image the attribute `rendition="auto"` renders the rendition based on the current device class, such as tablet. If that rendition is empty it renders the default rendition desktop per default, which is defined with `default.rendition.name` in the Web Content Manager Config Service Resource Environment Provider. If that is empty, it renders the main image.

For component and element tags that reference an image with the rendition attribute set to either **desktop**, **tablet**, or **smartphone** the specified rendition is rendered and no fallback is performed. Specifying `rendition="none"` renders the main image.

CF04 If you do not specify the rendition attribute, the main image renders.

CF06 If you do not specify the rendition attribute, `rendition="auto"` is the default.

Disabling renditions

Renditions are enabled by default. If you want to disable them, you must run a ConfigEngine task.

Procedure

1. Go to the *wp_profile_root*`/ConfigEngine` directory.
2. Run the following command:
   - Linux : `./ConfigEngine.sh disable-renditions -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
   - IBM i: `ConfigEngine.sh disable-renditions -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
   - Windows: `ConfigEngine.bat disable-renditions -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
3. Restart the WebSphere Portal Express server.

Enabling renditions

Renditions are enabled by default. If you disable them, you must run a ConfigEngine task to enable them.

About this task

Running this task sets **renditions.enabled=true** as a global property for all virtual portals in the Web Content Manager Config Resource Environment Provider Service.

Procedure

1. Go to the *wp_profile_root*/ConfigEngine directory.
2. Run the following command:
   - Linux : `./ConfigEngine.sh enable-renditions -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
   - IBM i: `ConfigEngine.sh enable-renditions -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
   - Windows: `ConfigEngine.bat enable-renditions -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
3. Restart the WebSphere Portal Express server.

Video start and end points

File components or elements that have a video file that is stored in an HTML5 video format, which includes MP4, webM, or ogg, are stored in Brightcove and have a Brightcove ID.

CF04

The video can be previewed in the content form and you can set starting and ending points for the video.

The following code is an HTML5 video player sample:

```
<video class="videoPlayer" controls="" preload="metadata" src='[Element context="current"
type="content" key="file" format="url"]#t=[Element context="current" type="content" key="file"
format="startTime_sec"],[Element context="current" type="content" key="file" format="endTime_sec"]
         Your browser does not support the video tag.
   </video>
```

The starting and ending points can be retrieved with the component or element tag and the parameter **format="startTime"** or **format="endTime"**, which return the time in seconds. **startTime_msec** and **endTime_msec** return the time in milliseconds.

The starting point frame is also used to generate the thumbnail of the video. The thumbnail can be retrieved with the parameter **rendition="thumbnail"**.

Limitation

The interactive cue point preview player in the content authoring form uses HTML 5 Media Fragment Identifiers for setting the start and end points of the video in the preview frame. Internet Explorer version 11 and earlier does not support these identifiers.

Delivering web content

The type of delivery method you use to deliver web content to your viewers depend on the type of content that is being delivered, and the type of viewers your website is intended for.

"Delivering web content on a portal page"
Using tools like Web Content Viewer Portlets, content associations, and web content page templates, you can build portal pages and display web content. You can also combine web content with other portlet-based content. Content associations tie viewers and portal pages to the site structure of your web content libraries.

"Access web content by using a servlet" on page 2087
Users can access content that is displayed by using the Web Content Manager servlet by connecting to a URL. A servlet delivered website is used when you don't need to use any WebSphere Portal based features such as authoring tools.

"Pre-rendered delivery" on page 2089
You can pre-render a complete IBM Web Content Manager site into HTML and save it to disk. The pre-rendered site can then be used as your live site and displayed to users that use either Web Content Manager or a web server. You deploy a pre-rendered site when you are not using any WebSphere Portal features and your content is static and is only updated periodically.

CF07 "Rendering modes for web content" on page 2093
Different presentation templates are created to render web content in different modes to display content in different contexts, such as a web content viewer portlet, or mobile devices.

Delivering web content on a portal page

Using tools like Web Content Viewer Portlets, content associations, and web content page templates, you can build portal pages and display web content. You can also combine web content with other portlet-based content. Content associations tie viewers and portal pages to the site structure of your web content libraries.

About this task

You can customize your portal delivery as well. Examples include:

- Creating your own web content page templates
- Deploying pre-configured Web Content Viewers
- Providing convenience features like customized error messages and friendly URLs

"Getting started with delivering web content on a portal page" on page 2017
The building blocks for delivering web content in a portal are web content viewers, web content page templates, and content mappings. These pieces provide a flexible framework that you can use to quickly assemble pages.

"Displaying content with Web Content Viewers" on page 2034
Display content from your web content system by adding a Web Content Viewer to the server where you want the content to show.

"Customizing web content delivery" on page 2036
Although web content viewers and page templates provide the basis for delivering web content, you can customize the environment to provide users with a better experience.

"Enabling remote rendering with WSRP and the Web Content Viewer" on page 2069

To display web content on a portal that does not include IBM Web Content Manager, you can use the Web Content Viewer and the WSRP support in the portal. The Web Content Viewer can then retrieve and display content from a web content system on a different server.

"Advanced administrative examples" on page 2074
You can undertake advanced administration for web content artifacts, such as web content pages and content associations.

"Web Content Viewer best practices and limitations" on page 2086
View some best practices and limitations for using Web Content Viewers.

Getting started with delivering web content on a portal page

The building blocks for delivering web content in a portal are web content viewers, web content page templates, and content mappings. These pieces provide a flexible framework that you can use to quickly assemble pages.

About this task

To help you get started, sample web content is also included in preinstalled libraries. The sample content demonstrates how the pieces work, and you can also adapt the sample content for your own use.

"Web Content Viewers"
Web Content Viewers are portlets that render content from a web content library as part of a portal page. If your presentation is simple, a single viewer can be sufficient. To provide a richer experience for your users, use multiple viewers to aggregate content from different libraries.

"Web content pages and templates" on page 2021
Web content pages are portal pages that are associated with content that is managed in IBM Web Content Manager. Similar to web content pages, web content templates are page templates that are associated with content in Web Content Manager.

"Web content associations" on page 2023
Web content associations are used to combine portal pages and associated web content items that are managed by IBM Web Content Manager so they can be managed and rendered consistently. Web content associations map portal pages to the site structure in the IBM Web Content Manager system.

"Creating content with sample web content template items" on page 2026
To illustrate how page templates, web content viewers, and content associations work together, IBM Web Content Manager provides sample web content. The sample content includes examples of web content template pages and predefined portlets that you can add to pages to render content.

"Link examples for Web Content Viewers" on page 2032
Web Content Viewers can broadcast and receive links to communicate with other viewers. Depending on the link settings that you use with the viewers, the behavior of the viewers can be different. These examples demonstrate how different broadcast and receive settings can affect what a viewer renders.

Web Content Viewers:

Web Content Viewers are portlets that render content from a web content library as part of a portal page. If your presentation is simple, a single viewer can be sufficient. To provide a richer experience for your users, use multiple viewers to aggregate content from different libraries.

How viewers locate content

When you add a Web Content Viewer to a web content page, the viewer locates the content to be rendered by evaluating several pieces of information:

- The portlet configuration settings for the viewer can identify the default content to be rendered when a user browses to a page that contains the viewer.
- If the viewer does not specify default content, it determines whether a default content association is defined for the page. If a content association exists, the viewer renders the default content of the referenced site area in IBM Web Content Manager.
- If the current request contains a public render parameter (**path-info** or **context**), the viewer renders the content that is identified by the render parameter. This setting overrides the content setting from the portlet configuration or from the content association on the page. An example of a case where a render parameter might be involved is when users click a link to a content item.

When content is rendered, a Web Content Viewer checks first for a render parameter on the request. As shown in Table 1, if no parameter exists, the viewer evaluates its own portlet configuration and any content association on the page that contains the viewer.

Table 319. How Web Content Viewers determine which content to render

Content reference in portlet configuration?	Content association on web content page?	Content that is rendered by viewer
Yes	No	Content that is identified by portlet configuration of the viewer.
No	Yes	Content that is identified by association on page.
Yes	Yes	Content that is identified by portlet configuration of the viewer. The content that is specified in the portlet configuration can use a relative path. In this case, the complete path to the target content is derived by combining the associations on the page and the viewer.

References to content can be direct or relative:

Direct path to the target content

A Web Content Viewer can reference either a site area or a specific item in the library. This example is a reference to the item `Article` in the site area `Articles` of the library `Web Content`:

```
Web Content/Articles/Article
```

When you configure the viewer with a direct path to content, the content association on the page that contains the viewer is ignored.

To configure a direct path to content, use the **Select content and path** setting in the **Content behavior** settings of the Web Content Viewer.

Relative path to the target content

When a content path based on a relative path is derived, the viewer appends the content path in its configuration to the content association on the page. For example:

- Content association on web content page: `Web Content/Articles`
- Content that is referenced in portlet configuration: `Article`
- Resolved content path: `Web Content/Articles/Article`

To configure a relative path to content, use the **Select content and use the content association of current page** setting in the **Content behavior** settings of the Web Content Viewer.

Depending on how you reference content, you can create Web Content Viewers and web content pages that are as specific or generic as you require.

Reference no content

You can define a content association on a web content page and then add a generic viewer that references no content. The viewer detects the site area that is defined by the content association on the page and renders content from the site area. No additional configuration of the Web Content Viewer is required.

Reference specific content

You can configure a viewer to point to a specific piece of content. You can then add this viewer to any web content page to render the mapped content, regardless of any content association on the page.

Reference content with a relative path

If you are using a consistent site structure with your web content libraries, you can take advantage of the relative path capability for referencing content. For example, you can create a reusable viewer that can render different content depending on the web content page where the viewer is deployed. By defining a viewer with a content association that uses a relative path, you can add instances of that viewer to different pages. The viewers then render different content, according to the content associations on the pages.

You can use one content association on a page and then add multiple Web Content Viewers on the page. In this case, the Web Content Viewers are configured to use a relative path into different site areas in the library. By changing only the content association on the page, you can then redirect the viewers to another library or other set of site area content.

Create content with Web Content Viewers

When added to a page, a viewer can create a copy of the content that is identified in the portlet configuration. This feature provides several advantages:

- You can create content items quickly and easily, within the scope of the page where they are used.
- You can modify the individual copies of the content independently of each other.
- Typically, there is no need to further adjust the configuration of the viewer after you add it to the page.

Web Content Viewers that are configured to create content can be used multiple times, either on the same page or on different pages. Each instance of the viewer references a separate copy of the content item that is referenced in the portlet configuration.

Copied content is stored in the site area that is identified by the default content association of the current page. In addition, the portlet configuration of the newly added viewer is automatically updated to specify a relative path to the copied content.

Link Web Content Viewers

Many Web Content Viewers can be added to a single portal page or a series of pages. Sometimes it is necessary for different Web Content Viewers to interact with each other. For example, a menu component might be placed in one viewer and a content item in another viewer. If you want the content item to change when a different link is clicked in the menu, you must link the two viewers.

Web Content Viewers can broadcast or receive links:

Broadcasting links
The state or context of a Web Content Viewer is not sent directly from one portlet to another. You can configure viewers to broadcast their current state or context to other viewers on the same page or to viewers on other pages. Any information broadcast by a Web Content Viewer is received only by viewers that are configured to receive this information.

Receiving links
A Web Content Viewer can receive the following information:

- Information about the state or context of the current content item or component that is being rendered by the viewer.
- Information from content items or components that are rendered by other viewers that are broadcasting links.

For examples of the different ways that you can use linking with Web Content Viewers, see *Link examples for Web Content Viewers.*

Web Content Viewers and remote servers

To display web content on a portal that does not include Web Content Manager, you can use the Web Content Viewer and the WSRP support in the portal. The Web Content Viewer can then retrieve and display content from a web content system on a different server.

Related tasks:

"Enabling remote rendering with WSRP and the Web Content Viewer" on page 2069
To display web content on a portal that does not include IBM Web Content Manager, you can use the Web Content Viewer and the WSRP support in the portal. The Web Content Viewer can then retrieve and display content from a web content system on a different server.

Related reference:

"Link examples for Web Content Viewers" on page 2032
Web Content Viewers can broadcast and receive links to communicate with other viewers. Depending on the link settings that you use with the viewers, the behavior of the viewers can be different. These examples demonstrate how different broadcast and receive settings can affect what a viewer renders.

Web content pages and templates:

Web content pages are portal pages that are associated with content that is managed in IBM Web Content Manager. Similar to web content pages, web content templates are page templates that are associated with content in Web Content Manager.

Pages and page templates are tied to web content by content associations. These associations are defined in the page properties and can be specified with the Associations window when you edit page properties. You can associate a page with one or more site areas in one or more web content libraries.

If managed pages are enabled, all managed pages are automatically associated with a corresponding page site area in the Portal Site library. This type of association is called a system content association and enables changes to the page to be managed by Web Content Manager. System content associations are managed by the portal and cannot be deleted or changed manually.

When there are multiple content associations for a page, one of the associations is designated as the default association. Typically, the default association is the system content association for the page. However, you can use the Associations window to specify a different content association as the default association.

Web content pages

With web content pages, you can take advantage of the following benefits when you render web content:

- If you add an unconfigured web content viewer to the page, the viewer automatically renders the default content of the site area that is specified by the default content association.
- Dynamic page selection determines the best web content page to use to render a content item when you click a link to the content item. For example, if you click a link to a content item in a search result, the portal evaluates the following set of content associations:
  - Associations that exist for the site area that directly contains the target content item.
  - Associations for any site areas that are ancestors of the site area that contains the target content item.

  The portal identifies the page that is mapped to the site area that is closest to the target content item. The viewer then renders the content item on that page.
- You can extend friendly URLs to reference content items that are rendered on a web content page. Friendly URLs for web content are composed by combining the friendly URL of the current page and the content path of the rendered content item.

You can create a web content page in two ways:

- Create the page from a web content page template.
- Add a content association to an existing portal page.

Web content page templates

To create a web content page template, create a page under the **Page Templates** label. This label is the root label for all page templates in the portal. You can access the **Page Templates** label by clicking the **Administration menu** icon and then by clicking either of the following locations:

- **Portal User Interface** > **Page Templates**
- **Portal User Interface** > **Manage Pages** > **Content Root** > **Hidden Pages**

When you create a web content page template, you define the layout, style, and contents of any web content page that is created from the template. Web content page templates have all the same flexibility and customization features as a standard portal page or portal page template. You can do common tasks like adding content with portlets, changing the style of the page, or changing the layout of objects on the page. By using viewers with other portlets in a web content page template, you can create pages that support a wide range of user goals. Likewise, you can rely on only viewers and create a website that is primarily composed of information in your web content system.

As with standard page templates, you can create web content pages from a web content page template:

- Manage Pages administration portlet
- Create Page tab in the site toolbar

When users create a web content page from a template, content that is associated with the page template is copied with the page itself. If you create multiple pages from the same page template, each page results in a separate copy of that content.

When you create a page from a template, page titles in any language are not copied. The following elements are copied to the new page:

- Portlet entities, including portlet preferences
- Page layout and style
- Theme and skin settings
- Portlet wires for communication with other portlets
- Page parameters
- Page description (all languages)

In addition, the following changes take place automatically, depending on the individual web content associations that exist on the page.

- If the page template is a managed page, with a system content association that references the Portal site library, the following changes apply:
  - A portal page site area is created in the Portal Site library, with the title of the site area that is derived from the title of the new page. The hierarchy structure of the portal page site area is automatically synchronized with the page hierarchy in the portal.
  - All authoring template mappings and all nested content are copied over into the new portal page site area. However, any nested portal page site areas are not copied.
- If a default content association references a library other than the Portal Site library, the following changes apply. These changes apply regardless of whether the page template is a managed page.
  - A site area is created, with the title of the site area that is derived from the following elements:

- The title of the new page.
- The name of the site area that is being derived from the friendly URL name of the page.

– The site area is created as a child of the site area that is defined as the default content association of the parent page of the new page. This support requires that the parent page is associated with a site area outside the Portal Site library.
– All site area properties and all nested content are copied over to the new site area.
– The default content association on the new page is modified to reference the newly created site area.

Web content viewers on the page template can be configured to reference content that is copied when a page is created from the template. When the page is created, the viewer configuration is automatically adjusted to point to the new content that is created during page instantiation.

Note: Managed pages must be enabled to support page templates that store their associated web content in the Portal Site library. If you disable managed pages, the content that is associated with a template is no longer copied during page instantiation. In addition, the corresponding preferences of any web content viewers that are on the page are not adjusted.

Hierarchical page templates

It is possible to create a hierarchy of templates, for examples, a parent template page with a child page. If the page metadata `ibm.portal.instantiation.page.include.descendants` is set to `true` on the parent page, then creating a page from the parent template not only creates a single page but the complete hierarchy that includes the children.

Related tasks:

"Creating a web content page" on page 2035
A web content page is a page that is associated to one or more site areas in IBM Web Content Manager. You can create a web content page from a web content template page, or you can convert an existing portal page into a web content page.

Web content associations:

Web content associations are used to combine portal pages and associated web content items that are managed by IBM Web Content Manager so they can be managed and rendered consistently. Web content associations map portal pages to the site structure in the IBM Web Content Manager system.

You can define a default content association and multiple other associations, which are used for dynamic page resolution. For each page, a system content association maps the page to its corresponding portal page site area in the Portal Site library. You also have the option of using page template instantiation to trigger the copying of web content into the Portal Site library or another library. This option is set by a page template parameter.

Each web content association consists of a reference to a portal page and a reference to a site area in a web content library. When a page contains a web content association, web content viewers added to the page can automatically render the content that is provided by the associated site area. In addition, a web

content page template that contains an association can create copies of associated content when you create a page by using the template.

When multiple associations are defined for the same web content page, one of those associations is identified as the default content association. When you create a page and Managed Pages are enabled on the system, a system content association is automatically created to the corresponding portal page site area in the Portal Site library. This system content association is designated as the default association, but you can change that setting later as needed.

The default content association has several uses:

- When you add a web content viewer to the page without configuring the viewer to reference content, it renders the content indicated by the default association.
- When you create a page from a web content page template, the default content association of the page template indicates the site area to be copied during page instantiation.
- If you are building a friendly URL to content on the page, the default association indicates the path to the rendered content. This content path fragment is appended to the friendly URL of the current page to generate the complete friendly URL.

All content associations for a page are used for dynamic page resolution. The portal uses dynamic page resolution to determine the best matching page for rendering a specific content item.

You can also configure each web content association to enable or disable page-based access control when you render content from the mapped site area. With this feature, users who are authorized to view the page are also assumed to have view access for content under the associated site area.

Web content associations are managed by the content mapping service of the portal. You can manipulate web content associations with the following methods:

- The Page Associations window available in the site toolbar through **Page** > **General** > **Details** > **Default site area**.
- The page properties available from the Manage Pages portlet
- XML configuration interface, by using the **xmlaccess** command
- Portal Scripting Interface
- REST API for content associations
- Public Java API for the content mapping service

Page context and user context

The content associations of a page can define the initial web content context of the page. This context is used for rendering when users first access a page. The context of the page can change when users interact with the content on the page. Each web content viewer on the page can be configured with an explicit context that overrides the rendering page context. The context of the portlet can also change if it is configured to receive links. When users click a link within the viewer that is configured to broadcast its links, the page context is updated. This new context is maintained until users click another link, or until users start a new session. When users start a new session, the original page context is used.

Content copying triggered by page template instantiation

When the page template parameter called `ibm.portal.instantiation.content.dynamic.copy.target.selection` is set to **true**, the default content association that references a library other than the Portal Site library is copied into the Portal Site library during page instantiation. This allows you to store associated web content outside of the Portal Site library and have this content that is copied into the Portal Site library during page template instantiation. Using a separate library for your page templates is useful if you want to update the library independently of the Portal Site library, either through importing and exporting or syndication. A separate library is also helpful if you use the same content items on several page templates.

This parameter does not affect web content that is associated with page templates through system content associations, such as web content that is stored in the Portal Site library. Such content is always copied to the new page site area associated with the new page.

If the parent page of the new page has both a system content association with the Portal Site library and a default content association that references another library, you can use the `ibm.portal.instantiation.content.preferred.copy.target` parameter to identify the copy target location.

`ibm.portal.instantiation.content.preferred.copy.target=internal` copies the content into the Portal Site library.

`ibm.portal.instantiation.content.preferred.copy.target=template` copies the content to the other library associated with the parent page. This is the default value.

Set page parameters on your web content page templates by using **Page Properties** > **Advanced** in the Manage Pages portlet or by using **Page** > **General** > **Edit Page Properties** > **Advanced** in the site toolbar.

Related concepts:

"Web content pages and templates" on page 2021
Web content pages are portal pages that are associated with content that is managed in IBM Web Content Manager. Similar to web content pages, web content templates are page templates that are associated with content in Web Content Manager.

Creating content with sample web content template items:

To illustrate how page templates, web content viewers, and content associations work together, IBM Web Content Manager provides sample web content. The sample content includes examples of web content template pages and predefined portlets that you can add to pages to render content.

About this task

In addition to examining how these rendering pieces are defined, you can also explore the web content libraries that contain the sample content.

Note: If you want to customize the sample web content that IBM WebSphere Portal Express provides, create copies of the sample web content libraries and customize those copies.

"Adding sample content with the site toolbar" on page 2027
The sample content that is provided with the portal includes four pre-configured content items that you can add to a page from the site toolbar. Dragging one of these items into a page automatically creates a copy of the item and adds the copy to the page. The predefined content items are available in the site toolbar in the **Web Content** category of the **Create** > **Content** tab.

"Creating content with the Articles template page" on page 2029
The sample content that is provided with IBM Web Content Manager includes a web content template page that is called **Articles**. This template page demonstrates how you can build pages with predefined content.

CF03 "Adding the Articles template page to a virtual portal" on page 2030
By default, virtual portals do not contain the Articles template page. To use the Articles template page in a virtual portal, follow the procedure given here.

"CSS styles used by the sample web content template items" on page 2031
The markup that is generated by the sample web content template items is primarily controlled by presentation templates that are stored in the Web Content Templates 3.0 library. These templates rely on the availability of several CSS class definitions in the `wp_oob_sample_styles` theme module.

"Adding the sample web content libraries in the authoring portlet" on page 2032
The templating sample content that is provided with IBM WebSphere Portal Express is delivered in two web content libraries: `Template Page Content 3.0` and `Web Content Templates 3.0`. You can use these libraries and their content as a starting point for working with web content page templates and developing your own templates.

Adding sample content with the site toolbar:

The sample content that is provided with the portal includes four pre-configured content items that you can add to a page from the site toolbar. Dragging one of these items into a page automatically creates a copy of the item and adds the copy to the page. The predefined content items are available in the site toolbar in the **Web Content** category of the **Create** > **Content** tab.

About this task

- The Article presents a simple article that is composed of a title, a short description, and a rich-text body. The default presentation template that is used to render individual articles includes the following elements:
  - Lightweight inline widgets to support tagging and rating
  - Extra site analytics data that is added to the generated markup
- The List of Articles presents a list of all articles that exist in the context of the current page. The viewer also enables users to create articles.
- The Rich Text presents a simple rich text element.
- The Image presents a simple image.

Procedure

To use these sample web content viewers, complete the following steps:

1. Go to the page where you want to add the viewers.
2. Edit the page, and select the **Create** > **Content** tab of the site toolbar.
3. Click **Web Content**. Now the **Create** > **Content** tab shows the Article, List of Articles, Rich Text, and Image content items.
4. Add the content items to your page by clicking the plus sign (+) or dragging the items onto the page. You can also adjust the arrangement of the portlets.
5. Click **Save & Exit**.

Results

When you add one of these content items to a page, new content is created. The content item is copied into the site area that is specified by the default content association of the page. A web content viewer instance is added to the page and automatically adjusted to reference the copied content item.

To help you better understand what these components are doing, here is a more detailed look.

Article

When added to a page, the Article renders a sample article from a web content library. The article also includes Edit and Delete icons to modify the article content or to delete the article from the web content library.

The **drag and drop** configuration that is mapped to the Article content item defines the preferences for the corresponding content viewer portlet. It has the following features:

- The viewer uses a customized portlet title (`Article`) instead of the default title to provide contextual information about the content that is rendered by the viewer. When you are assembling pages and adding web content viewers, taking advantage of details like customized titles is important for orienting users.

- To ensure that the content item to be rendered can be passed in by other viewers, the viewer is configured to receive links with the setting **Other portlet and this portlet**. For example, if you click a link in an instance of the List of Articles viewer on the same page, this viewer renders the linked content.
- The Article viewer also defines preferences that enable the generation of extra metadata for the page, which is based on the currently rendered article instance. This metadata includes description, keywords, and author.
- The default presentation template that is used to render articles (`Web Content Templates 3.0/Article`) includes an authoring tools component. The component enables users to modify the content of individual articles with inline editing. The authoring tools component is hidden automatically when the page is not in edit mode.

List of Articles

When added to a page, the List of Articles renders a list of sample articles from a web content library. It references a menu in web content manager that renders a list of all articles that are associated with the current page. The content also includes a **button** to create an article. The **drag and drop** configuration that is mapped to the List of Articles content item defines the preferences for the corresponding content viewer portlet. It has the following features:

- The List of Articles viewer does not contribute page metadata or a page title. This behavior occurs because the viewer renders a list of items instead of specific content that would determine the semantic content of the page.
- Because the viewer is rendering a list of items, the viewer is not listening to links that are broadcast from other portlets.
- The default presentation template that is used to render lists of articles (`Web Content Templates 3.0/List of Article`) includes an authoring tools component. The component enables users to create an article with inline editing. The authoring tools component is hidden automatically when the page is not in edit mode.
- The viewer is configured to broadcast links with the **Dynamically select a web content page** setting. This configuration results in the List of Articles viewer to determine the content that is rendered by other viewers on the same page, such as the Articles viewer.

Rich Text

The Rich Text content item consists of a name, which is not rendered by default, and a rich text body. The default presentation template that is used to render rich text (`Web Content Templates 3.0/Rich Text`) includes an authoring tools component. The component enables users to modify the content of the rich text item with inline editing. The authoring tools component is hidden automatically when the page is not in edit mode.

Image

The Image viewer content item consists of a name, which is not rendered by default, and a reference to an image. The default presentation template that is used to render images (`Web Content Templates 3.0/Image`) includes an authoring tools component. The component enables users to modify the image reference with inline editing. The authoring tools component is hidden automatically when the page is not in edit mode.

Related tasks:

"Creating a web content page" on page 2035
A web content page is a page that is associated to one or more site areas in IBM Web Content Manager. You can create a web content page from a web content template page, or you can convert an existing portal page into a web content page.

Creating content with the Articles template page:

The sample content that is provided with IBM Web Content Manager includes a web content template page that is called **Articles**. This template page demonstrates how you can build pages with predefined content.

About this task

The Articles template page is a managed page that contains two web content viewers. These viewers are configured to render content items that are stored in the site area for the page in the Portal Site library.

Procedure

To create a page that is based on the Articles template, complete the following steps:

1. Go to the page where you want to add the new page.
2. Edit the page and select **Create** > **Page** in the site toolbar.
3. Use the Create Page tab to create the page. Select the **Articles** template for the new page.

Results

The new page contains the List of Articles web content viewer and the Article viewer:

After you create a page with the Articles template, the new page contains two web content viewers. The List of Articles viewer shows a list of any articles in the site area that are associated with the page. The Article viewer shows a sample article that was created.

The Articles template demonstrates several key features of web content page templates:

- The Articles template page contains a system content association to the site area for the template page in the Portal Site library (`Portal Site/Content/Content Root/Hidden Pages/Page Templates/Articles`. This site area contains three content items that are used as the initial content for pages that are created from the page template. To see this association, edit the page, and then in the site toolbar, click **Page** > **General** > **Details** > **Default site area**.
- There are two web content viewers included with the Articles template:
  - The List of Articles viewer renders links to all articles stored in page site area.
  - The Article viewer renders a specific article that is selected in the List of Articles viewer. The viewer also contributes page metadata to the HTML head section of the rendered portal page.
- The content items that are provided by default require CSS styles that are defined in the `wp_oob_sample_styles` theme module. To make these styles available to the default content items, you must ensure that the page that

contains the items uses a theme profile that includes the `wp_oob_sample_styles` theme module. The deferred profile (`profile_deferred.json`) includes this theme module.

For more information about theme modules and theme profiles, see *The module framework.*

When you create a page that is based on the Articles template, several things happen:

- A page is created based on the page template. The new page has the same layout and style as the template and contains copies of the two web content viewers.
- The new page has a system content association to its corresponding portal page site area.
- The content items that are contained in the site area for the page template are copied into the site area that is associated with the new page.
- The Articles viewer and List of Articles viewer on the new page automatically render the newly created content that is associated with the new page. The rendering occurs because of the viewer configuration:
  - The configuration of the List of Articles viewer is updated during instantiation to point to the newly generated `List of Articles` content item.
  - The Article viewer is configured to directly retrieve its context from the content association of the containing page.

Note: The Articles page template is a managed page that stores its associated web content in the Portal Site library. If you disable managed pages, the content that is associated with this template is no longer copied during page instantiation. In addition, the corresponding preferences of the Articles viewer and List of Articles viewer are not adjusted.

"The module framework" on page 2526
The module framework allows extensions to contribute to different areas of a page to provide flexibility, enhance the user experience, and maximize performance.

Adding the Articles template page to a virtual portal: CF03

By default, virtual portals do not contain the Articles template page. To use the Articles template page in a virtual portal, follow the procedure given here.

Procedure

1. Syndicate the two libraries Web Content Templates 3.0 and Template Page Content 3.0 from the main portal installation to the virtual portal.
2. To add the template page to the virtual portal, start the following portal configuration engine task:
   - Linux :

     ```
     ./ConfigEngine.sh action-init-content-templating-pages
                       -DVirtualPortalContext=virtual_portal_context_url
     ```

   - IBM i:

     ```
     ConfigEngine.sh   action-init-content-templating-pages
                       -DVirtualPortalContext=virtual_portal_context_url
     ```

   - Windows:

     ```
     ConfigEngine.bat  action-init-content-templating-pages
                       -DVirtualPortalContext=virtual_portal_context_url
     ```

3. To move the referenced content items into the PortalSite library, start the following portal configuration engine task:
   - Linux :

     ```
     ./ConfigEngine.sh action-internalize-content-mappings-vp
                       -DVirtualPortalContext=virtual_portal_context_url
     ```

   - IBM i:

     ```
     ConfigEngine.sh   action-internalize-content-mappings-vp
                       -DVirtualPortalContext=virtual_portal_context_url
     ```

   - Windows:

     ```
     ConfigEngine.bat  action-internalize-content-mappings-vp
                       -DVirtualPortalContext=virtual_portal_context_url
     ```

Results

After you complete these steps, the Articles template page is ready for you to use in the virtual portal.

CSS styles used by the sample web content template items:

The markup that is generated by the sample web content template items is primarily controlled by presentation templates that are stored in the Web Content Templates 3.0 library. These templates rely on the availability of several CSS class definitions in the `wp_oob_sample_styles` theme module.

Any pages that render the sample items must use a theme profile that includes the `wp_oob_sample_styles` theme module or another module that contains the same CSS class definitions. An example of such a theme profile is the full theme profile that is installed by default.

The `wp_oob_sample_styles` theme module includes a single CSS file that is named `oob_samples.css`. This stylesheet is loaded from the path *`common_resources_root`*`/ibm/css/samples`. The *common_resources_root* node is specified in the WebSphere Integrated Solutions Console by the **`resources.commonResourcesRootURI`** property of the WP GlobalThemeConfig resource environment provider. The default value for this property is `dav:fs-type1/common-resources`. This value causes the CSS styles to be loaded from the portal file store with the following path: `/common-resources/ibm/css/samples/oob_samples.css`. For more information about setting the *common_resources_root* node, see *Adapting the list of required runtime configuration changes for your theme.*

Stylesheet note: The `Rich Text` presentation template that is used as the default presentation for Rich Text content items uses CSS styles that render differently depending on the layout container that contains the Rich Text web content viewer. Different classification CSS classes are assigned to these layout containers. As a result, the font sizes of headings and body elements are reduced when a rich text item is moved from the center column into a more narrow side column.

"Adapting the list of required runtime configuration changes for your theme" on page 2819
You must adapt the list of required runtime configuration changes for your theme.

Adding the sample web content libraries in the authoring portlet:

The templating sample content that is provided with IBM WebSphere Portal Express is delivered in two web content libraries: `Template Page Content 3.0` and `Web Content Templates 3.0`. You can use these libraries and their content as a starting point for working with web content page templates and developing your own templates.

About this task

Note: If you want to customize the sample web content that WebSphere Portal Express provides, create copies of the sample web content libraries and customize those copies.

Web Content Templates 3.0 library
: This library contains the shared components, authoring templates, and presentation templates that are used by the content items that are contained in the `Template Page Content 3.0` library. The library also contains the sample content items that are used with the "Articles" page template.

Template Page Content 3.0 library
: This library contains the content items that are used by web content viewer clones that create content when added to a page. These content items represent the base content that is copied when you add content from the **Web Content** category of the site toolbars **Create** > **Content** tab to a page. Initially, this library contains two content items. The **Article** content item represents a simple article that is created from the "Articles" authoring template in the Web Content Templates 3.0 library. The **List of Articles** content item is an instance of the "List of items" authoring template in the Web Content Templates 3.0 library. The item represents a list of all articles that exist in the context of the currently rendered page.

Virtual portal note: If you want to use the sample content with a specific virtual portal, you must syndicate these web content libraries to the virtual portal. If you fail to syndicate these libraries, an error is displayed when you add the sample content to a page.

Procedure

To work with the sample web content libraries, complete the following steps:

1. Open the authoring portlet for Web Content Manager by clicking **Applications** > **Content** > **Web Content Management**.
2. In the authoring portlet, click **Preferences** > **Configure**.
3. In the **Library Selection** section, add the `Template Page Content 3.0` and `Web Content Templates 3.0` libraries to the list of selected libraries.

Link examples for Web Content Viewers:

Web Content Viewers can broadcast and receive links to communicate with other viewers. Depending on the link settings that you use with the viewers, the behavior of the viewers can be different. These examples demonstrate how different broadcast and receive settings can affect what a viewer renders.

Example 1: Configuring links for a single portlet

In this scenario, a single Web Content Viewer is configured to show a dynamic component, such as a menu. The menu contains links to content in a site area. When you click a link, the viewer continues to render the component, but the component uses the target content to set the web content context. Based on the new context, the component generates appropriate markup. In this example of a menu, the component shows links to content of the site area where the target content is located.

Table 320. Example 1: Configuring links for a single Web Content Viewer

Web Content Viewer content	Broadcast links to	Receive links from
Component	None	This Web Content Viewer

When you display a component with a Web Content Viewer, you can also select an alternative presentation template in the content view of the content section. When a link is clicked in the component, the content that is then rendered uses the alternative presentation template.

Example 2: Configuring links for a menu and content

In this scenario, one Web Content Viewer contains a Web Content Manager menu and another Web Content Viewer contains Web Content Manager content. Links must be created between the two viewers to enable the rendered content to change when different links in the menu are selected.

Table 321. Example 2: Configuring links for a menu and content

Web Content Viewer content	Broadcast links to	Receive links from
Menu	This page	None
Content	None	Other Web Content Viewers and this viewer

Example 3: Configuring links for a navigator and content

In this scenario, one Web Content Viewer contains an item views navigator and another viewer contains some Web Content Manager content. Links must be created between the two viewers to enable the rendered content to change when different links in the navigator are selected. The navigator also changes to reflect the current state of the content that is rendered.

Table 322. Example 3: Configuring links for a navigator and content

Web Content Viewer content	Broadcast links to	Receive links from
Navigator	This page	Other Web Content Viewers and this viewer
Content	This page	Other Web Content Viewers and this viewer

Example 4: Configuring dynamic links for a navigator and web content pages

In this scenario, one Web Content Viewer contains a site views navigator, and several web content pages that are associated with different site areas. Each web

content page contains a viewer and is configured to show the default content item of the site area that is associated with the page.

Instead of manually creating links between the different viewers, you can use dynamic link broadcasting with the viewer. Dynamic link broadcasting automatically determines which web content page is used as the target for the links to the site area in the navigator.

Table 323. Example 4: Configuring dynamic links for a navigator and web content pages

Web Content Viewer content	Broadcast links to	Receive links from
Navigator	Dynamically select a web content page	None
Content on web content page	This page	Other Web Content Viewers and this viewer

Related concepts:

"Web Content Viewers" on page 2017
Web Content Viewers are portlets that render content from a web content library as part of a portal page. If your presentation is simple, a single viewer can be sufficient. To provide a richer experience for your users, use multiple viewers to aggregate content from different libraries.

Displaying content with Web Content Viewers

Display content from your web content system by adding a Web Content Viewer to the server where you want the content to show.

About this task

If your presentation is simple, a single Web Content Viewer can be sufficient. You can also use multiple Web Content Viewers to provide a richer experience for your users.

Depending on how you decide to deploy the servers in your environment, there are different ways to render content:

- You can install a Web Content Viewer locally on the same portal server where Web Content Manager is installed.
- You can install the viewer remotely on a different portal server.

  "Adding a Web Content Viewer Portlet"
  Add a Web Content Viewer Portlet to a page with the site toolbar.

  "Creating a web content page" on page 2035
  A web content page is a page that is associated to one or more site areas in IBM Web Content Manager. You can create a web content page from a web content template page, or you can convert an existing portal page into a web content page.

Adding a Web Content Viewer Portlet:

Add a Web Content Viewer Portlet to a page with the site toolbar.

Procedure

1. Go to the page that you want to add the new page.
2. Edit the page, and select **Create** in the site toolbar.
3. Click **Applications**. Now **Create** > **Applications** shows the available applications.

4. Search for the portlet Web Content Viewer.
5. Click **Add application to the page** that is indicated by the plus sign icon, or drag the items to the page to add the Web Content Viewer to your page
6. You can modify settings for the Web Content Viewer, such as a content association or portlet title.

Creating a web content page:

A web content page is a page that is associated to one or more site areas in IBM Web Content Manager. You can create a web content page from a web content template page, or you can convert an existing portal page into a web content page.

About this task

A web content page always restricts the sharing scope for public rendering parameters to the page itself. The corresponding page parameters are automatically added to the page when a page is associated to a site area.

Caching note: When you are using web content pages, you cannot use advanced web content caching but instead can use only the portlet fragment cache.

Procedure

1. There are two ways to create a web content page.
   - Follow these steps to create a web content page from a web content template page:
     a. Go to the page where you want to add the new page, and edit the page.
     b. Open the site toolbar, select **Create** > **Page** use the Create Page tab to create the page. Select a web content page template for the new page.

        Note: If managed pages are enabled, all page templates result in web content pages.
     c. Click **Create Page** to create a web content page from the selected template.

        If the page template has a default content association, the new page is automatically associated with a new copy of the referenced site area. Any other content associations that are not designated as the default association are copied without changes.
   - Follow these steps to convert a portal page to a web content page:
     a. Go to the page where you want to add the new page, and edit the page.
     b. Open the site toolbar and select **Page** > **General** > **Details** > **Default site area**
     c. In the Page Associations window, click **Add web content**.
     d. Select one or more site areas that you want to associate with the page, and click **OK**.
     e. Specify the default association by selecting the association in the **Default** column.
2. After you create the web content page, you can add web content viewers to the page from the **Create Applications** tab of the site toolbar.

   You can add a standard Web Content Viewer portlet, or you can add any predefined web content viewers that you create.

- If you add a standard web content viewer, the viewer renders any content from the site area that is indicated by the default content association of the page.
- If you add a predefined viewer that is configured to create content with the **Create content (based on selection)** setting, the following things happen:
  - The base content that is referenced by the viewer is copied into the site area that is referenced by the default content association of the page.
  - The new instance of the viewer renders the copied content in the site area that is referenced by the default content association of the page.

  An example of this type of predefined viewer is the Rich Text viewer that is available from the **Web Content** category of the **Content** tab.

Related concepts:

"Web content pages and templates" on page 2021
Web content pages are portal pages that are associated with content that is managed in IBM Web Content Manager. Similar to web content pages, web content templates are page templates that are associated with content in Web Content Manager.

Related tasks:

"Enabling page-based access control for web content pages" on page 2059
Typically, when you render content items in a web content viewer, access control enforcement on those content items is handled by IBM Web Content Manager. However, you can use page-based access control to delegate access control enforcement to the web content page that is used to display the content.

Customizing web content delivery

Although web content viewers and page templates provide the basis for delivering web content, you can customize the environment to provide users with a better experience.

About this task

For example, you can create custom objects like page templates and web content viewers. You can also provide users with conveniences like customized error messages and friendly URLs that reference web content.

"Creating web content page templates" on page 2037
Create web content page templates to quickly deploy new pages that contain web content. With a template, you can define the layout and presentation of the page, including adding web content viewers that are configured to render web content.

"Creating web content when you add a web content viewer to a page" on page 2038
To make it easier for users to find web content, the site toolbar provides palettes. You use these palettes to organize components that you can add, such as portlets, iWidgets, and web content.

"Customizing error messages for Web Content Viewers" on page 2040
If an error occurs during rendering, the Web Content Viewer shows an error screen. You can customize the default error screen, and you can create your own custom JSP file that is used to display error messages.

"Friendly URLs and Web Content Viewers" on page 2040
Friendly URLs provide a way for you to define a custom address for a portal page that is easy to remember and share. The Web Content Viewer expands on friendly URL support so you can specify extra path information in the friendly URL.

"Setting up a web content fallback page" on page 2057
Set up a web content fallback page to be used when a web content viewer cannot determine which page to use to display a content item. The fallback page can also be used when users do not have sufficient privileges to view the page originally associated with the content item.

"Enabling page-based access control for web content pages" on page 2059
Typically, when you render content items in a web content viewer, access control enforcement on those content items is handled by IBM Web Content Manager. However, you can use page-based access control to delegate access control enforcement to the web content page that is used to display the content.

"Previewing content on web content pages" on page 2060
When working with content in the authoring portlet, you can preview content items in a portal environment as part of a web content page. To preview content items, there must be a web content viewer on the associated web content page, and the viewer must be configured to receive links.

"Adding HTML meta tags for Search Engine Optimization" on page 2060
Search engine optimization (SEO) focuses on improving the visibility of a page or website in search engine results. A basic technique of SEO is adding HTML title and meta tags to your page source. These meta tags are used to define description information and other metadata that search web engines and crawlers can use when they create search indexes and collections. When you include content in a page with a web content viewer, you can improve the search engine optimization of the page by adding title and meta tags with values derived from the web content itself.

CF06 "Improving page loading performance with asynchronous web content rendering" on page 2065
You can increase page loading performance by separating portal page content delivery from web content rendering. To do so, you use the asynchronous web content rendering feature. If you enable asynchronous web content rendering, the portal serves the page immediately, but only with placeholder content. The Web Content Viewer then dynamically inserts the configured content into the portal page after the content has been completely rendered.

Related concepts:

"Preparing the site toolbar" on page 1900
The site toolbar enables content authors to work with content from the website instead of using the authoring portlet. Customize the site toolbars to improve the authoring experience for content authors.

Creating web content page templates:

Create web content page templates to quickly deploy new pages that contain web content. With a template, you can define the layout and presentation of the page, including adding web content viewers that are configured to render web content.

About this task

When a page is created from the template, the site structure that is required in the web content library is also created automatically. For example, if managed pages are enabled, a site area that corresponds to the page hierarchy is created in the Portal Site library. If managed pages are disabled, a site area is created as a child of the site area that is associated with the parent page of the new page. You can access the resulting site structure in the Web Content Manager authoring portlet.

Procedure

1. Using the administration interface, browse to the page templates location. You can access this location from either of the following paths:
   - Click **Portal User Interface** > **Page Templates**.

     Note: This path uses the site toolbar that is included with the Portal 8.0 theme.
   - Click **Portal User Interface** > **Manage Pages** > **Content Root** > **Hidden Pages** > **Page Templates**.
2. Create a page. When you create the page, use the **Basic** template and then define a content association for the page. The content that is contained in the mapped site area is copied to any page that is created by using the page template.
3. Edit the layout of the page and add any web content viewers or other portlets that you want to include in the template.

   If you add a viewer that is intended to render content that is copied when the page is created, then configure the viewer:
   a. Select **Edit Shared Settings**.
   b. Select **Select content and use the content association of current page** from the **Content behavior** section. This setting causes the viewer to reference content from the site area that is defined in the content association on the page that contains the viewer.

      Note: If you did not add a content association to the page template, this option is not available.

Results

After you create the template page, the new template is displayed in the list of available templates when you create a page.

Creating web content when you add a web content viewer to a page:

To make it easier for users to find web content, the site toolbar provides palettes. You use these palettes to organize components that you can add, such as portlets, iWidgets, and web content.

About this task

By default, the Content palette includes four sample content items. You can add your own content to the Content palette. For more details about how to do so, read *Customizing the Content palette*.

To add web content, you can use the preferred drag-and-drop configurations. You can also configure individual copies of the Web Content Viewer portlet to copy web content when you add these portlet copies to a page. Copies of the web content viewer appear in the Applications palette of the site toolbar.

To include a web content item in the Applications palette of the site toolbar, follow the procedure that is given here.

Procedure

1. Make a copy of the portlet called Web Content Viewer. To do so, use the portal administration interface. Give the copy a name that indicates the content item that the viewer represents.
2. Add the new web content viewer to a page. You need this page only temporarily to provide a way of configuring the web content viewer.
3. Open the **Configure** mode for the portlet.
4. From the **Content Type** section, select the content item that you want to add.
5. From the **Content Behavior** section, select **Select content and path**.
6. From the section that is named **When this Portlet is added to the page**, select **Create content (based on selection)**.

   Note: You cannot add portlets that use this setting to a page that does not have a default content association.
7. In the **Content** section, specify the content item or site area that this web content viewer represents.

Results

After you complete these steps, the copy of the web content viewer that represents your web content is displayed in the Applications palette of the site toolbar. Whenever you add this portlet copy to a page, the associated content item or site area is copied into the site area that is associated to the page by the default content association.

Notes for the XML configuration interface: To create the copies of the web content viewer, you can also use the portal XML configuration interface. To specify the behavior of the setting Create content (based on selection) by using with the XML configuration interface, specify the following portlet preference in the XML import file:

Preference:

```
com.ibm.portal.wcm.copy.contents
```

Value:

```
true
```

You can also specify the target site area that you want to be used when the portal copies the web content. To define a target site area, use the following portlet preference in the XML import file:

Preference:

```
WCM_COPY_CONTENT_RELATIVE_PATH
```

Value:

```
site_area_name
```

When you add the web content viewer that specifies this `WCM_COPY_CONTENT_RELATIVE_PATH` preference to a page, the portal first creates the specified site area under the default content association of the page. Afterward, the portal copies the web content that is associated with the web content viewer to the specified site area rather than to the default content association.

"Customizing the Content palette" on page 1904
The Content palette, which is accessed from the site toolbar, contains the content items a content author can add to a page.

Customizing error messages for Web Content Viewers:

If an error occurs during rendering, the Web Content Viewer shows an error screen. You can customize the default error screen, and you can create your own custom JSP file that is used to display error messages.

About this task

The default error screen provides a standard error message, which is shown on every type of error, and a more detailed error message. The detailed error message provides information about the cause of the error and is displayed when you click the **View details** link.

Procedure

1. Create a customized error JSP file.
   a. Copy the original `error.jsp` file from *wp_profile_root*`/installedApps/`*node_name*`/PA_WCMLRingPortJSR286.ear/ilwwcm⌂localrende.war/jsp/html` directory to create your custom error JSP file.

      Almost everything in the original JSP file can be changed according to your requirements. If you want to show the cause of the error, you must retain this part of the original file in your error JSP file:

      ```
      <%-- use errorbean from request --%>
      <jsp:useBean id="errorbean" scope="request"
          type="com.ibm.portal.portletui.messages.StatusMessageBean" />
      <% String msg = errorbean.getMessage(); %>
      ```

      The variable *msg* contains the message text of the error. In the original `error.jsp` file, this message is only shown in a separate window if a user selects the **View details** link.
2. Configure the Web Content Viewer to use the customized error JSP file.
   a. Log in to the portal as an administrator.
   b. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
   c. Locate the `Web Content Viewer` portlet.
   d. Click **Configure Portlet**.
   e. Edit the value of the **`ERROR_JSP`** parameter, and set the path to your customized error JSP file as the parameter value.

      Storing JSP files: JSP files are stored within a web application that runs on the portal. To reference a JSP file in another web application, use the following path: `contextPath;jspPath`. For example: `/wps/customapplication;/jsp/jspFilename.jsp`.

      A dynamic context path value can be defined by adding a token to the context path that corresponds to a key and value pair to the Web Content Manager configuration service environment provider. When this key is used as the token in the jsp value field, it is replaced dynamically at render time. For example: `[my.custom.key];myfile` where *my.custom.key* is a constant within the Web Content Manager configuration service.

Friendly URLs and Web Content Viewers:

Friendly URLs provide a way for you to define a custom address for a portal page that is easy to remember and share. The Web Content Viewer expands on friendly URL support so you can specify extra path information in the friendly URL.

By defining friendly URLs for your portal pages, users can browse the portal by using more concise URLs that better reflect the page structure. The additional path information in a friendly URL for web content points to a content item to be displayed in the Web Content Viewer.

"About friendly URLs for web content"
With friendly URLs for web content, you can construct URLs to content items that are clear and concise. Although you can construct friendly URLs that reference web content items, IBM Web Content Manager itself does not generate friendly URLs by default. However, to cause the web content viewer to generate friendly URLs, you can create a plug-in that implements a content URL generation filter.

 "How to validate friendly URLs for web content" on page 2045
Learn about the validation and customization of friendly URLs for web content, including use cases and customization options.

"Friendly URL for web content example" on page 2052
This example demonstrates how friendly URLs for web content work with multiple web content viewers on a single portal page. The example describes the portal page structure referenced by the friendly URLs and explains the underlying structure of the content in an IBM Web Content Manager site framework.

Related tasks:

"Creating a content URL generation filter class" on page 3237
A content URL generation filter is used to customize the URLs that are generated by a web content viewer. By creating a plug-in that implements a content URL generation filter, you can tailor the URLs to content items.

About friendly URLs for web content:

With friendly URLs for web content, you can construct URLs to content items that are clear and concise. Although you can construct friendly URLs that reference web content items, IBM Web Content Manager itself does not generate friendly URLs by default. However, to cause the web content viewer to generate friendly URLs, you can create a plug-in that implements a content URL generation filter.

These URLs are easier for users to remember and share and are a convenient way for users to create bookmarks to content items. External applications can also use friendly URLs to provide links directly to content items in the portal. To create effective friendly URLs for web content, you must understand how friendly URLs for portal pages are constructed and how friendly URLs for web content extend those URLs.

How friendly URLs for pages are constructed

For a page to be referenced as part of a friendly URL, you must assign a friendly URL name for the page. You can assign a friendly URL when you create the page, or you can edit the page properties after the page is created.

Friendly URLs take the following general form:

`http://host_name:port_number/context_root/portal/page_id/[!ut/p/encoded_suffix]`

The *page_id* portion of the friendly URL is made up of the friendly URL names of each page in the page structure. The page structure begins at the content root and ends with the currently selected page.

For example, you might have a portal page called Products with a friendly URL name of products. Under the Products page is another page called Appliances with a friendly URL name of appliances. When referenced as a complete friendly URL, you would enter the following URL to access the Appliances page:

```
http://www.example.com:10039/wps/portal/products/appliances
```

For friendly URLs to work for a specific page, you must define a friendly URL name for each page or label in the page structure. If you want to suppress a friendly URL name from showing in the friendly URL, you can specify a friendly URL name of com.ibm.portal.friendly.wildcard for the page. For example, if the Products page has a friendly URL name of com.ibm.portal.friendly.wildcard, the friendly URL in the previous example for the Appliances page is abbreviated:

```
http://www.example.com:10039/wps/portal/appliances
```

Note: When the portal displays a page using a friendly URL, the URL can include an encoded suffix at the end of the URL with the form !ut/p/*base_codec*/*rich_state*. This suffix contains information about the portals state that the portal might use when displaying the page. However, when bookmarking or sharing friendly URLs, it is not necessary to include the suffix.

How friendly URLs for web content are constructed

Friendly URLs for web content are constructed just as friendly URLs for pages but include additional information that identifies the path to a content item. When the portal decodes a friendly URL, it decodes the URL from beginning to end. Each path segment of the URL is matched with the friendly URL names of portal pages until no more matches can be located. The remainder of the URL is then considered to be path information to a content item.

This path information is mapped to a shared public render parameter that is scoped to the portal page identified by the URL. The fully qualified name of this **path-info** parameter is http://www.ibm.com/xmlns/prod/websphere/portal/publicparams:path-info. The **path-info** parameter can contain multiple values, with the individual values representing segments of a content path. The segments are concatenated using a forward slash (/) as a path separator.

Friendly URLs for web content take the following general form:

```
http://host_name:port_number/context_root/portal/page_id/path_to_content/[!ut/p/encoded_suffix]
```

When you add a web content viewer to a portal page, the web content viewer reads the **path-info** parameter. The viewer assembles the path to the content to be rendered by appending the path information to the path of the default content mapping defined for the current page. For example, you might have the following friendly URL for web content:

```
http://www.example.com:10039/wps/portal/products/appliances/welcome
```

Several conditions contribute to this URL:

- The portal page Products has a friendly URL name of products, and underneath the Products page is another page called Appliances with a friendly URL name of appliances.
- A web content library contains a site area called Appliances, which contains a content item called welcome. For this example, the web content library is called Web Content.
- The portal page Appliances has a default content mapping to the Web Content/Appliances site area.

When a web content viewer is added to the `Appliances` page, the web content viewer interprets the **path-info** information from the friendly URL. The viewer identifies `welcome` as path information that represents content in a web content library. By examining the default content mapping on the page, the web content viewer locates the `Web Content/Appliances` site area and then displays the `welcome` content item.

The *page_id* portion of the friendly URL is always evaluated first. Because of this priority, ensure that your naming schemes do not overlap when setting up your portal page hierarchy and your web content hierarchy. In particular, the *path_to_content* information cannot begin with segments that could be part of the `page_id` portion of the friendly URL. If the first segment of the *path_to_content* information matches the friendly URL name of a portal page at that point in the page hierarchy, the friendly URL could reference the wrong page.

Considerations for the path-info parameter:

- For a web content viewer to process the **path-info** parameter, the web content viewer must be configured to receive links. If it is configured to receive links, the web content viewer gives precedence to the **path-info** parameter over the **context** public render parameter. When you click links displayed by the web content viewer, the link automatically incorporates the path information for the linked item.
- Clicking **Clear page context** when editing the settings of a web content viewer also clears the **path-info** parameter.
- If a friendly URL includes an encoded suffix, it takes this form: `!ut/p/`*base_codec*`/`*rich_state*. Because this information is encoded, it is not intended to be read by people. However, the portal itself might act on the information, which can sometimes cause the wrong page to be displayed.

  If the **path-info** public shared render parameter is encoded in the *rich_state* portion of the suffix, the **path-info** contents overwrites the *path_to_content* portion of the friendly URL. It is also possible that there could be a mismatch between the **path-info** contents and the path information encoded in the *rich_state* section. If such a mismatch occurs, the portal replaces the *path_to_content* portion of the friendly URL with the *rich_state* information and directs the user to that page.

  The following tables demonstrate how the presence of *rich_state* information affects the page that is shown:

Table 324. Example of rich_state information affecting displayed page

Description	URL
The user navigates to URL in the portal.	`http://www.example.com:10039/wps/portal/home/content_item_1/!ut/p/b1/dY07Do...`
The user modifies the URL in the browsers address bar to go to `content_item_2`.	`http://www.example.com:10039/wps/portal/home/content_item_2/!ut/p/b1/dY07Do...`
Resulting URL.	`http://www.example.com:10039/wps/portal/home/content_item_1/!ut/p/b1/dY07Do...` Because the *rich_state* portion of the URL still contains path information pointing to `content_item_1`, the portal overwrites the *path_to_content* portion of the URL. The user remains on the same page instead of being directed to the page where `content_item_2` is displayed.

Table 325. Example of friendly URL for web content without rich_state information

Description	URL
The user navigates to URL in the portal.	`http://www.example.com:10039/wps/portal/home/content_item_1/!ut/p/b1/dY07Do...`
The user modifies the URL in the browsers address bar to go to `content_item_2`.	`http://www.example.com:10039/wps/portal/home/content_item_2`
Resulting URL.	`http://www.example.com:10039/wps/portal/home/content_item_2` Because the user removed the *`rich_state`* portion of the URL when modifying the URL, the *`path_to_content`* portion of the URL is evaluated. The user is directed to the page where `content_item_2` is displayed.

Content URL generation filters and friendly URLs

A content URL generation filter is used to customize the URLs that are generated by a web content viewer. The web content viewer generates a content URL whenever there is a URL to web content within content that the viewer is displaying. By creating a plug-in that implements a content URL generation filter, you can tailor the URLs to content items. For details, see *Creating a content URL generation filter class.*

Troubleshooting friendly URLs for web content

If you are seeing unexpected behavior when using friendly URLs for web content, review these issues to help identify why the friendly URL is not working. Friendly URLs for web content take the following general form:

`http://`*`host_name`*`:`*`port_number`*`/`*`context_root`*`/portal/`*`page_id`*`/`*`path_to_content`*`/[!ut/p/`*`encoded_suffix`*`]`

- Support for friendly URLs for web content is only enabled when the configuration properties `friendly.enabled` and `friendly.pathinfo.enabled` both have a value of `true` in the portal Configuration Service.
- The web content viewer displays a warning message in the following situations:
  - The friendly URL for web content references a content item that cannot be located.
  - The user does not have sufficient access rights to view the referenced content item.
- The portal page specified in the friendly URL for web content must have a default content mapping to an existing web content site area. If there is no default content mapping on the page, any web content viewers on the page display a warning message about the missing page context.
- If the target page does not contain a web content viewer that is configured to receive links, the content item specified in the friendly URL for web content is not displayed.
- If a web content viewer is not configured to broadcast links, links rendered by the viewer do not affect the friendly URL for web content.
- The default portal page selection does not show the path of the default content item in the friendly URL. The *`path_to_content`* portion of the URL includes the content path information only after users browse web content using links displayed by the viewer.

- Friendly URLs for web content are URL-encoded. When using friendly URLs for web content, special characters that show in any segment of the URL must be URL-encoded. For example, a space character in the URL would be replaced by its URL-encoded equivalent: `%20`. Some web browsers perform automatic decoding of the URL. In this case, you might see unencoded characters in the URL, but the portal always works with an encoded version of the URL.
- The segments of a friendly URL for web content are not localized for multiple languages. The *`path_to_content`* portion of a friendly URL for web content is composed of the unlocalized names of web content folders, site areas, and content items. For example, if you name these items with English terms, the friendly URL for web content is constructed of these English terms, even if the portal language is not English.

How to validate friendly URLs for web content:

Learn about the validation and customization of friendly URLs for web content, including use cases and customization options.

Friendly URLs for web content provide human-readable URLs that are easy for users to remember. A friendly URL points to a specific content item that is displayed on a specific portal page. By default, WebSphere Portal Express does not check whether a friendly URL addresses an existing content item or not. However, the following scenarios would benefit from validation and customized handling of invalid friendly URLs:

- A user mistypes a friendly URL.
- A user clicks a saved bookmark that points to a portal page or a content item that no longer exists.
- A search engine browses portal pages to update a search index.

If you use friendly URLs for web content, you can configure WebSphere Portal Express to validate the friendly URL associated with a request. If you enable friendly URL validation, portal assembles a content path by appending the path information to the path of the default content mapping that is defined for the resolved page. Afterward, portal checks whether that content path identifies a content item that is available in the current user context. The friendly URL for web content is valid if the portal finds a content item. Otherwise, portal sends an error response. Using the WebSphere Portal Express Configuration Service and individual page parameters, you can customize error responses in the following ways:

- Return an HTTP error code along with a localized message.
- Return an HTTP error code and display the resolved page.
- Return an HTTP error code and display the resolved page and render a specific content item.
- Return an HTTP error code and display a specific page.
- Return an HTTP error code and display a specific page that renders a specific content item.

CF03 "How to enable the validation of friendly URLs for web content" on page 2046
Learn about the properties and values that are required in WebSphere Portal Express Configuration Service Resource Environment Provider to validate friendly URLs for web content.

CF03 "Configuring the validation of friendly URLs for web content" on page 2046

After you enable the validation of friendly URLs for web content, you can choose from various configuration options. These options enable you to specify how the portal responds to friendly URLs that contain path information that does not identify an available content item. Learn about the parameter combinations you can specify and how the portal response varies based on these combinations.

CF03 "How to prevent friendly URL redirects for invalid friendly URLs for web content" on page 2051
If the validation of friendly URLs for web content is enabled and the path information of an incoming friendly URL is not valid, portal responds with the HTTP status code as defined by the portal Configuration Service property and page parameter **friendly.pathinfo.validation.errorCode**. However, depending on the configuration, portal does not always send the configured HTTP status code. Portal can identify conditions that require a different HTTP status code.

How to enable the validation of friendly URLs for web content:

Learn about the properties and values that are required in WebSphere Portal Express Configuration Service Resource Environment Provider to validate friendly URLs for web content.

Before you enable the validation of friendly URLs, verify that your portal server supports friendly URLs that contain path information to a content item as part of the URI. Verify the following properties and values in the WebSphere Portal Express Configuration Service:

- **friendly.enabled** is set to `true`.
- **friendly.pathinfo.enabled** is set to `true`.
- **friendly.pathinfo.invalid** is set to `false`.

If the previous properties are not set to the specified values, your portal server does not use friendly URLs for web content and validation of friendly URLs is not possible.

To enable the validation of friendly URLs for web content, set the **friendly.pathinfo.validation.enabled** property to `true` in the WebSphere Portal Express Configuration Service Resource Environment Provider. For more information about the **friendly.pathinfo.validation.enabled** property and the properties that are required to support friendly URLs, see *Configuration Service* in the related links.

Related reference:

"Configuration Service" on page 297
The portal Configuration Service is responsible for collecting the most essential configuration data of the IBM WebSphere Portal Express engine.

Configuring the validation of friendly URLs for web content:

After you enable the validation of friendly URLs for web content, you can choose from various configuration options. These options enable you to specify how the portal responds to friendly URLs that contain path information that does not identify an available content item. Learn about the parameter combinations you can specify and how the portal response varies based on these combinations.

You can specify the following parameters for the overall portal as properties and key value pairs in the portal Configuration Service or for individual pages as page

parameters. Page parameters that you set for a specific page override any global settings that are specified in the portal Configuration Service. Page parameters are inherited by all child pages. For more information, see *Configuration Service* in the related links.

friendly.pathinfo.validation.errorCode = (404)

This key specifies the HTTP status code that the portal returns if the path information of a friendly URL cannot be resolved to a content item for the requested page. You can specify one of the following values:

404 The default value. This HTTP status code tells a caller, such as a search crawler or web browser, that no content is found for the friendly URL. The missing content might be temporarily or permanently missing.

410 This HTTP status code informs a caller, such as a search crawler or a web browser, that the resource for the friendly URL is no longer available. This missing resource is permanently gone.

Portal can identify conditions that require a different HTTP status code than the one you configure by using **friendly.pathinfo.validation.errorCode**. For example, friendly URL redirects require the HTTP status code 302. To support the most common use cases, see the topic *Preventing friendly URL redirects for invalid friendly URLs for web content*.

friendly.pathinfo.validation.errorTextProvider

This key specifies the text provider of the localized HTTP status message to send as well as the configured HTTP status code. If you configure a text provider and a request URL has invalid path information, portal responds with a blank page that displays only the HTTP status code and the corresponding localized message that is specified by the text provider. The value of this parameter must be the ID of an implementation of the `com.ibm.workplace.wcm.api.plugin.textprovider.TextProvider` interface. To use the default messages of WebSphere Portal Express, specify the text provider with the ID `PathInfoValidationTextProvider`. If you implement a custom text provider, make sure that it supports message keys that are composed of the prefix `HTTP_STATUS_MESSAGE_` and the configured HTTP status code, for example: `HTTP_STATUS_MESSAGE_404`.

Important: Portal ignores this setting if you also specify the **friendly.pathinfo.validation.errorURI** property or page parameter.

friendly.pathinfo.validation.errorResourceBundle

This key specifies a Java resource bundle as an alternative to implementing a custom text provider. If you configure a Java resource bundle and a request URL has invalid path information, portal responds with a blank page displays only the HTTP status code and the corresponding localized message from the Java resource bundle. The value of this setting must be the fully qualified name of the Java resource bundle. If you provide a custom Java resource bundle, make sure that it contains message keys that are composed of the prefix `HTTP_STATUS_MESSAGE_` and the configured HTTP status code, for example: `HTTP_STATUS_MESSAGE_404`.

Important: Portal ignores this setting if you also specify the **friendly.pathinfo.validation.errorURI** property or page parameter. Portal also ignores this setting if you set the value of the

friendly.pathinfo.validation.errorTextProvider property or page parameter to a custom text provider ID.

friendly.pathinfo.validation.errorURI
This key specifies the piece of content URI that portal resolves if the request URL has invalid path information. The value of this parameter must be a piece of content URI that portal can resolve, for example:

nm:oid:*unique_page_name*
This navigation model URI redirects the request to a specific portal page based on the unique name of the target page.

custom:resolutionserviceuri
This custom implementation of the `com.ibm.portal.resolver.ResolutionService` interface resolves invalid path information to a dynamically determined navigational state. When portal resolves the piece of content URI, the content path that failed the portlet validation is passed to the resolution service as the **wcmContentPath** parameter.

friendly.pathinfo.validation.errorContentPath
This key specifies the full content path that portal sets as public Web Content Manager context of the resolved page if the request URL has invalid path information. Web Content Viewer portlets on the resolved page that are configured to listen to other portlets can then render the content with the specified path. The value of this setting must be the path of a content item that is available to users, for example: `/Web Content/home/human_resources/health/topic_not_found`.

Table 326. Portal responses to invalid friendly URLs for web content when parameters are set to specific values

Portal response to invalid friendly URLs for web content			**Properties and values**			
HTTP status code	**Page**	**Web content**	**friendly.pathinfo.validation.errorTextProvider**	**friendly.pathinfo.validation.errorURI**	**friendly.pathinfo.validation.errorContentPath**	**friendly.pathinfo.validation.errorTextProvider** or **friendly.pathinfo.validation.errorURI** or **friendly.pathinfo.validation.errorContentPath**
404	The page that is specified in the requested URL.	Web content is rendered according to the private or public Web Content Manager context, but not based on the path information. The path information was invalid and removed from the state.	N/A	N/A	N/A	N/A

Editing pages, labels, and URLs

How to prevent friendly URL redirects for invalid friendly URLs for web content:

If the validation of friendly URLs for web content is enabled and the path information of an incoming friendly URL is not valid, portal responds with the HTTP status code as defined by the portal Configuration Service property and page parameter **friendly.pathinfo.validation.errorCode**. However, depending on the configuration, portal does not always send the configured HTTP status code. Portal can identify conditions that require a different HTTP status code.

If you use the **friendly.pathinfo.validation.errorTextProvider** or the **friendly.pathinfo.validation.errorResourceBundle** settings, you can skip this information. With either of those settings, portal interrupts the request processing and sends an error response that contains only the configured HTTP status code and a localized status message if a friendly URL contains invalid path information.

If you do not use those settings to configure the friendly URL validation and if you require the portal to send the configured HTTP status code instead of 302, you need to limit the friendly URL redirects to valid friendly URLs for web content. By default, portal enforces a redirect by using the HTTP status code 302 if the incoming URL does not contain the friendly URL prefix of the addressed page or if the path information contained in the friendly URL does not match the path information from the portal state. Because the friendly URL validation component removes the path information from the state if it is not valid, the portal sends a 302 status code instead of the configured HTTP status code. Use the following combination of portal Configuration Service properties to prevent those friendly URL redirects when a friendly URL for web content is not valid:

- **friendly.redirect.enabled**=false
- **friendly.pathinfo.validation.redirect.onsuccess.enabled**=true

For more information about these properties, see *Configuration Service* in the related links.

If you limit friendly URL redirects, set the portal theme parameter **com.ibm.portal.theme.hasBaseURL** to true. If you have a custom theme, ensure that the theme writes the HTML **base** tag. Update the theme parameter by using the XML configuration interface as the following sample XML script illustrates:

```
<?xml version="1.0" encoding="UTG-8"?>

<request
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
type="update">

 <!-- This sample sets the hasBaseURL parameter in the Portal 8.5 Theme. -->
 <portal action="locate">
  <theme action="update" uniquename="ibm.portal.85Theme" >
   <parameter name="com.ibm.portal.theme.hasBaseURL"
    type="string" update="set">true</parameter>
  </theme>
 </portal>
</request>
```

Friendly URL for web content example:

This example demonstrates how friendly URLs for web content work with multiple web content viewers on a single portal page. The example describes the portal page structure referenced by the friendly URLs and explains the underlying structure of the content in an IBM Web Content Manager site framework.

The example also describes the configuration of the web content viewers.

CF03 Starting with the combined cumulative fix readme 03 (CF03), the example also describes the use of the function to validate friendly URLs for web content. This example assumes that WebSphere Portal Express is configured to support friendly URLs for web content and their validation.

Elements in the example

The example is composed of the following elements:

Portal page hierarchy

The portal page hierarchy in this example is:

```
Content Root
     > Home
          > Human Resources
     > Missing Content
```

Note: CF03 The page Missing Content applies only to the combined cumulative fix readme 03 (CF03).

The page Home has a friendly URL name of home, and the page Human Resources has a friendly URL name of hr. The pages can be accessed directly using the following friendly URLs for pages:

- http://www.example.com:10039/wps/portal/home
- http://www.example.com:10039/wps/portal/home/hr

CF03 The following page parameters apply to the following pages in the portal page hierarchy:

- The page Missing Content has the unique name missing.content and is hidden from the navigation by setting the **com.ibm.portal.Hidden** page parameter to true.
- The page Content Root has the **friendly.pathinfo.validation.errorURI** page parameter set to nm:oid:missing.content.
- The page Human Resources has the **friendly.pathinfo.validation.errorContentPath** page parameter set to /Web Content/Home/Human Resources/HR Default.

Web Content Manager site framework

The Web Content Manager site framework resembles the portal page hierarchy:

```
Web Content (Web Content Library)
     > Home (site area)
          > Human Resources (site area)
               > HR Welcome (content item)
               > Health (site area)
                    > Workplace Safety (content item)
                    > Personal Wellness (content item)
               > HR Default (content item)
     > Missing Content (site area)
          > Content Not Found (content item)
     > HR Menu (menu component)
```

Note: CF03 The pages HR Default, Missing Content, and Content Not Found apply only to the combined cumulative fix readme 03 (CF03).

The content items in the Home site area can be referenced by the following content paths:

- Web Content/home/human resources/hr welcome
- Web Content/home/human resources/health/workplace safety
- Web Content/home/human resources/health/personal wellness
- CF03 Web Content/home/human resources/hr default

CF03 The site area Missing Content stores a default content item that is displayed on the corresponding page by default.

The menu component HR Menu is defined to display content from the human resources site area and the health site area.

Content association

The portal page Human Resources has the default content association to the Web Content/home/human resources site area.

CF03 The portal page Missing Content has the default content association to the Web Content/missing content site area.

Web content viewers

The page Human Resources contains two instances of the web content viewer, Web Content Viewer A and Web Content Viewer B.

- The Web Content Viewer A viewer renders the menu component HR Menu and is configured to broadcast links to this portal page.
- The Web Content Viewer B viewer inherits the content to display from the content association defined for the page Human Resources. The viewer is configured to receive links from other portlets and from itself.

CF03 The page Missing Content contains one instance of the web content viewer. The viewer inherits the content to display from the content association defined for the page Missing Content. The viewer is configured to receive links from other portlets and from itself.

Browsing the example content

With the portal page and web content site framework defined, browsing the content demonstrates how the different elements interact:

1. Navigate to Human Resources page for the first time.
   - The URL that is displayed in the address bar of the browser is http://www.example.com:10039/wps/portal/home/hr/!ut/p/b1/...
   - The URL reflects the friendly URL names of the portal pages Home and Human Resources.
   - The Web Content Viewer A viewer renders the menu component and displays links to the content items HR Welcome, Workplace Safety, and Personal Wellness.
   - The Web Content Viewer B viewer shows the default content item HR Welcome from the site area Human Resources, because of the content association defined on the portal page.

     Note: When the portal page is first displayed, the path of the default content item is not included in the friendly URL.
2. Click **Workplace Safety** from the list of content items.
   - The URL that is displayed in the address bar in the browser is http://www.example.com:10039/wps/portal/home/hr/health/workplace%20safety/!ut/p/b1/...
   - The Web Content Viewer B viewer displays content item Workplace Safety.
   - The URL is adjusted so that the path to the content item (health/workplace%20safety) becomes part of the URL.
3. Click **HR Welcome** from the list of content items.
   - The URL that is displayed in the address bar of the browser is http://www.example.com:10039/wps/portal/home/hr/hr%20welcome/!ut/p/b1/...
   - The Web Content Viewer B viewer displays the content item HR Welcome again, giving the same result as when the portal page was viewed for the first time.

- Because the Web Content Viewer A viewer is broadcasting the link to the content item, the URL that is displayed in the browser is updated to reference the path to the content item (hr%20welcome).

Content item references with friendly URLs for web content

The URL displayed in the web browser can sometimes include the content item path when you browse pages and content with web content viewers. However, you can also reference content items directly in friendly URLs for web content.

For example, to reference the content items HR Welcome, Workplace Safety, and Personal Wellness in the context of the Human Resources page, you would use the following friendly URLs for web content:

- http://www.example.com:10039/wps/portal/home/hr/hr%20welcome
- http://www.example.com:10039/wps/portal/home/hr/health/workplace%20safety
- http://www.example.com:10039/wps/portal/home/hr/health/personal%20wellness

Note: These friendly URLs for web content include URL-encoded space characters (%20) instead of unencoded space characters. Your web browser might accept unencoded space characters when specifying content item names in friendly URLs for web content. However, to ensure consistent behavior from the portal, use the URL-encoded value.

CF03

Testing invalid friendly URLs for web content

Sometimes, the friendly URL entered by a user or requested by a search crawler can be wrong. The following table shows friendly URLs that contain path information that does not identify an available content item and an explanation of the portal response when an invalid friendly URL is requested.

Invalid friendly URL for web content: http://www.example.com:10039/wps/portal/home/products/appliances

Portal response:

HTTP Status code
404

Page Missing Content

Web content
Content Not Found

Explanation:

Resolving the page
The last path segment of the friendly URL that portal can match to a friendly URL name is home. Therefore, the resolved page is Home and /products/appliances becomes the path information of the request.

Validating the path information
When validating the friendly URL for web content, portal assembles the content path to validate by appending the path information to the path of the default content association of the

resolved page. As the page Home does not have a default content association to construct the content path, the friendly URL for web content is considered invalid.

Handling the invalid path information
The HTTP status code of the response is set to the default value (`404`) because **`friendly.pathinfo.validation.errorCode`** is not set. The resolved page (Home) inherits the **`friendly.pathinfo.validation.errorURI`** setting from Content Root. Therefore, the portal resolves the URI `nm:oid:missing.content` that addresses the page Missing Content. The Web Content Viewer portlet on the page Missing Content uses the default content mapping of the page to determine the web content to render (`Content Not Found`).

Invalid friendly URL for web content: `http://www.example.com:10039/wps/portal/home/hr/group incentives`
Portal response:

HTTP Status code
`404`

Page Missing Content

Web content
`HR Default`

Explanation:

Resolving the page
The last path segment of the friendly URL that portal can match to a friendly URL name is `hr`. Therefore, the resolved page is Human Resources and `/group incentives` becomes the path information of the request.

Validating the path information
When validating the friendly URL for web content, portal assembles the content path to validate by appending the path information to the path of the default content association of the resolved page. The result for the page Human Resources is `/Web Content/home/human resources/group incentives`. As there is no content item for the computed content path, the friendly URL for web content is considered invalid.

Handling the invalid path information
The HTTP status code of the response is set to the default value (`404`), because **`friendly.pathinfo.validation.errorCode`** is not set. The resolved page (Human Resources) inherits the **`friendly.pathinfo.validation.errorURI`** setting from Content Root. Therefore, portal resolves the URI `nm:oid:missing.content` that addresses the page Missing Content. Additionally, portal sets the public Web Content Manager context as defined by the page parameter **`friendly.pathinfo.validation.errorContentPath`** of the resolved page (`/Web Content/Home/Human Resources/HR Default`).

Invalid friendly URL for web content: `http://www.example.com:10039/wps/portal/home/hr/health/medical prevention and rehabilitation`
Portal response:

HTTP Status code
`404`

Page Missing Content

Web content
`HR Default`

Explanation:

Resolving the page
The last path segment of the friendly URL that portal can match to a friendly URL name is `hr`. Therefore, the resolved page is Human Resources and `/health/medical prevention and rehabilitation` becomes the path information of the request.

Validating the path information
When validating the friendly URL for web content, portal assembles the content path to validate by appending the path information to the path of the default content association of the resolved page. The result for the page Human Resources is `/Web Content/home/human resources/health/medical prevention and rehabilitation`. As there is no content item for the computed content path, the friendly URL for web content is considered invalid.

Handling the invalid path information
The HTTP status code of the response is set to the default value (`404`) because **`friendly.pathinfo.validation.errorCode`** is not set. The resolved page (Human Resources) inherits the **`friendly.pathinfo.validation.errorURI`** setting from Content Root. Therefore, the portal resolves the URI `nm:oid:missing.content` that addresses the page Missing Content. Additionally, the portal sets the public Web Content Manager context as defined by the page parameter **`friendly.pathinfo.validation.errorContentPath`** of the resolved page (`/Web Content/Home/Human Resources/HR Default`).

Related tasks:

"Hiding and displaying pages in the navigation" on page 1803
By default, pages that you create are displayed in the navigation of the portal site. If you do not want a page that you create to appear in the navigation, you can hide the page by setting the **`com.ibm.portal.Hidden`** page parameter to `true`. While this parameter does not affect your portal access control settings for the page, it is hidden from the navigation.

Managing custom unique names

Setting up a web content fallback page:

Set up a web content fallback page to be used when a web content viewer cannot determine which page to use to display a content item. The fallback page can also be used when users do not have sufficient privileges to view the page originally associated with the content item.

About this task

Note: Although a fallback page is one way of handling failed page resolution, you can also use a content page resolution filter to perform more advanced resolution.

With these filters, you can tailor how the viewer behaves if no page can be found for a content item. For more information, see *Creating a content page resolution filter class.*

Procedure

1. Create the portal page to be used as the web content fallback page.
   - Specify a unique name for the page so that you can reference the page later.
   - Assign any access rights required for users. For example, if the fallback page is available in the public part of the portal, ensure that anonymous users have view access to the page.
2. Add a web content viewer to the fallback page.
   a. Click the **Edit Page Layout** icon (small pencil) for the new page.
   b. Click **Add portlets** and select **Web Content Viewer** from the list of portlets.
3. Update the WebSphere Portal Express configuration service to enable the fallback page.
   a. Log in to the WebSphere Integrated Solutions Console..
   b. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
   c. Click **WP ConfigService**.
   d. Under **Additional Properties**, click **Custom Properties**.
   e. Click **New**, and enter the property name `wcm.fallback.page`. Set the string value to the unique name or object ID of the portal page that you created as the fallback page.
   f. Save the changes to the master configuration.
4. Restart the portal.

Results

The web content fallback page is displayed when a viewer is configured with a link broadcast setting of **Dynamically select a web content page** and one of the following conditions occurs:

- The web content viewer cannot determine which page to use to display the linked content item.
- The web content viewer identifies the page associated with the content item, but the user does not have sufficient privileges to view that page.

Related concepts:

"Dynamic web content page selection" on page 2085
The web content viewer provides a link broadcasting feature that dynamically determines the best web content page to use when rendering the linked content item. To perform this page selection, the viewer uses the content associations on the web content page.

Related tasks:

Creating a page from the site toolbar
A page displays content, such as portlets and other pages. Pages organize your site information. As you create pages, you also create new navigational elements to the site. You can create a page under an existing page or you can create a page that is a peer to an existing page. When you create a page you can also reference an existing page, apply a layout, and select supported markups.

"Creating a content page resolution filter class" on page 3231
A content page resolution filter is used to customize the behavior of the content page resolution filter chain. This method is used to tailor the response to a web content request in several ways, including overriding the content item that is displayed or the portal page that is used to display a content item in the web content viewer.

Enabling page-based access control for web content pages:

Typically, when you render content items in a web content viewer, access control enforcement on those content items is handled by IBM Web Content Manager. However, you can use page-based access control to delegate access control enforcement to the web content page that is used to display the content.

About this task

Page-based access control can be specified for individual content associations of a page. When page-based access control is enabled for a specific association, Web Content Manager does not perform additional access control checks when the associated site area contains the rendered content. This content includes not only direct children of the associated site area but also any nested site areas and their related content. Instead, the access control enforcement layer assumes that the same level of access that is granted on the page also applies to the rendered content. The affected content also includes any content items or components that are loaded during the rendering of the target content item. As a result, rendering performance is improved. If the viewer renders content that is not contained in the associated site area, normal access control enforcement is performed.

Page-based access control affects only the access control enforcement that is triggered by the web content viewer. Other access paths, such as the access control that is used by the search crawler, are not affected. In addition, Web Content Manager resources like images that are loaded directly by the browser are also not affected.

Context processor plug-ins note: Context processor plug-ins that are used with the web content viewer run in the access control context of the initial page request. Changes made to the rendering context that might affect whether page-based access control is enabled are evaluated after all other context processor plug-ins complete their configuration.

Procedure

1. To enable page-based access control, ensure that the web content page is associated with a site area in the web content system. You can manage content associations using the site toolbar or the Page Properties portlet.
2. For each content association for which you want to enable page-based access control, select **Use Portal Page Security** for the association.

   Note: If the user creating the page does not have sufficient permissions to enable page-based access control, the check box is disabled. The following access rights must be defined:
   - Administrator @ *wcm_library*, where *wcm_library* represents the library containing the content that is associated to the web content page.
   - Administrator @ CONTENT_MAPPINGS
   - Editor @ *wcm_page*, where *wcm_page* represents the web content page for which you want to enable page-based access.

Related tasks:

"Creating a web content page" on page 2035
A web content page is a page that is associated to one or more site areas in IBM Web Content Manager. You can create a web content page from a web content template page, or you can convert an existing portal page into a web content page.

Previewing content on web content pages:

When working with content in the authoring portlet, you can preview content items in a portal environment as part of a web content page. To preview content items, there must be a web content viewer on the associated web content page, and the viewer must be configured to receive links.

About this task

This preview shows the content item in a more accurate context, as it would be displayed to users. There are two ways to preview content items in a portal:

- You can use dynamic page selection. In this case, the portal determines the best match for the web content page to use for previewing the content item. The page selection is based on the content associations between the site area that contains the content item and the available web content pages.
- You can specify individual pages for previewing content.

Procedure

1. Enable the preview function in the authoring portlet. This step must be done only once.
   a. Select either **Edit Shared Settings** or **Configure** from the menu in the title bar of the authoring portlet.
   b. In the **Previewing Options** section, indicate the previewing method that you want to use.
      - To use dynamic page selection, select **Allow authors to preview content dynamically in a Web Content portal page**.
      - To preview content items on specific pages, select the pages to use for previewing from the list with the following heading: **Allow authors to preview content in the local portal pages**.
2. Preview the content as a web content page.
   a. Select a content item in the authoring portlet.
   b. Click **Preview**, and then select **Preview as a Web Content portal page**. A separate browser window opens to show the content item on its associated web content page.

Adding HTML meta tags for Search Engine Optimization:

Search engine optimization (SEO) focuses on improving the visibility of a page or website in search engine results. A basic technique of SEO is adding HTML title and meta tags to your page source. These meta tags are used to define description information and other metadata that search web engines and crawlers can use when they create search indexes and collections. When you include content in a page with a web content viewer, you can improve the search engine optimization of the page by adding title and meta tags with values derived from the web content itself.

About this task

Note: This support is available with combined cumulative fix 12 for IBM Web Content Manager Version 7.

By default, the HTML title for a page is defined by the page title in the portal. However, when you add a web content viewer to a page to render web content, you can override the value that is used for the HTML title. For metadata tags to be included as portlet preferences, you must set a custom HTML title so that only one portlet can contribute the metadata to the head section.

With the **Page Display Title** field in the portlet settings for the viewer, you can define an HTML title that better reflects the content on the page. You can even have the viewer pull the title directly from the rendered content.

Note: Although multiple web content viewers on the same page can set meta tag values, this practice does not necessarily result in improved SEO. This issue can be further complicated when multiple viewers set different values for the same meta tag name. When you have multiple viewers on the same page, select the viewer whose content best represents what the page is about. You can then use that viewer to define a new HTML title and any meta tags.

Procedure

To override the HTML title for a page and set meta tags, complete the following steps.

1. Select one web content viewer to be the primary viewer on the page. Click **Edit Shared Settings**, and select a value for the **Page Display Title** field in the portlet settings for the viewer.

   To override the HTML title, you must select a value other than **Use default title**. If you want the title value to come directly from the web content that is rendered by the viewer, select **Select from content**. This setting uses the value of the **Display title** field for the content item in Web Content Manager.

   After you save the changes, the page header is updated with the new title value. For example:

   ```
   <head>
      <title>Display title of the rendered web content</title>
   </head>
   ```

2. Create portlet preferences for each meta tag that you want to add to the page header. Each meta tag is defined by a pair of portlet preferences:

   - `meta.tag.name.`*`suffix`* identifies the name of the meta tag (for example, `keywords`).
   - `meta.tag.content.`*`suffix`* identifies the value of the meta tag.

   You can also define a specific attribute for the meta tag with the following portal preference: `meta.tag.attribute.`*`suffix`*`.`

   The *suffix* portion of each preference is used to associate a name preference with its related value preference. The suffix can be any value while it is unique across the preferences.

   There are two ways you can add portlet preferences:

   - The **Manage Portlets** portlet of the administration interface. Locate the instance of the web content viewer you want to modify, and select the **Configure portlet** icon.

- The XML configuration interface. Export the page that contains the instance of the web content viewer you want to modify. Edit the exported XML file with the meta tags you want to add, and update the page by using the XML file along with the **xmlaccess** command.

If you do not set a portlet preference for the attribute name, the attribute name "name" is used by default.

a. Specify the portal preference for the name of the meta tag. The meta tag name takes the following format:

   `meta.tag.name.suffix=name`

   If you want to specify an attribute other than the name attribute, you can define the attribute name with the following format:

   `meta.tag.attribute.suffix=attribute_name`

   For example, to add the following meta tag with the name `keywords`:

   ```
   <meta name="keywords" content=""/>
   ```

   Specify the following preference:

   ```
   meta.tag.name.1=keywords
   ```

   To add the following meta tag with the `http-equiv` attribute:

   ```
   <meta http-equiv="content-language" content="en-US"/>
   ```

   Specify the following preference:

   ```
   meta.tag.attribute.1=http-equiv
   ```

b. Specify the portal preference for the value of the meta tag. The value of the meta tag can be specified in three ways:
   - You can explicitly enter text for the meta tag value.
   - The meta tag value can be derived from the value of a text element in the rendered web content.
   - The meta tag value can be derived from properties that contain information about the rendered web content.

   Depending on how you want to specify the meta tag value, different portlet preferences are required. Only one value can be specified per suffix.

   Use preset text

   The meta tag value takes the following format:

   `meta.tag.content.text.suffix=text`

   The *suffix* portion must match the *suffix* value of the associated `meta.tag.name.suffix` preference. The *text* portion indicates the text to use for the meta tag value.

   Use the value of an element

   The meta tag value takes the following format:

   `meta.tag.content.element.suffix=name_of_element`

   The *suffix* portion must match the *suffix* value of the associated `meta.tag.name.suffix` preference. The *name_of_element* portion indicates the name of the element from the web content that is rendered.

Table 327. Elements for populating meta tag values

Element	Meta tag value
Text component	Text of the element
Date component	Date of the element
Image component	URL of the image
File component	URL of the file

Use a property

The meta tag value takes the following format:

`meta.tag.content.property.`*`suffix=property`*

The *suffix* portion must match the *suffix* value of the associated `meta.tag.name.`*`suffix`* preference. The *property* portion indicates the property that contains information about the web content that is rendered. The properties are associated with fields on the rendered content.

Table 328. Properties for populating meta tag values

Property	Meta tag value
`AdditionalViewers`	Name of additional viewers
`Authors`	Display names of the authors of the rendered content
`authtemplatename`	Name of the authoring template of the rendered content
`authtemplatetitle`	Display title of the authoring template of the rendered content
`Categories`	Titles of any categories associated with the rendered content
`CreationDate`	Creation date of the rendered content
`Creator`	Display name of the user who created the rendered content
`CurrentStage`	Name of the current workflow stage of the rendered content
`Description`	Localized description of the rendered content
`ExpiryDate`	Expiration date of the rendered content
`ID`	ID of the rendered content
`GeneralDateOne`	Date from the general date one field
`GeneralDateTwo`	Date from the general date two field
`Keywords`	Keywords associated with the rendered content
`LastModifiedDate`	Date that the rendered content was last modified
`LastModifier`	Display name of the user who made the last change to the rendered content
`Name`	Name of the rendered content
`Owners`	Display names of the owners of the rendered content

Table 328. Properties for populating meta tag values (continued)

Property	Meta tag value
`PublishDate`	Date the rendered content was published
`SitePath`	Site path of the rendered content
`Status`	Workflow status of the rendered content
`Title`	Localized title of the rendered content
`Workflow`	Name of the workflow of the rendered content

For several of the most common meta tags, default values are predefined. For these meta tags, you can create the portlet preference for only the meta tag name. The meta tag value is provided automatically, without the need for a corresponding name preference. The following meta tags have default values:

`Author` The default value is a list of the authors of the rendered content.

`Keywords`
The default value is list of any keywords that are associated with the rendered content.

`Description`
The default value is the localized description of the rendered content.

If you do not want to use the default value, you can set the value using one of the methods previously described.

c. Optional: If the value of the meta tag requires a scheme attribute, specify the scheme attribute with the `meta.tag.scheme.`*`suffix`* preference. The meta tag scheme attribute takes the following format:

```
meta.tag.scheme.suffix=attribute_value
```

For example, to add the following scheme attribute with the value `W3CDTF`:

```
<meta name="DC.date" content="2000-01-01T12:00+00:00" scheme="W3CDTF"/>
```

Specify the following preference:

```
meta.tag.scheme.1=W3CDTF
```

The format and scheme that are used to write date elements and content properties that are related to date and time information, such as the `LastModifiedDate` property, depends on the meta tag attribute name. By default, all date and time information is formatted according to the date format defined by the HTTP specification. The format that is used to write date and time information in other meta tags is the data and time format that is recommended by the World Wide Web Consortium (W3C) under the scheme named W3CDTF.

Examples

The following examples demonstrate the different ways of specifying portlet preferences and the resulting meta tags in the output.

- Setting the meta tag value with the user who created the rendered content:

```
meta.tag.name.1=DC.creator
meta.tag.content.property.1=Creator
```

Result:

```
<meta name="DC.creator" content="content admin"/>
```

- Setting the meta tag value with preset text:

  ```
  meta.tag.name.1=DC.publisher
  meta.tag.content.text.1=IBM
  ```

  Result:

  ```
  <meta name="DC.publisher" content="IBM"/>
  ```

- Setting multiple meta tag values with the default value for the author and the value of the text element `descelement` in the rendered content:

  ```
  meta.tag.name.1=author
  meta.tag.name.2=description
  meta.tag.content.element.2=descelement
  ```

  Result:

  ```
  <meta name="author" content="content author"/>
  <meta name="description" content="Information about IBM"/>
  ```

- Setting the meta tag with an `http-equiv` attribute and a value of the date that the rendered content was last modified.

  ```
  meta.tag.name.1=last-modified
  meta.tag.attribute.1=http-equiv
  meta.tag.content.property.1=LastModifiedDate
  ```

  Result:

  ```
  <meta http-equiv="last-modified" content="Mon, 01 Aug 2011 13:45:57 GMT"/>
  ```

- Setting the meta tag and with a scheme attribute and a value of the date that the rendered content was published.

  ```
  meta.tag.name.1=DC.date
  meta.tag.scheme.1=W3CDTF
  meta.tag.content.property.1=PublishDate
  ```

  Result:

  ```
  <meta name="DC.date" content="2011-08-01T08:15:30+02:00" scheme="W3CDTF"/>
  ```

Improving page loading performance with asynchronous web content rendering: CF06

You can increase page loading performance by separating portal page content delivery from web content rendering. To do so, you use the asynchronous web content rendering feature. If you enable asynchronous web content rendering, the portal serves the page immediately, but only with placeholder content. The Web Content Viewer then dynamically inserts the configured content into the portal page after the content has been completely rendered.

About this task

Asynchronous web content rendering separates the web content delivery into two steps:

1. First, IBM WebSphere Portal Express serves the page with a predefined static markup instead of the web content. This so called bootstrap markup then asynchronously triggers the second stage by using a resource URL.
2. In a second step, the Web Content Viewer portlet renders the requested web content, which then is inserted into the correct placeholder of the current portal page. For this step, the Web Content Viewer portlet uses the `XmlHttpRequest` function of the web browser and JSR 286 compliant serving of resources.

Asynchronous web content rendering is intended to be used for web content that needs a long time to be created. Examples are web content that is remotely served or content that is created by extensive back-end operations. Such content increases the total time for loading a portal page because the portal needs to aggregate all portlets on a page. Therefore, the user experience improves by selectively enabling asynchronous web content rendering for Web Content Viewer portlets that take a long time to render. Whether asynchronous web content rendering is useful depends on the page composition and the web content. The site administrator needs to evaluate it for each individual portlet.

Notes:

- By default, asynchronous web content rendering is disabled for all instances of the Web Content Viewer portlet. You enable it by using the Edit Shared Settings or Configure mode.
- If you enable asynchronous rendering, the Web Content Viewer portlet uses it only while the portal is in View mode.
- The portal does not use asynchronous web content rendering for requests by search crawlers. This way, the portal makes sure that web content is correctly analyzed and used by search engines.

  CF06 "Enabling asynchronous web content rendering"
  You enable asynchronous web content rendering by using the Edit Shared Settings or Configure mode.

  CF06 "Customizing loading markup for asynchronous web content rendering" on page 2067
  To adjust the loading markup to the user experience, you can customize it. For example, you can use a company-specific loading icon or text.

  CF06 "Using onPageLoad scenarios with asynchronous web content rendering" on page 2068
  Separating the page delivery from the web content delivery can increase the page loading time. However, all JavaScript functions that rely on the `onPageLoad` functions can access only the bootstrapping markup, but not the rendered web content markup. The web content markup is injected into the page as soon as it is ready.

  CF06 "Asynchronous web content rendering and caching" on page 2069
  The Web Content Viewer portlet supports setting specific portlet fragment caching configuration values. This caching also works with asynchronous web content rendering. However, the respective content for the fragment cache is different.

Enabling asynchronous web content rendering: CF06

You enable asynchronous web content rendering by using the Edit Shared Settings or Configure mode.

Before you begin

To enable asynchronous web content rendering, a user needs sufficient access rights: At least either Manager role privileges on the page with the Web Content Viewer or Manager role privileges on the Web Content Viewer portlet itself.

About this task

To enable asynchronous web content rendering for a single portlet instance, use the following procedure.

Procedure

1. Go to the page that contains the Web Content Viewer portlet for which you want to enable asynchronous web content rendering.
2. Change to **Edit** mode.
3. Open the display menu of the portlet.
4. Select **Edit Shared Settings** to enter the configuration mode.
5. Expand the **Advanced Options** section if it is not expanded yet.
6. Scroll down to the **Asynchronous Web Content Rendering** section.
7. To enable asynchronous web content rendering for this portlet, select the check box in the Asynchronous Web Content Rendering subsection.
8. Click **OK** to save and leave the Edit Shared Settings mode.

Optionally, you can also set a timeout for the loading icon for asynchronous web content rendering. If you enable this timeout, the portal marks web content as unavailable, if it takes too long to render. To enable the timeout, proceed as follows:

9. Select **Edit Shared Settings** to enter the configuration mode.
10. Expand the **Advanced Options** section if it is not expanded yet.
11. Scroll down to the **Asynchronous Web Content Rendering** section.
12. Specify the timeout in milliseconds for the asynchronous request. Increase or decrease the timeout value to adjust it to the use case and to the back-end turn around times. To disable the timeout check completely, set the timeout to the value zero (`0`). The asynchronous request then waits until a page redirect occurs or the browser window is closed.
13. Change from Edit mode to View mode.

Results

The web content now renders asynchronously. Until the web content is available, a loading icon and corresponding text appears.

What to do next

Note: Be aware of the following possible error scenarios with asynchronous web content rendering:

- If a timeout occurs, the placeholder area of the Web Content Viewer removes the waiting icon and displays an error text instead.
- If the request fails on the server side inside the `serveResource` method, an HTTP error code is displayed in the placeholder area with a corresponding IBM Web Content Manager error message.
- Issues in the web browser such as missing libraries or theme profiles are displayed in a similar way to indicate the problem.

Customizing loading markup for asynchronous web content rendering: CF06

To adjust the loading markup to the user experience, you can customize it. For example, you can use a company-specific loading icon or text.

About this task

To do so, use the following instructions.

Procedure

1. Create an IBM Web Content Manager HTML component in a Web Content Manager library. The body of this newly created Web Content Manager HTML component serves as the custom loader markup and is delivered by the Web Content Viewer portlet.
2. To notify the portlet to use a custom markup rather than the default content, set the page parameter `wcm.custom.asynchronous.rendering.loader`. As the value, specify the path to the HTML component. All Web Content Viewer portlets on that page then use the custom markup from the HTML component.
3. To address the configured web content, create the JSR 286 compliant Resource URL. To do so, use the `PortletResourceURL` rendering plug-in. This resource URL triggers the `serveResource` method of the Web Content Viewer portlet and returns the rendered web content.
4. Use this markup to update the HTML document object model. The `PortletResourceURL` supports the attributes that you can use with resource URLs, such as the resource identifier`id` or `cacheability`. For the custom asynchronous web content rendering scenario, you do not need to define any attributes. As more than one instance of this custom loading markup on a page is possible, use the `namespace` attribute of the portlet rendering plug-in to create unique identifiers.

Example

The following content is an example of a custom loader markup:

```
<div>
   <a href="[Plugin:PortletResourceURL]" id="[Plugin:Portlet key="namespace"]customAsyncRenderingHook"></a>
   <div style="width: 100%; text-align: center; padding-top: 5em;">
      <span>Loading web content...</span>
   </div>
</div>

<script type="text/javascript">
(function() {
   var hook = document.getElementById("[Plugin:Portlet key="namespace"]customAsyncRenderingHook");
   var xhr = new XMLHttpRequest();
   xhr.onreadystatechange = function() {
      if (xhr.readyState==this.DONE) {
         if (xhr.status==200) {
            hook.parentNode.innerHTML = xhr.responseText;
         } else if (xhr.status==0) {
            // implement timeout handling here ...
         } else {
            // implement error handling here
         }
      }
   };

   xhr.open("GET", hook.href);
   xhr.timeout = 5000;
   xhr.ontimeout = function() { console.error('Asynchronous rendering timed out.'); };
   xhr.send();
}());
</script>
```

Using onPageLoad scenarios with asynchronous web content rendering: CF06

Separating the page delivery from the web content delivery can increase the page loading time. However, all JavaScript functions that rely on the `onPageLoad` functions can access only the bootstrapping markup, but not the rendered web content markup. The web content markup is injected into the page as soon as it is ready.

About this task

In some scenarios, custom JavaScript code needs to run after the asynchronously loaded markup is ready. For such cases, IBM WebSphere Portal Express provides a

global object called wp_wcm_async. This object becomes available with the wp_wcm_async theme modules. To register custom functions to different scenarios, you can use either of the two following two functions:

- To register a function that is called after all asynchronous items on a page are rendered, use addOnPageLoad.
- To register a function that is called after the asynchronous item that is identified by the key is loaded, use addOnAsyncSpotLoad.

To uniquely identify the asynchronous item, use the portlet namespace for the key. Custom theme profiles need to add a moduleID dependency to the new asynchronous web content rendering theme module. In a default WebSphere Portal Express V 8.5 CF06 installation, the asynchronous rendering theme module is included in the Basic Content and Basic Content with Dojo profiles.

Asynchronous web content rendering and caching:

The Web Content Viewer portlet supports setting specific portlet fragment caching configuration values. This caching also works with asynchronous web content rendering. However, the respective content for the fragment cache is different.

If servlet fragment caching, portlet fragment caching, Web Content Viewer caching, and asynchronous web content rendering are all enabled, the Web Content Viewer portlet adds the default or custom loader markup to the fragment cache. It does not add the asynchronously rendered web content to this fragment cache. This way, it increases the possibility to cache an elaborated page setup even with user-specific web content. The reason is mainly because the user-specific content is added asynchronously. The initial page markup contains only the placeholder loading markup, which is static and can therefore be cached easily.

Enabling remote rendering with WSRP and the Web Content Viewer

To display web content on a portal that does not include IBM Web Content Manager, you can use the Web Content Viewer and the WSRP support in the portal. The Web Content Viewer can then retrieve and display content from a web content system on a different server.

About this task

When to use remote rendering: The preferred way to render content on one server from another server is to syndicate the content to the delivery server. On the delivery server, you can then locally render the content with a Web Content Viewer. However, remote rendering with WSRP is appropriate for service-oriented architecture (SOA) scenarios where you want to incorporate specific pieces of content into your website.

When you use the Web Content Viewer for remote rendering with WSRP, the following conditions apply:

- The remote web content server acts as the WSRP Producer.
- The portal with the Web Content Viewer acts as the WSRP Consumer.

Note: Remote rendering with WSRP is supported only when you render content from the default virtual portal.

Procedure

1. Set up the WSRP environment between the Producer portal and the Consumer portal, as described in *WSRP Services*. If you plan to use the **Edit Shared Settings** mode or the **Configure** mode in the portlet with WSRP, configure web service security between the Producer and the Consumer portals.
2. You might have basic authentication challenges when you configure the portlet on the Consumer. To avoid these challenges, customize the WSRP resource proxy for LTPA token forwarding. Go to *Customizing the WSRP resource proxy for LTPA token forwarding* for information.
3. Provide the Web Content Viewer Portlet as a WSRP service hosted on the remote web content server acting as the WSRP Producer.
4. Consume the remote Web Content Viewer that is provided as a WSRP service on the portal acting as the WSRP Consumer.
5. Configure the Web Content Viewer to display content, just as you would configure a local Web Content Viewer.

   When you use the viewer with WSRP, settings for selecting content from a web content library show content from the remote web content system.

   Note: Depending on the configuration of the Web Content Viewer, resources like resource bundle files or content processor plug-ins might be required. In such cases, the resources must be available on the remote web content server acting as the WSRP Producer.

   Limitations when using WSRP with the Web Content Viewer:

   - Because the concept of pages and web content pages does not exist in WSRP, you cannot use the dynamic link broadcasting feature with web content pages. When you specify how to broadcast links, do not select **Dynamically select a web content page** in the **Broadcast links to** field. Selecting this option has the same effect as broadcasting links to the current page.
   - Web content inline editing for your web content is not supported with WSRP.
   - The use of remote authoring action URLs in your web content is not supported with WSRP.
   - Tagging and rating for web content is not supported with WSRP.
   - Personalization elements are not supported with WSRP. Therefore, you cannot use features that require personalization rules. Examples: content targeting, federated documents, social rendering, and IBM Digital Data Connector (DDC) for WebSphere Portal Express.

   Limitations when using WSRP with the Web Content Viewer with other non-IBM WebSphere Portal WSRP Consumers: The link broadcasting feature of the viewer is not supported for the WSRP Consumers of other vendors. This limitation is because the concept of pages and web content pages does not exist in WSRP. When you specify how to broadcast links, you can select only the option **None**.

   "CORS and remote web content rendering with WSRP and the Web Content Viewer" on page 2071
   Cross-origin resource sharing (CORS) describes a mechanism for supporting requests that a web page sends to a server that is not in the same domain as the originating web page. The CORS concept must be supported by both the web browser and the server.

   "OpenAjax security and remote web content rendering with WSRP and the Web Content Viewer" on page 2073
   The Enabler from the Mashups 3.0.0.1 component that is included in IBM

WebSphere Portal Express as a theme module implements some features that are specified by the OpenAjax Alliance. One of them is a generic override for Dojo XMLHttpRequests

Related concepts:

"Web Content Viewers" on page 2017
Web Content Viewers are portlets that render content from a web content library as part of a portal page. If your presentation is simple, a single viewer can be sufficient. To provide a richer experience for your users, use multiple viewers to aggregate content from different libraries.

"WSRP services" on page 1433
IBM WebSphere Portal Express supports the Web Services for Remote Portlets (WSRP) standard. By using this standard, portals can provide portlets, applications, and content as WSRP services. Other portals can then integrate the WSRP services as remote portlets for their users.

Related tasks:

"Customizing the WSRP resource proxy for LTPA token forwarding" on page 1488
The WSRP resource proxy can forward single sign-on cookies (LTPA, LTPA2) from the client requests to resources in the same single sign-on domain.

"Providing WSRP services as a Producer" on page 1454
After you prepared your portal as a Producer portal, you can provide your portlets through WSRP. Providing portlets makes them available to Consumers. They can integrate them into their Consumer portals and use them as remote portlets. You can also withdraw portlets from being provided through WSRP. Consumer portals can then no longer use them.

"Configuring security on the Consumer portal" on page 1461
You can configure security for the WSRP Consumer. If you enable security, the WSRP Consumer sends a security token as part of the WSRP request message to the WSRP producer. The security token represents the identity of the user who is logged in to the Consumer Portal. The WSRP Producer uses the security token to process the WSRP requests under the user identity that is represented by the security token.

CORS and remote web content rendering with WSRP and the Web Content Viewer:

Cross-origin resource sharing (CORS) describes a mechanism for supporting requests that a web page sends to a server that is not in the same domain as the originating web page. The CORS concept must be supported by both the web browser and the server.

For more information about the CORS support in IBM WebSphere Portal Express, read *Manage CORS in WebSphere Portal Express*.

If you use remote rendering with WSRP and the Web Content Viewer portlet as your web content delivery model, you must make yourself familiar with CORS. In the **Edit shared settings** and **Configure** modes, a consumed Web Content Viewer portlet uses XMLHttpRequests to load information from the remote web content portal. CORS can prevent this remote connection from being successful. Usually, the remote web content portal that acts as the WSRP Producer is in a different domain than the portal with the Web Content Viewer portlet that acts as the WSRP Consumer. Therefore, the Producer portal can reject XMLHttpRequests when you try to configure the consumed Web Content Viewer portlet on your Consumer portal.

Web browsers can implement CORS in different ways or not at all. Therefore, you might experience issues only when you use a specific web browser. In case of such issues, the JavaScript console shows that requests made by the Web Content Viewer portlet result in an error with HTTP status code 403 (Forbidden). Example:
`PROPFIND http://`*`WSRP_CONSUMER_HOSTNAME`*`:`*`WSRP_CONSUMER_PORT`*`/`
`WSRP_CONSUMER_CONTEXT_ROOT``/WsrpProxyPortlet/ResourceProxy/.../`
`WSRP_PRODUCER_CONTEXT_ROOT``/mycontenthandler/dav/content/libraries/ 403 (Forbidden)`

If you experience issues when you use the **Edit shared settings** or **Configure** mode of the consumed Web Content Viewer portlet as described earlier, you can choose one of the following options:

- The best solution is to add the WSRP consumer as a trusted origin to the whitelist of the WSRP Producer. For more information, read *Manage CORS in WebSphere Portal Express*.

  Note: If you choose this option, be aware that you might need to repeat this configuration after you upgrade or migrate your WebSphere Portal Express to a newer version.
- Configure the WSRP resource proxy of the WSRP consumer to prevent it from forwarding the `Origin` HTTP header that CORS uses. If the requests do not contain the header, the remote web content portal does not reject the requests. For more information, read *Customizing the WSRP resource proxy HTTP header forwarding behavior*.

  Note: If you choose this option, make sure that you fully understand the implications of removing the `Origin` HTTP header. The target server treats all requests that are made through the WSRP resource proxy as same-origin requests, even if the target server supports CORS and normally rejects requests from that domain.
- Disable the CORS support of the WSRP Producer portal. To disable CORS, set the property `com.ibm.portal.csrf.enabled` of the portal WP Configuration Service resource environment provider to `false`. Then, restart your portal for the changes to take effect. For details, about how to set portal service configuration properties, read *Setting service configuration properties*.

  Note: If you choose this option, make sure that you fully understand the implications of disabling the CORS support. With disabled CORS support, the portal accepts all cross-origin requests that it rejects if the CORS support is enabled.

Related tasks:

"Customizing the WSRP resource proxy HTTP header forwarding behavior" on page 1490
By default, the WSRP resource proxy forwards all HTTP headers from the client request except for the host header and cookie headers. You can define further headers that you do not want to be forwarded.

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Manage CORS in WebSphere Portal

OpenAjax security and remote web content rendering with WSRP and the Web Content Viewer:

The Enabler from the Mashups 3.0.0.1 component that is included in IBM WebSphere Portal Express as a theme module implements some features that are specified by the OpenAjax Alliance. One of them is a generic override for Dojo XMLHttpRequests

It adds the following extra HTTP request headers:

com.ibm.lotus.openajax.virtualhost
This header specifies the virtual host name that the portal uses to create absolute URLs.

com.ibm.lotus.openajax.virtualport
This header specifies the virtual host port that the portal uses to create absolute URLs.

As a consumed Web Content Viewer portlet uses Dojo XMLHttpRequests in specific situations, those HTTP request headers can cause issues. For example, to configure the portlet to render a web content element remotely, the portlet dynamically loads the elements of the selected web content item from the remote web content portal, that is the WSRP Producer. The corresponding requests include the `com.ibm.lotus.openajax.*` HTTP request headers that are mentioned before. They identify the WSRP Consumer portal that renders the web content as a virtual host. The WSRP resource proxy then uses the virtual host as the target server. As a result, the WSRP resource proxy uses the web content delivery portal (the WSRP Consumer) as the target server instead of the remote web content portal. Eventually, the WSRP resource proxy requests fail with HTTP status code `404 (Not Found)`.

If you experience issues when you configure the consumed Web Content Viewer portlet as described earlier, you can choose one of the following options:

- As the Enabler component implements the override for Dojo XMLHttpRequests, check whether your portal really requires that component. If you find that you do not need any Enabler functions on your web content delivery portal, you can change your theme and theme modules to prevent the `mm_enabler` theme module from being loaded. For more information, read *The module framework*.
- Configure the WSRP resource proxy of the WSRP Consumer to prevent it from forwarding the `com.ibm.lotus.openajax.virtualhost` and `com.ibm.lotus.openajax.virtualport` HTTP headers that are set by the Enabler component. If the headers are not present in the Dojo XMLHttpRequests, the WSRP resource proxy addresses the remote web content portal correctly. For more information, read *Customizing the WSRP resource proxy HTTP header forwarding behavior*.

Related concepts:

"The module framework" on page 2526
The module framework allows extensions to contribute to different areas of a page to provide flexibility, enhance the user experience, and maximize performance.

Related tasks:

"Customizing the WSRP resource proxy HTTP header forwarding behavior" on page 1490
By default, the WSRP resource proxy forwards all HTTP headers from the client request except for the host header and cookie headers. You can define further headers that you do not want to be forwarded.

Advanced administrative examples

You can undertake advanced administration for web content artifacts, such as web content pages and content associations.

"Creating a web content page with the XML configuration interface"
As with other portal pages, you can create a web content page with the XML configuration interface (**xmlaccess** command). Page definition is similar to a standard portal page. However, there is an additional page parameter that specifies the site area that is associated with the web content page.

"Content associations reference" on page 2076
Content associations are used to associate web content pages with your web content site structure. When you select a folder to associate with a web content page, a content association is created and maintained within the portal.

"Dynamic web content page selection" on page 2085
The web content viewer provides a link broadcasting feature that dynamically determines the best web content page to use when rendering the linked content item. To perform this page selection, the viewer uses the content associations on the web content page.

Creating a web content page with the XML configuration interface:

As with other portal pages, you can create a web content page with the XML configuration interface (**xmlaccess** command). Page definition is similar to a standard portal page. However, there is an additional page parameter that specifies the site area that is associated with the web content page.

Procedure

1. When creating your **xmlaccess** command, specify your page parameters as you would for a standard portal page.

   The following block of code is an example of specified page parameters:

   ```
   <content-node action="update" content-parentref="parentOID" domain="rel" objectid="someOID"
   preserve-old-layout="true" type="page">
     <content-mapping-info>
       <content-mapping content-id="/mylibrary2/sitearea2" default="true"
   delegated-access-level="User"/>
       <content-mapping content-id="ddccb7ed-8485-48c8-b875-31d17d9da65b"
   default="false"/>
     </content-mapping-info>
   </content-node>
   ```

   Note: The value of the content-id attribute can be either the ID or the path to the web content item. If you are using the content path, the value must begin with the forward slash character (/) followed by the library name. When creating a web content page using the content path, you cannot build the path from the **Display title** fields of the items in the path. Instead you must use the **Name** fields of the items when specifying the path.

2. Because the web content viewer uses public render parameters to identify the content to render, include the page parameter **param.sharing.scope** when creating your **xmlaccess** command. Set the value for the parameter to `ibm.portal.sharing.scope.page`.

   The following block of code is an example parameter definition for web content pages when using the XML configuration interface:

```
<parameter name="com.ibm.portal.wcm.contentroot" type="string" update="set">
   <![CDATA[/mylib/mysite/mysitearea]]>
</parameter>
<parameter name="param.sharing.scope" type="string" update="set">
   <![CDATA[ibm.portal.sharing.scope.page]]>
</parameter>
```

3. When creating your **xmlaccess** command, add at least one web content viewer that is configured to listen to other portlets and make dynamic broadcasts. Adding the viewer ensures that content selected for this page is rendered correctly and that links between pages work properly.

   The following block of code is an example of how to add the web content viewer using the XML configuration interface:

```
<component action="update" active="true" deletable="undefined" domain="rel"
modifiable="undefined" objectid="7_U796BB1A0OS250IOS7F1BP3081" ordinal="100"
orientation="H" skinref="undefined" type="container" width="undefined">
  <component action="update" active="true" deletable="undefined" domain="rel"
  modifiable="undefined" objectid="7_U796BB1A0OS250IOS7F1BP3085" ordinal="100"
  orientation="V" skinref="undefined" type="container" width="undefined">
    <component action="update" active="true" deletable="undefined" domain="rel"
    modifiable="undefined" objectid="7_U796BB1A0OS250IOS7F1BP3087" ordinal="100"
    skinref="undefined" type="control" width="undefined">
      <portletinstance action="update" domain="rel" objectid="5_U796BB1A0OS250IOS7F1BP3083"
       portletref="3_U796BB1A008OD0IOS2ODAD28U4">
        <preferences name="WCM_BROADCASTS_TO" update="set">
          <value><![CDATA[WCM_LINKING_DYNAMIC]]></value>
        </preferences>
        <preferences name="WCM_LISTENS_TO" update="set">
          <value><![CDATA[WCM_LINKING_OTHER]]></value>
        </preferences>
      </portletinstance>
    </component>
  </component>
</component>
```

   Migration note: After Version 6.1.5, the format used by the XML configuration interface to represent content associations for a web content page has changed. Typically, the migration process automatically converts all existing web content pages to the updated format. However, if you create web content pages on the older portal after migration and then import the pages to the Version 8.5 portal, the page format is incompatible. In this case, you must manually run the `action-migrate-content-mappings` configuration task on the Version 8.5 portal to convert the new web content pages to the Version 8.5 format. To perform the conversion, run the following task from the *wp_profile_root*`/ConfigEngine` directory:

   - Windows: `ConfigEngine.bat action-migrate-content-mappings -DWasPassword=password -DPortalAdminPwd=password`
   - Linux: `./ConfigEngine.sh action-migrate-content-mappings -DWasPassword=password -DPortalAdminPwd=password`
   - IBM i: `ConfigEngine.sh action-migrate-content-mappings -DWasPassword=password -DPortalAdminPwd=password`

Related concepts:

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

"Public render parameters" on page 3070
Public render parameters allow JSR 286 portlets to share navigational state information. They are specially useful for coordinating the multiple navigation or viewer portlets that display different information items that are all related to the same parameter name. The portal stores all portlet render parameters, including public render parameters, as an encoded part of the current portal URL. Therefore, public render parameters are correctly preserved by typical browser navigation actions such as the Back button and bookmarking.

"REST API and content associations" on page 2080
If you are creating or extending an application and want to manage content associations with that application, you can use portal remote APIs. These APIs retrieve a list of content associations and then create, update, or delete associations.

Related information:

 Package com.ibm.portal.services.contentmapping

Content associations reference:

Content associations are used to associate web content pages with your web content site structure. When you select a folder to associate with a web content page, a content association is created and maintained within the portal.

Typically, the management of content associations is automatically handled by the portal. However, for situations where you want to work directly with content associations, several mechanisms are available: the XML configuration interface, the Portal Scripting Interface, and the REST API for content associations.

"XML configuration interface and content associations"
With the XML configuration interface (**xmlaccess** command), you can perform batch updates of content associations or export associations to import into another portal. Content association information is represented in the XML configuration schema by content-mapping-info elements.

"Portal Scripting Interface and content associations" on page 2078
With the Portal Scripting Interface, you can create scripts to automate the management of content associations. Using the ContentMapping bean with the Portal Scripting Interface, you can add, modify, and remove content associations.

"REST API and content associations" on page 2080
If you are creating or extending an application and want to manage content associations with that application, you can use portal remote APIs. These APIs retrieve a list of content associations and then create, update, or delete associations.

Related concepts:

"Web content associations" on page 2023
Web content associations are used to combine portal pages and associated web content items that are managed by IBM Web Content Manager so they can be managed and rendered consistently. Web content associations map portal pages to the site structure in the IBM Web Content Manager system.

XML configuration interface and content associations:

With the XML configuration interface (**xmlaccess** command), you can perform batch updates of content associations or export associations to import into another

portal. Content association information is represented in the XML configuration schema by content-mapping-info elements.

Export content associations

The content associations for a web content page are represented in an XML export file as nested content-mapping-info elements.

The following example represents a web content page with two content associations:

```
<content-node action="update" content-parentref="6_00000000000000000000000000A0" domain="rel"
 objectid="someOID" preserve-old-layout="true" type="label">
  <content-mapping-info>
    <content-mapping content-id="74-11" default="false"/>
    <content-mapping content-id="007" default="true" delegated-access-level="User"/>
  </content-mapping-info>
</content-node>
```

Note: If no content-mapping-info elements are present in an XML export document, there are currently no content associations defined for the web content page.

Import content associations

When importing content associations with an XML import file, associations for a web content page are represented in the content-mapping-info element for the web content page. Any content associations that are already defined for the web content page are removed when you perform the import process and replaced with the new associations.

The following example updates a web content page to have two specific content associations:

```
<content-node action="update" content-parentref="6_00000000000000000000000000A0" domain="rel"
 objectid="someOID" preserve-old-layout="true" type="label">
  <content-mapping-info>
    <content-mapping content-id="74-11" default="false" />
    <content-mapping content-id="007" default="true" delegated-access-level="User"/>
  </content-mapping-info>
</content-node>
```

Note: If no content-mapping-info element is present in an XML import document, no changes are made to the content associations currently defined for the web content page.

Delete content associations

You can delete content associations by specifying an empty content-mapping-info element in the XML import file.

The following example updates a web content page to delete any defined content associations:

```
<content-node action="update" content-parentref="6_00000000000000000000000000A0" domain="rel"
 objectid="someOID" preserve-old-layout="true" type="label">
  <content-mapping-info/>
</content-node>
```

Related concepts:

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

Portal Scripting Interface and content associations:

With the Portal Scripting Interface, you can create scripts to automate the management of content associations. Using the ContentMapping bean with the Portal Scripting Interface, you can add, modify, and remove content associations.

Note: Before a script can work with the ContentMapping bean, you must establish a user session with the portal using the **login** command of the Portal bean. The user identity must have sufficient permissions to administer the web content pages and web content library folders referenced by the script.

Retrieve content associations

To retrieve content association information, use the select method to specify the object ID of the web content page. You can often derive the object ID for a resource from another bean and use that as input for the select method. For example, you might have a web content page with the unique name `my.test.page`. Using the find method of the Content bean, you can determine the object ID of the `my.test.page` page.

Jacl example:

```
$set the_page [$Content find page uniquename "my.test.page"]
$ContentMapping select $the_page
```

Jython example:

```
the_page = Content.find('page','uniquename','my.test.page')
ContentMapping.select(the_page)
```

After you have the object ID of the web content page, you can use the list method and the get methods to access the content associations. The list method returns a list of content association IDs. The IDs can identify either the resource ID of a folder or the content path of the folder, depending on how the page is mapped. You can use the content association IDs returned by the list method as arguments for the get method.

Jacl example:

```
$set the_page [$Content find page uniquename "my.test.page"]
$ContentMapping select $the_page
foreach mid [$ContentMapping list mappings] {
  puts "  Mapping $mid info:"
  puts "  content id: [$ContentMapping get content-id $mid]"
  puts "  default? [$ContentMapping get isdefault $mid]"
  puts "  scope: [$ContentMapping get scope $mid]"
}
```

Jython example:

```
var the_page = Content.find('page','uniquename','my.test.page')
ContentMapping.select(the_page)
for mid in ContentMapping.list('mappings').split():
  print "  Mapping "+mid+" info:"
  print "  content id: "+ContentMapping.get('content-id', mid)
  print "  default? "+ContentMapping.get('isdefault', mid)
  print "  scope: "+ContentMapping.get('scope', mid)
```

The get method can return the default association for the selected web content page. The list method can retrieve a list of scopes that are defined for the associations of the web content page.

Jacl example:

```
$set the_page [$Content find page uniquename "my.test.page"]
$ContentMapping select $the_page
puts "available scopes: [$ContentMapping list scopes]"
puts "default mapping: [$ContentMapping get defaultmapping]"
puts "portal resource OID: [$ContentMapping get oid]"
```

Jython example:

```
var the_page = Content.find('page','uniquename','my.test.page')
ContentMapping.select(the_page)
print "available scopes: "+ContentMapping.list('scopes')
print "default mapping: "+ContentMapping.get('defaultmapping')
print "portal resource OID: "+ContentMapping.get('oid')
```

Add content associations

Use the add method to add new content associations to a web content page. You can assign a content association by specifying the content path of the folder or the ID of folder. If you identify the folder by content path, the association is internally transformed to actually point to the ID of the folder. As a result, if you rename the folder later, the association still points to the same folder.

Jacl example:

```
$ContentMapping select [$ContentNode find page uniquename "my.sample.page"]
$ContentMapping add content-path "/test1/mapping"
set the_content_id  .... ## obtain ID of content to be mapped
$ContentMapping add id $the_content_id
```

Jython example:

```
ContentMapping.select(Content.find('all','un','my.sample.page'))
ContentMapping.add('content-path','/test1/mapping')
var the_content_id = ... ## obtain ID of content to be mapped
ContentMapping.add('id',the_content_id)
```

Remove content associations

The ContentMapping bean provides two methods you can use to remove content associations from a web content page:

remove
: Removes an individual content association, as specified either by the resource ID of the folder or the content path of the folder.

delete Removes all content associations for the web content page.

The following examples demonstrate how to remove the content associations for two web content pages. The content associations of the first page are removed individually with the remove method, and the content associations of the second page are removed with the delete method.

Jacl example:

```
$set the_first_page [$Content find page uniquename "my.test.page"]
$ContentMapping select $the_first_page
foreach mid [$ContentMapping list mappings] {
  $ContentMapping remove $mid
}

$set another_page [$Content find page uniquename "my.second.test.page"]
$ContentMapping select $another_page
$ContentMapping delete
```

Jython example:

```
var the_page = Content.find('page','uniquename','my.test.page')
ContentMapping.select(the_first_page)
for mid in ContentMapping.list('mappings').split():
  ContentMapping.remove(mid)

var another_page = Content.find('page','uniquename','my.second.test.page')
ContentMapping.select(another_page)
ContentMapping.delete()
```

Modify content associations

To modify content associations, use the set method of the ContentMapping bean. You can change the following attributes:

- Default flag
- Delegation mode
- Mapping scope

When calling the set method, pass in the ID of the content association that you want to update.

The following example updates two content associations for the web content page identified by the unique name `my.test.page`. Several settings are specified for the first content association:

- The default flag is set to make this content association the default content association for the web content page.
- The association scope is specified as `_scp_`.
- Page-based access control is turned off by setting the delegation mode to `false`.

For the second content association, the association scope is removed by specifying an empty string.

Jacl example:

```
$ContentMapping select [$ContentNode find page uniquename "my.sample.page"]
set first_m_id [lindex [$ContentMapping list mappings] 0]
$ContentMapping set scope $first_m_id "_scp_"
$ContentMapping set default $first_m_id true
$ContentMapping set delegation $first_m_id false
set second_m_id [lindex [$ContentMapping list mappings] 1]
$ContentMapping set scope $second_m_id ""
```

Jython example:

```
ContentMapping.select(Content.find('all','un','my.sample.page'))
var first_m_id = ContentMapping.list('mappings').split()[0]
ContentMapping.set('scope',first_m_id,'_scp_')
ContentMapping.set('default',first_m_id,'true')
ContentMapping.set('delegation',first_m_id,'false')
var second_m_id = ContentMapping.list('mappings').split()[1]
ContentMapping.set('scope',second_m_id,'')
```

"Portal Scripting Interface" on page 1113
You can use the Portal Scripting Interface to configure your portal by running scripts from a command line.

REST API and content associations:

If you are creating or extending an application and want to manage content associations with that application, you can use portal remote APIs. These APIs retrieve a list of content associations and then create, update, or delete associations.

Based on the Representational State Transfer (REST) architecture, the APIs represent information about content associations as Atom feeds. To perform actions, you send HTTP requests to specific URLs.

Retrieve all content associations

This request returns a feed containing all content associations available in the system.

URL `http://hostname:port/context_root/mypoc?uri=contentmapping:objecttype:CONTENT_NODE&mode=download`

HTTP method
GET

Links Link information is provided for each entry in the Atom feed, as identified by the rel attribute.

Table 329. Link information in the Atom feed for retrieving content associations

Link	Description
rel="self"	Link to this Atom entry.
rel="edit"	Link to this item that can be used for POST, PUT, and DELETE operations.
rel="related"	Link that can be used to view the web content page with which the content association is associated.
rel="first"	Link to the first feed fragment. This link is only served if a feed fragment was served.
rel="last"	Link to the last feed fragment. This link is only served if a feed fragment was served.
rel="previous"	Link to the feed fragment preceding the current feed fragment. This link is only served if a feed fragment was served that does not start at the beginning of the feed.
rel="next"	Link to the next feed fragment. This link is only served if a feed fragment was served that does not contain the last entry of the feed.

Supported URL parameters

Table 330. Supported parameters for requests to retrieve content associations

Parameter	Description
start-index	Identifies the start index of the feed fragment to be served. The default value is `0`.
max-results	Identifies the maximum number of entries to be served by this request, as determined by the configuration of the server.

Retrieve content associations for a specific web content page

This request returns a feed containing the content associations defined for a specific web content page.

URL The web content page is identified either by its object ID or by its unique name.

`http://hostname:port/context_root/mypoc?uri=contentmapping:oid:serialized_object_id`

`http://hostname:port/context_root/mypoc?uri=contentmapping:oid:unique_name`

HTTP method
GET

Links Link information is provided for each entry in the Atom feed, as identified by the `rel` attribute.

Table 331. Link information in the Atom feed for retrieving content associations for a specific web content page

Link	Description
rel="self"	Link to this Atom entry.
rel="edit"	Link to this item that can be used for POST, PUT, and DELETE operations.
rel="related"	Link that can be used to view the web content page with which the content association is associated.

Modify content associations

This request updates the content associations defined for a specific web content page.

URL The web content page is identified either by its object ID or by its unique name.

`http://hostname:port/context_root/mypoc?uri=contentmapping:oid:serialized_object_id`

`http://hostname:port/context_root/mypoc?uri=contentmapping:oid:unique_name`

HTTP method
PUT

Links Link information is provided for each entry in the Atom feed, as identified by the `rel` attribute.

Table 332. Link information in the Atom feed for modifying content associations

Link	Description
rel="self"	Link to this Atom entry.
rel="edit"	Link to this item that can be used for POST, PUT, and DELETE operations.
rel="related"	Link that can be used to view the web content page with which the content association is associated.

Supported URL parameters

Table 333. Supported parameters for requests for modifying content associations

Parameters	Description
update	The following values are supported for the **update** parameter: **merge** This mode merges the content associations in the request with the content associations on the server. The request updates existing content associations and adds new content associations, but the request does not delete other content associations already on the server. **replace** This mode replaces all current content associations on the server with the content associations specified in the request. The request updates existing content associations, adds new content associations, and deletes other content associations on the server that are not represented in the request. **delete** This mode deletes the content association specified in the request from the web content page.

Delete content associations

This request deletes either all content associations for a specific web content page or an individual content association to specific content item.

URL The web content page is identified either by its object ID or by its unique name.

`http://hostname:port/context_root/mypoc?uri=contentmapping:oid:serialized_object_id`

`http://hostname:port/context_root/mypoc?uri=contentmapping:oid:unique_name`

HTTP method
DELETE

Supported URL parameters

Table 334. Supported parameters for requests for deleting content associations for a web content page

Parameters	Description
content	Indicates the content associations to be deleted. If the **content** parameter is not specified, all content associations for the web content page are deleted. If the content ID for a content item is specified as the value of the **content** parameter, only one content association is deleted. The content association deleted is the one that maps the web content page to the specified content item. Any other content associations are unaffected.

Related tasks:

"Creating a web content page with the XML configuration interface" on page 2074
As with other portal pages, you can create a web content page with the XML configuration interface (**xmlaccess** command). Page definition is similar to a standard portal page. However, there is an additional page parameter that specifies the site area that is associated with the web content page.

Dynamic web content page selection:

The web content viewer provides a link broadcasting feature that dynamically determines the best web content page to use when rendering the linked content item. To perform this page selection, the viewer uses the content associations on the web content page.

Understanding dynamic page selection is useful when examining how multiple associations affect link resolution and when troubleshooting why a link is not targeting the expected page.

Dynamic page selection is enabled when the web content viewer is configured to use the **Dynamically select a web content page** link broadcasting option. To render a content item, the dynamically selected target page must contain at least one web content viewer. The viewer must be configured to receive links from other portlets.

When users select a link to a content item, the chain of content page resolution filters runs to determine which page renders the selected item. The same mechanism is used when previewing web content on pages or when selecting search results produced from the search seedlist 1.0 feature. You can control how the page is determined by adding a custom content page resolution filter into this filter chain. For more information, see *Creating a content page resolution filter class.*

The default filter plug-ins perform the following tests to determine a web content page.

1. An ordered list with all parent site areas of the selected content item is created. If the selected item itself is a site area, it is part of that list. The order in the list matches the order in the Web Content Manager content hierarchy. The topmost parent is the last item in the list, and the direct parent of the selected item (or the item itself) is the first item.
2. Based on this ordered list, a lookup is performed to find the web content page with the following criteria:
   - The current user has view access to the page.
   - The page is mapped to the first site area for which a page content association exists.

   If the content associations indicate that multiple pages map equally well, the web content viewer selects a single page using the following rules:

- If the current page is among the pages found, the current page takes precedence over the other results.
- If one of the pages that is indicated by the content associations is the default association for the page, that page takes precedence over other results.
- If the previous rules do not identify a page, a page is selected arbitrarily from the set of found pages.

3. The content item that gets rendered depends on the situation.
   - If a web content page can be determined in the previous test, the selected content item is rendered on this page.
   - If no page can be identified by the content associations, the web content fallback page is used to render the content item.
   - If no fallback page is configured or if the user does not have view rights on the fallback page, the Web Content Manager servlet renders the item.

Related tasks:

"Setting up a web content fallback page" on page 2057
Set up a web content fallback page to be used when a web content viewer cannot determine which page to use to display a content item. The fallback page can also be used when users do not have sufficient privileges to view the page originally associated with the content item.

"Creating a content page resolution filter class" on page 3231
A content page resolution filter is used to customize the behavior of the content page resolution filter chain. This method is used to tailor the response to a web content request in several ways, including overriding the content item that is displayed or the portal page that is used to display a content item in the web content viewer.

Web Content Viewer best practices and limitations

View some best practices and limitations for using Web Content Viewers.

User authentication

User authentication to Web Content Viewers is managed by IBM WebSphere Portal Express and IBM WebSphere Application Server.

Security and WSRP

When you display web content from remote servers by using WSRP and a Web Content Viewer, configure security and authentication between the servers:

- The portal server that acts as the WSRP Consumer
- The web content server that acts as the WSRP Producer

See *Security for WSRP services* for details.

User access to Web Content Manager content and components

Users are able to view only content and components that can be accessed by either a portal user ID or the user of the WSRP Consumer. This access must be defined in Web Content Manager. If a user ID or the user of the WSRP Consumer does not have sufficient rights to view a content or component, errors can occur.

Content and component limitations

Not all content or components that are built in a Web Content Manager solution are suitable for inclusion in a portal page:

- Content or components to be shown within a portal page must be self-contained and not rely on other content or components.
- When you create presentation templates or page styles to use when you display content within a portlet, reference only the content you want to show. Add components like menus and navigators in separate portlets, and link the components to other content portlets as required.
- JavaScript URLs are not supported.

Using JavaScript:

When a web page is rendered by Web Content Manager, some tags might be rewritten. Web Content Manager uses double quotation marks for attributes in HTML tags. If you use JavaScript to produce HTML tags, Web Content Manager does not recognize them if you use single quotation marks.

Other limitations

- The results of a POST operation in a form are only displayed within the portlet that sent the POST. You cannot send the result of a POST to another portlet.
- An anonymous portal user is also considered an anonymous Web Content Manager user, so overriding the log-in does not work for anonymous users.
- If a Web Content Manager proxy server is being used with Web Content Viewers, URLs rewritten by the proxy are not fully qualified. Instead, the URLs are relative to the server. To address this issue, redirect mappings can be created in the HTTP Server configuration that passes the URLs to the proxy server.
- Category selection trees cannot be used with the local Web Content Viewer.
- Only advanced caching can be used with a local Web Content Viewer.
- Tagged web content that is displayed in the Web Content Viewer is only available when there is a single instance of the portlet on the page. When you click a tag result, the Tag Center broadcasts the information about what content to display by using a public render parameter. If you are displaying multiple instances of content in the viewer, the instances show the content that you tagged rather than their original content.

Related tasks:

"Adding existing blogs or blog libraries to a page" on page 2002
If you created a blog or blog library for another page and now want to use it again, add a web content viewer to the new page and edit its settings to point to the existing blog or blog library.

"Adding a blog or blog library to a page" on page 2001
With Editor access to the portal or the portal page, you can add a blog or blog library to a page. Choose a blog to collaborate with your team on a single topic. Choose a blog library to collaborate with your team on multiple topics in a centralized view.

Access web content by using a servlet

Users can access content that is displayed by using the Web Content Manager servlet by connecting to a URL. A servlet delivered website is used when you don't need to use any WebSphere Portal based features such as authoring tools.

Accessing a web page by using a servlet

The following URL structure is used to connect to a web page:

```
http://[HOST]:[PORT]/wps/wcm/connect/[PATH]?srv=
```

Non-ascii characters:

Non-ascii characters cannot be used in the query string section of URLs. For this reason, it is best not to name Web Content Manager items using Non-ascii characters if you plan to use URLs to call Web Content Manager items.

- *[PATH]* can be the path to a site area or content item. This setting must be entered for all types of content, including components. In the case of components, this is the path to the site area or content item that the component is displayed with.
- *srv=* is either *cmpnt* or *page*.

Table 335. Service options

Service option	Details
`srv=cmpnt`	This option retrieves a component either from the component library or from a site area or content item. You must also specify the following: **`source=`** This determines where the component is being sourced from. This is either: • library • sitearea • content **`cmpntname=componentname`** This is the name of the component being retrieved.
`srv=page`	This retrieves a content item. As *srv=page* is returned as default, this can be omitted from the URL. The presentation template to use when displaying this content is specified by adding: `presentationtemplate=library/presentationtemplatename`

Examples:

URL to content:

```
http://[HOST]:[PORT]/wps/wcm/connect/[PATH]
```

Example: `http://host:10039/wps/wcm/connect/sitearea/content`

URL to content with a presentation template defined:

```
http://[HOST]:[PORT]/wps/wcm/connect/[PATH]
?presentationtemplate=[libraryname/presentationtemplatename]
```

Example: `http://host:10039/wps/wcm/connect/sitearea/content?presentationtemplate=library/presentationtemplate`

URL to a library component:

```
http://[HOST]:[PORT]/wps/wcm/connect/[PATH]
?srv=cmpnt&source=library&cmpntname=[componentname]
```

Example: `http://host:10039/wps/wcm/connect/sitearea/content?srv=cmpnt&source=library&cmpntname=component`

URL to a content component:

```
http://[HOST]:[PORT]/wps/wcm/connect/[PATH]
?srv=cmpnt&source=content&cmpntname=[componentname]
```

Example: `http://host:10039/wps/wcm/connect/sitearea/content?srv=cmpnt&source=content&cmpntname=component`

Applying Custom Caching and Expiring Parameters.

Like any other URL request that is made to a Web Content Manager Server, Custom Caching and Expiring parameters can be added to a request. See the topic, "Using Custom Caching" for further information.

Example:

`http://[HOST]:[PORT]/wps/wcm/connect/[PATH]?CACHE=SITE&EXPIRES=REL+9000s`

In this example, the content being retrieved by this URL is saved in the Basic Site Cache, and expired after 9000 seconds (two and half hours).

Pre-rendered delivery

You can pre-render a complete IBM Web Content Manager site into HTML and save it to disk. The pre-rendered site can then be used as your live site and displayed to users that use either Web Content Manager or a web server. You deploy a pre-rendered site when you are not using any WebSphere Portal features and your content is static and is only updated periodically.

Restrictions

- Site areas and content item names cannot contain characters that are considered invalid in file names by the operating system on which you are pre-rendering. For example, on a Windows server, these characters are invalid: `/ \ : * ? " < > |`.
- The path to the content item, including the directory path to which you are pre-rendering (for example, site area/content) cannot exceed the operating system's maximum path length:
  - Windows: 255 characters
  - IBM iLinux: 1024 characters
- The Search component cannot be used in pre-rendered sites.
- The Page navigation component cannot be used in pre-rendered sites.
- Personalization elements can be pre-rendered only if the personalization rule is configured for anonymous access.

Site security

Item security for different users set in an Web Content Manager environment is not transferred to pre-rendered sites. The security for the entire pre-rendered site is based on the `connect.moduleconfig.cacher.rendereruser` property as specified in the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console.

"Pre-render methods" on page 2090
Pre-rendering can be configured to run automatically, or you can manually pre-render a website by using a URL.

"How to access the pre-rendered site" on page 2091
Pre-rendered sites are accessed either through IBM Web Content Manager, or through a web server.

Related concepts:

"Pre-rendering options" on page 425
You can enable pre-rendering so that content can be viewed either through a IBM Web Content Manager application or as a stand-alone site that is accessed through

a web server.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Pre-render methods

Pre-rendering can be configured to run automatically, or you can manually pre-render a website by using a URL.

Administrator access: To pre-render a website, you must have administrator access to the library that contains the site area.

Automatically pre-rendering a website

Pre-rendering can be run according to the cacher settings specified for the **WCM WCMConfigService** service as part of the pre-rendering configuration.

Manually pre-rendering a website

Pre-rendering can also be initiated through the URL interface. For example:

`http://host_name:port_number/wps/wcm/connect?MOD=Cacher&SRV=cacheSite&sitearea=sitearea_name&library=library_name`

Table 336. CacherModule options

Service	Required Parameters	Optional Parameters
SRV=cacheSite Initializes pre-rendering for the site area with a delay as given (in seconds).	`sitearea`=site area name	DELAY=<delay> LIBRARY=<library> **Note:** If no library is specified, the default library is used, as specified by the `defaultLibrary` property in the `WCM WCMConfigService` service.
SRV=flushSiteCache Clears (flushes) the site cache. Deletes all pre-rendered data.	`sitearea`=site area name	LIBRARY=<library> **Note:** If no library is specified, the default library is used, as specified by the `defaultLibrary` property in the `WCM WCMConfigService` service.
SRV=flushPageCache Flushes the page from the site cache. The site area and page are determined from the request URL.		
No SRV specified The CacherModule attempts to retrieve the page from the cache.		

Pre-rendering individual content items

You can also pre-render individual content items by using the following URL:

`http://host_name:port_number/wps/wcm/connect/library_name/site_area_name/content?MOD=Cacher`

Note:

- To pre-render individual content items, the site area that is specified in the URL must either be a site area set in **connect.moduleconfig.cacher.task.siteareas** in the **WCM WCMConfigService** service, or you must have previously manually pre-rendered the site area using "SRV=cacheSite" so that the site area already exists in the location you pre-render to.

Related concepts:

"Pre-rendering options" on page 425
You can enable pre-rendering so that content can be viewed either through a IBM Web Content Manager application or as a stand-alone site that is accessed through a web server.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

How to access the pre-rendered site

Pre-rendered sites are accessed either through IBM Web Content Manager, or through a web server.

Accessing the pre-rendered site through a Web Content Manager application

To enable users to access the pre-rendered site through a Web Content Manager application, specify the `connect.businesslogic.module.default.class` property in the `WCM WCMConfigService` service by using the WebSphere Integrated Solutions Console.

- Property name: `connect.businesslogic.module.default.class`
- Value: `com.aptrix.cacher.CacherModule`

Users can access the site through the following URL:

`http://host_name:port_number/wps/wcm/connect/library_name/sitearea_name`

The *library_name* parameter is optional. If no library is specified, the default library is used, as specified by the `defaultLibrary` property in the **WCM WCMConfigService** service.

Connect tags:

Connect tags are not processed by the CacherModule and are rendered intact. When the pre-rendered page is accessed by a user, only then are the connect tags processed.

Pre-rendering JSP components:

Extended cache support needs to be enabled to support pre-rendering JSP components. This setting is disabled by default. See the Knowledge Centre

topic that is called **Web Content Manager pre-rendering service** for details on how to enable the `prerender.extended.support.enabled` property.

Links to content not yet pre-rendered:
A component, such as a menu, that contains links to content not yet pre-rendered is retrieved by the CacherModule and added to the pre-rendered site. This only applies to content belonging to sites configured to be pre-rendered.

Custom expiring:
Custom caching parameters cannot be used in connect tags and URL requests in pre-rendered sites. "`EXPIRES=`" and "`CONNECTORCACHEEXPIRY=`" can be used to override your server's default basic and data cache settings.

Authoring portlet:
The authoring portlet can still be accessed when the default class is changed from `RendererModule` to `CacherModule` as long as it has not been added to the lists of sites to be pre-rendered.

CacherModule as default:
If using the URL interface when the `CacherModule` is the default, you do not need to specify `?mod=cacher`. Instead, enter the request as follows:

`http://`*`host_name`*`:`*`port_number`*`/wps/wcm/connect?SRV=cacheSite&library=`*`library_name`*`&sitearea=`*`sitearea_name`*

Accessing the pre-rendered site through a web server

If your web server is not used for WebSphere Portal Server, you can configure your web server to map to the following alias and Web Content Manager directories:

Table 337. Alias and directory details

Alias	Directory
/wps/wcm/connect	[ILWWCM_HOME]/ilwwcm/cacher

When using a web server to view a pre-rendered site, the previous directories require execute access.

Users access the site using the following URL:
`http://`*`host_name`*`:`*`port_number`*`/wps/wcm/connect/`*`library_name`*`/`*`sitearea_name`*

Use the following configuration properties in the `WCM WCMConfigService` to change the context of the URLs generated with pre-rendering:

- `connect.moduleconfig.cacher.task.cacherurl`
- `connect.moduleconfig.cacher.task.servletpath`

For example, to set a context of `/sales`, use the following properties:

Cacher URL

- Property name: `connect.moduleconfig.cacher.task.cacherurl`
- Value: `http://${WCM_HOST}:${WCM_PORT}/sales`

Servlet path

- Property name: `connect.moduleconfig.cacher.task.servletpath`
- Value: `/connect`

If your web server is used for both a WebSphere Portal server and accessing the pre-rendered site, you must change the context of the URLs. Any context that starts with the WebSphere Portal server context, `/wps` for example, is redirected to WebSphere Portal server.

Connect tags cannot be used:
Connect tags are not processed by the CacherModule and are rendered intact. When the page is viewed through a web server, connect tags cannot be processed. Therefore, connect tags cannot be used in sites that are to be viewed through a web server.

Pre-rendering JSP components:
The pre-rendering feature cannot be used to pre-render JSP components.

Dynamic elements:
When viewing a pre-rendered site through a web server, any dynamic elements such as menus and navigators are displayed as rendered by the configured CacherModule user, not by the user that is accessing the site. This means personalization cannot be used.

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Rendering modes for web content

CF07

Different presentation templates are created to render web content in different modes to display content in different contexts, such as a web content viewer portlet, or mobile devices.

Render modes

These modes are supported when web content is rendered. You can create separate presentation templates for each type and select them when you create a site area template or content template:

- **Default Presentation Template**: This presentation template is used to render an item within a Web Content Viewer portlet.
- CF07 **Summary Presentation Template**: This presentation template is used when the summary render mode is used to render an item.
- CF07 **JSON Record Presentation Template**: This presentation template is used when the JSON render mode is used to render an item on mobile devices.
- CF07 **XML Document Presentation Template**: This presentation template is used when the XML render mode is used to render an item on mobile devices.
- CF07 **HTML Document Presentation Template**: This presentation template is used when the HTML render mode is used to render an item as a complete web page.

You then select a different presentation template for each rendering mode by clicking **Select Presentation Template** in the **Item Properties** section when you create a site area template or content template.

Defining rendering modes in a URL

You can specify a rendering mode in a URL by adding this parameter to the URL: `renderMode=`*`mode`*

These render modes are predefined: **`summary, json, xml, html`**. You can use the Web Content Manager API to define further render modes.

For example, to specify the URL to use the JSON rendering mode, you might use a URL like this:

`http://`*`myserver:port`*`/wps/wcm/myconnect/`*`mylibrary/mysitearea/mycontent`***`?renderMode=json`**

To specify more than one render mode, use a comma-separated list. For example, to specify the URL to use the JSON rendering mode, or if no JSON presentation template is specified, the XML rendering mode, you might use a URL like this:

`http://`*`myserver:port`*`/wps/wcm/myconnect/`*`mylibrary/mysitearea/mycontent`***`?renderMode=json,xml`**

Vanity URLs

You can associate vanity URLs with portal pages and labels. Vanity URLs are short URLs that people can easily remember. They are shorter than full WebSphere Portal Express URLs. They are sometimes also called marketing URLs. You can publish vanity URLs for marketing campaigns through different channels, such as email or print. This way, you can use vanity URLs to direct customers to a specific portal page or content item. Interested site visitors who want to view your campaign can then remember or copy the short vanity URL and type it into the browser address field.

Business users can create short and arbitrary URLs as vanity URLs. The vanity URLs can point to pages that marketing people can post in ads or magazines. To create vanity URLs, you use the IBM WebSphere Portal Express toolbar. Businesses can provide URLs with the following benefits to their customers and portal site visitors:

- Business users can assign vanity URLs to pages or to content on pages easily and change them frequently, for example, for promotion purposes.
- For site visitors, vanity URLs are self-speaking, short, and easy to remember. Site visitors can easily remember and type vanity URLs.

Technical and usage details about vanity URLs:

- Business and marketing users can easily define and manage vanity URLs by using the portal toolbar. Managing vanity URLs does not require administrator access and use of the portal administration.
- Vanity URLs include the host name and the vanity name. They are part of the metadata of the portal page to which they resolve. However, they are not bound to the hierarchy of the friendly name path.
- WebSphere Portal Express provides a new vanity URL servlet. That servlet is called if a URL contains the portion `host/wps/vanityurl`, followed by a vanity URL segment. For example, in the vanity URL `host/wps/vanityurl/hotnews`, `hotnews` is the vanity URL segment. The servlet resolves the vanity URL segment to the appropriate portal page.
- When a site visitor goes to a vanity URL, this URL does not remain in the browser **URL address** field. Instead, the portal resolves the vanity URL to the full portal page URL and redirects the site visitor to the appropriate portal page.

- Vanity URLs are part of the portal page and are syndicated with the page. They are stored in the portal page site area item. Therefore, to be able to use vanity URLs, you must enable Managed pages.
- You can give a portal page multiple vanity URLs.
- You can use a vanity URL to address one or more specific content items on the page. When a user accesses the vanity URL, the portal shows the page with the content item that you specified.
- You can choose a specific locale for the target page of the vanity URL. When a user accesses the page, the portal shows the page in the locale that you specified. You can also attach multiple locales to a vanity URL. This way, the user can view the page in the preferred language.
- In their ease of use, vanity URLs are similar to friendly URLs. However, unlike friendly URLs, they do not include the portal context. They are also not constructed as a portal navigation path; therefore portal site visitors cannot go to a vanity URL by using the portal navigation.
- You can make your vanity URLs even shorter by using an HTTP server rewrite rule. You can then omit the segment `wps/vanityurl` and reduce the vanity URL to the host name and the vanity URL segment as follows: `host/hotnews`. For more information, read *Providing short vanity URLs*.

Example of a vanity URL for a portal page:

- A portal page can have the following friendly name path: `host/wps/portal/home/products/newandexiciting`.
- You can define a vanity URL segment that is named `coolstuff`. You can then post the following vanity URL to your customers: `host/wps/vanityurl/coolstuff`.
- You can reduce the vanity URL even further by using an HTTP server rewrite rule and then omitting the segment `wps/vanityurl`. You can now give your site visitors the shorter vanity URL: `host/coolstuff`.
- When a user enters the vanity URL in the browser address field, the vanity URL servlet resolves the vanity URL segment to the URL of the appropriate portal page.

Vanity URLs and URL mappings:

URL mappings were deprecated starting with WebSphere Portal Express Version 8.5. Instead, you can now use friendly URLs or Vanity URLs as an alternative to URL mapping. Vanity URLs are similar to URL mappings in that you can define them independent from the page hierarchy. However, the following differences apply between vanity URLs and URL mappings:

- Vanity URLs are managed by business and marketing users by using the toolbar, not by administrators by using the portal administration. This way, vanity URLs are easier to manage than URL mappings.
- Vanity URLs are not bound to the portal page hierarchy. Now, you can have a single path segment for the vanity URL.
- Vanity URLs are managed in Web Content Manager as part of a page. A vanity URL can therefore be part of a project. It can be affected by versioning, workflow and syndication.
- Vanity URLs do not have to contain the URL path segment `/wps/portal`. Additionally, if you use an HTTP server rewrite rule, you can omit the `/wps/vanityurl` segment as well.
- Vanity URLs are attached to pages and do not exist independently from pages.

- Vanity URLs are independent from the portal site and its content taxonomy and hierarchy. In this regard, vanity URLs are similar to URL Mappings, but they do not include the portal context.

If you prefer to use URL mappings, you can continue to use existing URL mappings. You can also reinstall the old URL mapping portlet. You find the installable WAR file for the portlet under `PortalServer/ap/wp.ap.urlmapping/installableApps/urlmapping.war`.

Deciding between vanity URLs and friendly URLs

Depending on your requirements, you can use vanity URLs, or friendly URLs:

- If you want to have a short URL as an entry point to a specific portal page or content item, use a vanity URL.
- If you want to have a friendly URL that your site visitors see when the portal shows the page, use a friendly name.
- If you want to be able to publish the page through the Web Content Manager workflow, use a vanity URL. For example, this URL can be useful for a marketing campaign.
- If you want to address a specific portal page through URL generation tags or APIs, use unique name IDs. For more information, see *URL generation in WebSphere Portal*.

You can create both vanity URLs and friendly URLs for the same portal page.

"URL generation in WebSphere Portal" on page 2835
Generating Portal URLs correctly is one of the most important tasks in programming a WebSphere Portal Express based application. There are several programming tools and techniques available for generating WebSphere Portal Express URLs in custom code. The following section introduces the programming tools available and discusses when it is most appropriate to use each of the tools.

Related tasks:

"Providing short vanity URLs" on page 2101
You might want to make your vanity URLs as short and simple as possible for your customers. You can create vanity URLs that contain only the vanity segment by omitting the string `/wps/vanityurl`. In this case, you must use a web server and define a rewrite rule. If you also use IBM Web Application Bridge, or if you have static files in the root of the HTTP server document directory, adapt the rewrite rule.

Viewing and creating vanity URLs

To view and create vanity URLs, you work with the WebSphere Portal Express toolbar.

Before you begin

To create, update, and delete a vanity URL for a specific page, the user must have editor rights on the page and on the Virtual Resource Vanity_URL.

Procedure

1. From the portal action bar, select **Open the toolbar**.
2. Select **Page**.
3. To view existing vanity URLs for the page, select **General**.
4. To create a new vanity URL for the page, proceed as follows:
   a. Select **Vanity URL**.
   b. Click **New vanity URL**.
   c. To complete the creation of the vanity URL, follow the guidance that is given by the user interface.

How vanity URLs work

Learn about vanity URLs, how they work, and how you work with them.

In a new WebSphere Portal Express Version 8.5 installation, vanity URL support is enabled. If you upgrade your WebSphere Portal Express from a previous version to Version 8.5, vanity URL support is disabled. You can enable and disable vanity URL support as required by using a portal configuration task. For more information, see *Enabling vanity URL support*. For vanity URLs to work, you must also enable managed pages. If vanity URL support is not enabled and a user tries to access a vanity URL, the portal gives a 404 return code.

Vanity URLs are stored as part of the page data on the Web Content Manager portal page site area. When you create a vanity URL, both the vanity URL and the information for resolving the vanity URL is stored in the Vanity URL property of the portal page site area item. This storage method has the following consequences:

- You manage vanity URLs by using the portal toolbar and the Managed Pages features. Therefore, if you want to use vanity URLs, Managed Pages must be enabled. The Managed Pages feature is enabled by default in a WebSphere Portal Express Version 8.5 installation. If you upgrade your portal from a previous version to Version 8.5 and want to use vanity URLs, you must enable Managed Pages.
- Assigning a new vanity URL to a page, or changing or deleting an existing vanity URL in the scope of a project creates a draft of the page.
- To export vanity URL information, you do not use the XML configuration interface (XMLAccess), but the JCR export feature of the portal page site area.

WebSphere Portal Express provides a vanity URL servlet. It resolves an incoming vanity URL request to the appropriate portal page or content item.

You can assign multiple vanity URLs to a page. A vanity URL can have different locales that are attached to it.

Vanity URLs are not included in the portal search seedlist. To provide good ranking for your vanity URL pages with search engines, assign friendly names to those pages. The friendly names are listed in the portal search seedlist. To achieve better search rankings, the portal search seedlist does not list the additional Vanity URLs.

If you have virtual portals, the following rules apply:

- You must assign a vanity URL that is unique across all of your virtual portals.
- The host name of the current virtual portal is used as the host name of the vanity URL. If the virtual portal was defined by using a context path, the host name of the virtual portal context path is used.
- For a vanity URL in the default virtual portal, the host name of that default virtual portal is used as the host name of the vanity URL.

An example process flow of a business user who works with a vanity URL is as follows:

1. You have a shoe shop, and you want to advertise a shoe promotion sale.
2. You have a portal page that has the following friendly URL:
   `http://hostname:port/wps/portal/home/shoe_promotion_page`
3. When you create a vanity URL, you define the vanity URL segment. Example: `shoe-sale`. You can also select from the following options:
   - Portal content item: Use this option to specify a content item on the target page for the vanity URL. When a site visitor accesses the vanity URL, the portal shows the site visitor the page with the content item that you specified.
   - Locale: If you use this option to specify a locale for the target page for the vanity URL. When a site visitor accesses the vanity URL, the portal shows the site visitor the page in the language and locale that you specified.
4. To advertise your shoe sale, insert your vanity URL segment `shoe-sale` into the URL, and add a preceding segment `vanityurl`. The URL now looks as follows:
   `http://hostname/wps/vanityurl/shoe-sale`

   This URL is the vanity URL that you pass out in your advertisements for the shoe sale.
5. When a user accesses the page by using this URL, the portal redirects the user to your shoe sale page under the URL given earlier:
   `http://hostname:port/wps/portal/home/shoe_promotion_page`

   When the portal redirects the user, it also adds state information to the URL. For example, this state information includes information about the portal content and the locale as selected when you created the vanity URL in earlier steps.
6. You can make the vanity URLs shorter by omitting the portal root context `/wps` and the string `/vanityurl`. In this case, you must use a web server and define a rewrite rule. For more information, see *Providing short vanity URLs*. You can then pass out the following URL for your advertising campaign:
   `http://hostname:port/shoe-sale`

When a user accesses this URL, the HTTP server rewrites this URL to the longer URL, and then redirects the user as described before.

Related tasks:

"Enabling vanity URL support" on page 2100
In a new WebSphere Portal Express Version 8.5 installation, vanity URL support is enabled. If you upgrade your WebSphere Portal Express from a previous version to Version 8.5, vanity URL support is disabled. You can enable and disable vanity URL support as required by using a portal configuration task.

"Providing short vanity URLs" on page 2101
You might want to make your vanity URLs as short and simple as possible for your customers. You can create vanity URLs that contain only the vanity segment by omitting the string `/wps/vanityurl`. In this case, you must use a web server and define a rewrite rule. If you also use IBM Web Application Bridge, or if you have static files in the root of the HTTP server document directory, adapt the rewrite rule.

Administering vanity URLs

IBM WebSphere Portal Express provides some configuration tasks. You can use these tasks to administer vanity URL support. You can also configure your IBM HTTP Server so that you can use short vanity URLs.

About this task

Staging vanity URLs to production

A vanity URL is a portal artifact that is stored with the portal page that it targets. Vanity URLs are managed and stored in the Web Content Manager Portal Site library. To stage vanity URLs to production, you stage the IBM Web Content Manager page that the vanity URL targets.

"Enabling vanity URL support" on page 2100
In a new WebSphere Portal Express Version 8.5 installation, vanity URL support is enabled. If you upgrade your WebSphere Portal Express from a previous version to Version 8.5, vanity URL support is disabled. You can enable and disable vanity URL support as required by using a portal configuration task.

"Providing short vanity URLs" on page 2101
You might want to make your vanity URLs as short and simple as possible for your customers. You can create vanity URLs that contain only the vanity segment by omitting the string `/wps/vanityurl`. In this case, you must use a web server and define a rewrite rule. If you also use IBM Web Application Bridge, or if you have static files in the root of the HTTP server document directory, adapt the rewrite rule.

"Configuring the vanity URL preview link" on page 2103
The user interface for managing vanity URLs has a preview link. By default, this link shows the full vanity URL. If you installed an HTTP server and configured it to allow short vanity URLs, you can configure the preview link to show the short vanity URL instead.

"Synchronizing the vanity URL database" on page 2104
Vanity URLs are stored as part of the page in the JCR database in the portal page site area of Web Content Manager. For performance reasons, the data is also stored in the WebSphere Portal Express database. When the data is modified, the portal synchronizes the data between both sides. However, under certain circumstances it can happen that the data is not synchronized. For such cases, the portal provides a configuration task that synchronizes the data.

"Setting an error URI for undefined vanity URLs" on page 2105
You can configure how the portal behaves if a user tries to access an undefined vanity URL.

Related concepts:

"Syndication and staging" on page 2503
You can use syndication to update content that was originally created by deploying portal solution releases with either the XML configuration interface or through a Portal Application Archive (PAA) file. You can also set up syndication between virtual portals or primary portals on the same system or between virtual portals on different systems.

Enabling vanity URL support

In a new WebSphere Portal Express Version 8.5 installation, vanity URL support is enabled. If you upgrade your WebSphere Portal Express from a previous version to Version 8.5, vanity URL support is disabled. You can enable and disable vanity URL support as required by using a portal configuration task.

About this task

If vanity URL support is not enabled and a user tries to access a vanity URL, the portal gives a 404 return code.

Note: For vanity URLs to work, managed pages also must be enabled as a prerequisite. For more information, read *Enabling managed pages after migration*. If you disable managed pages, this step also disables vanity URLs. If you do not disable vanity URLs and you enable managed pages again, vanity URLs also work again.

Enabling vanity URL support

To enable vanity URL support, you use the configuration task **enable-vanityurl-support**. This task sets a new custom property in the Resource Environment Provider of the WP Configuration Service. The property name is **vanityurl.support.enabled**. When you run the configuration task, the property is set to the value `true`.

Note: It is mandatory to enable managed pages to have vanity URLs enabled. If managed pages support is not enabled, the task **enable-vanityurl-support** fails. In this case, run the task **enable-managed-pages** first.

Disabling vanity URL support

To disable vanity URL support, you use the configuration task **disable-vanityurl-support**. This task deletes the custom property **vanityurl.support.enabled** from the Resource Environment Provider of the WP Configuration Service. If the portal then receives a request to serve a vanity URL, it gives a 404 return code.

Syntax

You call these configuration tasks as follows:

IBM i

Enable: `ConfigEngine.sh enable-vanityurl-support -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*

Disable: `ConfigEngine.sh disable-vanityurl-support -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*

Linux

Enable: `./ConfigEngine.sh enable-vanityurl-support -DPortalAdminPwd=password -DWasPassword=password`

Disable: `./ConfigEngine.sh disable-vanityurl-support -DPortalAdminPwd=password -DWasPassword=password`

Windows

Enable: `ConfigEngine.bat enable-vanityurl-support -DPortalAdminPwd=password -DWasPassword=password`

Disable: `ConfigEngine.bat disable-vanityurl-support -DPortalAdminPwd=password -DWasPassword=password`

Remember: After you run the **enable-vanityurl-support** or **disable-vanityurl-support** task, restart the server. Go to "Starting and stopping servers, deployment managers, and node agents" on page 1216 for specific instructions.

Related tasks:

"Enabling managed pages" on page 376
By default, support for managed pages is enabled for the default virtual portal. However, you can also manually enable this support if managed pages are disabled.

"Enabling managed pages" on page 913
After migration, you must manually enable support for managed pages. Without managed pages support, some features like the project menu are not available on the migrated server.

Related reference:

"Troubleshooting pages" on page 1741
When you work with pages, you might encounter problems that are related to projects, access rights, or other issues.

Providing short vanity URLs

You might want to make your vanity URLs as short and simple as possible for your customers. You can create vanity URLs that contain only the vanity segment by omitting the string `/wps/vanityurl`. In this case, you must use a web server and define a rewrite rule. If you also use IBM Web Application Bridge, or if you have static files in the root of the HTTP server document directory, adapt the rewrite rule.

About this task

Example: You advertise your shoe sale by using the short vanity URL `http://hostname/shoe-sale`. The HTTP server rewrites this URL to `http://hostname/wps/vanityurl/shoe-sale`. The portal then redirects the user to `http://hostname/wps/portal/home/shoe_promotion_page`.

To be able to use such short vanity URLs, you must use a web server. For details about using a web server with your portal, see the topic about Preparing a remote web server for your environment in this portal product documentation.

Procedure

If you use the IBM HTTP Server as your web server, modify the file `httpd.conf` to define the rewrite rule. Proceed by the following steps:

1. Open the file `httpd.conf` with an editor.
2. Activate the following modules:

```
proxy_module
proxy_http_module
rewrite_module
```

3. Activate the rewrite engine by adding the following line:

   ```
   RewriteEngine   On
   ```

4. Add the rewrite rule by adding the following line:

   ```
   RewriteRule ^/([^/]+)$              /wps/vanityurl/$1        [P]
   ```

   This rule redirects all single path requests to the vanity URL servlet. The `P` flag at the end of the line tells the rewrite engine to use a proxy request. This flag is required for the IBM WebSphere Application Server plug-in to handle the request without an extra redirect.

5. Optional: If your website editors work in projects and you want them to be able to use short vanity URLs by the HTTP server, you need an extra rewrite rule as follows:

   ```
   RewriteRule     ^/\$project/([^/]+)/([^/]+)$             /wps/vanityurl/\$project/$1/$2        [
   ```

   This rule rewrites all URLs that start with `/$project/`*`project name`*`/`*`vanity name`*.

6. Optional: The rules that are given in the previous steps might prevent static files in the document directories of your HTTP server from being served. To have them served, add conditions before the rewrite rule as in the following example:

   ```
   RewriteCond     %{DOCUMENT_ROOT}%{REQUEST_FILENAME}     !-f
   RewriteCond     %{DOCUMENT_ROOT}%{REQUEST_FILENAME}     !-d
   RewriteCond     %{DOCUMENT_ROOT}%{REQUEST_FILENAME}     !-l
   ```

   In this example, `f` means file, `d` means directory, and `l` means symbolic link. With these conditions added, the portal does not apply the rewrite rule on requests that match a file, directory, or symbolic link. The user accesses the file, directory, or link and is not redirected to the target website of the vanity URL. For more information, see the information under *Apache Module mod_rewrite*.

   Note: Depending on your environment, it is good practice not to use periods in your vanity URLs to avoid conflicts with files in the HTTP server context root.

7. Optional: If you use Web Application Bridge, add a rewrite rule to avoid namespace conflicts. Web Application Bridge must be mapped to the root context. As a result, vanity URLs and Web Application Bridge are in the same namespace, which can result in conflicts. Therefore, if you use Web Application Bridge, you might also define a more specific rewrite rule than the rule given earlier. Example:

   ```
   RewriteRule ^/([^/\.]+)$             /wps/vanityurl/$1        [P]
   ```

   With this rewrite rule, the portal redirects only names that consist of only one segment and contain no periods. This rewrite rule avoids conflicts with file names, such as `shoe_sale.html`. For project work, modify the rule as required.

8. Optional: If required, configure the preview link in the vanity URL user interface to show the short vanity URL. The user interface for managing vanity URLs has a preview link. By default, this link goes directly to the vanity servlet, and the portal shows the full vanity URL, for example `http://`*`hostname`*`/wps/vanityurl/shoe-sale`. You can configure the preview link to point to the HTTP server instead, which shows the short version of the vanity URL. To configure the preview link target, you use the portal

configuration task `enable-vanityurl-httpserver-preview`. For more information, see *Configuring the vanity URL preview link*.

Related concepts:

"Integrating with web applications" on page 977
The web application bridge uses reverse proxy technology to integrate web-based content providers, such as the Microsoft SharePoint server, with IBM WebSphere Portal Express. Administrators must first define the virtual web applications or content providers. A lightweight iFrame portlet renders the content from the backend applications. Users can then access the iFrame on a page without requiring direct network access to the backend application. A special engine maps Uniform Resource Identifier (URIs) on the iFrame portlet to real URIs from the content providers.

Configuring the vanity URL preview link

The user interface for managing vanity URLs has a preview link. By default, this link shows the full vanity URL. If you installed an HTTP server and configured it to allow short vanity URLs, you can configure the preview link to show the short vanity URL instead.

About this task

By default, the preview link points directly to the vanity URL servlet. Example:

`http://hostname/wps/vanityurl/shoe-sale`

If you installed an HTTP server and configured it to allow short vanity URLs, you can configure the preview link to point to the HTTP server instead. It then shows the short vanity URL, for example as follows:

`http://hostname/shoe-sale`

You switch between these two options by using the appropriate portal configuration tasks:

- If you want the preview link to point to the HTTP server, run the portal configuration task **en**`able-vanityurl-httpserver-preview`.
- If you want the link to go to the vanity servlet and show the full vanity URL, run the portal configuration task **dis**`able-vanityurl-httpserver-preview`. This setting is the default.

The syntax for these configuration tasks is as follows:

IBM i

```
ConfigEngine.sh enable-vanityurl-httpserver-preview
-DPortalAdminPwd=password -DWasPassword=password

ConfigEngine.sh disable-vanityurl-httpserver-preview
-DPortalAdminPwd=password -DWasPassword=password
```

Linux

```
./ConfigEngine.sh enable-vanityurl-httpserver-preview
-DPortalAdminPwd=password -DWasPassword=password

./ConfigEngine.sh disable-vanityurl-httpserver-preview
-DPortalAdminPwd=password -DWasPassword=password
```

Windows

```
ConfigEngine.bat enable-vanityurl-httpserver-preview
-DPortalAdminPwd=password -DWasPassword=password

ConfigEngine.bat disable-vanityurl-httpserver-preview
-DPortalAdminPwd=password -DWasPassword=password
```

Related tasks:

"Providing short vanity URLs" on page 2101
You might want to make your vanity URLs as short and simple as possible for your customers. You can create vanity URLs that contain only the vanity segment by omitting the string `/wps/vanityurl`. In this case, you must use a web server and define a rewrite rule. If you also use IBM Web Application Bridge, or if you have static files in the root of the HTTP server document directory, adapt the rewrite rule.

Synchronizing the vanity URL database

Vanity URLs are stored as part of the page in the JCR database in the portal page site area of Web Content Manager. For performance reasons, the data is also stored in the WebSphere Portal Express database. When the data is modified, the portal synchronizes the data between both sides. However, under certain circumstances it can happen that the data is not synchronized. For such cases, the portal provides a configuration task that synchronizes the data.

About this task

For example, if the JCR database on the Web Content Manager side is restored, but the portal database is not restored, the data is not synchronized any more. The configuration task for synchronizing the data is `sync-vanityurl-data`. It reads the data that is stored in Web Content Manager and updates the WebSphere Portal Express database.

Syntax

You call the task as follows:

IBM i

```
ConfigEngine.sh sync-vanityurl-data -DPortalAdminPwd=password
-DWasPassword=password
```

Linux

```
./ConfigEngine.sh sync-vanityurl-data -DPortalAdminPwd=password
-DWasPassword=password
```

Windows

```
ConfigEngine.bat sync-vanityurl-data -DPortalAdminPwd=password
-DWasPassword=password
```

Extra parameters:

You can specify the following parameters with this task. Each individual parameter requires the prefix `-D` on the command.

`RunParallel = (false)|true`

Use this parameter to specify whether you want the task to run with multiple threads or not. If you want the task to run in a single thread, specify the value `false`. This value is the default value. If you want the task to run with multiple threads, specify the value `true`. Each thread requires a database connection.

Parameters for virtual portals:

If you have virtual portals, the portal applies this configuration task to all virtual portals by default. To limit the task to a specific virtual portal, you identify the virtual portal by adding one of the following parameters to the command. Each individual parameter requires the prefix `-D` on the command.

`VirtualPortalHost`

Use this parameter to specify the host name of the virtual portal. For example, the host name can be `vp.example.com`.

Note: You can specify the `VirtualPortalHost` parameter alone only if the host name is unique. If the host name of the virtual portal is the same as the host name of the default virtual portal, you must also specify the `VirtualPortalContext` parameter.

`VirtualPortalContext`

Use this parameter to specify the virtual portal context that identifies the virtual portal. For example, the context can be `vp1`.

Example:

```
./ConfigEngine.sh sync-vanityurl-data
                  -DPortalAdminPwd=password -DWasPassword=password
                  -DVirtualPortalHost=vp.example.com
```

Setting an error URI for undefined vanity URLs

You can configure how the portal behaves if a user tries to access an undefined vanity URL.

About this task

The vanity URL servlet resolves the appropriate portal page or content item according to the incoming vanity URL. In a request to an undefined vanity URL, this servlet responds by either of the following two ways:

- It sends a 404 return code.
- It redirects the user to a defined error URI. You can configure this error URI by using a portal configuration task.

The configuration task for configuring an error URI for vanity URLs is `set-vanityurl-error-uri`. It sets a new custom property in the Resource Environment Provider of the WP ConfigService. The property name is `vanityurl.error.uri`. Calling the configuration task sets the value for this property. If the property is not set in the Resource Environment Provider and a user requests an undefined vanity URL, the portal sends a 404 return code.

Syntax

You call the task as follows:

IBM i

```
ConfigEngine.sh set-vanityurl-error-uri
-DPortalAdminPwd=password -DWasPassword=password
```

Linux

```
./ConfigEngine.sh set-vanityurl-error-uri
-DPortalAdminPwd=password -DWasPassword=password
```

Windows

```
ConfigEngine.bat set-vanityurl-error-uri
-DPortalAdminPwd=password -DWasPassword=password
```

Extra parameters:

If you want the vanity URL to redirect the user to an error URI, you must specify the following parameter with this task. It requires the prefix `-D` in the command.

ErrorURI = *URI_for_redirect*

If the vanity URL of the request is not defined, the vanity URL servlet redirects the requests to the URI specified here. If the value for the parameter is the empty string and the vanity URL of the request is undefined, the portal sends a 404 return code.

Example:

```
./ConfigEngine.sh set-vanityurl-error-uri
                  -DPortalAdminPwd=password -DWasPassword=password
                  -DErrorURI=cm:oid:ibm.portal.Home
```

The error URI specified in this example redirects the user to the portal home page.

Social rendering

IBM WebSphere Portal Express page editors can use social rendering to feature social data that is hosted on a remote IBM Connections server in the context of portal pages.

Page editors can create web content items that represent lists of social objects and detail views for individual social objects. A list of social objects shows the results of a specific query for social data from Connections. For example, the list can

consist of specific blog posts, files, or discussion topics. A detail view shows detailed information about a specific social object.

Page editors can control the visual appearance of the social data that is displayed on your portal pages. They do so by selecting the formatting component of choice from a predefined, yet extensible set of formatting components. These components are also called appearance components.

Site designers create the appearance components by using the IBM Web Content Manager Authoring portlet. They define them in a style that is consistent with your portal pages. The appearance component concept provides a clear separation between the following two roles:

- Website designers who define the corporate appearance of your website and deliver the appearance components to your page editors
- Page editors who build your portal pages by assembling the appropriate set of components and content to a meaningful context for your site visitors.

With this concept, your page editors do not need to know the markup generation and CSS styling details of the appearance components. Even without that knowledge they can still choose from a rich, but consistent set of visual designs for your social data.

To control the social data that is displayed on your portal pages, your page editors use inline editing on the underlying social rendering content items. The social rendering content items are also referred to as view definitions. They combine both the selection logic that defines which social objects are displayed and the appearance component selection that controls the visual representation of the data. For example, they can show the most recent blog entries that are created in the Connections community to which the current page is associated. Page editors can select individual view definitions from a set of predefined view definitions and drop them onto portal pages. When a page editor drops a view definition onto a portal page, the view definition is copied to the page. The page editor can then modify it independently of other view definitions on the same page or other pages.

As a result, with social rendering the social data displayed on your portal pages is fully controlled by Web Content Manager. The appearance components define the visual appearance by which the social data is rendered on the page. The view definition content items define which data is selected and which appearance component is used to visualize the data. This way, you control the social data that is rendered on your portal pages in the same way as other web content. Social rendering includes support for projects, versioning, workflows, and syndication.

Social rendering provides you the following components:

- The following set of view definitions for social lists:
  - List of Blog Posts
  - List of Communities
  - List of Community Events
  - List of Community Forum Topics
  - List of Community Blog Posts
  - List of Community Content
  - List of Community Files
  - List of Files
  - List of Forum Topics

  - List of People
- A view definition for forum topic details named Forum Topic Details
- Two appearance components for visualizing the social lists in two different ways:

  Simple:
  A condensed simple list design

  Comprehensive:
  A comprehensive list design
- Two appearance components for visualizing the details of an individual forum topic:

  Forum Topic Details:
  An appearance component for visualizing the detailed information about the topic itself

  Replies
  An appearance component for visualizing the nested thread of replies for the forum topic.
- A set of DDC list-rendering profiles. You can use them to extend social rendering. They are based on the IBM Digital Data Connector (DDC) for WebSphere Portal Express.

You can use these view definitions and appearance components as starting points for creating your own solution. Do not modify the view definitions and appearance components that WebSphere Portal Express provides, but copy them and modify the copies.

To use social rendering, you need to set up your WebSphere Portal Express for integration with Connections.

"Roadmap: How to work with social rendering" on page 2109
Before you can use social rendering in your IBM WebSphere Portal Express, you need to set up IBM Connections integration. After you do that, your users can start working with the default view definitions that social rendering provides. You might want to configure and customize the social data that is rendered on your portal pages for your site visitors. In this case, you can configure and administer social rendering as required for your portal. You can also customize the view definitions, or create your own custom appearance components.

"Working with lists of social objects" on page 2110
You can design lists of social objects in different ways that are related to their content, visual design, and other characteristics. You can also use the IBM WebSphere Portal Express Tag Cloud portlet in combination with your lists of social objects, so that your site visitors can navigate social data based on tags. These tasks are usually done by page editors.

"Configuring global settings for social rendering" on page 2121
You can apply some global configuration settings to social rendering. These global settings apply to all social lists in your WebSphere Portal Express.

"Administering social lists" on page 2131
You can administer several aspects of social lists. For example, you can add your own social lists to the content shelf, or you can tune the social object caches for performance.

"Customizing view definitions for portal site visitors" on page 2136
You can customize social rendering view definitions in a number of ways. For example, you can determine the social data that is shown and the visual appearance of the data. You customize social rendering by working with the

social list definition authoring template. For custom view definitions, you can also create your own authoring templates.

"Adding widgets to a community" on page 2235
As an owner of an IBM Connections community, you can define the set of widgets that are available in the community. For this purpose, you use the Customize option in Connections. For example, you might choose to add the Blog widget to a specific community. This way, community owners have control over the set of services available in the communities they own.

"Extending social lists by using the digital data connector" on page 2236
The social rendering feature in IBM WebSphere Portal Express Version 8.5 is implemented as a IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

Related concepts:

"IBM Digital Data Connector (DDC) for WebSphere Portal Express" on page 3255
You can use the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework to integrate data from external data sources on your portal pages by using IBM Web Content Manager presentation components. External data means that the data does not need to be stored directly in IBM Web Content Manager. For example, you can use DDC to render social data that you have on your IBM Connections server or on other social platforms in the context of your portal pages. Other possible data sources include news feeds, task lists, product catalog information, to name just a few.

Related reference:

"Digital Data Connector profiles for social rendering" on page 2147
Starting with Version 8.5, IBM WebSphere Portal Express includes a set of IBM Digital Data Connector (DDC) for WebSphere Portal Express profiles. You can use them with the social rendering DDC plug-in that is identified by the extension ID `ibm.portal.ddc.sr`.

Roadmap: How to work with social rendering

Before you can use social rendering in your IBM WebSphere Portal Express, you need to set up IBM Connections integration. After you do that, your users can start working with the default view definitions that social rendering provides. You might want to configure and customize the social data that is rendered on your portal pages for your site visitors. In this case, you can configure and administer social rendering as required for your portal. You can also customize the view definitions, or create your own custom appearance components.

To go the fast path of using social lists, proceed as follows:

1. Set up Connections integration.
2. If you want to use the Forum Topic Details view, you must also install the Connections page resolver component.
3. You can now work with the default social lists immediately. Read the tasks that are listed under *Working with lists of social objects*. These tasks are done by a page editor or by site visitors.

To go the advanced path of working with social lists, proceed as follows:

1. Set up Connections integration.
2. If you want to use the Forum Topic Details view, you must also install the Connections page resolver component.
3. You can now work with the default social lists immediately. Read the tasks that are listed under *Working with lists of social objects*. These tasks are done by a page editor or by site visitors.

4. To configure social rendering in your portal, read *Configuring global settings for social rendering*. These tasks are done by an administrator.
5. To administer social rendering, read *Administering social lists*. These tasks are done by an administrator.
6. To customize your social rendering view definitions and appearance components, read *Customizing social lists for portal site visitors*. These tasks are done by a website designer.
7. To enable your page editors to create your own social lists, read *Creating custom authoring templates for social lists*. This work task is done by a website designer.

Working with lists of social objects

You can design lists of social objects in different ways that are related to their content, visual design, and other characteristics. You can also use the IBM WebSphere Portal Express Tag Cloud portlet in combination with your lists of

social objects, so that your site visitors can navigate social data based on tags. These tasks are usually done by page editors.

About this task

"Concept of the lists of social objects provided with the social rendering feature"
The social rendering feature provides you with a set of predefined lists view definitions and a detail view definition for forum topic details.

"Using the view definitions provided with social rendering on your portal pages" on page 2115
The social rendering feature provides you with a set of predefined view definitions. You can add them to the pages of your WebSphere Portal Express and modify them according to your requirements. For example, you can define which types of social objects are listed, how they are filtered, sorted, and presented. These tasks are done by a page editor.

"Using social lists with your own custom theme" on page 2117
The social lists that social rendering provides work with portal pages that have the Portal 8.5 theme with a Basic Content theme profile. To use them with your own custom theme, you add the `wp_social_rendering_85` theme module to your theme.

CF03 "Configuring a page with lists of social objects for Tag Cloud support" on page 2117
Learn how to enable Tag Cloud portlet support on your portal page. You can enable Tag Cloud support if you are using a default portal theme profile or a custom portal theme profile.

"Using the portal Tag Cloud with lists of social objects" on page 2118
To get the most benefit from social rendering together with tagging, you can put the WebSphere Portal Express Tag Cloud portlet on pages that contain social lists. This way your site visitors can reduce the contents of social lists by selecting individual tags from the tag cloud. The list of social objects is then restricted to content items that are tagged with the tag or tags that the user selected.

Related tasks:

Integrating with IBM Connections
Connections portlets give IBM WebSphere Portal Express users access to additional collaboration and social networking features such as Activities, Blogs, and Bookmarks. Users can also view Connections business card information and tags and link to Connections features directly from the portal server.

"Enabling remote rendering with WSRP and the Web Content Viewer" on page 2069
To display web content on a portal that does not include IBM Web Content Manager, you can use the Web Content Viewer and the WSRP support in the portal. The Web Content Viewer can then retrieve and display content from a web content system on a different server.

Concept of the lists of social objects provided with the social rendering feature

The social rendering feature provides you with a set of predefined lists view definitions and a detail view definition for forum topic details.

The lists of social objects are defined by web content items of content type Social List Definition. The following lists are available after you installed IBM WebSphere Portal Express:

- List of Blog Posts
- List of Communities
- List of Community Events
- List of Community Forum Topics
- List of Community Blog Posts
- List of Community Content
- List of Community Files
- List of Files
- List of Forum Topics
- List of People

These list definitions define individual queries against the search service of the remote IBM Connections server. The specific queries for the individual list definitions are built based on the element data that is contained in those content items. In addition to the query, the content items also hold the reference to the list appearance component responsible for transforming the query result data into visual markup.

The lists generate a visual enumeration of social objects that are relevant in the specific context of a portal page. For example, these social objects can be all recent blog posts that are tagged with a specific tag. To see a detail view of a social object, a site visitor can click the link that is rendered for the item in the list. The process of bringing up this details view is called social object resolution. You can choose between the following options for resolving a social object that a user clicks:

- Taking the user to a portal page where the social object details are rendered by a social rendering detail view
- Taking the user to a portal page where the social object details are rendered by a Connections portlet
- Taking the user to the details view for the social object in the Connections user interface.

The resolution process can be controlled by various concepts described in *Configuring globally how social object links are resolved*.

In contrast to social list view definitions, social rendering detail view definitions render detailed information about a single social object. For example, such detail information can be the full body text and the nested thread of replies for an individual forum topic. Additionally, the details view typically also renders user interfaces that allow interactions with the social object, such as form fields by which site visitors can post new replies. WebSphere Portal Express Version 8.5 provides a social rendering details view definition for forum topics named Forum Topic Details.

You can create more list and details view definitions as extensions within the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

"Social object resolution" on page 2113
When a portal user clicks a link to an object, the portal takes the user to the details view of that object. This process is called social object resolution. For example, a user might click a specific forum topic that is listed in the Community Forum Topics list. In this case, the social object resolution takes the user to a portal page that provides a details view of the forum topic that the user clicked. You can influence the result of the resolution that the user views by setting various parameters. These parameters are described here.

Related concepts:

"IBM Digital Data Connector (DDC) for WebSphere Portal Express" on page 3255
You can use the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework to integrate data from external data sources on your portal pages by using IBM Web Content Manager presentation components. External data means that the data does not need to be stored directly in IBM Web Content Manager. For example, you can use DDC to render social data that you have on your IBM Connections server or on other social platforms in the context of your portal pages. Other possible data sources include news feeds, task lists, product catalog information, to name just a few.

Related tasks:

"Configuring globally how social object links are resolved" on page 2127
You can include one or many attributes of social objects in the design component that defines the visual design of your social list. Among other features, social objects have different resolvable links that enable users to open details views of the social objects or the community to which the social objects belong. If you plan to add these links to your social list, you can decide how you want the social objects and their home community to be resolved when users click the corresponding links. IBM WebSphere Portal Express can either resolve the links in the context of the portal itself, or redirect the user to the IBM Connections user interface. You can globally configure how these types of links of social objects are resolved for the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Social object resolution:

When a portal user clicks a link to an object, the portal takes the user to the details view of that object. This process is called social object resolution. For example, a user might click a specific forum topic that is listed in the Community Forum Topics list. In this case, the social object resolution takes the user to a portal page that provides a details view of the forum topic that the user clicked. You can influence the result of the resolution that the user views by setting various parameters. These parameters are described here.

The social object resolution process is implemented by the connections resolver that is contained in the IBM Connections Portlets for IBM WebSphere Portal Express. To enable social object resolution, you need to install this resolver first.

The resolution result for a specific social object depends on the following parameters:

1. The type of link that points to the social object. This link can be either of the following two types:
   - A portal URL. In this case, the link is called a POC (piece of content) link.
   - An Connections URL.
2. The resolution root page parameter that is defined in your view definition.
3. Whether the social object is contained in a community or not, and if it is contained in a community, which community that is.
4. The type of object that the user clicked, for example whether it is a forum topic or a blog post.

The type of link that points to the social object determines the resolution outcome as follows:

Connections URL:

If the link to the social object is an Connections URL, the social object

resolution process is not triggered. Instead, the user is taken directly to the corresponding Connections user interface that shows the details of the object that the user clicked. You can set the portal-wide default type for your social object links in the portal configuration. For more information about how to do so, read *Configuring globally how social object links are resolved*. You can always overrule that default in your appearance components by using the `[AttributeResource attributeName=""]` tag as follows:

- To generate default links to the current social object, specify `[AttributeResource attributeName="link"]`.
- To generate a WebSphere Portal Express type link, specify `[AttributeResource attributeName="portalLink"]`.
- To generate an Connections type link, specify the `[AttributeResource attributeName=rawLink]`.

WebSphere Portal Express URL:

If the link to the social object is a WebSphere Portal Express URL, the connections resolver starts the social object resolution. It evaluates this process in the following three phases:

1. Determine the set of candidate pages
2. Determine the appropriate page from the set of candidate pages
3. Determine the final fallback resolution target for the case that the resolver finds no matching page from the set of candidate pages.

The connections resolver determines the candidate pages based on the resolution root page parameter and the ID of the community that contains the social object. You can specify the resolution root page parameter in the social list definition authoring template by using the element Custom Resolution Root Page. For more information, read *Customizing list view definitions by using inline editing*. You can use the resolution root page parameter to identify a specific portal page by using its custom unique name. To identify the current portal page that renders the current view definition, you can also use the value `current`. If you identify a portal page by using the resolution root page parameter, the connections resolver considers the identified page and all of its descendant pages to be candidate pages for the current social object resolution process.

Note: The value of the resolution root page parameter is passed to the connections resolver as a root page URL parameter. If the resolution root page parameter is not set and the social object belongs to a community, the connections resolver considers all portal pages that are associated with this community to be candidate pages. For more information, read *Managing community associations*.
If the set of candidate pages is not empty, the social object resolution process tries to determine the appropriate page from the set of candidate pages. To do so, it searches the candidate pages for a page that contains a suitable viewer portlet that matches the type of the social object that is to be resolved. Whether a portlet entity can render a detail view for a specific social object is determined based on specific portlet preferences. For example, the drag-and-drop configuration for the Forum Topic Details view definition sets the portlet preference `IC_Forums.topic=true` to indicate that this portlet can render a detail view for a forum topic. For a full list of the supported portlet preferences, read *Connections Portlets for WebSphere Portal Express*.

If the connections resolver finds no candidate page or candidate page that contains a suitable viewer portlet, the portal takes the user to the default page for the social object that the user clicked. To identify the default pages for specific types of social

objects, you assign those pages-specific unique names. For example, the default name for identifying the default page for social objects that are served by the Forums service is `ibm.conn.forums`. An administrator can change the default unique names. For more information, read *Connections Portlets for WebSphere Portal Express: Configuring unique names*.

If the connections resolver does not find the default page, the final fallback is either to redirect the user to a defined portal error page or to take the user to the details view in the Connections user interface. An administrator can control this behavior by running the portal configuration tasks `disable-poc-redirect-to-connections` or `enable-poc-redirect-to-connections`. For more details about the social object resolution, read *Connections Portlets for WebSphere Portal Express: IBM Connections Portlets for WebSphere Portal: Configuring navigation between portlets*.

Related tasks:

"Managing community associations" on page 1290
You can create, view, modify, or delete community associations on a page with the Page Associations window, the XML configuration interface, and Portal Scripting Interface.

"Configuring globally how social object links are resolved" on page 2127
You can include one or many attributes of social objects in the design component that defines the visual design of your social list. Among other features, social objects have different resolvable links that enable users to open details views of the social objects or the community to which the social objects belong. If you plan to add these links to your social list, you can decide how you want the social objects and their home community to be resolved when users click the corresponding links. IBM WebSphere Portal Express can either resolve the links in the context of the portal itself, or redirect the user to the IBM Connections user interface. You can globally configure how these types of links of social objects are resolved for the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Using the view definitions provided with social rendering on your portal pages

The social rendering feature provides you with a set of predefined view definitions. You can add them to the pages of your WebSphere Portal Express and modify them according to your requirements. For example, you can define which types of social objects are listed, how they are filtered, sorted, and presented. These tasks are done by a page editor.

About this task

Notes:

- Social rendering view definitions are represented by Web Content Manager content items. Therefore, you can drag and drop these view definitions only to managed pages or pages that have an explicitly defined web content association to a site area in Web Content Manager. For more information, see *Web content associations*.

- The list view definitions that are provided with social rendering use the Connections search service remote API to retrieve the social objects that are displayed in the list. This action has the following consequences:
  - Only information that is available in the Connections search feed can be displayed in the social lists.
  - Updates to social objects in Connections do not appear in the social lists that are provided with social rendering until the index of the Connections search service was updated.

  For more details about how to administer the Connections search service, read the information about *Administering Search* in the Connections product documentation.

Procedure

To add a social rendering view definition to a portal page and modify it as required, proceed as follows:

1. Select the **Edit Mode** of the page.
2. Add the social list of your choice to the portal page:
   a. Select **Create** > **Content** from the toolbar.
   b. Open the **Social Content** site area from the selection list.
   c. Select the view definition of your choice and place it on the page by drag-and-drop or by clicking the **Add this content to the page** plus sign icon. You can choose from the following types of lists:
      - List of Community Files
      - List of Community Content

Administering Search

Using social lists with your own custom theme

The social lists that social rendering provides work with portal pages that have the Portal 8.5 theme with a Basic Content theme profile. To use them with your own custom theme, you add the `wp_social_rendering_85` theme module to your theme.

About this task

The predefined social lists require that the social rendering CSS styles are loaded by the theme that is associated to the page with the social list. The theme loads these styles if the theme profile assigned to the current theme incorporates the `wp_social_rendering_85` theme module. The Portal 8.5 theme with either full or deferred profiles fulfills this requirement.

If you want to use social rendering with your own custom theme or a custom theme profile, add the `wp_social_rendering_85` theme module to that theme profile. For example, you can do so by using the `add-theme-modules` configuration task. If the theme profile that is active on the current page does not contain the social rendering theme module, the social rendering CSS classes are missing. In this case, the markup does not look as expected.

Related tasks:

"Customizing the CSS styles of social lists" on page 2225
The lists of social objects rely on the availability of several CSS class definitions in the `wp_social_rendering_85` theme module.

"Adding the social rendering theme module to a theme profile" on page 2132
For the social lists provided by social rendering to work, the theme that renders these lists needs to load CSS and JavaScript files. To include the CSS and JavaScript files in your theme, you need to add the `wp_social_rendering_85` theme module to your theme.

Configuring a page with lists of social objects for Tag Cloud support

Learn how to enable Tag Cloud portlet support on your portal page. You can enable Tag Cloud support if you are using a default portal theme profile or a custom portal theme profile.

Procedure

- If you are using default portal theme profiles within your portal installation, complete the following steps to enable Tag Cloud portlet support on your portal page:
  1. Locate the page in the Manage pages portlet.
  2. Click **Edit Page Properties** for the specific page.
  3. Click **Advanced options**.
  4. Click **I want to set parameters**.

5. Add the new parameter **resourceaggregation.profile** with the value set as the profile override for the specific page. For example, `profiles/profile_search_tag.json`.

   Note: The search_tag theme profile is a hidden profile, therefore it cannot be selected in the theme profile drop-down list. This profile needs to be set manually.
6. Click **Add**.
7. Click **OK** to save the new parameter.
8. Click **OK** to save your changes to the page properties.

- If you are using a custom theme, complete the following steps to enable Tag Cloud support on your portal page:
  1. Verify that your page inherits the default portal theme or a custom theme that supports the default theme profiles.
  2. Locate the theme profile definition file by using WebDAV. For more information about accessing theme profile definition files, see *Profile schema definition* in the related links.
  3. Open your theme profile `JSON` file and add the following lines to the `moduleIDs` JSON array:

     Note: If one or more of the following theme modules are already in the list of `moduleIDs`, you do not have to add them again.
     - `wp_pagebuilder_ui`
     - `wp_tagging_rating_tagcloud`
     - `dojo`
  4. Save your changes and restart your portal server.

Related concepts:

"Profile schema definition" on page 2558
You can write a profile schema with valid JSON.

Using the portal Tag Cloud with lists of social objects

To get the most benefit from social rendering together with tagging, you can put the WebSphere Portal Express Tag Cloud portlet on pages that contain social lists. This way your site visitors can reduce the contents of social lists by selecting individual tags from the tag cloud. The list of social objects is then restricted to content items that are tagged with the tag or tags that the user selected.

About this task

To configure tag selection for social lists from the tag cloud, a page editor proceeds by the following steps:

Procedure

1. CF03 Set a theme profile that supports lists of social objects as well as the Tag Cloud portlet. For more information, see *Configuring a page with lists of social objects for Tag Cloud support* in the related links.
2. Add the WebSphere Portal Express Tag Cloud portlet to the page that contains the list of social objects.
3. Optional: Depending on your portal theme, you might need to select **Edit Mode** for the page. Some themes require this step before you can select the Edit Shared settings option for the Tag Cloud portlet in the next step.

4. Select the **Edit Shared Settings** mode of the Tag Cloud portlet. If you cannot open the portlet menu, first select the **Edit Mode** for the page as described in the previous step.
5. Configure the Tag Cloud portlet to listen to Transmitted Tags. Set the **Tag display modes** setting to **Transmitted tags only**. For more information about configuring the Tag Cloud, see *Configuring the portal Tag Cloud for social rendering*.
6. Set the portlet **Action Mode** setting to **Expose public render parameter**.
7. Click **OK** to save your changes.
8. Enable the **Tag Selection Support** option for the list of social objects for which you want to make the Tag Cloud available to your users. For more information about how to set options for social lists, see *Customizing social list definitions by using inline editing*.

Results

After you set this configuration, the Tag Cloud portlet communicates with those lists of social objects on the page for which the Tag Selection Support option is activated in their social list definition. The tag cloud is filled dynamically with all tags associated with any of the individual social objects that are contained in those lists. If a user selects one or more tags from the tag cloud, those social lists on the page that have the Tag Selection Support option activated in their social list definition are dynamically filtered to contain only those entries that are tagged with all of the tags that the user selected from the tag cloud. Lists of social objects that have the Tag Selection Support option disabled in their definition do not transmit their tags to the tag cloud. These lists are not affected when site users select tags in the tag cloud.

Notes:

- By default, the Tag Selection Support option is disabled.
- If a user selects tags in the tag cloud, that tag selection remains active until one of the following conditions occurs:
  - The user deselects the tags again in the tag cloud.
  - The render state of the page that the user views is cleared. For example, this occurs when the user logs out from the portal.
- The page editor can add a general tag filter to the social list definition. To do this, the Page Editor specifies tag names in the **Filter by Tags** option of the social list definition. Such a tag filter is always active for all site visitors. Users cannot remove the tags that are specified in that filter by deselecting them in the tag cloud. Additional tags that a user selects by using the tag cloud are dynamically added to the list of tags that are applied to the list of social objects.
- If a social list has many different tags associated with it, the tag cloud might show only a subset of the available tags. This restriction can depend on two configuration options:
  - You can configure the limit for tags that an individual social list transmits from Connections. You set this limit in the WP Connections Integration Service resource environment provider. For more information, see the topic about *Configuring the tags transmission limit*.
  - You can configure the Tag Cloud portlet to show only a limited number of tags. This subset contains the most relevant tags, in other words tags that users assigned most often.
- The tag selection support for social list does not rely on tag federation between WebSphere Portal Express and Connections to be enabled.

- The social lists do not support interactions with the **Tags** portlet that is provided as one of the Connections portlets for WebSphere Portal Express.

Configuring the portal Tag Cloud for social rendering:

If you include the WebSphere Portal Express Tag Cloud portlet on your social pages, you need to configure it to work with social lists.

About this task

You can configure each individual Tag Cloud portlet instance separately. Use the Edit Shared Settings option from the portlet menu and configure the **Tag display modes** option. You can choose between two tag display modes. Depending on the option that you select, the tag cloud displays either persisted tags or transmitted tags only. There is no option to display both types of tags at the same time. For tagging to work with social lists, you need to set this option to Transmitted tags only.

Persisted tags only
: Persisted tags are served by the portal server and can include federated tags, depending on your tagging federation settings. This setting is the default setting.

Transmitted tags only
: Transmitted tags are transmitted by portlets on the same page. As tag transmission within the browser works without server interaction. The transmitted tags are displayed without further filtering. For your users to be able to tag items in social lists, you need to set the tag display mode to

this option. In transmitted tags mode, the Tag Cloud always shows the All view. Other views are not available in this mode. Users cannot switch views in this mode.

These options are added to the ones that are described in *Configuring the Tag Cloud*.

Configuring global settings for social rendering

You can apply some global configuration settings to social rendering. These global settings apply to all social lists in your WebSphere Portal Express.

About this task

Typically, an administrator configures these settings.

To configure these settings, you configure the appropriate properties in the WP Connections Integration Service resource environment provider. You access this service in the WebSphere Integrated Solutions Console under the resource environment providers.

These properties define the default settings if no other values are set for individual social lists in the corresponding social view definitions. Page editors with the appropriate access permissions can override some of these settings for individual social lists.

"Configuring the Connections server type" on page 2122
You can use social rendering with an on-premises IBM Connections server or with an Connections server that runs in the Smart Cloud for Social Business. If you use the latter type of connections server, you need to adapt the configuration accordingly.

"Configuring the maximum number of items loaded from Connections" on page 2123
You can define a value for the maximum number of social objects that you want the IBM Connections to return when data for a list of social objects is requested.

"Configuring portal user ID conversion based on directory service" on page 2124
When you use social rendering with an IBM Connections server, you must configure both IBM WebSphere Portal Express and Connections against the same directory service. Depending on the directory service that you use, WebSphere Portal Express needs to convert the user IDs of portal users to a format that the Connections server accepts. For example, this conversion is required if both WebSphere Portal Express and Connections are configured against a Domino Directory service or a Microsoft Active Directory.

"Configuring the tags transmission limit" on page 2124
You can configure your lists of social objects that retrieve data from the IBM Connections to transmit tags to the Tag Cloud portlet. You can limit the number of tag names that are loaded from Connections. You configure this limit in the WP Connections Integration Service resource environment provider.

"Configuring globally how social object data is served" on page 2125
Among other features, social objects have different links that enable users to download related data. For example, users can use links to download a file or the profile image of the author. You can globally configure how social object data is served to the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

"Configuring globally how social object links are resolved" on page 2127
You can include one or many attributes of social objects in the design component that defines the visual design of your social list. Among other features, social objects have different resolvable links that enable users to open details views of the social objects or the community to which the social objects belong. If you plan to add these links to your social list, you can decide how you want the social objects and their home community to be resolved when users click the corresponding links. IBM WebSphere Portal Express can either resolve the links in the context of the portal itself, or redirect the user to the IBM Connections user interface. You can globally configure how these types of links of social objects are resolved for the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

"Configuring file type icon mappings" on page 2129
Social rendering provides two types of list appearance components for result lists: `simple` and `comprehensive`. Both list appearances components show file type-specific icons when they render list entries that refer to individual files. In this case, the file type is determined based on the file extensions of the individual files. You can configure the set of file types that you want to use in the WP Connections Integration Service resource environment provider. In the context of social lists, a file type is defined by a file type name and a list of file extensions. This list defines the mapping between individual files and your file types. In your social list appearance components, you can then access the file type name for a specific file by using the Web Content Manager `[AttributeResource attributeName="fileType"]` tag. That tag is defined in the IBM Digital Data Connector (DDC) for WebSphere Portal Express profile. You can then use the file type name to render the appropriate image, for example, by assigning a corresponding CSS class.

Configuring the Connections server type

CF03

You can use social rendering with an on-premises IBM Connections server or with an Connections server that runs in the Smart Cloud for Social Business. If you use the latter type of connections server, you need to adapt the configuration accordingly.

About this task

To configure the Connections server type, you set a custom property named `server.type` in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console. Supported values for this property are as follows:

on-premise
Specify this value if the Connections server runs on your premises. This value is the default value.

SC4SB
Specify this value if your Connections server runs in the Smart Cloud for Social Business.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Select **WP ConnectionsIntegrationService**.
4. Under **Additional properties**, click **Custom properties**.
5. Locate the property named `server.type`. If this property does not exist yet, create it.
6. Set the value for the `server.type` property to one of the values listed earlier as required.
7. Save your changes.
8. Restart your portal server for the changes to take effect.

What to do next

Configuring the maximum number of items loaded from Connections

You can define a value for the maximum number of social objects that you want the IBM Connections to return when data for a list of social objects is requested.

About this task

To configure this maximum value, proceed by the following steps:

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Select **WP ConnectionsIntegrationService**.
4. Under **Additional properties**, click **Custom properties**.
5. Edit the value for the `search.page.size` property as required. The default value is `50`.
6. Save your changes.
7. Restart your portal server for the changes to take effect.

What to do next

Performance note: Setting this value to a high figure can affect the response time of the Connections server.

Note: A page editor can override this default value for an individual social list by editing the social list definition and setting the value in the field Maximum Results. For more information, see *Customizing social list definitions by using inline editing*.

Related tasks:

"Customizing social list definitions by using inline editing" on page 2137
You can customize your list view definitions by defining the following settings in inline editing mode. List view definitions are represented by content items of the social list definition authoring template. This customization is normally done by a web designer or a page editor.

Configuring portal user ID conversion based on directory service

When you use social rendering with an IBM Connections server, you must configure both IBM WebSphere Portal Express and Connections against the same directory service. Depending on the directory service that you use, WebSphere Portal Express needs to convert the user IDs of portal users to a format that the Connections server accepts. For example, this conversion is required if both WebSphere Portal Express and Connections are configured against a Domino Directory service or a Microsoft Active Directory.

About this task

To configure the user ID conversion, set the following custom property in the WP Connections Integration Service Resource Environment Provider in the WebSphere Integrated Solutions Console:

`use.userid.conversion`
Set this property to one the following values:

`true`
Specify this value if you want to apply the user ID conversion.

`false`
Specify this value if you do not want the user ID conversion to be applied. This value is the default value.

Supported values for this property are as follows:

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Select **WP ConnectionsIntegrationService**.
4. Under **Additional properties**, click **Custom properties**.
5. Locate the property `use.userid.conversion`. If this property is not listed yet, create it new.
6. Set the value for the property `use.userid.conversion` to one of the values that are listed earlier.
7. Save your changes.
8. Restart your portal server for the changes to take effect.

Configuring the tags transmission limit

You can configure your lists of social objects that retrieve data from the IBM Connections to transmit tags to the Tag Cloud portlet. You can limit the number of tag names that are loaded from Connections. You configure this limit in the WP Connections Integration Service resource environment provider.

About this task

Notes:

- Loading too many tags can affect performance.
- You set this maximum limit in the WP Connections Integration Service. The Tag Cloud can further reduce the number of shown tag names. This reduction depends on the configuration of the tag cloud.

To configure the tags transmission limit, proceed by the following steps:

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Select **WP ConnectionsIntegrationService**.
4. Under **Additional properties**, click **Custom properties**.
5. Edit the value for the `transmitted.tags.limit` property as required. The default value is `100`.
6. Save your changes.
7. Restart your portal server for the changes to take effect.

What to do next

For more information, see the topic about *Using the portal Tag Cloud with social lists*.

Related tasks:

"Using the portal Tag Cloud with lists of social objects" on page 2118
To get the most benefit from social rendering together with tagging, you can put the WebSphere Portal Express Tag Cloud portlet on pages that contain social lists. The list of social objects is then restricted to content items that are tagged with the tag or tags that the user selected.

Configuring globally how social object data is served

Among other features, social objects have different links that enable users to download related data. For example, users can use links to download a file or the profile image of the author. You can globally configure how social object data is served to the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

About this task

Social object data can be served to the users in the following two ways:

- Directly from IBM Connections.
- By using the Ajax proxy of WebSphere Portal Express. Benefits include the possibility to serve all data to your users through IBM WebSphere Portal Express without direct web access from the web browser to Connections.

You have two methods to specify how social object data is served:

- You can globally configure how social object data is served by default. You configure the data serve method in the WP Connections Integration Service resource environment provider. This setting sets the default data serve method for all social lists in your portal. As a result, all your design components that do

not explicitly request a specific data serve mode use this default method for serving resources. This configuration method makes the data serve method switchable for all social lists.

- You can explicitly override the default data serve method in your individual design components. To override the default setting, you use specific *attributeName* values in the AttributeResource tags that you use in your design components. These values determine a specific data serve method. This way, you can specify for individual types of data by which method you want them to be served.

For example, this configuration affects the following attributes: authorImageLink, communityEntryLink, downloadLink, and entryLink. For details about which attributes are available for a specific type of social object, read *Rendering profiles for social lists*.

To globally configure how social object data is served by default, set the resource.serving.url.type property of the WP Connections Integration Service resource environment provider. You can then still choose between using the default method or overriding it for individual data in individual design components:

- To use the default method for serving resource, use the attribute name without any prefix. For example, such attribute names are authorImageLink, communityEntryLink, downloadLink, and entryLink values for the attributeName. The portal then generates links that point either to Connections or to the portal. This depends on the value that you specified for the resource.serving.url.type property.
- To override the default method, you prefix the corresponding attributeName values in the design component with either of the following prefixes. To determine whether you can apply the prefixed version, look at the profile details:
  - raw. Use this prefix to serve resources directly through Connections.
  - portal. Use this prefix to serve resources from the portal to the browser.

Example: You want to generate a file download link that always points directly to Connections, independently of the resource.serving.url.type setting. In this case, you add the [AttributeResource attributeName="*raw*DownloadLink"] tag to your design component instead of using the tag [AttributeResource attributeName="downloadLink"]. This option keeps the data serve method switchable based on the resource.resolution.url.type setting.

Specify either of the following two values for the resource.serving.url.type property:

portal

Specify this value to define that the authorImageLink, communityEntryLink, downloadLink, entryLink, and other link attributes contain URLs through which you can access the social objects by using the Ajax proxy of the portal. In this case, their values equal the values of the corresponding portalAuthorImageLink, portalCommunityEntryLink, portalDownloadLink, and portalEntryLink attributes for the design component. This value is the default setting.

connections

Specify this value to define that the authorImageLink, communityEntryLink, downloadLink, entryLink and other link attributes contain URLs by which you can access the social objects directly from Connections. In this case,

their values equal the values of the corresponding `rawAuthorImageLink`, `rawCommunityEntryLink`, `rawDownloadLink`, and `rawEntryLink` attributes for the design component.

To globally configure the method by which social object data is served, proceed by the following steps:

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Select **WP ConnectionsIntegrationService**.
4. Under **Additional properties**, click **Custom properties**.
5. Set the `resource.serving.url.type` property to a value of either `connections` or `portal` as required.
6. Save your changes.
7. Restart your portal server for the changes to take effect.

Related reference:

"Digital Data Connector profiles for social rendering" on page 2147
Starting with Version 8.5, IBM WebSphere Portal Express includes a set of IBM Digital Data Connector (DDC) for WebSphere Portal Express profiles. You can use them with the social rendering DDC plug-in that is identified by the extension ID `ibm.portal.ddc.sr`.

Configuring globally how social object links are resolved

You can include one or many attributes of social objects in the design component that defines the visual design of your social list. Among other features, social objects have different resolvable links that enable users to open details views of the social objects or the community to which the social objects belong. If you plan to add these links to your social list, you can decide how you want the social objects and their home community to be resolved when users click the corresponding links. IBM WebSphere Portal Express can either resolve the links in the context of the portal itself, or redirect the user to the IBM Connections user interface. You can globally configure how these types of links of social objects are resolved for the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

About this task

Social object links can be resolved for the users in the following two ways:

- The linked resources can be rendered in the Connections user interfaces.
- The linked resources can be rendered on a portal page

You have two ways to specify how social object links are resolved:

- You can globally configure in the WP Connections Integration Service resource environment provider how social object links are resolved by default. This setting sets the link resolution method for all social lists in your portal. As a result, all your design components that do not explicitly request a specific resource link resolution method use this default method for resolving links. You can use this configuration method to switch the link resolution method globally for all social lists.
- You can explicitly override the default link resolution method in your individual design components. To override the default setting, you use specific *`attributeName`* values in the `AttributeResource` tags that you use in your design

components. These values determine a specific link resolution method. This way, you can specify for individual types of links by which method you want them to be resolved.

For example, this configuration affects the `link` and `communityLink` attributes. For details about which attributes are available for a specific type of social object, read *Rendering profiles for social lists*.

To globally configure how social object links are resolved by default, you set the `resource.resolution.url.type` property of the WP Connections Integration Service resource environment provider. You can then still choose between using the default method or overriding it for individual data in individual design components:

- To use the default method for resolving links, use the attribute names without any prefix. For example, such attribute names are `link` and `communityLink` values for the `attributeName`. The portal then generates links that resolve either to the Connections user interface or to a portal page. The link resolution method depends on the value that you specified for the `resource.resolution.url.type` property.
- To override the default method, you prefix the corresponding `attributeName` values in the design component with either of the following prefixes:
  - `raw`. Use this prefix to resolve links directly in Connections.
  - `portal`. Use this prefix to resolve links in the portal.

Example: You want to generate a social object link that always points directly to the Connections server, independently of the `resource.serving.url.type` setting. In this case, you add the `[AttributeResource attributeName="rawLink"]` tag to your design component instead of using the tag `[AttributeResource attributeName="link"]`. This option keeps the link resolution method switchable based on the `resource.resolution.url.type` setting.

You can specify one of the following values for the `resource.resolution.url.type` property:

contextual

This value is the default value. Specify this value to determine that the portal sets the social object resolving mode to either `portal` or `connections`. The portal determines the setting, depending on whether the Connections portlets "refresh" for WebSphere Portal Express are installed on your portal or not:

- If these portlets are installed, the portal uses the `portal` mode.
- If the portlets are not installed, the portal uses the `connections` mode.

Therefore, if you install these portlets while the social object resolving mode is set to `contextual`, the social object resolving mode switches from `connections` to `portal`.

portal

Specify this value to determine that the `link` and `communityLink` attributes contain URLs that display social objects in the context of the WebSphere Portal Express that renders the social list. In this case, their values equal the values of the corresponding `portalLink` and `portalCommunityLink` attributes for the design component. For details about the portal resolution mechanism, read *Social object resolution*. You can use this setting only if the Connections portlets are installed.

connections

Specify this value to determine that the `link` and `communityLink` attributes

contain URLs that route the user to Connections and resolve the links in the context of Connections. In this case, their values equal the values of the corresponding `rawLink` and `rawCommunityLink` attributes for the design component.

To globally configure how social object links are resolved by default, proceed by the following steps:

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Select **WP ConnectionsIntegrationService**.
4. Under **Additional properties**, click **Custom properties**.
5. Set the `resource.resolution.url.type` property to a value of either `contextual`, `connections`, or `portal` as required.
6. Save your changes.
7. Restart your portal server for the changes to take effect.

What to do next

To determine the default link resolution method that is currently in effect in your social list designs, check the value of the portlet request attribute `ibm.portal.default.social.object.resolution.mode`. This attribute is set to either `connections` or `portal`. This value indicates the default social object resolution mode.

You can disable this request attribute by setting the property `enable.default.social.object.resolution.mode.request.param` to the value `false` in WP Configuration Service resource environment provider. In this case, the attribute `ibm.portal.default.social.object.resolution.mode` is always set to the value `disabled`.

Related concepts:

"Social object resolution" on page 2113
When a portal user clicks a link to an object, the portal takes the user to the details view of that object. This process is called social object resolution. For example, a user might click a specific forum topic that is listed in the Community Forum Topics list. In this case, the social object resolution takes the user to a portal page that provides a details view of the forum topic that the user clicked. You can influence the result of the resolution that the user views by setting various parameters. These parameters are described here.

Related reference:

"Digital Data Connector profiles for social rendering" on page 2147
Starting with Version 8.5, IBM WebSphere Portal Express includes a set of IBM Digital Data Connector (DDC) for WebSphere Portal Express profiles. You can use them with the social rendering DDC plug-in that is identified by the extension ID `ibm.portal.ddc.sr`.

Configuring file type icon mappings

Social rendering provides two types of list appearance components for result lists: `simple` and `comprehensive`. Both list appearances components show file type-specific icons when they render list entries that refer to individual files. In this case, the file type is determined based on the file extensions of the individual files. You can configure the set of file types that you want to use in the WP Connections

Integration Service resource environment provider. In the context of social lists, a file type is defined by a file type name and a list of file extensions. This list defines the mapping between individual files and your file types. In your social list appearance components, you can then access the file type name for a specific file by using the Web Content Manager `[AttributeResource attributeName="fileType"]` tag. That tag is defined in the IBM Digital Data Connector (DDC) for WebSphere Portal Express profile. You can then use the file type name to render the appropriate image, for example, by assigning a corresponding CSS class.

About this task

The mappings are defined in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console. To modify the mappings, proceed as follows:

Procedure

1. Log in to the WebSphere Integrated Solutions Console
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP ConnectionsIntegrationService**.
4. Under **Additional properties**, click **Custom properties**.
5. Edit the values for the appropriate `file.type.mapping.`*`type`* properties as required. The value for each property is a comma-separated list of file extensions. An example setting is `file.type.mapping.text = log, txt`. This mapping means that the Web Content Manager `[AttributeResource attributeName="fileType"]` tag returns the string `text` for all files with a `log` or `txt` file type extension.

What to do next

For your reference, the following topic lists the default file type mappings.

"File type mappings reference"
The social lists show specific icons for the different file and service types in the result lists. You can modify the file type mappings that are used for displaying these icons. For your reference, these mappings are listed here.

File type mappings reference:

The social lists show specific icons for the different file and service types in the result lists. You can modify the file type mappings that are used for displaying these icons. For your reference, these mappings are listed here.

Administering social lists

You can administer several aspects of social lists. For example, you can add your own social lists to the content shelf, or you can tune the social object caches for performance.

About this task

Typically, an administrator does these administration tasks.

"Adding the social rendering theme module to a theme profile" on page 2132
For the social lists provided by social rendering to work, the theme that renders these lists needs to load CSS and JavaScript files. To include the CSS and JavaScript files in your theme, you need to add the `wp_social_rendering_85` theme module to your theme.

"Performance tuning for lists of social objects" on page 2133
Social data that is rendered on your portal pages by using the social rendering feature is retrieved from a remote IBM Connections server. To reduce network traffic and improve performance, the data is cached on IBM WebSphere Portal Express.

"Enabling social rendering in a virtual portal" on page 2133
Before you use social rendering in a virtual portal, you must deploy the new

web content library and templates. The version and fix pack of your IBM WebSphere Portal Express determines how you do so.

"Using Social Rendering with Tivoli Access Manager and WebSEAL" on page 2135
After you enable social rendering, your IBM WebSphere Portal Express acts as a client that sends HTTP requests to the IBM Connections server. If you use IBM Security Access Manager and WebSEAL to manage the access to your portal and Connections server, configure the portal so that it does not encode the WebSEAL session cookies.

CF06 "Removing the previous version of social rendering" on page 2135
You can remove the Social Lists 1.0 library and its configuration to remove it from the toolbar after you deploy the Social Lists 1.1 Library. Once you have removed the library, remove the drag and drop configuration with a separate command.

Adding the social rendering theme module to a theme profile

For the social lists provided by social rendering to work, the theme that renders these lists needs to load CSS and JavaScript files. To include the CSS and JavaScript files in your theme, you need to add the `wp_social_rendering_85` theme module to your theme.

About this task

The presentation components that the social rendering feature provides and that the social lists use rely on specific CSS styles and JavaScript files that the theme needs to load. To load those styles, you need to make sure that the `wp_social_rendering_85` theme module is available in the theme profile that is active on the page that renders the social list. If the `wp_social_rendering_85` theme module is not loaded for a page, the social list does not look as expected, and users cannot interact with the social lists on that page.

To determine which WebSphere Portal Express theme profiles already specify the `wp_social_rendering_85` theme module, review the theme profiles that come with the portal installation.

To add the theme module to your theme, you register the theme module by using the `add-theme-modules` portal configuration task. For more information, see the following examples.

- To add the social rendering theme module to a custom profile of a custom theme, run the task as follows:
  - For Linux :

```
./ConfigEngine.sh add-theme-modules
     -DThemeUniqueName=my.custom.theme
     -DThemeProfileFileName=profile_my_custom_profile.json
     -DModuleIDs=wp_social_rendering_85
```

  - For IBM i:

```
ConfigEngine.sh add-theme-modules
     -DThemeUniqueName=my.custom.theme
     -DThemeProfileFileName=profile_my_custom_profile.json
     -DModuleIDs=wp_social_rendering_85
```

  - For Windows:

```
ConfigEngine.bat add-theme-modules
     -DThemeUniqueName=my.custom.theme
     -DThemeProfileFileName=profile_my_custom_profile.json
     -DModuleIDs=wp_social_rendering_85
```

- To remove the social rendering theme module from the lightweight profile of the Portal 8.5 theme, run the remove task as follows:
  - For Linux :

```
./ConfigEngine.sh remove-theme-modules
     -DThemeUniqueName=my.custom.theme
     -DThemeProfileFileName=profile_my_custom_profile.json
     -DModuleIDs=wp_social_rendering_85
```

  - For IBM i:

```
ConfigEngine.sh remove-theme-modules
     -DThemeUniqueName=my.custom.theme
     -DThemeProfileFileName=profile_my_custom_profile.json
     -DModuleIDs=wp_social_rendering_85
```

  - For Windows:

```
ConfigEngine.bat remove-theme-modules
     -DThemeUniqueName=my.custom.theme
     -DThemeProfileFileName=profile_my_custom_profile.json
     -DModuleIDs=wp_social_rendering_85
```

Performance tuning for lists of social objects

Social data that is rendered on your portal pages by using the social rendering feature is retrieved from a remote IBM Connections server. To reduce network traffic and improve performance, the data is cached on IBM WebSphere Portal Express.

Social rendering uses the caching infrastructure of the IBM Digital Data Connector (DDC) for WebSphere Portal Express. For more information, read *Digital Data Connector cache tuning*.

Related reference:

"Digital Data Connector cache tuning" on page 3297
To improve performance, you can tune the caches for the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

Enabling social rendering in a virtual portal

Before you use social rendering in a virtual portal, you must deploy the new web content library and templates. The version and fix pack of your IBM WebSphere Portal Express determines how you do so.

Related tasks:

"Social Lists" on page 905
After you migrate from a previous WebSphere Portal Version to Version 8.5, you must run a configuration task. The configuration task is run to deploy the new web content library and templates before you can use the Social Lists features. If you already used the social rendering feature from 8.0.0.1, your existing web content libraries and all portlet clones that were created during the enablement on 8.0.0.1 is not changed.

Deploying social rendering in a virtual portal up to CF05:

In WebSphere Portal Express Version 8.5 with fix pack 05 or earlier, run the portal configuration task `action-enable-social-rendering`. Running this task deploys the Social Lists 1.0 library to the virtual portal. It also creates the required drag-and-drop configurations for the social rendering view definitions in the toolbar.

About this task

When you run this task on a virtual portal, identify the virtual portal by adding either one of the following parameters to the task. Each parameter requires the prefix `-D`.

`VirtualPortalHostName`
Specify the virtual portal context that identifies the virtual portal. For example, `vp.example.com`

`VirtualPortalContext`
Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

Procedure

1. Open a command prompt.
2. Change to the *wp_profile_root*`/ConfigEngine` directory.
3. Run the following command:
   - Linux : `./ConfigEngine.sh action-enable-social-rendering -DPortalAdminPwd=`*password* `-DWasPassword=`*password* `-DVirtualPortalContext=`*vp1*
   - IBM i: `ConfigEngine.sh action-enable-social-rendering -DPortalAdminPwd=`*password* `-DWasPassword=`*password* `-DVirtualPortalContext=`*vp1*
   - Windows: `ConfigEngine.bat action-enable-social-rendering -DPortalAdminPwd=`*password* `-DWasPassword=`*password* `-DVirtualPortalContext=`*vp1*

Deploying social rendering in a virtual portal with CF06 or later: CF06

WebSphere Portal Express Version 8.5 fix pack 06 introduces a new configuration task. In portal Version 8.5 fix pack 06 or later, use the configuration task **`deploy-social-rendering`** to enable social rendering in a virtual portal. You must also run this configuration task on the base portal to deploy the Social Lists 1.1 library.

About this task

To deploy the Social Lists 1.1 library on the base portal, proceed as follows:

Procedure

1. Open a command prompt.
2. Change to the *wp_profile_root*`/ConfigEngine` directory.
3. Run the following command:
   - Linux : `./ConfigEngine.sh deploy-social-rendering -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
   - IBM i: `ConfigEngine.sh deploy-social-rendering -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
   - Windows: `ConfigEngine.bat deploy-social-rendering -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

To deploy the Social Lists 1.1 library on a virtual portal, proceed as follows:

4. Open a command prompt.
5. Change to the *wp_profile_root*`/ConfigEngine` directory.

6. Run the following command:
   - Linux : `./ConfigEngine.sh deploy-social-rendering -DPortalAdminPwd=password -DWasPassword=password -DVirtualPortalContext=vp1`
   - IBM i: `ConfigEngine.sh deploy-social-rendering -DPortalAdminPwd=password -DWasPassword=password -DVirtualPortalContext=vp1`
   - Windows: `ConfigEngine.bat deploy-social-rendering -DPortalAdminPwd=password -DWasPassword=password -DVirtualPortalContext=vp1`

Using Social Rendering with Tivoli Access Manager and WebSEAL

After you enable social rendering, your IBM WebSphere Portal Express acts as a client that sends HTTP requests to the IBM Connections server. If you use IBM Security Access Manager and WebSEAL to manage the access to your portal and Connections server, configure the portal so that it does not encode the WebSEAL session cookies.

About this task

If you do not configure your portal as described here, the social rendering portlets do not show any results. Examples of such portlets are List of Blog Posts, List of Files, List of Forum Topics.

Procedure

1. On a stand-alone portal, log in to the WebSphere Integrated Solutions Console. On a portal cluster, log in to the WebSphere Integrated Solutions Console on the Deployment Manager.
2. Go to **Resources** > **Resource Environment** > **Resource Environment Providers.**.
3. Select **WP ConfigService**.
4. Under the Additional Properties heading, select **Custom Properties**.
5. Create or edit the property `cookie.escaping.ignore` and specify the value according to your WebSEAL configuration. The value of this property is a regular expression. It must match the name of the cookie that you do NOT want to be escaped. For example, if the WebSEAL session cookies have the names `PD-H-SESSION-ID` and `PD-S-SESSION-ID`, specify the value `PD-H-SESSION-ID|PD-S-SESSION-ID`.
6. For the changes to take effect, restart the portal server.

Results

You can now use the social rendering portlets.

Related tasks:

"Security Access Manager" on page 1626
IBM WebSphere Portal Express supports the use of IBM Security Access Manager. Existing Security Access Manager users can use the Security Access Manager services to assist them in their deployment.

Removing the previous version of social rendering

You can remove the Social Lists 1.0 library and its configuration to remove it from the toolbar after you deploy the Social Lists 1.1 Library. Once you have removed the library, remove the drag and drop configuration with a separate command.

About this task

The difference between the deprecated Social Lists 1.0 library and the Social lists 1.1 library is the use of OneUI styles. The latest versions of the social rendering uses the Social Lists 1.1 library and does not depend on the OneUI styles.

Procedure

1. In the Web Content Manager Authoring portlet, click **Social Lists 1.0** > **Content** > **Social Content site area**.
2. Click **Show hidden fields**.
3. Select the **Properties** tab.
4. In the Keywords text field, remove the text `ibm.portal.toolbar.NewContent`.
5. Click **Save**.
6. Remove references in your applications to Social Lists 1.0 library and its related configuration artifacts.
7. Change to the *wp_profile_root*`/ConfigEngine` directory.
8. Run the following command.
   - Linux : `./ConfigEngine.sh remove-social-rendering-library -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh remove-social-rendering-library -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat remove-social-rendering-library -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
9. Examine the log output with the console, or the ConfigTrace.log file. If the **`remove-social-rendering-library`** task completed successfully, continue to the next step and remove the configuration that removes the drag and drop configurations for social rendering view definitions in the toolbar..
10. Run the following command.
    - Linux : `./ConfigEngine.sh remove-social-rendering-config -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
    - IBM i: `ConfigEngine.sh remove-social-rendering-config -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
    - Windows: `ConfigEngine.bat remove-social-rendering-config -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*

Related concepts:

"Static resources" on page 2522
Static resources include the markup that is defined by `.html`, `.css`, and `.js` files that are used by the theme. Some `.json` files are used to define menu options, module definitions, and module profiles.

Customizing view definitions for portal site visitors

You can customize social rendering view definitions in a number of ways. For example, you can determine the social data that is shown and the visual appearance of the data. You customize social rendering by working with the social list definition authoring template. For custom view definitions, you can also create your own authoring templates.

About this task

Typically, a website designer does these customizing tasks.

Note: If you want to customize the web content that the sample web content library named Social Lists 1.0 provides, create a copy of that library and customize that copy.

"Customizing social list definitions by using inline editing"
You can customize your list view definitions by defining the following settings in inline editing mode. List view definitions are represented by content items of the social list definition authoring template. This customization is normally done by a web designer or a page editor.

"Customizing forum topic details view definitions by using inline editing" on page 2142
You can customize your forum topics details view definitions by defining the following settings in inline editing mode. Forum topic details are represented by content items of the forum topic details authoring template. This customization is normally done by a web designer or a page editor.

"Request attributes for changing search queries dynamically" on page 2143
The definitions of your list views are represented by content items of the Social List Definition authoring template. You can override specific elements of such list view definitions by using the request attributes that are described here. To work with request attributes in your web content, use the `RequestAttribute` rendering plug-in. Changing a list view definition by using request attributes is a way to modify the content of your lists dynamically, for example based on user input.

"Customizing the visual design of your view definitions" on page 2146
You can customize the visual appearance of the markup that your social rendering view definitions generate. The markup generation is controlled by the appearance component that your individual list view definition content items reference.

"Creating custom authoring templates for list definitions" on page 2230
Social rendering provides you a set of view definitions that you can use to add social data to your portal pages. These list view definition content items are created from the social list definition IBM Web Content Manager authoring template. You can create your own custom list view definitions by creating new content items from this authoring template. To customize social rendering even further, you can also create your own authoring templates to extend the data set that makes up your list view definitions.

"Implementing interactions with social objects" on page 2231
Site designers can implement design components that suppor interactions between the user and the social data. For example, a user can post a new reply to a forum topic or delete a previous reply.

Customizing social list definitions by using inline editing

You can customize your list view definitions by defining the following settings in inline editing mode. List view definitions are represented by content items of the social list definition authoring template. This customization is normally done by a web designer or a page editor.

About this task

To define these settings, you need the access permissions for editing the web content item that represents the view definition. You do not need edit access permissions to the **Web Content Viewer** portlet that shows the view definition.

Note: The list view definitions that are provided with social rendering use the Connections search service feed to retrieve the social objects displayed in the list. This has the following consequences:

- Only information that is available in the Connections search feed can be displayed in the social lists.
- Updates to social objects in Connections do not appear in the social lists provided with social rendering until the index of the Connections search service was updated.

For more details about how to administer the Connections search service, read the information about *Administering Search* in the Connections product documentation.

The following settings and options are available for customizing social list view definitions by using inline editing:

Name Use this setting to specify a name for the list of social items. The name must consist of at least one alphanumeric character (`a-z, A-Z,0-9`). It can include spaces and the following special characters: `$ - _ . ! ( ) ,`

Display Title
Use this setting to specify the display title for the list of social objects. If you use the default presentation template, a change to the display title also changes the heading shown for the list of social objects on the page. By alternative, you can specify **Localizations** instead of a display title. In this case, the portal ignores the default display title and uses the display title of the respective language instead. Social rendering provides a default text provider named Social Rendering. It includes a translated default display title for each language that the portal supports. To display the translated default titles, proceed as follows:

1. Click **Localizations**.
2. Select the Text Provider **Social Rendering**.
3. In the **Text Provider Key** field, type the key `SR_CONTENT_FILES`.
4. To save your updates, click **Save and Close**.

Content Sources
Use this setting to select the content sources that you want to include in the list of social objects. You can select multiple content sources. Each content source corresponds to a IBM Connections service. Social rendering supports the following Connections services: activities, blogs, bookmarks, communities, files, libraries, forums, profiles, wikis, and events.

Note: Outside social rendering, some of the Connections services serve multiple social objects. For example, the **Forums** service serves objects of type **Forum topic** and **Reply**. Social lists serve only the object types that are listed in the following table.

Table 338. Content sources, the corresponding Connections services, and the content types that they serve in social lists

Content source	Connections service	Content type that the content source serves in social lists
Activities	Activities	Activity
Blogs	Blogs	Blog post
Bookmarks	Bookmarks	Bookmark
Communities	Communities	Community
Events	Events	Event
Files	Files, Libraries	File

Table 338. Content sources, the corresponding Connections services, and the content types that they serve in social lists (continued)

Content source	Connections service	Content type that the content source serves in social lists
Forums	Forums	Forum topic
Profiles	Profiles	Profile
Wikis	Wikis	Wiki page

Filter by Community
You can limit the contents of a social list to a community by filtering. The following options are available:

Limit to community that is associated with this page
If you select this option, the list contains only social objects from the community that is associated with the current page.

Limit to selected community
You can use this option to select a community. If you select a community, the list contains only social objects from the selected community.

Do not limit to a community
If you select this option, the list is not limited to social objects that belong to communities. Social objects are listed, independent of whether they belong to a community or not.

For more information, read the WebSphere Portal Express product documentation under the topic about *Managing community associations*.

Note: User profiles are not considered to be content of a community. Therefore, if you activate community filtering, the resulting lists do not contain any user profile entries.

Filter by Type of Access
Select this option to display only public objects in this list. If you do not select this option, the list can also include social objects that are owned by or shared with the current user who views the list.

Filter by Search Term
Use this setting to specify the text for which you want the portal to search when it retrieves the social objects for the list from Connections. This field corresponds to the `query` parameter of the Connections Search API. For more information about the supported values and operators, read the Search service documentation for the Connections server.

Filter by Tags
Use this setting to specify a comma-separated list of tags to adjust the list of social objects. If you specify a tag filter here, the list displays only social objects that are tagged with these specific terms. If the same tags are deselected from a tag cloud portlet, this filter still applies as it is specified by the author, not by the end user. For more information, read *Using the portal Tag Cloud with lists of social objects*.

Tag Selection Support
Select this option to make this social list reflect tag selection information

that is generated by the portal Tag Cloud portlet. If a user selects a tag in the portal Tag Cloud, the portal adds this tag dynamically to the existing tag filter of the current social list.

Dynamic Filtering
Use this setting to select the dynamic contexts for filtering the list. The following options are available:

Enable dynamic search term filtering
If you select this option, the list shows the social objects for a search query based on the public render parameter `filters` with the value `sr:searchterm:`*`searchterm`*, where *`searchterm`* is the search term that the user specified. If a dynamic search term is available, it overrides the `Filter by Search Term` setting. For more information about the public rendering parameter `filters`, read *Dynamic list-rendering contexts*.

Enable dynamic author filtering
If you select this option, the list is filtered based on the selected IBM Connections user profile. The list shows the social objects of which the author is the user represented by the selected user profile. Selecting a user profile means that the user clicks a user profile link from a list that is resolved by the connections POC resolver in the portal. For more information about the social object resolution, read *Specifying in the design component how social object links are resolved*.

Sorting Criteria
Use this setting to specify the sorting criteria that are used for the list of social objects. You can choose between the **Last updated** and **Relevance** options.

Sorting Order
Use this setting to specify the sorting order that is used for the list of social objects. You can choose between **Ascending** and **Descending** order.

List Appearance
Use this setting to select a component that formats the list of social objects. You can select only IBM Web Content Manager Personalization components that have the keyword `ibm.portal.socialrendering` assigned in their profile section. To enable the profile section for IBM Web Content Manager components, you must set the `control.Cmpnt=com.aptrix.pluto.taxonomy.ProfileControl` property in the `WCMConfigService.properties` file and restart your portal. For more information about this type of Web Content Manager Personalization components, see *Customizing the visual design of social lists*.

By default, you can choose between two appearance types:

Simple
The Simple appearance is useful for a mobile view, as it contains fewer data.

Comprehensive
The Comprehensive appearance provides more information of the following types:

- The person who made the last update to the social object
- The date of the last update to the social object
- Tags that are assigned to the social object

- The summary of the social object.

Both of these default appearances are responsive to the theme columns, screen width, and screen orientation. Social rendering uses default CSS styles to provide this responsiveness. For example, they can be useful if users use different types of devices to view the lists or change between portrait and landscape views on a mobile device.

Maximum Results (hidden)

This field is an optional input field. This setting is hidden by default. To make it show, click **Show hidden fields** at the beginning or end of the screen. Use this setting to specify the maximum number of content items included in this list. This figure determines the maximum number of social objects that Connections returns. Specify a positive integer. It is good practice to match this number with the number of results that the Personalization component can display that you specify at the List Appearance element. To determine that number, multiply the **Results per page** by the **Maximum pages to include** of the Personalization component.

You can also configure this setting globally for all social list portlets in the WP Connections Integration Service in the WebSphere Integrated Solutions Console. For more information, see *Configuring the maximum number of items loaded from Connections*. If you leave the **Maximum Results** field empty for a social list, then the value that is set in the WP Connections Integration Service applies as the default.

Custom Properties (Hidden)

This field is an optional input field. It is hidden by default. To make it show, click **Show hidden fields** at the beginning or end of the screen. Add one or more custom properties in this input field. You can use such more custom properties to add more flexibility to the layout of your list as required. For example, you can change the layout of your social list by defining a specific condition that uses the custom property added in this field. The following code sample shows how you change the color of the social list heading by specifying the string `blue` at the `Custom Properties` element:

```
[Plugin:Equals text1="blue" text2="[Element context='current' type='content' key='custom']"]
   <h2 style="color:blue;">[Property context="current" type="content" field="title"]</h2>
[/Plugin:Equals]
[Plugin:NotEquals text1="blue" text2="[Element context='current' type='content' key='custom']"]
   <h2 style="color:black;">[Property context="current" type="content" field="title"]</h2>
[/Plugin:NotEquals]
```

Custom Link Resolution Root Page (Hidden)

You can use this field to control the social object resolution behavior for links that users click in this list. For more detailed information, read *Social Object Resolution*.

Related concepts:

"Social object resolution" on page 2113
When a portal user clicks a link to an object, the portal takes the user to the details view of that object. This process is called social object resolution. For example, a user might click a specific forum topic that is listed in the Community Forum Topics list. In this case, the social object resolution takes the user to a portal page that provides a details view of the forum topic that the user clicked. You can influence the result of the resolution that the user views by setting various parameters. These parameters are described here.

Related tasks:

"Using the portal Tag Cloud with lists of social objects" on page 2118
To get the most benefit from social rendering together with tagging, you can put the WebSphere Portal Express Tag Cloud portlet on pages that contain social lists. This way your site visitors can reduce the contents of social lists by selecting individual tags from the tag cloud. The list of social objects is then restricted to content items that are tagged with the tag or tags that the user selected.

"Customizing the visual design of your view definitions" on page 2146
You can customize the visual appearance of the markup that your social rendering view definitions generate. The markup generation is controlled by the appearance component that your individual list view definition content items reference.

"Managing community associations" on page 1290
You can create, view, modify, or delete community associations on a page with the Page Associations window, the XML configuration interface, and Portal Scripting Interface.

"Configuring the maximum number of items loaded from Connections" on page 2123
You can define a value for the maximum number of social objects that you want the IBM Connections to return when data for a list of social objects is requested.

Administering Search

Customizing forum topic details view definitions by using inline editing

You can customize your forum topics details view definitions by defining the following settings in inline editing mode. Forum topic details are represented by content items of the forum topic details authoring template. This customization is normally done by a web designer or a page editor.

About this task

To define these settings, you need the access permissions for editing the web content item that represents the view definition. You do not need edit access permissions to the **Web Content Viewer** portlet that shows the view definition.

The following settings and options are available for customizing social list view definitions by using inline editing:

Name Use this setting to specify a name for this item. The name must consist of at least one alphanumeric character (`a-z, A-Z,0-9`). It can include spaces and the following special characters: `$ - _ . ! ( ) ,`

Display Title
Use this setting to specify the display title for this item.

Details Appearance
Use this setting to select the appearance component that generates the details view of this item. You can select only IBM Web Content Manager Personalization components that have the keyword `ibm.portal.socialrendering` assigned in their profile section. To enable the profile section for Web Content Manager components, you must set the `control.Cmpnt=com.aptrix.pluto.taxonomy.ProfileControl` property in the `WCMConfigService.properties` file and restart your portal. For more information about this type of Web Content Manager Personalization components, read *Customizing the visual design of social lists*. By default,

there is only one appearance component for forum topic details view definitions. It is named Forum Topic Details.

Index Page
Use this setting to control the target for the **Show Index Page** link that is shown by default by the forum topic details appearance component. Specify one of the following values:

parent With this setting, the **Show Index Page** link points to the parent page of the current page.

unique_name_of_a_portal_page
With this setting, the **Show Index Page** link points to the portal page with the unique name that you specify.

Maximum Results (hidden)
This field is an optional input field. The default value is `200`. This setting is hidden by default. To make it show, click **Show hidden fields** at the beginning or end of the screen. Use this setting to specify the maximum number of replies that you want to be loaded for the given forum topic. Specify a positive integer. It is good practice to match this number with the number with the **Results per page** value thst you configure in the appearance component that you use with this forum topic details view definition.

Initial List Size (hidden)
This field is an optional input field. The default value is `10`. This setting is hidden by default. To make it show, click **Show hidden fields** at the beginning or end of the screen. Use this setting to specify the maximum number of replies that you want to show in the initial rendering of the forum topic details. The forum topic details appearance component supports a **View more replies** link that shows all replies that have been loaded.

Request attributes for changing search queries dynamically

The definitions of your list views are represented by content items of the Social List Definition authoring template. You can override specific elements of such list view definitions by using the request attributes that are described here. To work with request attributes in your web content, use the `RequestAttribute` rendering plug-in. Changing a list view definition by using request attributes is a way to modify the content of your lists dynamically, for example based on user input.

You can use the following request attributes:

ibm.portal.sr.search.access
Use this request attribute to dynamically set the type of access that you want to use for filtering the list. This request attribute overrides the Filter by Type of Access setting of your list view definition. You can use the following values:

public Use this value to include only public objects in the list.

private
Use this value to include public objects and private objects to which the user has access. The value `private` corresponds to the value `personalOnly` of the IBM Connections Scopes API. This value `personalOnly` is described in the scopes feed summary element as `Search for your content`. This scope matches public documents

and documents that are private and to which the user has access based on the user ID, group IDs, communities to which the user belongs.

shared
Use this value to include only private objects to which the user has access. The value `shared` corresponds to the value `personalOnlyByACL` of the Connections Scopes API. This value `personalOnlyByACL` is described in the scopes feed summary element as `Search for your private content`. This scope matches only documents to which the user has access based on the user ID, group IDs, communities to which the user belongs. This scope includes only documents that the user owns or that were explicitly or implicitly shared with the user.

ibm.portal.sr.search.authorid
Use this request attribute to dynamically set the external ID (`extID`) of the user that you want to use for filtering the list. The external ID is specific to Connections. You can retrieve the `extID` that belongs to the user of a selected Connections user profile by using the `ConnectionsContext` rendering plug-in. With regards to author filtering, this request attribute overrides the Dynamic Filtering setting of your list view definition.

ibm.portal.sr.search.community
Use this request attribute to dynamically set the UUID of a specific Connections community. If you specify a community, the list contains only social objects from that community. This request attribute overrides the Filter by Community setting of your list view definition.

ibm.portal.sr.search.max
Use this request attribute to dynamically set the maximum number of items that you want to include in the list. This request attribute overrides the Maximum Results setting of your list view definition.

ibm.portal.sr.search.queryURI
Use this request attribute to override the URI used to query the Connections server. Normally, the portal generates the query URI based on the list view definition and the request attributes described here. By using this request attribute, you can provide a URI that replaces the one computed by the portal. You can use the following placeholders in a custom query URI:

{$search.public}
If your custom query URI starts with this string, the portal replaces it with the HTTP link of the Search service of the Connections server.

{$search.protected}
If your custom query URI starts with this string, the portal replaces it with the HTTPS link of the Search service of the Connections server.

ibm.portal.sr.search.searchterm
Use this request attribute to dynamically set the search term that you want to use for filtering the list. With regards to search term filtering, this request attribute overrides the Filter by Search Term setting and the Dynamic Filtering setting of your list view definition.

ibm.portal.sr.search.sortby
Use this request attribute to dynamically set the criteria that you want to

use for sorting the list. Supported values depend on the Search service of your Connections server. Usually, the following values are supported:

date Use this value to sort your list by the last modified date of the list entries.

relevance
Use this value to sort your list by the relevance of the list entries.

In addition to these two values, you can also specify the name of any other sortable field of Connections objects, for example the `title`. This request attribute overrides the Sorting Criteria setting of your list view definition.

ibm.portal.sr.search.sortdir
Use this request attribute to dynamically set the order by which you want to sort the list. You can use the following values:

asc Use this value to sort your list in ascending order.

desc Use this value to sort your list in descending order.

This request attribute overrides the Sorting Order setting of your list view definition.

ibm.portal.sr.search.source
Use this request attribute to dynamically set the type of content source that you want to use for filtering the list. This request attribute overrides the Filter by Content Source setting of your list view definition. You can use the following values:

allconnections
Use this value to get results from all content sources. This value is the default value.

activities
Use this value to get results from activities only.

blogs Use this value to get results from blogs only.

communities
Use this value to get results from communities only.

dogear
Use this value to get results from dogears and bookmarks only.

events Use this value to get results from events only.

forums
Use this value to get results from forums only.

profiles
Use this value to get results from profiles.

wikis Use this value to get results from wikis only.

files Use this value to get results from files only.

To combine different content source types for your search, provide multiple values and separate them by commas. Example:
`ibm.portal.sr.search.source=blogs,forums,files`.

ibm.portal.sr.search.tags
Use this request attribute to dynamically set the tags that you want to use for filtering the list. To specify more than one tag as a filter, use blanks or

commas as separator characters between the tags. This request attribute overrides the Filter by Tags setting of your list view definition.

Customizing the visual design of your view definitions

You can customize the visual appearance of the markup that your social rendering view definitions generate. The markup generation is controlled by the appearance component that your individual list view definition content items reference.

"Customizing the markup generation"
You create the visual designs for your social rendering view definitions by using social rendering appearance components. Social rendering appearance components are implemented as IBM Web Content Manager Personalization components. Personalization components that you use with social rendering must wrap a IBM Digital Data Connector (DDC) for WebSphere Portal Express selection rule.

"Using the business card" on page 2223
You can integrate the business card and online status in a list of social objects by using live text micro format.

"Customizing the CSS styles of social lists" on page 2225
The lists of social objects rely on the availability of several CSS class definitions in the `wp_social_rendering_85` theme module.

Related concepts:

"Personalization element" on page 1820
A personalization element stores a reference to a personalization rule or content spot that is generated by Portal Personalization. To use a personalization element, you must create a personalization component.

Customizing the markup generation:

You create the visual designs for your social rendering view definitions by using social rendering appearance components. Social rendering appearance components are implemented as IBM Web Content Manager Personalization components. Personalization components that you use with social rendering must wrap a IBM Digital Data Connector (DDC) for WebSphere Portal Express selection rule.

About this task

In general, a Web Content Manager Personalization component combines a portal Personalization selection rule with formatting information. This information defines how data returned by that selection rule is transformed into markup that is rendered on a portal page. Social rendering delegates the data selection logic to the underlying DDC framework and uses only the markup generation capabilities of Web Content Manager Personalization components. To trigger the loading of the data, social rendering DDC selection rules that work on the Pluggable Resources resource collection. For more information, read *Technical concepts*.

For extracting the individual pieces of metadata of social objects contained in a social list, you can use the Web Content Manager `AttributeResource` tag. For more information about Web Content Manager Personalization components, see the topic about *Personalization element* in the Web Content Manager product documentation.

"Digital Data Connector profiles for social rendering" on page 2147
Starting with Version 8.5, IBM WebSphere Portal Express includes a set of IBM Digital Data Connector (DDC) for WebSphere Portal Express profiles. You can use them with the social rendering DDC plug-in that is identified by the extension ID `ibm.portal.ddc.sr`.

Related concepts:

"Technical concepts" on page 3257
Before you use the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework, you can familiarize yourself with its main technical concepts and building blocks.

Digital Data Connector profiles for social rendering:

Starting with Version 8.5, IBM WebSphere Portal Express includes a set of IBM Digital Data Connector (DDC) for WebSphere Portal Express profiles. You can use them with the social rendering DDC plug-in that is identified by the extension ID `ibm.portal.ddc.sr`.

You can use these profiles to define social lists and detail views for the following types of social data that is served by the IBM Connections server:

- Blogs, blog posts, and blog post comments, as served by the Blogs service:
  - Blogs (`ibm.portal.sr.blogs`)
  - Blog details (`ibm.portal.sr.blogs.details`)
  - Blog posts (`ibm.portal.sr.blogs.posts`)
  - Blog post comments (`ibm.portal.sr.blogs.post.comments`)
- Communities and community members as served by the Communities service:
  - Communities (`ibm.portal.sr.communities`)
  - Community members (`ibm.portal.sr.communities.members`)
- Forums, forum topics, forum topic replies as served by the Forums service:
  - Forums (`ibm.portal.sr.forums`)
  - Forum topics (`ibm.portal.sr.forums.topics`)
  - Forum topic replies (`ibm.portal.sr.forums.replies`)
  - Forum topic and reply attachments (`ibm.portal.sr.forums.attachments`)
- User profiles, user network connections as served by the Profiles service:
  - Profiles (`ibm.portal.sr.profiles`)
  - Profiles connections (`ibm.portal.sr.profiles.connections`)
- Wiki pages, as served by the Wikis service:
  - Wiki pages (`ibm.portal.sr.wikis.pages`)
  - Wiki page comments (`ibm.portal.sr.wikis.page.comments`)
  - Wiki page attachments (`ibm.portal.sr.wikis.attachments`)
- Search results as served by the Connections search service:
  - Social objects (`ibm.portal.sr.search`)
- Tags that are served with the search results of the Connections search service: (`ibm.portal.sr.tags`).
- Common profile: (`ibm.portal.sr.common`).

The profiles listed so far partly inherit attribute definitions from a set of profiles that are available for inheritance purposes only. You cannot see these profiles in the tag helper because they are used only by other profiles that inherit attribute definitions from them and thereby reuse them. Note that you might need to selectively overwrite parts of these profiles if the feed that you intend to consume does not serve data as expected by the profiles listed in the following:

- Common profile: (`ibm.portal.sr.common`)
- Modifier support profile: (`ibm.portal.sr.modifiersupport`)
- Tag support profile: (`ibm.portal.sr.shared.tagsupport`)

- OpenSearch support profile: (`ibm.portal.sr.shared.opensearchsupport`).

All list view definitions that WebSphere Portal Express provides use the Social Objects 1.0 profile. This profile works against the search services. for more information, read *The social objects profile*.

The Forum Topic Details view definition is uses the Forum Topics profile. For more information, read *Forums, forum topics, and forum topic replies profiles*.

The profiles define the attribute names that you can use in your `[AttributeResource]` tags when you generate the HTML markup for your bean lists. You can either manually add the `AttributeResource` tags to the design component of a social list, or you can use the **Insert a Tag** user interface of IBM Web Content Manager. Example: If a profile defines an attribute that is named `title`, you can write out the title value of the items in your list by using the following tag: `[AttributeResource attributeName="title"]`.

Note: CF03 When you integrate an Connections server that runs in the Smart Cloud for Social Business, the following item attributes always return empty string values: `authorObjectID`, `memberObjectID`, and `modifierObjectID`.

The profiles that WebSphere Portal Express includes are listed in the following topics.

"Blog-related profiles" on page 2150
These profiles provide access to IBM Connections blog-related feed data for blogs, blogs details, blog posts, and blog post comments.

"Communities and community members profiles" on page 2164
These profiles provide access to IBM Connections community and community members feed data.

"Forum-related profiles" on page 2172
These profiles provide access to IBM Connections forum-related feed data for forums, forum topics, and forum topic replies profiles.

"Profiles and profiles connections profiles" on page 2189
These profiles provide access to IBM Connections profile related feed data.

"Social objects profile" on page 2196
The social objects profile provides access to IBM Connections social objects feed data.

"Tags profile" on page 2205
The tags profile provides access to the IBM Connections tags facet that is served by the connections search service.

"Wiki-related profiles" on page 2205
These profiles provide access to wiki-related feed data for wiki pages, wiki page comments, and wiki page attachments.

"Common profile" on page 2218
The common profile provides general aspects that are available in various feeds that are served by IBM Connections. You can use the common profile when you create your own custom profiles.

"Modifier support profile" on page 2221
The modifier support profile provides general modifier aspects. These modifier aspects are available in various feeds that are served by IBM Connections. You can reuse them when you create your own profiles.

"Tag support profile" on page 2222
The tag support profile provides access to a list of tags that is associated with the social objects served by IBM Connections feed data.

"OpenSearch support profile" on page 2223
The OpenSearch support profile provides access to information that is defined in the OpenSearch specification. The OpenSearch specification is commonly used in the Atom feed format.

Related concepts:

"Web content tags" on page 1833
You use tags to reference elements within presentation templates and element designs.

Related tasks:

"Configuring file type icon mappings" on page 2129
Social rendering provides two types of list appearance components for result lists: `simple` and `comprehensive`. Both list appearances components show file type-specific icons when they render list entries that refer to individual files. In this case, the file type is determined based on the file extensions of the individual files. You can configure the set of file types that you want to use in the WP Connections Integration Service resource environment provider. In the context of social lists, a file type is defined by a file type name and a list of file extensions. This list defines the mapping between individual files and your file types. In your social list appearance components, you can then access the file type name for a specific file by using the Web Content Manager `[AttributeResource attributeName="fileType"]` tag. That tag is defined in the IBM Digital Data Connector (DDC) for WebSphere Portal Express profile. You can then use the file type name to render the appropriate image, for example, by assigning a corresponding CSS class.

Integrating with IBM Connections
Integrating with IBM Connections is a multiple step process. Review the high-level steps before you begin.

"Configuring globally how social object data is served" on page 2125
Among other features, social objects have different links that enable users to download related data. For example, users can use links to download a file or the profile image of the author. You can globally configure how social object data is served to the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

"Configuring globally how social object links are resolved" on page 2127
You can include one or many attributes of social objects in the design component that defines the visual design of your social list. Among other features, social objects have different resolvable links that enable users to open details views of the social objects or the community to which the social objects belong. If you plan to add these links to your social list, you can decide how you want the social objects and their home community to be resolved when users click the corresponding links. IBM WebSphere Portal Express can either resolve the links in the context of the portal itself, or redirect the user to the IBM Connections user interface. You can globally configure how these types of links of social objects are resolved for the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Related reference:

Setting parameters to format dates
These parameters are used to set the format of dates.

Blog-related profiles:

These profiles provide access to IBM Connections blog-related feed data for blogs, blogs details, blog posts, and blog post comments.

Blogs profile

The blogs profile provides access to Connections blogs feed data. It declares the following attribute names:

Author's email address
`authorEmail`
: This attribute references the email address of the author of the social object.

Author's ID
`authorID`
: This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
`authorImageLink`
: This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

Author's name
`authorName`
: You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
`authorObjectID`
: This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
`authorUID`
: This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
`body HTML`
: The HTML content of this item.

Body plain
`body plain`
: The plain content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the body attribute of this item.

Can create blog post
canCreateBlogPost
If the current user has permission to create posts for this blog, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Community UUID
communityUUID
If the current blog is a community blog, this attribute specifies the UUID of the community that contains the blog. If the current blog is not contained in a community, this attribute is empty.

Feed entry
entry The original feed entry of this item.

Handle
handle This attribute represents the handle of this blog.

ID
id The unique identifier for this item.

Is closed
isClosed
If the current blog is in state `closed`, this attribute returns the string `true`. Otherwise, it returns `false`.

Is commenting graduated ideas enabled
isCommentingGraduatedIdeasEnabled
If the Commenting Graduated Ideas feature is enabled, this attribute returns the string `true`. Otherwise, it returns `false`.

Is community blog
isCommunityBlog
If the current blog is a community blog, this attribute returns the string `true`. Otherwise, it returns `false`.

Is frozen
isFrozen
If the current blog is in state `frozen`, this attribute returns the string `true`. Otherwise, it returns `false`.

Is ideation blog
isIdeationBlog
If the current blog is an ideation blog, this attribute returns the string `true`. Otherwise, it returns `false`.

Is moderated
isModerated
If the moderation feature is enabled for the current blog, this attribute returns the string `true`. Otherwise, it returns `false`.

Is open
isOpen If the current blog is in state `open`, this attribute returns the string `true`. Otherwise, it returns `false`.

Is private
isPrivate
If the current blog is contained in a private community, this attribute returns the string `true`. Otherwise, it returns `false`.

Is public
isPublic
If the current blog is contained in a public community, this attribute returns the string `true`. Otherwise, it returns `false`.

Is restricted
isRestricted
If the current blog is contained in a restricted community, this attribute returns the string `true`. Otherwise, it returns `false`.

Is Vote Limit enabled
isVoteLimitEnabled
If the Vote Limit feature is enabled, this attribute returns the string `true`. Otherwise, it returns `false`.

Is Voting Graduated Ideas enabled
isVotingGraduatedIdeasEnabled
If the Voting Graduated Ideas feature is enabled, this attribute returns the string `true`. Otherwise, it returns `false`.

View URL
link This attribute specifies the URL that points to the details view of this blog. This attribute is computed by the social rendering Digital Data Connector plug-in.

Number of Likes
numberOfLikes
This attribute specifies the number of people who like this blog.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal view URL
portalLink
This attribute specifies the WebSphere Portal Express URL that points to the details view of this blog. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published
This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink
Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw Community entry URL
rawCommunityEntryLink
This attribute specifies the Connections URL of the Atom entry that represents the community that contains this blog. This attribute is empty for stand-alone blogs.

Raw view URL
rawLink
This attribute specifies the URL that points to the details view of this blog on the Connections server.

Raw service doc URL
rawServiceDocLink
This attribute specifies the URL of the service document feed of this blog. This attribute is computed by the social rendering Digital Data Connector plug-in.

Summary
summary
A summary of the content of this item.

Tags
tags This attribute specifies the tags that are associated with this item.

Time zone
timezone
This attribute specifies the time zone information for the current blog.

Title
title The title of this item.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Blog UUID
uuid This attribute specifies the UUID of the current blog.

Vote limit
voteLimit
This attribute represents the configured vote limit for this blog.

Number of remaining votes
votesLeft
This attribute represents the number of votes that remain for this blog.

Accept value for weblog entries
weblogEntriesAccept
This attribute specifies the accept value for weblog entries for this blog. For more information, read the Connections Remote API documentation.

In addition to these attributes, the blogs profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Total Number of Items
totalNumberOfItems
This list property specifies the total number of items that were found for this search.

Requested Number of Items
requestedNumberOfItems
This list property specifies the requested number of items for this search.

Start Index
startIndex
This list property specifies the start index for the paged list of items.

Raw first URL
rawFirstLink
This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
rawNextLink
This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
rawPreviousLink
This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
rawLastLink
This list property specifies the Connections URL of the last page of items that are found for this search.

Is truncated
isTruncated
If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

Raw tags link
rawTagsLink
This attribute specifies the URL of the Atom feed that represents the tags for this list of blogs.

Blog details profile

The blog details profile provides access to Connections blog details feed data. It declares the following attribute names:

Can create blog post
canCreateBlogPost
If the current user has permission to create posts for this blog, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

ID
id The unique ID of this blog.

Blog posts URL
rawBlogPostsLink
This attribute specifies the URL that points to the Atom feed serving the blog posts for this blog.

Raw Atom entry URL
rawEntryLink
This attribute specifies the URL of the Atom resource that represents this blog.

Raw view URL
rawLink
This attribute specifies the URL pointing to the details view of this blog on the Connections server.

Raw service doc URL
rawServiceDocLink
This attribute specifies the URL of the service document feed of this blog. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw Weblog Entries URL
rawWeblogEntriesLink
This attribute specifies the URL of the Weblog entries feed of this blog.

Summary
summary
This attribute specifies the summary of the content of this blog.

Title
title This attribute specifies the title of this blog.

Updated date
updated
This attribute indicates the most recent time when this blog was updated. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Accept value for weblog entries
weblogEntriesAccept
This attribute specifies the accept value for weblog entries for this blog.

Blog posts profile

The blog posts profile provides access to Connections blog posts feed data. It declares the following attribute names:

Author's email address
authorEmail
: This attribute references the email address of the author of the social object.

Author's ID
authorID
: This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink
: This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's name
authorName
: You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID
: This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID
: This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
body HTML
: The HTML content of this item.

Body plain
body plain
: The plain content of this item.

Body content type
bodyContentType
: This attribute specifies the content type identifier for the body attribute of this item.

Can create blog post comment
canCreateBlogPostComment
If the current user has permission to create comments for this blog post, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Can delete blog post.
canDeleteBlogPost
If the current user has permission to delete this blog post, this attribute returns the string `true`. Otherwise, it returns `false`.

Can edit blog post.
canEditBlogPost
If the current user has permission to edit this blog post, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Accept value for comment entries
commentEntriesAccept
This attribute specifies the accept value for comment entries for this blog post.

Community UUID
communityUUID
If the current blog post is contained in a community blog, this attribute specifies the UUID of the community that contains the blog. If the current blog post is not contained in a community blog, this attribute is empty.

Feed entry
entry The original feed entry of this item.

ID
id The unique identifier for this item.

View URL
link This attribute specifies the URL that points to the details view of this blog post. This attribute is computed by the social rendering Digital Data Connector plug-in.

Number of comments
numberOfComments
This attribute specifies the number of comments that were posted on this blog post.

Number of Likes
numberOfLikes
This attribute specifies the number of people who like this blog post.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author

of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal view URL
portalLink
This attribute specifies the WebSphere Portal Express URL that points to the details view of this blog post. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published
This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink
Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw publishing entry URL
rawBlogPostPublishingEntryLink
This attribute specifies the URL to the publishing entry of this blog post. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw edit comments URL
rawCommentsEditLink
This attribute specifies the Connections URL that points to the comments collection of this blog post.

Raw View comments URL
rawCommentsReadLink
This attribute specifies the Connections URL that points to the feed of comments for this blog post.

Raw edit entry URL
rawEditLink
This attribute specifies the URL to the editable entry of this blog post.

Raw Atom entry URL
rawEntryLink
This attribute specifies the Connections URL of the Atom entry that represents this blog post.

Raw likes edit URL
rawLikesEditLink
This attribute specifies the Connections URL of the entry that makes it possible to edit the "liked" status of this blog post.

Raw View Likes URL
rawLikesLink
This attribute specifies the Connections URL that points to the "recommend" collection of this blog post.

Raw view URL
rawLink
This attribute specifies the URL of the details view of this blog post on the Connections server.

Raw service doc URL
rawServiceDocLink
This attribute specifies the URL of the service document feed of this blog. This attribute is computed by the social rendering Digital Data Connector plug-in.

Summary
summary
A summary of the content of this item.

Tags
tags This attribute specifies the tags that are associated with this item.

Title
title The title of this item.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

User likes
userLikes
If this blog post is liked by the current user, this attribute returns the string `true`. Otherwise, it returns `false`.

In addition to these attributes, the blog posts profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Total Number of Items
totalNumberOfItems
This list property specifies the total number of items that were found for this search.

Requested Number of Items
requestedNumberOfItems
This list property specifies the requested number of items for this search.

Start Index
startIndex
This list property specifies the start index for the paged list of items.

Raw first URL
rawFirstLink
This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
rawNextLink
This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
rawPreviousLink
This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
rawLastLink
This list property specifies the Connections URL of the last page of items that are found for this search.

Is truncated
isTruncated
If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

Raw tags link
rawTagsLink
This attribute specifies the URL of the Atom feed that represents the tags for this list of blog posts.

Blog post comments profile

The blog post comments profile provides access to Connections blog post comments feed data. It declares the following attribute names:

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's name
authorName
You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID
This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID
This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
body HTML
The HTML content of this item.

Body plain
body plain
The plain content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the body attribute of this item.

Can delete blog post comment
canDeleteBlogPostComment
If the current user has permission to delete this comment, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Feed entry
entry The original feed entry of this item.

ID
id The unique identifier for this item.

Number of Likes
numberOfLikes
This attribute specifies the number of people who like this blog post comment.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink

This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published

This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink

Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink

This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw publishing entry URL
rawBlogPostCommentPublishingEntryLink

This attribute specifies the URL to the publishing entry of this blog post comment. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw edit URL
rawEditLink

This attribute specifies the Connections URL of the entry that makes it possible to edit this blog post comment.

Raw Atom entry URL
rawEntryLink

This attribute specifies the Connections URL of the Atom entry that represents this blog post comment.

Raw likes edit URL
rawLikesEditLink

This attribute specifies the Connections URL of the entry that makes it possible to edit the "liked" status of this blog post comment.

Raw view Likes URL
rawLikesLink

This attribute specifies the Connections URL that points to the "recommend" collection of this blog post comment.

Raw view URL
rawLink

This attribute specifies the URL of the details view of this blog post comment on the Connections server.

Summary
summary

This attribute specifies the summary of the content of this blog post comment.

Title
title The title of this item.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

User likes
userLikes
If this blog post comment is liked by the current user, this attribute returns the string `true`. Otherwise, it returns `false`.

In addition to these attributes, the blog post comments profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Total Number of Items
totalNumberOfItems
This list property specifies the total number of items that were found for this search.

Requested Number of Items
requestedNumberOfItems
This list property specifies the requested number of items for this search.

Start Index
startIndex
This list property specifies the start index for the paged list of items.

Raw first URL
rawFirstLink
This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
rawNextLink
This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
rawPreviousLink
This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
rawLastLink
This list property specifies the Connections URL of the last page of items that are found for this search.

Is truncated
isTruncated
If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

Related tasks:

"Configuring globally how social object data is served" on page 2125
Among other features, social objects have different links that enable users to download related data. For example, users can use links to download a file or the profile image of the author. You can globally configure how social object data is served to the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Communities and community members profiles:

These profiles provide access to IBM Connections community and community members feed data.

Communities profile

The communities profile provides access to Connections communities feed data. It declares the following attribute names:

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

Author's name
authorName
You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID
This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute

represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID
This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
body HTML
The HTML content of this item.

Body plain
body plain
The plain content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the body attribute of this item.

Community image URL
communityImageLink
This attribute specifies the URL to the image of this community. This attribute is computed by the social rendering Digital Data Connector plug-in.

Community UUID
communityUUID
This attribute specifies the UUID of this community.

Feed entry
entry The original feed entry of this item.

ID
id The unique identifier for this item.

Is moderated
isModerated
If this community is a moderated community, this attribute returns the string `true`. Otherwise, it returns `false`.

Is post-moderated
isPostModerated
If the `post-moderation` feature was enabled for this community, this attribute returns the string `true`. Otherwise, it returns `false`.

Is pre-moderated
isPreModerated
If the `pre-moderation` feature was enabled for this community, this attribute returns the string `true`. Otherwise, it returns `false`.

Is public
isPublic
If this community is a public community, this attribute returns the string `true`. Otherwise, it returns `false`.

Is restricted
isRestricted
If this community is a restricted (invite-only) community, this attribute returns the string `true`. Otherwise, it returns `false`.

View URL
link This attribute specifies the URL that points to the details view of this community. This attribute is computed by the social rendering Digital Data Connector plug-in.

Number of members
numberOfMembers
This attribute specifies the number of members of this community.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal community image URL
portalCommunityImageLink
This attribute specifies the WebSphere Portal Express URL to the image of this community. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal view URL
portalLink
This attribute specifies the WebSphere Portal Express URL that points to the details view of this community. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published
This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw activity stream URL
rawActivityStreamLink
This attribute specifies the Connections URL of the subcommunities feed of this community.

Author's raw Atom entry URL
rawAuthorEntryLink
Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink
This attribute specifies the link to the profile image of the author of the

social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw bookmarks URL
rawBookmarksLink
This attribute specifies the Connections URL of the bookmarks feed of this community.

Raw community image URL
rawCommunityImageLink
This attribute specifies the Connections URL to the image of this community. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw Atom entry URL
rawEntryLink
This attribute specifies the Connections URL of the Atom entry that represents this community.

Raw feeds URL
rawFeedsLink
This attribute specifies the Connections URL of the feeds feed of this community.

Raw forum topics URL
rawForumTopicsLink
This attribute specifies the Connections URL of the forum topics feed of this community.

Raw invites URL
rawInvitesLink
This attribute specifies the Connections URL of the invitations feed of this community.

Raw view URL
rawLink
This attribute specifies the URL of the details view of this community on the Connections server.

Raw members URL
rawMembersLink
This attribute specifies the Connections URL of the members feed of this community.

Raw parent community URL
rawParentCommunityLink
This attribute specifies the Connections URL of the parent communities feed of this community.

Raw subcommunities URL
rawSubCommunitiesLink
This attribute specifies the Connections URL of the subcommunities feed of this community.

Summary
summary
This attribute specifies the summary description of this community.

Tags
tags This attribute specifies the tags that are associated with this item.

Title
title The title of this item.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

User is Member
userIsMember
If the current user is a member of the current community, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

User membership edit URL
userMembershipEditLink
This attribute specifies the URL to the editable resource that represents the membership relation between the currently logged in user and the current community.

User Membership URL
userMembershipLink
This attribute specifies the URL to the resource that represents the membership relation between the currently logged in user and the current community. This attribute is computed by the social rendering Digital Data Connector plug-in.

User Membership Role
userMembershipRole
This link specifies the membership role of the currently logged in user in the current community.

In addition to these attributes, the communities profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Total Number of Items
totalNumberOfItems
This list property specifies the total number of items that were found for this search.

Requested Number of Items
requestedNumberOfItems
This list property specifies the requested number of items for this search.

Start Index
startIndex
This list property specifies the start index for the paged list of items.

Raw first URL
rawFirstLink
This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
rawNextLink
This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
rawPreviousLink
This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
rawLastLink
This list property specifies the Connections URL of the last page of items that are found for this search.

Is truncated
isTruncated
If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

Community members profile

The communities members profile provides access to Connections communities members feed data. It declares the following attribute names:

Body HTML
body HTML
The HTML content of this item.

Body plain
body plain
The plain content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the body attribute of this item.

ID
id ID

Member is active
memberActive
This attribute indicates whether this community member is currently available.

Member's email
memberEmail
This attribute specifies the email address of this community member.

Member's ID
memberID
This attribute specifies the internal ID of this community member.

Member's image URL
memberImageLink
This attribute specifies the URL of the profile image of this community member. This attribute is computed by the social rendering Digital Data Connector plug-in.

Member's name
memberName
This attribute specifies the name of this community member.

Member's role
memberRole
This attribute specifies the role of the community member.

Member's type
memberType
This attribute specifies the type of the community member, for example, whether the member is a person or a group.

Portal view URL
portalLink
This attribute specifies the WebSphere Portal Express URL that points to the details view of this community member. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal member's image URL
portalMemberImageLink
This attribute specifies the WebSphere Portal Express URL of the profile image of this community member. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published
This attribute indicates the time at which this community member record was created. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw Atom entry URL
rawEntryLink
This attribute specifies the Connections URL of the Atom entry that represents this community member.

Raw member's image URL
rawMemberImageLink
This attribute specifies the Connections URL of the profile image of this community member. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw profile URL
rawProfileLink
This attribute specifies the Connections URL of the user profile Atom entry that represents this community member.

Raw VCard URL
rawVCardLink
This attribute specifies the Connections URL of the VCard resource of this community member.

Summary
summary
This attribute specifies the summary information for this community member.

Title
title Title

Updated date
updated
This attribute indicates the most recent time at which this community record was updated. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

In addition to these attributes, the community members profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Total Number of Items
totalNumberOfItems
This list property specifies the total number of items that were found for this search.

Requested Number of Items
requestedNumberOfItems
This list property specifies the requested number of items for this search.

Start Index
startIndex
This list property specifies the start index for the paged list of items.

Raw first URL
rawFirstLink
This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
rawNextLink
This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
rawPreviousLink
This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
rawLastLink
This list property specifies the Connections URL of the last page of items found for this search.

Is truncated
isTruncated
If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

"Configuring globally how social object data is served" on page 2125
Among other features, social objects have different links that enable users to download related data. For example, users can use links to download a file or the profile image of the author. You can globally configure how social object data is served to the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Forum-related profiles:

These profiles provide access to IBM Connections forum-related feed data for forums, forum topics, and forum topic replies profiles.

Forums profile

The forums profile provides access to Connections forums feed data. It declares the following attribute names:

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

Author's name
authorName
You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID
This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute

represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID
This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
body HTML
The HTML content of this item.

Body plain
body plain
The plain content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the body attribute of this item.

Can create topic
canCreateTopic
If the user can create topics for the current forum (community forum or stand-alone forum), this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

CanPostTopic
canPostTopicCmtyForum
If the user can create topics for this community forum, this attribute returns the string `CanPostTopic`. Otherwise, it returns an empty string. This function includes stand-alone forums.

Raw community Atom entry URL
communityLink
This attribute specifies the Connections URL of the Atom entry that represents the community that contains this forum. This attribute is empty for stand-alone forums.

UUID of the associated community
communityUUID
If the current forum is a community forum. This attribute specifies the UUID of the community that contains the forum. If the current forum is not contained in a community, this attribute is empty.

Feed entry
entry The original feed entry of this item.

Atom feed URL
entryLink
This attribute specifies the URL of the Atom entry that represents this forum. This attribute is computed by the social rendering Digital Data Connector plug-in.

ID
id The unique identifier for this item.

Is community forum
isCommunityForum
If this forum is a community forum, this attribute returns the string `true`. Otherwise, it returns `false`.

Is locked
isLocked
If this forum is locked, this attribute returns the string `true`. Otherwise, it returns `false`.

View URL
link This attribute specifies the URL that points to the details view of this forum. This attribute is computed by the social rendering Digital Data Connector plug-in.

Member list
memberList
This attribute lists the members of this forum.

Raw member list link
memberListLink
This attribute specifies the Connections URL of the members feed of this forum.

Is moderated
moderation
If the moderation feature is enabled for the current forum, this attribute returns the string `true`. Otherwise, it returns `false`.

Number of topics
numberOfTopics
This attribute specifies the number of forum topics that exist in this forum.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal Atom Feed URL
portalEntryLink
This attribute specifies the WebSphere Portal Express URL of the Atom entry that represents this forum. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal view URL
portalLink
This attribute specifies the WebSphere Portal Express URL that points to the details view of this forum. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published
This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink
Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw replies URL for community forums
rawCmtyForumRepliesLink
This attribute specifies the Connections URL of the replies feed for this community forum. This feed includes data about access rights for creating topics. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw Atom entry URL
rawEntryLink
This attribute specifies the Connections URL of the Atom entry that represents this forum.

Raw view URL
rawLink
This attribute specifies the Connections URL that points to the details view of this forum.

Raw replies URL
rawRepliesLink
This attribute specifies the Connections URL of the replies feed for this forum.

title The title of this item.

Type
type This attribute specifies the type of this forum.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

In addition to these attributes, the forums profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Total Number of Items
totalNumberOfItems
This list property specifies the total number of items that were found for this search.

Requested Number of Items
requestedNumberOfItems
This list property specifies the requested number of items for this search.

Start Index
startIndex
This list property specifies the start index for the paged list of items.

Raw first URL
rawFirstLink
This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
rawNextLink
This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
rawPreviousLink
This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
rawLastLink
This list property specifies the Connections URL of the last page of items that are found for this search.

Is truncated
isTruncated
If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

Raw tags link
rawTagsLink
This attribute specifies the URL of the Atom resource that represents the tag cloud of this forum.

Forum topics profile

The forum topics profile provides access to Connections forum topics feed data. It declares the following attribute names:

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's name
authorName
You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID
This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID
This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
body HTML
The HTML content of this item.

Body plain
body plain
The plain content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the body attribute of this item.

Can create reply
canCreateReply
If the current user has permission to reply to this forum topic, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Can create reply
canDeleteTopic
If the current user has permission to delete this forum topic, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Feed entry
entry The original feed entry of this item.

Atom entry URL
entryLink
This attribute specifies the URL of the Atom entry that represents this forum topic. This attribute is computed by the social rendering Digital Data Connector plug-in.

ID
id The unique identifier for this item.

Is Answered question
isAnswered
If this forum topic is a question and the question was answered, this attribute returns the string `true`. Otherwise, it returns `false`.

Is topic locked
isLocked
If this forum topic is locked, this attribute returns the string `true`. Otherwise, it returns `false`.

Is question
isQuestion
If this forum topic is a question, this attribute returns the string `true`. Otherwise, it returns `false`.

View URL
link This attribute specifies the URL that points to the details view of this forum. This attribute is computed by the social rendering Digital Data Connector plug-in.

Number of Likes
numberOfLikes
This attribute specifies the number of people who like this forum topic.

Number of replies
numberOfReplies
This attribute specifies the number of replies that exist for this forum topic.

Permissions
permissions
This attribute specifies the permissions that the current user was granted on the current forum topic.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where

you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal Atom entry URL
portalEntryLink
This attribute specifies the WebSphere Portal Express URL of the Atom entry that represents this forum topic. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal view URL
portalLink
This attribute specifies the WebSphere Portal Express URL that points to the details view of this forum. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published
This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink
Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw edit URL
rawEditLink
This attribute specifies the Connections URL of the entry that makes it possible to edit this forum topic.

Raw Atom entry URL
rawEntryLink
This attribute specifies the Connections URL of the Atom entry that represents this forum topic.

Raw likes edit URL
rawLikesEditLink
This attribute specifies the Connections URL of the entry that makes it possible to edit the `liked` status of this forum topic.

Raw view URL
rawLink
This attribute specifies the Connections URL that points to the details view of this forum.

Raw Replies URL
rawRepliesLink
This attribute specifies the Connections URL of the replies feed for this forum topic.

Summary
summary
A summary of the content of this item.

Tags
tags This attribute specifies the tags that are associated with this item.

Title
title The title of this item.

Type
type This attribute specifies the type information for this forum topic.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

User likes
userLikes
If this forum topic is liked by the current user, this attribute returns the string `true`. Otherwise, it returns `false`.

In addition to these attributes, the forum topics profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Total Number of Items
totalNumberOfItems
This list property specifies the total number of items that were found for this search.

Requested Number of Items
requestedNumberOfItems
This list property specifies the requested number of items for this search.

Start Index
startIndex
This list property specifies the start index for the paged list of items.

Raw first URL
rawFirstLink
This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
rawNextLink
This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
rawPreviousLink
This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
rawLastLink
This list property specifies the Connections URL of the last page of items that are found for this search.

Is truncated
isTruncated
If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

Raw tags link
rawTagsLink
This attribute specifies the URL of the Atom resourceS that represents the tag cloud of this list of forum topics.

Forum topic replies profile

The forum topic replies profile provides access to Connections forum topic replies feed data. It declares the following attribute names:

Answer flag element
answerFlag
This attribute represents the feed element that indicates whether or not a forum topic reply is marked as the answer to a question.

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's name
authorName
You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID
This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID
This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
body HTML
The HTML content of this item.

Body plain
body plain
The plain content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the body attribute of this item.

Can accept answer
canAcceptAnswer
If the current user has permission to accept this forum topic reply as the answer to the forum topic question, this attribute returns the string `true`. Otherwise, it returns `false`.

Can create reply
canCreateReply
If the current user has permission to reply on this forum topic reply, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Can decline answer
canDeclineAnswer
If the current user has permission to decline that this forum topic reply answers the forum topic question, this attribute returns the string `true`. Otherwise, it returns `false`.

Can delete reply
canDeleteReply
If the current user has permission to delete this forum topic reply, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Feed entry
entry The original feed entry of this item.

ID
id The unique identifier for this item.

Is answer
isAnswer
If this forum topic reply was marked as an answer to the question, this attribute returns the string `true`. Otherwise, it returns `false`.

Is deleted
isDeleted
If this forum topic reply was deleted, this attribute returns the string `true`. Otherwise, it returns `false`.

Modifier's email address
modifierEmail
This attribute references the email address of the modifier of the social object.

Modifier's ID
modifierID
This attribute references the internal ID of the modifier of the social object.

Modifier's image URL
modifierImageLink
This attribute specifies the link to the profile image of the modifier of the social object. The Connections server that provides the social object also stores the profile image of the modifier. This attribute contains a URL from which users can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*.This attribute is computed by the social rendering bean list provider plug-in.

Modifier's name
modifierName
You can use this attribute to include the name of the modifier of the social object in the design of a social list.

Modifier's object ID
modifierObjectID
This attribute references the serialized object ID of the modifier of the social object. In contrast to the `modifierID` attribute, the `modifierObjectID` attribute represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering bean list provider plug-in.

Modifier's UID
modifierUID
This attribute specifies the value of the UID attribute of the modifier of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering bean list provider plug-in.

Nesting level
nestingLevel
This attribute specifies the nesting level of this forum topic reply. This attribute is computed by the social rendering Digital Data Connector plug-in.

Number of attachments
numberOfAttachments
This attribute specifies the number of attachments that were been uploaded for this reply.

Number of nesting levels to close
numberOfLevelsToClose
This attribute returns the delta between the nesting levels of the previous forum topic reply and the current forum topic reply. This attribute is computed by the social rendering Digital Data Connector plug-in.

Number of Likes
numberOfLikes
This attribute specifies the number of people who like this forum topic reply.

Number of replies
numberOfReplies
This attribute specifies the number of replies that were posted to this forum topic reply.

Permissions
permissions
This attribute specifies the permissions that the current user was granted on the current forum topic reply.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published
This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink
Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw edit URL
rawEditLink
This attribute specifies the Connections URL of the entry that makes it possible to edit this forum reply.

Raw Atom entry URL
rawEntryLink
This attribute specifies the Connections URL of the Atom entry that represents this forum topic reply.

Raw likes edit URL
rawLikesEditLink
This attribute specifies the Connections URL of the entry that makes it possible to edit the `liked` status of this forum topic reply.

Modifier's raw Atom entry URL
rawModifierEntryLink
Link to the Atom entry that represents the modifier of this item. This URL addresses the Connections server directly. This attribute is computed by the social rendering bean list provider plug-in.

Modifier's raw image URL
rawModifierImageLink
This attribute specifies the link to the profile image of the modifier of the social object. The Connections server that provides the social object also stores the profile image of the modifier. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering bean list provider plug-in.

Modifier's portal image URL
portalModifierImageLink
This attribute specifies the link to the profile image of the modifier of the social object. The Connections server that provides the social object also stores the profile image of the modifier. This attribute contains a URL where you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Modifier's portal URL
portalModifierLink
This attribute specifies the link for rendering the details view of the modifier of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw view replies URL
rawRepliesLink
This attribute specifies the Connections URL of the replies feed for this forum topic reply.

Raw type
rawType
This attribute specifies the type information for this forum topic reply as served by the Connections server.

Raw type document node
rawTypeNode
This attribute selects the document node that provides type information for this forum topic reply that is served by the Connections server.

Reply parent ID
replyParentID
This attribute specifies the internal ID of the parent object of this forum topic reply.

Requires new nesting level
requiresNewLevel
If this forum topic reply is the first nested reply for the previous forum topic reply, this attribute returns the string `true`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Summary
summary
A summary of the content of this item.

Title
title The title of this item.

Type
type This attribute specifies the normalized type information for this forum topic reply. This attribute is computed by the social rendering Digital Data Connector plug-in.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

User likes
userLikes
If this forum topic reply is liked by the current user, this attribute returns the string `true`. Otherwise, it returns `false`.

In addition to these attributes, the forum topic replies profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Total Number of Items
totalNumberOfItems
This list property specifies the total number of items that were found for this search.

Requested Number of Items
requestedNumberOfItems
This list property specifies the requested number of items for this search.

Start Index
`startIndex`
This list property specifies the start index for the paged list of items.

Raw first URL
`rawFirstLink`
This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
`rawNextLink`
This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
`rawPreviousLink`
This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
`rawLastLink`
This list property specifies the Connections URL of the last page of items that are found for this search.

Is truncated
`isTruncated`
If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

Forums topic and reply attachments profile

The forums topic and reply attachments profile provides access to Connections forums attachments feed data. It declares the following attribute names:

Attachment's size
`byteSize`
This attribute specifies the size of the attachment in bytes.

Download URL
`downloadLink`
This attribute represents a link to this attachment. This attribute contains a URL by which users can download the attachment either directly from Connections or by using the Ajax proxy of the portal. If the download link is not available, this attribute does not have a value. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering bean list provider plug-in.

File extension
`fileExtension`
This attribute specifies the file extension of this attachment. For example, the file extension can be `.jpg`, `.mp3`, `.pdf`, or empty. This attribute is computed by the social rendering bean list provider plug-in.

File type
`fileType`
This attribute specifies the file type of this attachment. For example, the file type can be audio, code, compressed, contact, data, flash, graphic, pdf, presentation, text, video, wordProcessing, or dataDocs. The portal sets this attribute according to the value of the `fileExtension` attribute. The

`fileType` attribute value is derived from the configured file type extension mappings of the WP Connections Integration Service resource environment provider. For more information, read *Configuring file type icon mappings*. This attribute is computed by the social rendering bean list provider plug-in.

ID
`id` This attribute specifies the unique identifier for this attachment.

Mime type
`mimeType`
This attribute specifies the mime type of this attachment.

Attachment's name
`name` This attribute specifies the name of this attachment.

Portal download URL
`portalDownloadLink`
This attribute represents a link to this attachment. This attribute contains a URL from which users can download the attachment by using the Ajax proxy of the portal. To download the attachment from Connections without using the Ajax proxy, use the `rawDownloadLink` attribute instead. If the download link is not available, this attribute does not have a value. This attribute is computed by the social rendering bean list provider plug-in.

Portal thumbnail URL
`portalThumbnailLink`
This attribute represents a link to a thumbnail view of this attachment. To point to the thumbnail from Connections without using the Ajax proxy, use the `rawThumbnailLink` attribute instead. If the thumbnail link is not available, this attribute does not have a value. This attribute is computed by the social rendering bean list provider plug-in.

Published date
`published`
This attribute indicates the time when the attachment was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw download URL
`rawDownloadLink`
This attribute represents a link to this attachment. This attribute contains a URL from which users can download the attachment directly from Connections. To download the attachment from Connections by using the Ajax proxy of the portal, use the `portalDownloadLink` attribute instead. If the download link is not available, this attribute does not have a value.

Raw thumbnail URL
`rawThumbnailLink`
This attribute represents a link to a thumbnail view of this attachment. To point the thumbnail from Connections by using the Ajax proxy of the portal, use the `portalThumbnailLink` attribute instead. If the thumbnail link is not available, this attribute does not have a value.

Thumbnail URL
`thumbnailLink`
This attribute represents a link to a thumbnail view of this attachment. If the thumbnail link is not available, this attribute does not have a value. For

more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering bean list provider plug-in.

Updated date
`updated`
This attribute indicates the time of the last update of this attachment. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Related tasks:

"Configuring file type icon mappings" on page 2129
Social rendering provides two types of list appearance components for result lists: `simple` and `comprehensive`. Both list appearances components show file type-specific icons when they render list entries that refer to individual files. In this case, the file type is determined based on the file extensions of the individual files. You can configure the set of file types that you want to use in the WP Connections Integration Service resource environment provider. In the context of social lists, a file type is defined by a file type name and a list of file extensions. This list defines the mapping between individual files and your file types. In your social list appearance components, you can then access the file type name for a specific file by using the Web Content Manager `[AttributeResource attributeName="fileType"]` tag. That tag is defined in the IBM Digital Data Connector (DDC) for WebSphere Portal Express profile. You can then use the file type name to render the appropriate image, for example, by assigning a corresponding CSS class.

"Configuring globally how social object data is served" on page 2125
Among other features, social objects have different links that enable users to download related data. For example, users can use links to download a file or the profile image of the author. You can globally configure how social object data is served to the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Profiles and profiles connections profiles:

These profiles provide access to IBM Connections profile related feed data.

Profiles profile

The profiles profile provides access to Connections profile feed data. It declares the following attribute names:

Assistant's ID
`assistantID`
This attribute specifies the internal ID of the assistant of the user who represented by this profile.

Assistant's profile URL
`assistantLink`
This attribute specifies the URL of the user profile that represents the assistant of the user who is represented by this profile. This attribute is computed by the social rendering IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

Assistant's name
assistantName
This attribute specifies the name of the assistant of the user who is represented by this profile.

Blog URL
blogURL
This attribute specifies the URL of the current profile.

Building
building
This attribute specifies the building identifier for this profile.

Email
email This attribute specifies the email address of this profile.

Alternate email
emailAlternate
This attribute specifies the alternate email address of this profile.

Fax number
faxNumber
This attribute specifies the FAX number of this profile.

Floor
floor This attribute specifies the floor identifier for this profile.

ID
id The unique identifier for this profile.

Image URL
imageLink
This attribute specifies the URL of the photo of this profile. This attribute is computed by the social rendering Digital Data Connector plug-in.

Is active
isActive
This attribute indicates whether the user represented by this profile is currently available.

Is manager
isManager
If the user represented by this profile is a manager, this attribute returns the string `true`. Otherwise, it returns `false`.

Job title
jobTitle
This attribute specifies the job title of this profile.

UID of the manager of this user
managerUID
This attribute specifies the UID of the profile that represents this user's manager.

Name
name This attribute specifies the name of this profile.

Office number
officeNumber
This attribute specifies the office number of this profile.

Organization unit
organizationUnit
This attribute specifies the organization unit identifier of this profile.

Pager number
pagerNumber
This attribute specifies the pager number of this profile.

Assistant's profile URL
portalAssistantLink
This attribute specifies the WebSphere Portal Express URL of the user profile that represents the assistant of the user who is represented by this profile. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal image URL
portalImageLink
This attribute specifies the WebSphere Portal Express URL of the photo of this profile. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal VCard URL
portalVCardLink
This attribute specifies the WebSphere Portal Express URL of the VCard that describes this user profile. This attribute is computed by the social rendering Digital Data Connector plug-in.

Profile key
profileKey
This attribute specifies the key of this profile.

Profile type
profileType
This attribute specifies the profile type of this profile.

Raw assistant's entry URL
rawAssistantEntryLink
This attribute specifies the Connections URL of the user profile entry that represents the assistant of the user who is represented by this profile.

Raw assistant's URL
rawAssistantLink
This attribute specifies the Connections URL of the user profile that represents the assistant of the user who is represented by this profile. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw Atom entry URL
rawEntryLink
This attribute specifies the Connections URL of the Atom entry that represents this profile.

Raw image URL
rawImageLink
This attribute specifies the Connections URL of the photo of this profile. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw view URL
rawLink
This attribute specifies the URL of the details view of this profile on the Connections server.

Raw profile type URL
rawProfileTypeLink
This attribute specifies the URL of the profile type resource that is associated with this profile.

Raw pronunciation URL
rawPronunciationLink
This attribute specifies the Connections URL of the pronunciation resource of this profile.

Raw VCard URL
rawVCardLink
This attribute specifies the Connections URL of the VCard resource that is associated with this profile.

Summary
summary
This attribute specifies the summary information for this profile.

Tags
tags This attribute specifies the tags that are associated with this item.

Phone number IP
telephoneNumberIP
This attribute specifies the IP phone number of this profile.

Phone number mobile
telephoneNumberMobile
This attribute specifies the mobile phone number of this profile.

Phone number office
telephoneNumberOffice
This attribute specifies the office phone number of this profile.

Title
title The display name of this profile.

Updated date
updated
This attribute indicates the time of the last update of this profile. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

User's ID
userID This attribute specifies the internal ID of this profile.

Raw user network connection link
rawUserNetworkConnectionLink
This attribute specifies the URL to the user network connection entry that contains data about whether the current user and the selected user are colleagues. This attribute is computed by the social rendering Digital Data Connector plug-in.

User network status
userNetworkStatus
This attribute specifies the status of the connection between the current user and a selected user. This attribute can take the following values:

accepted
This value means that the logged in user accepted an invitation.

pending
This value means that the logged in user can accept an invitation.

unconfirmed
This value means that the invited user did not yet accept the invitation of the current user.

User's UID
userUID
This attribute specifies the UID of this profile.

VCard URL
vCardLink
This attribute specifies the URL of the VCard that describes this user profile. This attribute is computed by the social rendering Digital Data Connector plug-in.

Organization code
xOrganizationCode
This attribute specifies the organization code of this profile.

In addition to these attributes, the profiles profile also provides access to the following list properties:

Raw tags link
rawTagsLink
This list property specifies the URL of the Atom feed that represents the tags for this list of profiles.

Raw colleague link
rawColleagueLink
This list property specifies the URL of the Atom feed that represents the colleagues for the user that is represented by the current feed.

Profiles connections profile

The profiles connections profile provides access to Connections profiles connections feed data. It declares the following attribute names:

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute,

read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's name
authorName
You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID
This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID
This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
body HTML
The HTML content of this item.

Body plain
body plain
The plain content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the body attribute of this item.

Is connection pending
connectionIsPending
If this profile connection is pending, this attribute returns the string `true`. Otherwise, it returns `false`.

Connection message
connectionMessage
This attribute specifies the connection request message.

Connection status
connectionStatus
This attribute specifies the status information of this profile connection.

Connection type
connectionType
This attribute specifies the type information of this profile connection.

Feed entry
entry The original feed entry of this item.

ID
id The unique identifier for this item.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the

social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published
This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink
Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw edit URL
rawEditLink
This attribute specifies the URL of the editable resource that represents this profile connection.

Raw Atom entry URL
rawEntryLink
This attribute represents the Connections link to the Atom resource that represents this social object. This attribute contains a URL where you can access the feed directly from Connections. To retrieve the feed from Connections by using the Ajax proxy of the portal, use the `portalEntryLink` attribute instead.

Summary
summary
A summary of the content of this item.

Title
title The title of this item.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

In addition to these attributes, the profiles connections profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Related tasks:

"Configuring globally how social object data is served" on page 2125
Among other features, social objects have different links that enable users to download related data. For example, users can use links to download a file or the profile image of the author. You can globally configure how social object data is served to the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Social objects profile:

The social objects profile provides access to IBM Connections social objects feed data.

It declares the following attribute names:

Access control
accessControl
This attribute indicates whether this social object is public, private, or shared.

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

Author's name
authorName
You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID
This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID
This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body
body This attribute specifies the content of this item.

Body plain
body plain
This attribute specifies the plain content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the body attribute of this social object.

Community Atom feed URL
communityEntryLink
This attribute represents the link to the Atom resource that represents the community of this social object. This attribute contains a URL for accessing the feed either directly from Connections or by using the Ajax proxy of the portal. If the social object does not belong to a community, this attribute does not have a value. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Community view URL
communityLink
This attribute represents the link to the community that contains this social object. This attribute contains a URL by which users can view the community in the context of either Connections or the portal. If the social object does not belong to a community, this attribute does not have a value. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Community UUID
communityUUID
This attribute references the internal Universally Unique Identifier (UUID) of the community that contains this social object. It represents the community identifier from the Connections server where the social object is stored. If the social object does not belong to a community, this attribute does not have a value.

Download URL
downloadLink
If the social object is a file, this attribute represents a link to that file. This attribute contains a URL by which users can download the social object either directly from Connections or by using the Ajax proxy of the portal. If the download link is not available, this attribute does not have a value. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Feed entry
entry The original feed entry of this item.

Atom entry URL
entryLink
This attribute represents the link to the Atom resource that represents this social object. This attribute contains a URL for accessing the feed either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Event end date
eventEndDate
You can use this attribute to show the end date for this event. If the event recurs and therefore has multiple end dates, this attribute represents the end date that matches the event start date that is available through the `eventStartDate` attribute. To format the generated data string, you can use the format parameter of the `AttributeResource` tag. For more information about the Web Content Manager date formatting options, read *Setting parameters to format dates* in the Web Content Manager product documentation. This attribute is computed by the social rendering Digital Data Connector plug-in.

All event end dates
eventEndDates
This attribute specifies the list of all end dates of this event.

Event parent ID
eventParentID
This attribute specifies the internal ID of the parent event of this event. If this social object is not an event, this attribute is empty.

Event start date
eventStartDate
You can use this attribute to show the start date for this event. If the event recurs and therefore has multiple start dates, this attribute represents the next start date. If all start dates are in the past, the method returns the last start date. The event end date that corresponds to the event start date is available through the `eventEndDate` attribute. To format the generated data string, you can use the format parameter of the `AttributeResource` tag. For more information about the Web Content Manager date formatting options, read *Setting parameters to format dates* in the Web Content Manager product documentation. This attribute is computed by the social rendering Digital Data Connector plug-in.

All event start dates
eventStartDates
This attribute specifies the list of all start dates of this event.

File extension
fileExtension
This attribute carries the file extension of this social object. For example, the file extension can be `.jpg`, `.mp3`, or`.pdf`. If the social object is not a file, this attribute does not have a value.

File type
fileType
This attribute specifies the file type of this social object. For example, the file type can be `audio`, `code`, `compressed`, `contact`, `data`, `flash`, `graphic`, `pdf`, `presentation`, `text`, `video`, `wordProcessing`, or `dataDocs`. The portal sets this attribute according to the value of the `fileExtension` attribute. The `fileType` attribute value is derived from the configured file type extension mappings of the WP Connections Integration Service resource environment provider. For more information, read *Configuring file type icon mappings*. If the social object is not a file, this attribute does not have a value. This attribute is computed by the social rendering Digital Data Connector plug-in.

ID
id The unique identifier for this item.

Is answered question
isAnswered
If this social object is an answered forum topic question, this attribute returns the string `true`. If the social object is a forum topic but not an answered question, it returns `false`. If this social object is not a forum topic, this attribute is empty.

Is All-day event
isEventAllDay
If this social object is an all-day event, this attribute returns the string `true`. If the social object is an event but not an all-day event, it returns `false`. If this social object is not an event, this attribute is empty.

Is repeating event
isEventRepeating
If this social object is a repeating event, this attribute returns the string `true`. If the social object is a non-repeating event, it returns `false`. If this social object is not an event, this attribute is empty.

Is question
isQuestion
If this social object is a forum topic question, this attribute returns the string `true`. If the social object is a forum topic but no question, this attribute returns `false`. If this social object is not a forum topic, this attribute is empty.

Number of Likes
likes This attribute specifies the number of people who like this social object. This attribute is for internal use only and does not show up in the UI.

View URL
link This attribute represents the link to this social object. This attribute contains a URL where you can view the social object in the context of either Connections or the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Live number of comments
liveNumberOfComments

This attribute specifies the number of comments that exist for a file, blog post, or wiki page. In contrast to the numberOfComments attribute, the liveNumberOfComments attribute retrieves its value not from the search result feed but directly from the corresponding Connections service API. As a result, the value reflects the current value of this attribute, independent of the time of the last search crawl. Using this attribute instead of the numberOfComments attribute introduces some performance overhead for getting the live data. Use it only in lists in which the user can create or delete comments. If this social object is not a file, blog post, or wiki page, this attribute returns 0.

Live number of likes
liveNumberOfLikes

This attribute specifies the number of people who liked this social object. In contrast to the numberOfLikes attribute, the liveNumberOfLikes attribute retrieves its value not from the search result feed, but directly from the corresponding Connections service API. As a result, the value reflects the current value of this attribute, independent of the time of the last search crawl. Using this attribute instead of the numberOfLikes attribute introduces some performance overhead for getting the live data. Use it only in lists in which the user can like or unlike the social objects. If this social object does not support the like operation, this attribute returns 0.

Live number of replies
liveNumberOfReplies

This attribute specifies the number of replies that exist for this forum topic. In contrast to the numberOfReplies attribute, the liveNumberOfReplies attribute retrieves its value not from the search result feed but directly from the forums feed. As a result, the value reflects the current value of this attribute, independent of the time of the last search crawl. Using this attribute instead of the numberOfReplies attribute introduces some performance overhead for getting the live data. Use it only in lists in which the user can create or delete replies. If this social object is not a forum topic, this attribute returns 0.

Number of comments
numberOfComments

This attribute specifies the number of comments that are associated with this file, event, or blog post. If the current social object is not a file, event or blog post, this attribute returns 0. This attribute is computed by the social rendering Digital Data Connector plug-in.

Number of Likes
numberOfLikes

This attribute specifies the number of people who like this social object.

Number of replies
numberOfReplies

This attribute specifies the number of replies that exist in this forum topic. If this social object is not a forum topic, this attribute returns 0.

Author's portal image URL
portalAuthorImageLink

This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where

you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal community Atom entry URL
portalCommunityEntryLink
This attribute represents the link to the Atom resource that represents the community of this social object. This attribute contains a URL for accessing the feed by using the Ajax proxy of the portal. To retrieve the feed from Connections without using the Ajax proxy, use the `rawCommunityEntryLink` attribute instead. If the social object does not belong to a community, this attribute does not have a value. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal community view URL
portalCommunityLink
This attribute represents the link to the community that contains this social object. This attribute contains a URL by which users can view the community in the context of the portal. To access the community in the context of Connections, use the `rawCommunityLink` attribute instead. If the social object does not belong to a community, this attribute does not have a value. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal download URL
portalDownloadLink
If the social object is a file, this attribute represents a link to that file. This attribute contains a URL by which users can download the social object by using the Ajax proxy of the portal. To download the social object from Connections without using the Ajax proxy, use the `rawDownloadLink` attribute instead. If the download link is not available, this attribute does not have a value. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal Atom entry URL
portalEntryLink
This attribute represents the portal link to the Atom resource that represents this social object. This attribute contains a URL for accessing the feed by using the Ajax proxy of the portal. To retrieve the feed from Connections without using the Ajax proxy, use the `rawEntryLink` attribute instead. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal view URL
portalLink
This attribute represents the link to this social object. This attribute contains a URL where you can view the social object in the context of the portal. To access the social object in the context of Connections, use the `rawLink` attribute instead. This attribute is computed by the social rendering Digital Data Connector plug-in.

User profile job title
profileJobTitle

You can use this attribute to show the job title of individual users when social objects of the type profile are rendered. The attribute value is empty for social objects of types other than profile.

User profile phone number
profilePhoneNumber

You can use this attribute to show the phone number of individual users when social objects of the type profile are rendered. The attribute value is empty for social objects of types other than profile.

Published date
published

This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink

Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink

This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw Comment IDs
rawCommentIDs

This attribute is internally used to compute the `numberOfComments` attribute. It does not show up in the web content authoring UI.

Number of comments
rawComments

This attribute specifies the number of comments that are associated with this social object. This attribute is for internal use only and does not show up in the UI.

Raw community Atom entry URL
rawCommunityEntryLink

This attribute represents the link to the Atom resource that represents the community of this social object. This attribute contains a URL where you can access the feed directly from Connections. To retrieve the feed from Connections by using the Ajax proxy of the portal, use the `portalCommunityEntryLink` instead. If the social object does not belong to a community, this attribute does not have a value.

Raw community view URL
rawCommunityLink

This attribute represents the link to the community that contains this social object. This attribute contains a URL where you can view the community in the context of Connections. To access the community in the context of the portal, use the `portalCommunityLink` attribute instead. If the social object does not belong to a community, this attribute does not have a value.

Raw download URL
rawDownloadLink

If this social object is a file, this attribute represents a link to that file. This attribute contains a URL where you can download the social object directly from Connections. To download the social object from Connections by using the Ajax proxy of the portal, use the `portalDownloadLink` attribute instead. If the download link is not available, this attribute does not have a value.

Raw Atom entry URL
rawEntryLink

This attribute represents the IBM Connections link to the Atom resource that represents this social object. This attribute contains a URL where you can access the feed directly from Connections. To retrieve the feed from Connections by using the Ajax proxy of the portal, use the `portalEntryLink` attribute instead.

Raw view URL
rawLink

This attribute represents the link to this social object. This attribute contains a URL where you can view the social object details in the context of Connections. To access the social object in the context of the portal, use the `portalLink` attribute instead.

Raw number of comments
rawNumberOfComments

This attribute is internally used to compute the `numberOfComments` attribute. It does not show up in the authoring UI.

Raw replies URL
rawRepliesLink

This attribute specifies the Connections URL of the replies feed for this forum topic. If this social object is not a forum topic, this attribute is empty.

Raw type
rawType

This attribute carries the Connections component category term of the social object as it is used by the Connections search API. Among other information, the value includes the name of the Connections service and the service-specific content type. For example, the `rawType` of a social object can be `communities:blogs:entry`. For more information about Connections content types, read the Connections documentation.

Relevance score
relevanceScore

This attribute specifies the relative relevance of this social object in the context of a search query. The value of this attribute typically ranges between 0 and 1. However, values less than 0 or more than 1 can occur. You can consider a score that is smaller than 0 to be equivalent to 0 and a score that is larger than 1 to be equivalent to 1.

Service
service

The service attribute carries the name of the Connections service that hosts the social object. The portal sets this attribute according to the value of the `rawType` attribute and the service type mappings that are configured in the WP Connections Integration Service resource environment provider. For example, such services can be activities, blogs, bookmarks, calendars,

communities, forums, profiles, or wikis. For more information about Connections services, read the Connections documentation. This attribute is computed by the social rendering Digital Data Connector plug-in.

Summary
summary
A summary of the content of this item.

Tags
tags This attribute specifies the tags that are associated with this item.

Title
title The title of this item.

Type
type The type attribute carries the name of the content type of the social object. The portal sets this attribute according to the value of the `rawType` attribute and the resource type mappings that are configured in the WP Connections Integration Service resource environment provider. For example, such types can be `activity`, `blog`, `bookmark`, `calendar`, `community`, `file`, `forum`, `profile`, `statusUpdate`, or `wiki`. For more information about Connections content types, read the Connections documentation. This attribute is computed by the social rendering Digital Data Connector plug-in.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

URI type
uriType
This attribute specifies the type information for the URI of this social object. This attribute is computed by the social rendering Digital Data Connector plug-in.

Related tasks:

"Configuring file type icon mappings" on page 2129
Social rendering provides two types of list appearance components for result lists: `simple` and `comprehensive`. Both list appearances components show file type-specific icons when they render list entries that refer to individual files. In this case, the file type is determined based on the file extensions of the individual files. You can configure the set of file types that you want to use in the WP Connections Integration Service resource environment provider. In the context of social lists, a file type is defined by a file type name and a list of file extensions. This list defines the mapping between individual files and your file types. In your social list appearance components, you can then access the file type name for a specific file by using the Web Content Manager `[AttributeResource attributeName="fileType"]` tag. That tag is defined in the IBM Digital Data Connector (DDC) for WebSphere Portal Express profile. You can then use the file type name to render the appropriate image, for example, by assigning a corresponding CSS class.

"Configuring globally how social object data is served" on page 2125
Among other features, social objects have different links that enable users to download related data. For example, users can use links to download a file or the profile image of the author. You can globally configure how social object data is served to the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Related reference:

Setting parameters to format dates
These parameters are used to set the format of dates.

Tags profile:

The tags profile provides access to the IBM Connections tags facet that is served by the connections search service.

The tags profile declares the following attribute names:

ID
id The tag name that represents this tag.

Frequency
frequency
This attribute specifies how often this tag was assigned.

Wiki-related profiles:

These profiles provide access to wiki-related feed data for wiki pages, wiki page comments, and wiki page attachments.

Wiki pages profile

The wiki pages profile provides access to IBM Connections wiki pages feed data. It declares the following attribute names:

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL from which users can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

Author's name
authorName
You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID
This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute

represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID
This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
body HTML
The HTML content of this item.

Body plain
body plain
The plain content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the body attribute of this item.

Can create comment
canCreateComment
If the current user has permission to create comments to this wiki page, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Download size
downloadSize
This attribute specifies the download size of this wiki page.

Feed entry
entry The original feed entry of this item.

ID
id The unique identifier for this item.

Modifier is active
isModifierActive
This attribute indicates whether the user who made the most recent update to this wiki page is currently available.

Label
label This attribute specifies the label of this wiki page.

Library title
libraryTitle
This attribute specifies the title of the library that contains this wiki page.

Library UUID
libraryUUID
This attribute specifies the UUID of the library that contains this wiki page.

Modifier's email
modifierEmail
This attribute specifies the email address of the user who made the most recent update to this wiki page.

Modifier's ID
modifierID
This attribute specifies the internal ID of the user who made the most recent update to this wiki page.

Modifier's Image URL
modifierImageLink
This attribute specifies the photo URL of the user who made the most recent update to this wiki page. This attribute is computed by the social rendering Digital Data Connector plug-in.

Modifier's name
modifierName
This attribute specifies the name of the user who made the most recent update to this wiki page.

Number of attachments
numberOfAttachments
This attribute specifies the number of documents that are attached to this wiki page.

Number of comments
numberOfComments
This attribute specifies the number of comments that were posted on this wiki page.

Number of Likes
numberOfLikes
This attribute specifies the number of people who like this wiki page.

Number of Versions
numberOfVersions
This attribute specifies the number of versions that exist for this wiki page.

Permissions
permissions
This attribute specifies the permissions that the current user was given on the wiki page.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL from which users can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal modifier's image URL
portalModifierImageLink
This attribute specifies the WebSphere Portal Express photo URL of the user who made the most recent update to this wiki page. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal modifier's URL
portalModifierLink

This attribute specifies the WebSphere Portal Express URL that points to the details view of the user profile of the user who made the most recent update to this wiki page. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published

This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink

Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink

This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Portal body
portalBody

This attribute specifies the actual content of the wiki page when URL rewriting is performed. Links from that point to other wiki pages are rewritten into portal URLs so that clicking those links triggers a corresponding social object resolution. File attachment URLs are rewritten into Ajax proxy URLs. This attribute is computed by the social rendering bean list provider plug-in.

Raw body
rawBody

This attribute specifies the actual content of the wiki page. The content is served as is without any URL rewriting. This attribute is computed by the social rendering bean list provider plug-in.

Raw body fragment URL
rawBodyFragmentLink

This attribute specifies the Connections URL of the body fragment of this wiki page.

Raw comments URL
rawCommentsLink

This attribute specifies the Connections URL of the comments feed for this wiki page.

Raw download URL
rawDownloadLink

This attribute specifies the Connections URL of this wiki page. Users can use this URL to download this wiki page.

Raw edit URL
rawEditLink
This attribute specifies the Connections URL of the editable resource that represents this wiki page.

Raw Atom entry URL
rawEntryLink
This attribute specifies the Connections URL of the Atom resource that represents this wiki page.

Raw likes edit URL
rawLikesEditLink
This attribute specifies the Connections URL of the entry that makes it possible to edit the `liked` status of this wiki page.

null
rawLikesRemoveLink
null

Raw view URL
rawLink
This attribute specifies the Connections URL of the resource that holds the information whether the current user likes this wiki page. This resource can be modified.

Raw Modifier's entry URL
rawModifierEntryLink
This attribute specifies the URL of the Atom resource that represents the user profile of the user who made the most recent update to this wiki page. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw modifier's image URL
rawModifierImageLink
This attribute specifies the Connections photo URL of the user who made the most recent update to this wiki page. This attribute is computed by the social rendering Digital Data Connector plug-in.

Nested comments URL
rawNestedCommentsLink
This attribute specifies the Connections URL of the comments feed for this wiki page. This feed contains data about access rights and the `liked` status. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw attachments URL
rawWikiPageAttachmentsLink
This attribute specifies the Connections URL of the attachments feed for this wiki page. This attribute is computed by the social rendering Digital Data Connector plug-in.

Summary
summary
A summary of the content of this item.

Tags
tags This attribute specifies the tags that are associated with this item.

Title
title The title of this item.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

User likes
userLikes
If this wiki page is liked by the current user, this attribute returns the string `true`. Otherwise, it returns `false`.

UUID
uuid This attribute specifies the UUID of this wiki page.

Version number
versionNumber
This attribute specifies the version number of this wiki page.

Version UUID
versionUUID
This attribute specifies the version UUID of this wiki page.

Visibility
visibility
This attribute specifies the visibility information of this wiki page.

In addition to these attributes, the wiki pages profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Wiki page comments profile

The wiki page comments profile provides access to Connections wiki page comments feed data. It declares the following attribute names:

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink

This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL from which users can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's name
authorName

You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID

This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID

This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
body HTML

This attribute specifies the HTML content of this item.

Body plain
body plain

This attribute specifies the plain content of this item.

Body plain with new line replacement
bodyNewLine2BR

This attribute specifies the plain content of the item. In contrast to the `body plain` attribute, all new line characters are replaced by the appropriate HTML representation. For example the content might contain a line break:

```
Today is
a nice day.
```

The line break is replaced by the HTML line brake tag:

```
Today is<br>a nice day.
```

This attribute is computed by the social rendering bean list provider plug-in.

Body content type
bodyContentType

This attribute specifies the content type identifier for the body attribute of this item.

Can delete comment
canDeleteComment
If the current user has permission to delete the comment, this attribute returns the string `true`. Otherwise, it returns `false`. This attribute is computed by the social rendering Digital Data Connector plug-in.

Comment UUID
commentUUID
This attribute specifies the UUID of this wiki page comment.

Feed entry
entry The original feed entry of this item.

ID
id The unique identifier for this item.

Permissions
permissions
This attribute specifies the permissions that the current user was given on the wiki page comment.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL from which users can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published
This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink
Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Raw edit URL
rawEditLink
This attribute specifies the Connections URL of the editable resource that represents this wiki page comment.

Raw edit media URL
rawEditMediaLink
This attribute specifies the Connections URL of the editable media resource that represents this wiki page comment.

Raw Atom entry URL
rawEntryLink
This attribute specifies the Connections URL of the Atom resource that represents this wiki page comment.

Raw view URL
rawLink
This attribute specifies the Connections URL of the details view of this wiki page comment.

Summary
summary
A summary of the content of this item.

Title
title The title of this item.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Version number
versionNumber
This attribute specifies the version number of this wiki page comment.

In addition to these attributes, the wiki page comments profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Total Number of Items
totalNumberOfItems
This list property specifies the total number of items that were found for this search.

Requested Number of Items
requestedNumberOfItems
This list property specifies the requested number of items for this search.

Start Index
startIndex
This list property specifies the start index for the paged list of items.

Raw first URL
rawFirstLink
This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
rawNextLink
This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
rawPreviousLink
This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
rawLastLink
This list property specifies the Connections URL of the last page of items that are found for this search.

Is truncated
isTruncated
If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

Wiki page attachments profile

The wiki page attachments profile provides access to Connections wiki page attachments feed data. It declares the following attribute names:

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL from which users can download the image either directly from Connections or by using the Ajax proxy of the portal. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering bean list provider plug-in.

Author's name
authorName
You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID
This attribute references the serialized object ID of the author of the social object. In contrast to the `authorID` attribute, the `authorObjectID` attribute

represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering bean list provider plug-in.

Author's UID
authorUID
This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering bean list provider plug-in.

Body HTML
body This attribute specifies the HTML content of this item.

Body content type
bodyContentType
This attribute specifies the content type identifier for the `body` attribute of this item.

Body plain
bodyPlain
This attribute specifies the plain content of this item.

Attachment's size
byteSize
This attribute specifies the size of the attachment in bytes.

Download URL
downloadLink
This attribute represents a link to this attachment. This attribute contains a URL from which users can download the attachment either directly from Connections or by using the Ajax proxy of the portal. If the download link is not available, this attribute does not have a value. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering bean list provider plug-in.

Feed entry
entry This attribute specifies the original feed entry of this item.

File extension
fileExtension
This attribute carries the file extension of this attachment. For example, the file extension can be `.jpg`, `.mp3`, `.pdf`, or empty. This attribute is computed by the social rendering bean list provider plug-in.

File type
fileType
This attribute specifies the file type of this attachment. For example, the file type can be audio, code, compressed, contact, data, flash, graphic, pdf, presentation, text, video, wordProcessing, or dataDocs. The portal sets this attribute according to the value of the `fileExtension` attribute. The `fileType` attribute value is derived from the configured file type extension mappings of the WP Connections Integration Service resource environment provider. For more information, read *Configuring file type icon mappings*. This attribute is computed by the social rendering bean list provider plug-in.

ID
id This attribute specifies the unique identifier for this attachment.

Mime type
mimeType
This attribute specifies the mime type of this attachment.

Attachment's name
name This attribute specifies the name of this attachment.

Author's portal image URL
portalAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL from which users can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering bean list provider plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering bean list provider plug-in.

Portal download URL
portalDownloadLink
This attribute represents a link to this attachment. This attribute contains a URL from which users can download the attachment by using the Ajax proxy of the portal. To download the attachment from Connections without using the Ajax proxy, use the `rawDownloadLink` attribute instead. If the download link is not available, this attribute does not have a value. This attribute is computed by the social rendering bean list provider plug-in.

Published date
published
This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink
This attribute specifies the link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering bean list provider plug-in.

Author's raw image URL
rawAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering bean list provider plug-in.

Raw download URL
rawDownloadLink
This attribute represents a link to this attachment. This attribute contains a URL from which users can download the attachment directly from Connections. To download the attachment from Connections by using the Ajax proxy of the portal, use the `portalDownloadLink` attribute instead. If the download link is not available, this attribute does not have a value.

Raw Atom entry URL
rawEntryLink
This attribute specifies the Connections URL of the Atom entry that represents this attachment.

Summary
summary
This attribute specifies a summary of the content of this social object.

Title
title This attribute specifies the title of this social object.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

In addition to these attributes, the wiki page attachments profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

Total Number of Items
totalNumberOfItems
This list property specifies the total number of items that were found for this search.

Requested Number of Items
requestedNumberOfItems
This list property specifies the requested number of items for this search.

Start Index
startIndex
This list property specifies the start index for the paged list of items.

Raw first URL
rawFirstLink
This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
rawNextLink
This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
rawPreviousLink
This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
rawLastLink
This list property specifies the Connections URL of the last page of items that are found for this search.

Is truncated
isTruncated
If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

Related tasks:

"Configuring file type icon mappings" on page 2129
Social rendering provides two types of list appearance components for result lists: `simple` and `comprehensive`. Both list appearances components show file type-specific icons when they render list entries that refer to individual files. In this case, the file type is determined based on the file extensions of the individual files. You can configure the set of file types that you want to use in the WP Connections Integration Service resource environment provider. In the context of social lists, a file type is defined by a file type name and a list of file extensions. This list defines the mapping between individual files and your file types. In your social list appearance components, you can then access the file type name for a specific file by using the Web Content Manager `[AttributeResource attributeName="fileType"]` tag. That tag is defined in the IBM Digital Data Connector (DDC) for WebSphere Portal Express profile. You can then use the file type name to render the appropriate image, for example, by assigning a corresponding CSS class.

"Configuring globally how social object data is served" on page 2125
Among other features, social objects have different links that enable users to download related data. For example, users can use links to download a file or the profile image of the author. You can globally configure how social object data is served to the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Common profile:

The common profile provides general aspects that are available in various feeds that are served by IBM Connections. You can use the common profile when you create your own custom profiles.

Note: You cannot use the common profile as is. Therefore, the common profile is not available to the Tag Helper.
For more information about how to extend this profile, read *XPath list-rendering profile keys*.

The common profile defines the following attributes:

Author's email address
authorEmail
This attribute references the email address of the author of the social object.

Author's ID
authorID
This attribute references the internal ID of the author of the social object. It represents the author ID from the Connections server where the social object is stored.

Author's image URL
authorImageLink

This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image either directly from Connections or by using the Ajax proxy of the portal. This attribute is computed by the social rendering IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in. For more information about this attribute, read *Configuring globally how social object data is served*.

Author's name
authorName

You can use this attribute to include the name of the author of the social object in the design of a social list.

Author's object ID
authorObjectID

This attribute references the serialized object ID of the author of the social object. In contrast to the **authorID** attribute, the **authorObjectID** attribute represents an ID that is used by IBM WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's UID
authorUID

This attribute specifies the value of the UID attribute of the author of the social object. This value reflects the UID user attribute as defined by the user repository of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Body HTML
body HTML

The HTML content of this item.

Body plain
body plain

The plain content of this item.

Body content type
bodyContentType

This attribute specifies the content type identifier for the body attribute of this item.

Feed entry
entry The original feed entry of this item.

ID
id The unique identifier for this item.

Author's portal image URL
portalAuthorImageLink

This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL where you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's portal URL
portalAuthorLink
This attribute specifies the link for rendering the details view of the author of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Published date
published
This attribute indicates the time when the social object was published. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Author's raw Atom entry URL
rawAuthorEntryLink
Link to the Atom entry that represents the author of this item. This URL directly addresses the Connections server. This attribute is computed by the social rendering Digital Data Connector plug-in.

Author's raw image URL
rawAuthorImageLink
This attribute specifies the link to the profile image of the author of the social object. The Connections server that provides the social object also stores the profile image of the author. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering Digital Data Connector plug-in.

Summary
summary
A summary of the content of this item.

Title
title The title of this item.

Updated date
updated
This attribute indicates the time of the last update of the social object. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

In addition to these attributes, the common profile also provides access to the following list properties:

Updated date
updated
This list property indicates the time of the last update of the list that is represented by the feed at hand. To display the date in the format of your choice, you can use all date format options that Web Content Manager provides.

Raw URL to this feed
selfLink
This list property specifies the link to this feed.

Feed title
title This list property specifies the link to this feed.

To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Related reference:

"XPath list-rendering profile keys" on page 3277
The following list shows the set of list-rendering profile entry keys that are available in the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

Modifier support profile:

The modifier support profile provides general modifier aspects. These modifier aspects are available in various feeds that are served by IBM Connections. You can reuse them when you create your own profiles.

In contrast to the author information described in the *Common profile*, contributors of additional information to a social object who are not the initial authors are regarded as modifiers. As not all social objects have additional modifications, the modifier support profile is separate from the common profile.

The modifier support profile declares the following attribute names:

Modifier's email address
`modifierEmail`
: This attribute references the email address of the modifier of the social object.

Modifier's ID
`modifierID`
: This attribute references the internal ID of the modifier of the social object.

Modifier's image URL
`modifierImageLink`
: This attribute specifies the link to the profile image of the modifier of the social object. The Connections server that provides the social object also stores the profile image of the modifier. This attribute contains a URL from which users can download the image either directly from Connections or by using the Ajax proxy of IBM WebSphere Portal Express. For more information about this attribute, read *Configuring globally how social object data is served*. This attribute is computed by the social rendering bean list provider plug-in.

Modifier's name
`modifierName`
: You can use this attribute to include the name of the modifier of the social object in the design of a social list.

Modifier's object ID
`modifierObjectID`
: This attribute references the serialized object ID of the modifier of the social object. In contrast to the `modifierID` attribute, the `modifierObjectID` attribute represents an ID that is used by WebSphere Portal Express rather than by Connections. This attribute is computed by the social rendering bean list provider plug-in.

Modifier's UID
modifierUID
This attribute specifies the value of the UID attribute of the modifier of the social object. This value reflects the UID user attribute that is defined by the user repository of the portal. This attribute is computed by the social rendering bean list provider plug-in.

Modifier's raw Atom entry URL
rawModifierEntryLink
This attribute specifies the link to the Atom entry that represents the modifier of this item. This URL addresses the Connections server directly. This attribute is computed by the social rendering bean list provider plug-in.

Modifier's raw image URL
rawModifierImageLink
This attribute specifies the link to the profile image of the modifier of the social object. The Connections server that provides the social object also stores the profile image of the modifier. This attribute contains a URL for downloading the image directly from Connections. This attribute is computed by the social rendering bean list provider plug-in.

Modifier's portal image URL
portalModifierImageLink
This attribute specifies the link to the profile image of the modifier of the social object. The Connections server that provides the social object also stores the profile image of the modifier. This attribute contains a URL where you can download the image from Connections by using the Ajax proxy of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Modifier's portal URL
portalModifierLink
This attribute specifies the link for rendering the details view of the modifier of this item in the context of the portal. This attribute is computed by the social rendering Digital Data Connector plug-in.

Related tasks:

"Configuring globally how social object data is served" on page 2125

You can globally configure how social object data is served to the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

Tag support profile:

The tag support profile provides access to a list of tags that is associated with the social objects served by IBM Connections feed data.

It declares the following attribute name:

Tags
tags This attribute specifies the tags that are associated with this item.

OpenSearch support profile:

The OpenSearch support profile provides access to information that is defined in the OpenSearch specification. The OpenSearch specification is commonly used in the Atom feed format.

Specifically, this profile supports list properties that are required to make paging possible. Paging becomes necessary if the backend service does not return all available data records in a single feed and provides links for retrieving the next page of data records.

The OpenSearch support profile declares the following attribute names:

Total Number of Items
`totalNumberOfItems`
: This list property specifies the total number of items that were found for this search.

Requested Number of Items
`requestedNumberOfItems`
: This list property specifies the requested number of items for this search.

Start Index
`startIndex`
: This list property specifies the start index for the paged list of items.

Raw first URL
`rawFirstLink`
: This list property specifies the Connections URL of the first page of items that were found for this search.

Raw next URL
`rawNextLink`
: This list property specifies the Connections URL of the next page of items that were found for this search.

Raw previous URL
`rawPreviousLink`
: This list property specifies the Connections URL of the previous page of items that were found for this search.

Raw last URL
`rawLastLink`
: This list property specifies the Connections URL of the last page of items that are found for this search.

Is truncated
`isTruncated`
: If the list that represents a search result is truncated, this list property returns the string `true`. Otherwise, it returns `false`.

Using the business card:

You can integrate the business card and online status in a list of social objects by using live text micro format.

About this task

You can find a sample HTML component that includes this micro format in the IBM Connections library at the following location:

Social Lists 1.0 > **Components** > **Fragments** > **Business Card**. This HTML component is referenced by the default **Comprehensive** list appearance option for social objects that you can select when you customize social list definitions.

The business card sample identifies a user by the `authorObjectID` attribute of a social object that is returned by Connections.

If your IBM WebSphere Portal Express is configured to show the Connections business card information, use the `authorID` attribute instead of `authorObjectID` . For more information, read *Integrating with Connections*.

The following sample shows how you can map the different social object attributes to the microformat class attributes. This microformat works with both the WebSphere Portal Express business card and with the Connections business card. This means that the sample works, independent of whether WebSphere Portal Express is configured to show the portal business card or the Connections business card.

```
<span class='vcard X-sametime-resolve'>
   <span class="lotusMeta">
      <a target="" title="" href="javascript:SemTagMenu.a11y(event)"
                  class="fn lotusPerson" style="text-decoration:none;"
                  onclick="return false;">
                  [AttributeResource attributeName="authorName" separator=","]
      </a>
   </span>
   <span style="display: none;"
         class="userObjectId">[AttributeResource attributeName="authorObjectID"
         separator=","]</span>
   <span style="display: none;"
         class="x-lconn-userid">[AttributeResource attributeName="authorID"
         separator=","]</span>
</span>
```

For more information, read *Integrating the business card and online status in a custom portlet*.

Notes:

- CF03 If you integrate an Connections server that runs in the Smart Cloud for Social Business, support for the business card is currently not available. The Business Card HTML component that is contained in the Social Lists 1.0 library does not generate the business card microformat in this case. You can check whether you integrate an Connections server that runs in the Smart Cloud for social business in your own design components. To do so, use the `[Plugin:ConnectionsContext type="config" key="server.config"]`. For details, read *Configuring global settings for social rendering*.
- If you want to use the business card on a WebSphere Portal Express page, the page editor must add the `portal.livetext.hcard` theme capability to the page. To achieve this, the page editor can add the `wp_liveobject_framework` theme module to the current page profile. For more information, read *The module framework*.

Related concepts:

"The module framework" on page 2526
The module framework allows extensions to contribute to different areas of a page to provide flexibility, enhance the user experience, and maximize performance.

Related tasks:

Integrating with IBM Connections
Connections portlets give IBM WebSphere Portal Express users access to additional collaboration and social networking features such as Activities, Blogs, and Bookmarks. Users can also view Connections business card information and tags and link to Connections features directly from the portal server.

"Integrating the Business card and online status in a custom portlet" on page 3105
If IBM WebSphere Portal Express is configured to work with IBM Sametime, you can integrate the business card and online awareness in a custom portlet. Person names then appear with a dynamic status indicator. Users of the portlet can move the cursor over the name of an active person and then click **Click for Business Card**.

Customizing the CSS styles of social lists:

The lists of social objects rely on the availability of several CSS class definitions in the `wp_social_rendering_85` theme module.

About this task

Pages that render the sample items must use a theme profile that includes the `wp_social_rendering_85` theme module or another module that contains the same CSS class definitions. An example of such a theme profile is the Basic Content theme profile that is installed by default.

The `wp_social_rendering_85` theme module includes a single CSS file that is named `sr.css`. This style sheet is loaded from the following directory location: *`PortalServer_root`*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/modules/sr/v8.5/css/sr.css`.

The `wp_social_rendering_85` theme module defines the capability with the name `social_rendering_85` and the version `8.5`. No prerequisites are required to use this theme module.

Style sheet note: The lists of social objects use CSS styles that render differently, depending on the layout container that contains the social list web content viewer. Different classification CSS classes are assigned to these layout containers. As a result, the styles change when a social list web content viewer is moved from the center column into a narrower side column or vice versa. Furthermore, the styles are responsive to screen width and screen orientation. This responsiveness is achieved by using HTML5 and CSS3 media queries.

"Providing custom styles for social lists" on page 2226
The default CSS styles that are used to define the visual appearance of social lists are defined in the `wp_social_rendering_85` theme module. You can define your own styles.

"CSS class hierarchy for social lists" on page 2228
To define its visual appearance, the default markup for social lists uses several CSS classes. They are defined in the `wp_social_rendering_85` theme module. Learn about the purpose of the most important CSS classes.

"Using media queries to target mobile devices" on page 2229
The default social list CSS styles use CSS3 media queries to target specific mobile devices and implement responsive web design. Learn more about media queries.

Providing custom styles for social lists:

The default CSS styles that are used to define the visual appearance of social lists are defined in the `wp_social_rendering_85` theme module. You can define your own styles.

About this task

To create your own styles, proceed by the following steps:

Procedure

1. Create your own custom theme module. For information about how to create a new theme module, see the topic about *Define the module* in the WebSphere Portal Express product documentation.
2. Add an extension point to your theme module that adds CSS styles to the HEAD section of the page. As an example, the `wp_social_rendering_85` theme module uses the following extension point:

```
<extension point="com.ibm.portal.resourceaggregator.module" id="social_rendering_head" >
   <module id="wp_social_rendering_85">
      <capability id="social_rendering_85" value="8.5"/>
      <contribution type="head">
         <sub-contribution type="css">
            <uri value="res:{rep=WP GlobalThemeConfig;key=resources.modules.ibm.contextRoot}/modules/sr/v8.5/css/master_sr.css" />
            <uri type="rtl"
                 value="res:{rep=WP GlobalThemeConfig;key=resources.modules.ibm.contextRoot}/modules/sr/v8.5/css/master_sr_rtl.css"/>
            <uri deviceClass="smartphone"
                 value="res:{rep=WP GlobalThemeConfig;key=resources.modules.ibm.contextRoot}/modules/sr/v8.5/css/master_sr_mobile.css"/>
            <uri deviceClass="tablet"
                 value="res:{rep=WP GlobalThemeConfig;key=resources.modules.ibm.contextRoot}/modules/sr/v8.5/css/master_sr_mobile.css"/>
         </sub-contribution>
      </contribution>
   </module>
</extension>
```

   Make sure to leave the `social_rendering` capability ID and the `8.5` capability version number intact as it is, but change the module ID from `wp_social_rendering_85` to a value of your choice.
3. Make a copy of the theme profile provided with the portal, for example `profile_basic_content.json`. You can use that copied profile on your pages with social lists. If you update the default theme profile provided with the portal, your updates will be overwritten if you install a fix pack or otherwise upgrade your portal.
4. Add the new module ID from a previous step to your copy of the theme profile.
5. Copy the default CSS files from the social rendering theme into the new theme module. These files are in the following directory: *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/modules/sr/v8.5/css`

   The following CSS files are available:

Table 339. CSS files available in the social rendering theme

CSS file name	Purpose
`sr.css`	This file contains the basic social rendering list styles.
`sr_wptheme.css`	This file contains all styles that depend on `wptheme` sample CSS classes to detect wide, narrow, and thin columns.
`sr_rtl.css`	This file contains the style overrides for bidirectional languages.

Table 339. CSS files available in the social rendering theme (continued)

CSS file name	Purpose
sr_wptheme_rtl.css	This file contains the style overrides for wide, narrow, and thin column definitions in bidirectional languages.
sr_mobile.css	This file contains the style overrides and media queries for mobile devices.

The following table shows the master CSS files. They import the CSS files that are shown in the previous table.

Table 340. Master CSS files of the social rendering theme

CSS file name	Purpose
master_sr.css	This master CSS file links to the basic CSS styles for left-to-right languages.
master_sr_rtl.css	This master CSS file links to the basic CSS styles for bidirectional languages.
master_sr_mobile.css	This master CSS file links to the CSS styles for mobile devices and left-to-right and bidirectional languages.
master_sr_mobile_rtl.css	This master CSS file links to the CSS styles for mobile devices and bidirectional languages

6. Remove wp_social_rendering_85 from your new theme profile, and add the identifier of your new theme module instead. Repeat this process for all profiles that you are using in your website. By default, the wp_social_rendering_85 module is part of the following theme profiles:
   - profile_wab.json
   - profile_search_tag.json
   - profile_dojo_deferred.json
   - profile_dojo_basic_content.json
   - profile_basic_content.json
   - profile_deferred.json

   In the following code section, replace wp_social_rendering_85 by *your_theme_module_id*:

```
"wp_ic4_wai_resources",
 "wp_worklight_ext",
"wp_social_rendering_85",
"wp_sametime_proxy"
      ],
```

7. Save your changes.
8. Optional: If you updated your custom theme profile in a separate environment, copy your updated custom profile to the portal.
9. Optional: If you built your own custom theme and you do not use the wptheme sample CSS classes, make sure to modify the CSS rules in the CSS files sr_wptheme.css and sr_wptheme_rtl.css accordingly.
10. Optional: If you added more CSS files or renamed existing ones, make sure to update the master_*.css files, as they import one or more of the other sr_*.css files and make them available to the theme module.

11. Optional: If you add more `master_*.css` files or change their names, make sure to update the CSS contribution in the `plugin.xml` file of your theme module. See the following sample code snippet:

```
...
   <sub-contribution type="css">
      <uri value="res:{rep=WP GlobalThemeConfig;key=resources.modules.ibm.contextRoot}/modules/sr/v8.5/css/master_sr.css" />
      <uri type="rtl"
           value="res:{rep=WP GlobalThemeConfig;key=resources.modules.ibm.contextRoot}/modules/sr/v8.5/css/master_sr_rtl.css"/>
      <uri deviceClass="smartphone"
           value="res:{rep=WP GlobalThemeConfig;key=resources.modules.ibm.contextRoot}/modules/sr/v8.5/css/master_sr_mobile.css"/>
      <uri deviceClass="tablet"
           value="res:{rep=WP GlobalThemeConfig;key=resources.modules.ibm.contextRoot}/modules/sr/v8.5/css/master_sr_mobile.css"/>
      <uri ...additional contributions go here.../>
   </sub-contribution>
...
```

12. Optional: If you use social rendering with your own theme, modify the profiles of your custom theme accordingly.
13. Modify the CSS files that you copied to the new theme module in an earlier step as required. After you modified the CSS files, invalidate browser cache for your updates to take effect. To invalidate your cache, click **Theme Analyzer** > **Utilities** > **Control Center** > **Invalidate Cache**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

Results

After you complete this procedure, you can use your own custom styles for your social lists.

"Defining theme modules" on page 2547
You can define theme modules in XML or JSON.

CSS class hierarchy for social lists:

To define its visual appearance, the default markup for social lists uses several CSS classes. They are defined in the `wp_social_rendering_85` theme module. Learn about the purpose of the most important CSS classes.

Table 341. Social rendering CSS classes and their purposes

CSS class	Purpose
`srComponent`	This class is a top-level wrapper class that is set around the whole list.
`srSimple`	This class is a wrapper class that is set around the whole list in simple design within an `srComponent` container.
`srComprehensive`	This class is a wrapper class that is set around the whole list in comprehensive design within an `srComponent` container.
`srTable`	This class is set on the table that contains the list entries as row elements.
`srLeftColumn`	This class is set on the table cell that contains the entry icon.
`srMainColumn`	This class is set on the table cell that contains the entry title and metadata.
`srCountIcons`	This class is set on list items for the Likes and Comments icon.
`srLikeIcon`	This class is set on list item for the number of Likes.

Table 341. Social rendering CSS classes and their purposes (continued)

CSS class	Purpose
srCommentIcon	This class is set on list item for the number of Comments.
srShareIcon	This class is set on list item for access control status.
srMetaData	This class is a wrapper class that is set on container for date and tags metadata.
srMetaDate	This class is set on the date container of the entry.
srMetaTags	This class is set on the tags container of the entry.
srSummary	This class is set on the summary container of the entry.
srSocialBar	This class is set on the Social Bar component in each entry.
srRepliesList	This class is set on the outside container of the list of replies.
srViewSocialObject	This class is set on the part of a Social Bar that contains the View link.
srReply*	All classes that are used for styling replies in the forum topic details view are prefixed with srReply.

By using the CSS classes shown in this table, you can build specific rules to style every aspect of a social list entry individually. In the sr_wptheme.css style file, you can find a number of CSS rules that are used as overrides for basic CSS definitions on narrow and thin columns. To identify a narrow or thin column in the WebSphere Portal Express default Portal 8.5 theme, use CSS rules like the following one:

```
.wpthemeThin   .lotusui30 .srComponent .srSimple .srEntryTitle,
.wpthemeNarrow .lotusui30 .srComponent .srSimple .srEntryTitle {
    font-size: 0.63em;
}
```

Columns with the wpthemeThin CSS rule assigned to them are even smaller than columns with wpthemeNarrow assigned to them. If you want to define separate styles for narrow and thin columns, you can use the following CSS rules. The following code sample sets a smaller font size for the entry title on narrow columns and an even smaller font size for thin columns:

```
.wpthemeNarrow .lotusui30 .srComponent .srSimple .srEntryTitle {
    font-size: 0.63em;
}

.wpthemeThin .lotusui30 .srComponent .srSimple .srEntryTitle {
    font-size: 0.58em;
}
```

Using media queries to target mobile devices:

The default social list CSS styles use CSS3 media queries to target specific mobile devices and implement responsive web design. Learn more about media queries.

About this task

The media query that social rendering uses has the following format:

```
@media screen and (max-width: $valuepx) {
   ....
}
```

where `$value` is an integer value that defines the maximum screen width in pixels. The rules within this query block do not apply to screens with larger screen widths than specified. To define responsive styles, you can use multiple queries of this type with decreasing maximum screen widths. For example, you can start hiding elements within your markup on a tablet in portrait mode. You can then continue hiding even more elements on a smartphone in landscape mode, and show only a minimum data volume on smartphones in portrait mode.

Example

The default social list markup defines a social bar for each entry type, which takes up vertical space. To save vertical space on mobile devices, you can hide either the social bar View link or the complete social bar. In the following sample, you want to set up the following space arrangements for display on smartphones:

- In smartphone landscape mode, you want to hide the View link in the social bar of the social object.
- In smartphone portrait mode, you want to hide the social bar. This way, you reserve the complete vertical space for showing only the title and summary of the social object.

To achieve this reduction, you can use CSS3 media queries as shown herein the following code sample:

```
@media screen and (max-width: 480px) {
    .lotusui30 .srComponent .srViewSocialObject {
        display: none;
        width: 0px;
    }
}

@media screen and (max-width: 320px) {
    .lotusui30 .srComponent div.srSocialBar {
        display: none;
    }
}
```

The media queries in this sample work as follows:

1. The first media query makes sure that the View link in the social bar is hidden on displays that are 480 pixels or narrower.
2. The second media query makes sure that the social object social bar is hidden completely on displays that are 320 pixels wide or narrower.

For displays that are 321 to 480 pixels wide, only the first query applies. For screens that are 320 pixels wide or narrower, both queries apply.

Creating custom authoring templates for list definitions

Social rendering provides you a set of view definitions that you can use to add social data to your portal pages. These list view definition content items are created from the social list definition IBM Web Content Manager authoring template. You can create your own custom list view definitions by creating new

content items from this authoring template. To customize social rendering even further, you can also create your own authoring templates to extend the data set that makes up your list view definitions.

About this task

Your presentation components can then use the additional data that is provided by your custom authoring templates to control the rendering behavior for the lists. For example, you can add an option to have the page editor control whether the paging component for the social list is rendered or not. Social rendering can render content items that are created by such an extended authoring template in the same way as the default social lists do.

If you create a custom authoring template, make sure that it contains all the elements that are recognized by the `ListRenderingContext` rendering plug-in. This way you ensure that the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework can establish the appropriate query context when retrieving data from the remote IBM Connections server. To create a custom authoring template, proceed by the following steps:

Procedure

1. Copy the Social List Definition authoring template.
2. Keep all elements that the template already contains.
3. Add new elements as required.
4. Optional: You can also change the default for the existing elements or modify the authoring template user interface for those elements.

Implementing interactions with social objects

Site designers can implement design components that suppor interactions between the user and the social data. For example, a user can post a new reply to a forum topic or delete a previous reply.

About this task

To create such interactive designs, site designers need to implement an HTML form to send a POST action request to the Web Content Viewer portlet that displays the social list. The HTML form must include the URI of a data sink and parameters that identify the action that the designer wants to run. The portlet then dispatches to the target data sink that processes the form data and returns a data source that holds the result. For example, the result can be a JSON object that contains the status of the operation that is triggered with the POST action request and an error or success message. The portlet stores the result in the portlet session or as a private render parameter. To access the result in the formatting components, site designers can use the `SessionAttribute` rendering plug-in and the `RenderParam` rendering plug-in.

For more information about the action URL, render parameter, and session attribute rendering plug-ins, read *Utility rendering plug-ins*.

The following topics describe how you implement user interactions that are related to forum topics by using the social-rendering specific data sink. Additionally, you can implement further user interaction by using the generic XML Digital Data Connector data sink and the social rendering list-rendering profiles. For more information, read *The generic XML Digital Data Connector data sink* and *Digital Data Connector profiles for social rendering*.

"Interacting with forums"
WebSphere Portal Express provides a built-in data sink that supports different interactions with forums.

To implement the IBM Connections data integration, the social rendering feature in IBM WebSphere Portal Express Version 8.5 uses a custom IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

"Digital Data Connector profiles for social rendering" on page 2147
Starting with Version 8.5, IBM WebSphere Portal Express includes a set of IBM Digital Data Connector (DDC) for WebSphere Portal Express profiles. You can use them with the social rendering DDC plug-in that is identified by the extension ID `ibm.portal.ddc.sr`.

Interacting with forums:

WebSphere Portal Express provides a built-in data sink that supports different interactions with forums.

About this task

To implement such an interaction, the HTML form that targets the Web Content Viewer portlet must include all of the following:

- The URI of the forums data sink. The URI must be specified in the `action.uri` form field
- The name of the action that you want to have performed
- Extra input data that is required for the specified action. The URI of the forums data sink must contain the identifier of the target social object, for example, a forum topic or a forum topic reply. You must add the identifier to the scheme-specific part of the URI after a separating colon, `sr:forums:$REPLY_ID`. The forums data sink also expects the `action` form field to be submitted along with the form POST request. It specifies the action that you want to have performed on the target resource that is identified by the URI. The data sink supports the following actions:

  `createReply:`
  The forums data sink creates a new reply to the target social object, which must be either a forum topic or another forum topic reply.

deleteReply
The forums data sink deletes the target social object, which must be reply.

Depending on the action, the data sink requires extra form data.

Note: The update operation for individual replies that Forum Topic Details appearance component supports is implemented as a post to *The generic XML Digital Data Connector data sink*.

Related concepts:

"The generic XML Digital Data Connector data sink" on page 3263
The IBM Digital Data Connector (DDC) for WebSphere Portal Express framework contains a generic data sink. You can use the data sink in combination with HTML forms generated by your IBM Web Content Manager design components.

Creating a reply:

When you run a `createReply` action, the forums data sink uses a number of extra form fields.

About this task

They are listed here:

parentEntryLink
Specifies the raw Atom entry link of the forum topic or forum topic reply to post a reply to. This link must point directly to the Connections server rather than to the Ajax proxy of the portal.

parentRepliesLink
Specifies the raw replies link of the forum topic or forum topic reply to post a reply to. This link must point directly to the Connections server rather than to the Ajax proxy of the portal. -

replyTitle
Specifies the optional title of the reply to create.

replyContent
Specifies the content of the reply to create.

The following code snippet shows a sample form for creating a reply. It uses the `AttributeResource` tag of Web Content Manager to set the ID, the entry link, and the replies link of the parent social object in the context of a social list.

```
<form method="POST"
    enctype="multipart/form-data" action="[Plugin:ActionURL action="post"
    param="resultSessionAttribute=myResult" param="resultRenderParameter=myResult"
        compute="always"]">
    <input type="hidden" name="_charset_"
           value="[Plugin:EvaluateEL value="${pageContext.response.characterEncoding}"
           compute="once"]"/>
    <input type="hidden" name="action.uri"
           value="forums:sr:[AttributeResource attributeName="id"]"/>
    <input type="hidden" name="action" value="createReply"/>
    <input type="hidden" name="parentEntryLink"
           value="[AttributeResource attributeName="rawEntryLink"]"/>
    <input type="hidden" name="parentRepliesLink"
           value="[AttributeResource attributeName="rawRepliesLink"]"/>
  Title:
    <input type="text" name="replyTitle"/><br/>
    <textarea name="replyContent" rows="3" cols="25">Please enter your reply.</textarea><br/>
    <input type="submit" value="Post"/>
</form>
```

If the createReply action is successful, the forums data sink returns a JSON object. Example:

```
{
  "status":"success",
  "message":"Your reply has been created.",
  "formData":{
      "action.uri":"forums:sr:8fd51c01-6505-4d78-b364-415edf649e91",
      "action":"createReply",
      "parentEntryLink":"https://.../forums/atom/topic?topicUuid=8fd51c01-6505-4d78-b364-415edf649e91",
      "parentRepliesLink":"https://.../forums/atom/replies?topicUuid=8fd51c01-6505-4d78-b364-415edf649e91"
  },
  "resultData":{
      "replyID":"urn:lsid:ibm.com:forum:815b1a6d-5a3c-4730-91d2-094075ff2e5d"
  }
}
```

If the createReply action fails, the forums data sink returns a JSON object as seen in the following sample:

```
{
  "status":"error",
  "message":"Your reply could not be created. If the problem persists, contact the system administrator.",
  "formData":{
      "action.uri":"forums:sr:8fd51c01-6505-4d78-b364-415edf649e91",
      "action":"createReply",
      "parentEntryLink":"https://.../forums/atom/topic?topicUuid=8fd51c01-6505-4d78-b364-415edf649e91",
      "parentRepliesLink":"https://.../forums/atom/replies?topicUuid=8fd51c01-6505-4d78-b364-415edf649e91",
      "replyTitle":"My Forum Topic Reply",
      "replyContent":"This is my reply to the forum topic."
  }
}
```

Note that the formData property contains the actual form input, which includes all additional form data that you submit. If the action is successful, the replyTitle and replyContent are not returned to the caller.

Deleting a reply:

When you run a deleteReply action, the forums data sink uses a number of extra form fields.

About this task

They are listed here:

replyEntryLink
Specifies the raw Atom entry link of the forum topic reply that you want to delete. This link must point directly to the Connections server rather than to the Ajax proxy of the portal.

deleteReason
Specifies the reason for deleting the reply. This field is optional.

The following code snippet shows a sample form for deleting a reply. It uses the AttributeResource tag of Web Content Manager to set the ID and the entry link of the reply in the context of a social list that contains forum topic replies:

```
<form method="POST" enctype="multipart/form-data"
    action="[Plugin:ActionURL action="post"
    param="resultSessionAttribute=myResult"
    param="resultRenderParameter=myResult" compute="always"]">
    <input type="hidden" name="_charset_" value="[Plugin:EvaluateEL
           value="${pageContext.response.characterEncoding}" compute="once"]"/>
    <input type="hidden" name="action.uri"
           value="forums:sr:[AttributeResource attributeName="id"]"/>
    <input type="hidden" name="action" value="deleteReply"/>
    <input type="hidden" name="replyEntryLink"
           value="[AttributeResource attributeName="rawEntryLink"]"/>
```

```
  Reason:
    <input type="text" name="replyDeleteReason"/><br/>
    <input type="submit" value="Post"/>
</form>
```

If the `deleteReply` action is successful, the forums data sink returns a JSON object. Example:

```
{
  "status":"success",
   "message":"The reply has been deleted.",
   "formData":{
      "action.uri":"forums:sr:urn:lsid:ibm.com:forum:815b1a6d-5a3c-4730-91d2-094075ff2e5d",
      "action":"deleteReply",
      "replyEntryLink":"https://.../forums/atom/reply?replyUuid=815b1a6d-5a3c-4730-91d2-094075ff2e5d"
  }
}
```

If the `deleteReply` action fails, the forums data sink returns a JSON object as seen in the following sample:

```
{
   "status":"error",
   "message":"The reply could not be deleted. If the problem persists, contact the system administrator.",
   "formData":{
      "action.uri":"forums:sr:urn:lsid:ibm.com:forum:815b1a6d-5a3c-4730-91d2-094075ff2e5d",
      "action":"deleteReply",
      "replyEntryLink":"https://.../forums/atom/reply?replyUuid=815b1a6d-5a3c-4730-91d2-094075ff2e5d",
      "replyDeleteReason":"This is my reason for deleting the reply."
  }
}
```

The `formData` property contains the actual form input, which includes all additional form data that you submit. If the action is successful, the `replyDeleteReason` is not returned to the caller.

Adding widgets to a community

As an owner of an IBM Connections community, you can define the set of widgets that are available in the community. For this purpose, you use the Customize option in Connections. For example, you might choose to add the Blog widget to a specific community. This way, community owners have control over the set of services available in the communities they own.

About this task

When you use portal pages as the front end for communities, the pages typically contain social content that interact with one or more widgets of the community. For example, the List of Community Blog Posts shows blog posts that were created by using the Blog widget. You can flag such social content items with Drag and Drop configurations to depend on specific sets of widgets that are available in the associated community. You set this flag by setting a specific portlet preference on the portlet entity of the associated Drag and Drop configuration. Whenever a page editor adds such portlet to a community page, the portal infrastructure tries to dynamically add the required widgets to the associated community.

To flag a drag and drop configuration to require a specific set of widgets, you set the following preference on the portlet entity:

`ibm.portal.instantiation.community.widgets=`*`comma separated list of widget definition IDs`*

You set this preference by using the Manage Portlets portlet, or the XML configuration interface (XMLAccess).

The following list shows the supported widget definition IDs

- `StatusUpdates`

- Forum
- Bookmarks
- Files
- Blog
- IdeationBlog
- Activities
- Wiki
- Calendar
- MediaGallery
- Feeds
- SubcommunityNav
- RelatedCommunities

Example: To flag a drag and drop configuration to require the Blog and Wiki widgets, set the preference as follows:

```
ibm.portal.instantiation.community.widgets=Blog,Wiki
```

By default, the portal tries a best effort to add the widget. If the operation fails for whatever reason, the portal still adds the social content item to the page, but it does not add the widget to the community. If you require a different behavior, you can set an additional portlet preference to generate an error message instead. To flag a drag and drop configuration to generate an error message if the required widgets cannot be added to the associated community, set the following portlet preference:

```
ibm.portal.instantiation.community.widgets.failonerror=[true|false]
```

The default value is `false`. You set this preference by using the Manage Portlets portlet, or the XML configuration interface (XMLAccess). With the `failonerror` portlet preference enabled, the portal does not add the social content item to the page, but shows an error message instead.

The drag-and-drop configurations for the community-focused list view definitions have the setting `failonerror` set to the value `false`. The following list shows these configurations for your reference:

- List of Community Forum Topics:
  `ibm.portal.instantiation.community.widgets=Forum`
- List of Community Blog Posts:
  `ibm.portal.instantiation.community.widgets=Blog`
- List of Community Events:
  `ibm.portal.instantiation.community.widgets=Calendar`
- List of Community Content: `ibm.portal.instantiation.community.widgets=Forum,Bookmarks,Files,Blog,Activities,Wiki,Calendar`
- List of Community Files: `ibm.portal.instantiation.community.widgets=Files`

Note: The portlet preferences that are described here are ignored on non-community pages, that is on pages that are not associated to a specific community.

Extending social lists by using the digital data connector

The social rendering feature in IBM WebSphere Portal Express Version 8.5 is implemented as a IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

About this task

This approach makes it possible to use the extensibility features of this framework to extend the social rendering feature with extra capabilities:

- Realize custom queries against the IBM Connections server.
- Retrieve data from Connections services other than the search service.
- Make it possible for portal site visitors to contribute social information through user interfaces that are generated by IBM Web Content Manager features.

  "The social rendering Digital Data Connector plug-in"
  To implement the IBM Connections data integration, the social rendering feature in IBM WebSphere Portal Express Version 8.5 uses a custom IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

  "Implementing custom Connections queries" on page 2238
  IBM Connections provides a comprehensive remote API. You can use this API to access social data through Atom feeds.

  "Dynamic Connections source URL construction" on page 2239
  To dynamically construct IBM Connections query URLs, you can use the `[Plugin:ConnectionsContext]` and `[Plugin:ResourceURL]`.

  "Organizing your custom Connections queries" on page 2239
  For the different query URLs that you want to use, you can create multiple dynamic or static IBM Connections query URL components. For convenient use of these query URL components, you can create a generic authoring template for all list definitions that you want to build from those queries.

Related concepts:

"IBM Digital Data Connector (DDC) for WebSphere Portal Express" on page 3255
You can use the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework to integrate data from external data sources on your portal pages by using IBM Web Content Manager presentation components. External data means that the data does not need to be stored directly in IBM Web Content Manager. For example, you can use DDC to render social data that you have on your IBM Connections server or on other social platforms in the context of your portal pages. Other possible data sources include news feeds, task lists, product catalog information, to name just a few.

Using the list-rendering cache

The social rendering Digital Data Connector plug-in

To implement the IBM Connections data integration, the social rendering feature in IBM WebSphere Portal Express Version 8.5 uses a custom IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in.

You identify this social rendering DDC plug-in by using the DDC plug-in extension ID `ibm.portal.ddc.sr`.

The social rendering DDC plug-in delegates the data loading and XML transformation to the generic XML DDC plug-in. As a result, you can control this data transformation by XPath based list-rendering profiles. WebSphere Portal Express Version 8.5 includes a set of such profiles for a subset of the available Connections services. For more detailed information, read *Digital Data Connector profiles for social rendering*. You can use these profiles as is, or extend them by

creating custom extensions of the profiles, or create your own list-rendering profiles. The social rendering DDC plug-in adds various computed attributes to the profiles.

The social rendering DDC plug-in supports the `source` list-rendering context attribute. You can use this attribute to directly specify the source URL that serves the Connections XML data. To dynamically construct those source URLs, you can use the `[Plugin:ConnectionsContext]` and `[Plugin:URLParam]` tags. For more detailed information, read *Dynamic IBM Connections source URL construction*.

"Dynamic Connections source URL construction" on page 2239
To dynamically construct IBM Connections query URLs, you can use the `[Plugin:ConnectionsContext]` and `[Plugin:ResourceURL]`.

"Digital Data Connector profiles for social rendering" on page 2147
Starting with Version 8.5, IBM WebSphere Portal Express includes a set of IBM Digital Data Connector (DDC) for WebSphere Portal Express profiles. You can use them with the social rendering DDC plug-in that is identified by the extension ID `ibm.portal.ddc.sr`.

Implementing custom Connections queries

IBM Connections provides a comprehensive remote API. You can use this API to access social data through Atom feeds.

About this task

For more information about the API, read *IBM Connections 4.5 API Documentation*.

You can build custom queries for social data by constructing corresponding query URLs. To render the result of such a query on your portal pages by using IBM Web Content Manager design components, proceed as follows:

Procedure

1. Identify or create the list-rendering profile for the data format that your query URL serves. For example, your query might use the Connections Forums remote API to query for a specific set of forum topics. In this case, you can use the forum topics `ibm.portal.sr.forums.topics` profile to transform the result documents that this URL serves.
2. Establish the list-rendering context for this query. To do so, specify your query URL as a source attribute, and address the appropriate IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in that can handle your request. You have two choices:
   - If the profile that you use is based on the profiles that are included with IBM WebSphere Portal Express Version 8.5, you can use the social rendering DDC plug-in.
   - If you use a custom list-rendering profile, you can use either the generic XML DDC plug-in or a custom DDC plug-in that you deployed.

   Example: To retrieve the list of all public communities, you establish the list-rendering context as follows:

   ```
   [Plugin:ListRenderingContext action="set"
      extension-id="ibm.portal.ddc.sr"
      profile="ibm.portal.sr.communities"
      attribute="source=https://www.ibm.com/connections/communities/service/atom/catalog/public"]
   ```
3. To render the result, you must render an appearance component of Digital Data Connector. In that component, you extract the individual pieces of information.

You do so by using the [AttributeResource] tag and the attribute names that the list-rendering profile that you use supports. Example: In the community query that is shown in the previous step, you can render a link to a detail view of the community. You do so by adding the following markup to your Result Design section of the DDC appearance component:

```
<a href="[AttributeResource attributeName='link']">
    [AttributeResource attributeName='title']
</a>
```

4. After the rendering of the appearance component is completed, make sure to remove the list rendering context again. This is especially important if you want to nest list rendering contexts to render nested lists. You remove the list rendering context as follows:

   ```
   [Plugin:ListRenderingContext action="remove"]
   ```

   For more information, read *Setting the list-rendering context*.

The IBM Connections context rendering plug-in

 IBM Connections 4.5 API Documentation

Dynamic Connections source URL construction

To dynamically construct IBM Connections query URLs, you can use the [Plugin:ConnectionsContext] and [Plugin:ResourceURL].

The [Plugin:ConnectionsContext] plug-in serves relevant Connections context and configuration information. This includes the service base URLs, the UUID of the community that is associated to the current page, and the source URL of social Atom object entries that a user clicked. For more detailed information about this plug-in, read *The connection context rendering plug-in*.

You can use the [Plugin:ResourceURL] to construct complex query URLs. You do so by adding one or more query parameters to an existing Connections service base URL. For more detailed information about this plug-in, read *The resource URL plug-in*.

Example: To dynamically construct the query URL that serves the information about the members of the community that associated to the current page, you create an HTML component that contains the following markup:

```
[Plugin:ResourceURL param="role=all" param="format=full"
   param="sortBy=created" param="sortOrder=desc"
   url="[Plugin:ConnectionsContext type='service'
   key='communities']/service/atom/community/members"
   compute="always"]
```

Related information:

The IBM Connections context rendering plug-in

Organizing your custom Connections queries

For the different query URLs that you want to use, you can create multiple dynamic or static IBM Connections query URL components. For convenient use of these query URL components, you can create a generic authoring template for all list definitions that you want to build from those queries.

About this task

When you work with IBM Digital Data Connector (DDC) for WebSphere Portal Express, the generic authoring template must comprise short text elements for identifying the following elements:

- The DDC plug-in ID and the profile name. For example, they can be elements named `provider` and `profile`.
- Component references to the query URL HTML component and the appearance component. For example, they can be elements named `sourceref` and `design`.

You can now create individual list definition content items from this authoring template for your Connections queries. To set up the query-specific list-rendering context and to render the query-specific appearance component, you can use a generic presentation template for all those queries as follows:

```
[Plugin:ListRenderingContext compute="always"
   extension-id="[Element context='current' type='content' key='provider']"
   profile="[Element context='current' type='content' key='profile']"
   attribute="source=[Element context='current' type='content' key='sourceref']"]
   [Element context="current" type="content" key="design" compute="always"]
```

For example, a list definition content item for the query that was defined in *Dynamic Connections source URL Construction* specifies the following settings:

- It sets the `provider` field to `ibm.portal.ddc.sr`.
- It sets the `profile` field to `ibm.portal.sr.communities.members`.
- The `sourceref` component reference points to the query HTML component. For a description of that component, read *Dynamic Connections source URL construction*.
- The design component reference points to an appearance component that generates the list of community member markup. The markup is generated based on the attributes that are defined in the `ibm.portal.sr.communities.members` list-rendering profile.

Setting up marketing campaigns

Use these tools and features to setup marketing campaigns for your website.

"Personalization"
Portal Personalization provides automatic customization of website content for individual users and user groups.

"Social Media Publisher" on page 2421
The Social Media Publisher for Web Content Manager is an extension to Web Content Manager that allows businesses to promote their web content on social networks, and provide some basic statistics about the promoted content.

Personalization

Portal Personalization provides automatic customization of website content for individual users and user groups.

Personalization can recognize a specific user based on a profile or can determine characteristics of a user based on previous purchases, products or pages viewed, and so forth. Personalization then selects content that is appropriate for that profile. If a person has a high salary range, Personalization can be configured to

retrieve information about a commercial website premium product. If an individual belongs to a particular geographic region, content specific to that region may be targeted to the individual. The page is assembled with the proper personalized information, and the user sees her personalized page.

Personalization is composed of

- Personalization browser - The Personalization user interface:
  - registers resource collections
  - authors rules, campaigns, and content spots
  - maps rules into content spots for a particular campaign

  Since objects are authored through the Personalization server, the Personalization browser can display rules in production as well as view rules in a staging environment.
- Rules engine - The rules engine executes rules created in the Personalization browser. A programming interface exists for Personalization to invoke rules, Personalization rules may be invoked through the Personalized List portlet, or rules may be invoked through Web Content Manager Personalization components. Rules associated with pages or portlets through Portal Administration are also automatically triggered.
- LikeMinds Recommendation engine - The recommendation engine evaluates recommendation rules created in the Personalization browser.
- Resource engine - The resource engine resolves the queries produced by rules into content pieces to be returned. Content for Personalization is created and approved using whatever content management tool you choose, or may come from an LDAP or any other database. Content is accessed via a set of Resource Collection classes.
- A logging framework - The logging framework is used to record information about website usage to the feedback database and the recommendation engine. It is entirely up to the site developers to decide what information is logged.

The engines are sometimes collectively referred to as the Personalization run time server.

The engine identifies the particular user. Personalization retrieves that person's profile. For example, a person may have a salary range included in her profile. Personalization then selects content that is appropriate for that profile. If a person has a high salary range, region code, or other information, Personalization can be configured to retrieve information about a commercial website premium product. The page is assembled with the proper personalized information. The user sees her personalized page.

Types of Personalization

There are three types of Personalization:

Simple filtering
: A site displays content based on predefined groups of site visitors. For example, if a site visitor is in the Human Resources department, the site provides access to URLs containing Human Resources policy manuals.

Rules engines
: In a rules based system, the site owner defines a set of business rules which determine what category of content is shown when a certain profile type visits the site. An example would be: Display all four wheel drive SUVs to visitors in the northeast in the 21 to 35 age group.

This approach has the advantage of driving the site's behavior with the business objectives of the site owner. The site owner is usually the owner of a marketing campaign or some other business manager.

Collaborative filtering
A site visitor rates a selection of products, explicitly or implicitly. Those ratings are compared with the ratings offered by other visitors. Software algorithms detect similarities. For example, a visitor receives book recommendations based on the similar purchases of others.

Rules versus collaborative filtering

When complex filtering is required, a rule-based system may work better than collaborative filtering, and vice versa. The following table details examples where one type of personalization is better than the other.

Table 342. When to use rules filtering versus collaborative filtering.

Scenario	Which filtering type to use	Reason
If the number of items offered and users who purchase them are rather low.	Rules	Very little room to compute user similarity necessary for collaborative filtering.
If price points are high or purchasing frequency is low.	Rules	Finite, limited arenas - collaborative filtering fails because of the inherent lack of diversity.
If there is a pre-existing dependency between items. Example: Disability policy required for homeowner	Rules	Recommending a disability policy just because collaborative filtering says many others "like this user" also bought a policy is incorrect--one must have the homeowner policy first.
If number of items offered and users who purchase them are rather high.	Collaborative	Cannot write rules covering all items.
If price points are low, all quite dissimilar, or the products offered have a wide range of user appeal.	Collaborative	The wide variance fits the collaborative filtering approach. Collaborative filtering also lowers the risk of making "bad" recommendations.
When not much information is gathered about the user, but the user can be identified, possibly by a login or cookie.	Collaborative	In this case, user attributes on which to base rules may be lacking. Collaborative filtering can compare the user's experiences on the site to other users.

1. “How a site is personalized” on page 2244
   Use this topic to understand how to define a personalized list of new articles for a website, such as a section of an intranet site for targeted employee bulletins or where the content of the site is tailored to the particular user.
2. “Personalization terms” on page 2245
   The concepts and principles for working with Portal Personalization require an understanding of terminology.

3. “The Personalization interface” on page 2296
   The Portal Personalization user interface consists of three portlets: the Personalization Navigator, Personalization Editor, and the Personalized List.
4. “Publishing personalization rules overview” on page 2298
   WebSphere Portal Express Personalization sends published rules across HTTP to a servlet which resides on each personalization server. This servlet can receive publishing data or initiate new publishing jobs. When a user begins a publishing job from the personalization authoring environment, the local servlet is provided with the set of information necessary to complete the job. The local servlet contacts the destination endpoint servlet (which could be the same servlet) and sends its data to it. The destination servlet reports success or failure.
5. “The Web Content resource collection” on page 2308
   The Web Content resource collection is installed and configured out of the box. This predefined collection allows you to write rules that select lists of content from IBM Web Content Manager. Rules specify which Web content to show in a Portal Personalization component in Web Content Manager.
6. “The Portal User resource collection” on page 2311
   Portal Personalization comes with a Portal User resource collection. This collection uses public APIs provided by IBM WebSphere Portal Express to access user information.
7. “LikeMinds Recommendations” on page 2313
   Personalization contains a dynamic recommendation system based on LikeMinds. LikeMinds is software that is used with your e-commerce applications. LikeMinds analyzes user interactions that occur on your Web site and generates real time predictions and recommendations to your Web site users.
8. “Feedback and analytics” on page 2344
   Personalization provides a complete logging framework for collecting data on how visitors are using your Web site. If Feedback is enabled, data is automatically collected about each Personalization rule that is fired. In addition, development tools enable Web sites to collect a variety of data related to visitors' actions and behavior. By default this data is logged to a standard database schema for later analysis and reporting. The framework is also extensible, allowing Web sites to customize and supplement the way data is collected and stored to more fully meet their needs.
9. “Developing a personalized portlet” on page 2385
   This exercise demonstrates how to use Personalization features of WebSphere Portal and Rational Application Developer to build your first personalized portlet. Your final result is a working portlet that uses Personalization rules and content spots to display personal news based on user attributes (or profiles).
10. “Personalization programming reference” on page 2402
    IBM WebSphere Portal Express provides the programming model, processes, and APIs for the Personalization rules and resource engines.

Related concepts:

Your final result is a working portlet that uses Personalization rules and content spots to display personal news based on user attributes (or profiles).

How a site is personalized

Use this topic to understand how to define a personalized list of new articles for a website, such as a section of an intranet site for targeted employee bulletins or where the content of the site is tailored to the particular user.

Developing a personalized portlet or website

1. A web developer defines an area of a site that needs Personalization. This area may be a personalized list of new articles appearing in a website, a place on an intranet site for targeted employee bulletins such as changes to benefit plans, a product list on a commerce website, or any other place where the content of the site should be tailored to the particular user.
2. A set of Resource Collections and Application Objects are defined. Together, these objects make up the business vocabulary that represents the terms and objects upon which Personalization decisions are based. These objects may be defined in the web page by pointing to an IBM Java Content Repository item type. These objects may be generated through a set of Personalization wizards provided with IBM Rational Application Developer; or they may be developed according to a set of public programming interfaces.
3. The Resource Collections and Application Objects are registered to the Personalization server through the Personalization browser by importing .hrf files. These files define Resource Collections. The developer can also manually create the Resource Collection and Application Object references in the Personalization Browser.

   Note: The classes used for the Resource Collections and Application Objects must be on the classpath for both the application being personalized and for the Personalization browser web application. One way to achieve this task is to use a shared library placed either on the application server, or on the individual web applications. If you are using stock resource collections provided with IBM WebSphere Portal Express, such as the Portal User Resource Collection or the Java Content Repository Resource Collection, these classpaths are already registered properly.
4. Programmers now use the objects and terms defined through the Resource Collections and Application Objects to write rules and map those rules to content spots using campaigns.
5. Portlet and website developers may either configure a Personalization Rule Display portlet to show the rule or content spot or may call into the Personalization programming interfaces to execute the appropriate rules or content spots which the programmers have defined.

Note: The Content Spot provides a way for the site developers to develop personalized pages before the rules are authored as well as a way to more loosely tie a particular rule to a page. It is then up to a programmer to "map" the Content Spot to a Rule using a Rule Mapping within a Campaign in a Personalization browser.

Using Personalization Rules

1. A user navigates to the page containing Personalization rules or content spots.
2. The application invokes Personalization to find content or make decisions.
3. Personalization identifies the correct rules to execute. If a Content Spot with the name given to execute is not found, a rule is looked for directly with this name.
4. The Personalization server searches for all Rule Mappings for the Content Spot. The server looks for Rule Mappings which have started, but not yet ended.

5. The Rule Mappings are ordered based on the priority and split values. The rules associated with each mapping are executed in turn until a rule returns content.

   Note: It is possible to configure Personalization so that only the first rule (higher priority) will get executed.
6. For each rule executed, Personalization retrieves the user's profile and evaluates the rule to select the content which meets the conditions of the rule. The rules engine will invoke the resource engine as necessary to retrieve content pieces.
7. The content is returned to the web page, and displays for the user.

Related concepts:

"Developing a personalized portlet" on page 2385
This exercise demonstrates how to use Personalization features of WebSphere Portal and Rational Application Developer to build your first personalized portlet. Your final result is a working portlet that uses Personalization rules and content spots to display personal news based on user attributes (or profiles).

Personalization terms

The concepts and principles for working with Portal Personalization require an understanding of terminology.

1. "Resources, resource instances, and resource collections" on page 2246
   Before you can personalize IBM WebSphere Portal Express resources, you need to understanding the terms for portal objects stored in the content repository.
2. "User resources" on page 2247
   Your Web site visitors want to quickly access the Web content that meets their needs and interests. The needs and interests of the site visitors are stored as properties in the user profile data store.
3. "Content resources" on page 2248
   Web content resources consist of data that is formatted and displayed on Web pages. Examples include news articles, products, statistics and educational materials.
4. "Attribute Based Administration" on page 2248
   Attribute based administration provides a facility to customize the layout of a page for individual authenticated users by using rules to show or hide pages or portlets. This implementation tells the portal to show or hide pages and portlets based on dynamic characteristics that are determined at runtime. Attribute Based Administration is only available for authenticated users. For anonymous users, all pages are shown.
5. "Rules" on page 2250
   Rules are used to define how your Web site interacts with individual and groups of Web site visitors. Rules are composed of easy-to-read logic statements that, in their final form, specify how to evaluate various conditions and what actions to take based on those conditions.
6. "Content spots" on page 2271
   A content spot is a placeholder or slot for a rule on a Web page. When the page is viewed, the content spot uses its rule mapping to determine which rule to execute. When the rule is executed, any actions defined within the rule take place. Each content spot has a unique name. A content spot's content type must be defined when it is created and should not be changed.
7. "Rule spot mappings" on page 2272
   For a rule to be used on your Web site, it must be mapped to an existing content spot. A rule spot mapping is merely an association between a content

spot and a rule. Changing the rule that is executed in the run-time environment is as easy as mapping a different rule to a content spot.

8. "Campaigns" on page 2272
   Campaigns are a means of organizing and implementing sets of personalization behavior. A useful analogy is an advertising campaign, which targets specific audiences with high-priority information for a specified period of time. Campaigns achieve this by allowing you to preferentially display campaign-related content in the content spots of a Web site. To accomplish such a goal, a campaign contains a set of rule-to-content spot mappings, start dates, and stop dates.
9. "Application object" on page 2273
   An application object is a java object existing at a known location in the request context. Defining an application object involves specifying the object's class name (as a Java class), and specifying a key (string key into a session attribute) to find it in the request context. Personalization calls methods on these objects during rule execution and uses their results in its decision making. Application Objects that implement the SelfInitializingApplicationObject interface are automatically instantiated as needed by Personalization.
10. "Request Context" on page 2295
    This is the interface used to access various attributes for rules. For HTTP contexts, it provides access to the HttpRequest and HttpSession attributes. For non-HTTP contexts, it provides the same interface to a surrogate for the request and session.
11. "Query framework" on page 2296
    The query framework is an object representation of a query. The framework is not specifically oriented toward querying either object or relational databases. A set of common operators is defined, but what an attribute represents is determined by the interpreter of the query.

Resources, resource instances, and resource collections:

Before you can personalize IBM WebSphere Portal Express resources, you need to understanding the terms for portal objects stored in the content repository.

A *resource* is a Java class that defines the properties of a user or content object. In database terms, it is analogous to the database schema that defines the column names and types for a database table. Resource classes must implement the com.ibm.websphere.personalization.resources.Resource interface

A *resource instance* is an instance of the resource class. Again, using a database analogy, the resource instance is similar to a row of a database table because it contains actual values for each property defined by the resource.

A *resource collection* is a Java class that represents and allows access to a collection of resource instances. It is similar to a database table with a fixed schema and a number of rows. Resource collection classes must implement the com.ibm.websphere.personalization.resources.ResourceDomain3 interface. Rational Application Developer provides a wizard that can create resource collections that store data in SQL databases or LDAP repositories. The classes that can make up the resource collection are as follows:

Resource Class
An instance of `com.ibm.websphere.personalization.resources`.

Resource Manager Class
An instance of
`com.ibm.websphere.personalization.resources.ResourceManager3`.

Domain Class
An instance of
`com.ibm.websphere.personalization.resources.ResourceDomain3`.

Translator Class
An instance of
`com.ibm.websphere.personalization.resources.AuthIDTranslator`.

For more details, refer to the Javadoc API documentation for Personalization APIs You can provide your own implementation of these classes or use the RAD Personalization Wizard to generate classes that query against SQL or LDAP repositories.

While resources, resource instances, and resource collections are easily mapped to familiar database concepts, it is important to note that the actual content store they refer to does not have to be a database table. It can be a file system, an LDAP repository, an XML store, or virtually any content store accessible by Java.

Related information:

"Using the Personalization APIs" on page 2409
Personalization provides open APIs that enable the Personalization run-time environment and Rational Application Developer to access user and content data in customer data stores.

User resources:

Your Web site visitors want to quickly access the Web content that meets their needs and interests. The needs and interests of the site visitors are stored as properties in the user profile data store.

Many sites obtain the user needs and preferences by using an HTML input form. The input form includes information that seldom changes (such as the user name and address) and information that must be updated over time (such as gift wish lists). In addition to explicit information provided by the site visitor in the HTML input form, a business might also programmatically update the user profile data store with information obtained from other sources. These sources could include an analysis of a user's actions on the Web site and data from a user's non-Web interactions with the business.

Although users are unique, personalizing Web content does not often require creating totally unique content for each user. Users can be profiled or grouped into categories that facilitate personalization. For example, on an internal Web site, certain information might be appropriate for managers, while other content may be suitable for salespersons.

Note: The Portal User Collection resource collection included with Personalization cannot currently be used to select lists of users in select content rules. The resource collection may be used to profile the user in a profiler rule. This applies to both the user resource collection which is installed with Personalization as well as any custom resource collections created with the manager class com.ibm.websphere.personalization.resources.wps.UserManager.

Content resources:

Web content resources consist of data that is formatted and displayed on Web pages. Examples include news articles, products, statistics and educational materials.

The content is displayed when a user requests a JSP or servlet that dynamically generates and formats a Web page in the appropriate format, such as HTML or XML. When personalizing your Web site, you only have to customize the content you want to selectively display (or suppress) based on the user. For example, a given page might consist of 40% static content and 60% variable content based on particular user characteristics or business conditions, while other pages might be 100% static content.

Content resources can be file content or structured content.

Attribute Based Administration:

Attribute based administration provides a facility to customize the layout of a page for individual authenticated users by using rules to show or hide pages or portlets. This implementation tells the portal to show or hide pages and portlets based on dynamic characteristics that are determined at runtime. Attribute Based Administration is only available for authenticated users. For anonymous users, all pages are shown.

Portal Personalization rules can be used to control whether a page is displayed in the site navigation; this is managed by choosing a rule appropriate for the user attribute you want to enable to see the page. If the rule returns true, the page or portlet will be shown, otherwise, it will be hidden. If Personalization is not installed or is not enabled in the properties settings, you will not see this option.

Access Control and Visibility Rules

Access Control and Visibility Rules both impact what appears on a portal page or portlet. Access Control determines what a user is allowed to see on a page or in a portlet. In order to see pages and portlets, a user must be explicitly defined as a member of the group that has access. The groups are arranged in a hierarchy and each group is assigned roles such as administrators or editors.

Visibility rules determine what a user will see, or what has been targeted towards a user, and Access Control is based on group membership, visibility rules use any type of information, including LDAP attributes, or time of day. For example if you want to hide a portlet for an individual in a certain geography, store the location as an attribute in LDAP, and assign a visibility rule hiding the portlet. For example, a user may have access to the revenue figures for all divisions for the entire year, but these figures should not be displayed prominently except when they are first released. For a week after the figures are first released, the figures for the employee's division should show prominently on their home page. The visibility rule hides figures for divisions the employee is not in and only shows the employee's figures the week after they are released.

Access Control takes precedent over visibility rules. You must have access to a page or portlet prior to applying visibility rules. Access Control also determines if a page or portlet will be returned in a search; if a user does not have access, he will not be able to see the portlet or page in search results. If a user has access to a

portlet or page, but has the visibility rule set to hide the page or portlet, it will show up in search results.

"Assigning attribute based administration rules to pages and portlets"
Attribute based administration rules can be assigned manually in the portal in the Edit Properties and Edit Layout portlets, or through the XML configuration interface. The rule must be present on the system in order to assign it to a page or portlet. You can usually use Personalization Publish to accomplish this.

"Changing the error condition behavior" on page 2250
If an error occurs when locating or using a rule assigned to a page or portlet, by default that page or portlet will be hidden. If a user or expected application does not exist, the system will continue. This behavior may be appropriate, but in a development environment, you may need to change this behavior for testing purposes. Update the PersonalizationService.properties file to override this behavior globally.

Assigning attribute based administration rules to pages and portlets:

Attribute based administration rules can be assigned manually in the portal in the Edit Properties and Edit Layout portlets, or through the XML configuration interface. The rule must be present on the system in order to assign it to a page or portlet. You can usually use Personalization Publish to accomplish this.

Before you begin

- In order to map rules, non-administrator users must be given at least user access to the rule that is being mapped and edit access to the page or portlet where the rule is being mapped.
- Pages or portlets on derived pages show an inherited visibility rule if no rule is defined for them. You cannot clear the inherited visibility rules on derived pages.

About this task

Using the XML configuration interface, you can assign a rule to a page or portlet. Set the parameter **com.ibm.portal.navigation.rule** to indicate the rule to assign to the page or portlet. The value of the parameter should be the unique id or UUID of the rule. The UUID can be found by exporting the rule in the Personalization user interface and inspecting the exported XML for the **jcr:uuid** parameter.

Procedure

Example

For example, to assign a rule with the UUID `7ce9d5004ee31f41b0d3b944c9f7965c` to a page or portlet, add the following parameter to the content-node in the XML access script:

```
<parameter name="com.ibm.portal.navigation.rule" type="string"
update="set"><![CDATA[7ce9d5004ee31f41b0d3b944c9f7965c]]</parameter>
```

Related concepts:

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

Changing the error condition behavior:

If an error occurs when locating or using a rule assigned to a page or portlet, by default that page or portlet will be hidden. If a user or expected application does not exist, the system will continue. This behavior may be appropriate, but in a development environment, you may need to change this behavior for testing purposes. Update the PersonalizationService.properties file to override this behavior globally.

Before you begin

About this task

The property rulesEngine.visibilityDefault specifies whether a page or portlet renders if there is a problem with the assigned rule. Changing the property value to show means the page or portlet will display even if the assigned rule cannot be found or if there is a problem with the rule.

The property rulesEngine.throwObjectNotFoundException specifies what happens if an object such as a user is not found when needed during rule execution. This may occur when Personalization cannot find the current user or when an expected application object does not exist on the session or request at the expected key. When set to false, a null user or object is not treated as an error but is instead only printed to the logs as a warning. Personalization will continue as if the requested attribute of the null object is itself null.

For example, if no user object is found and rulesEngine.throwObjectNotFoundException is set to false, a rule such as `Show page or portlet when user.name is null` would return `show`. A null user is treated as if the user name is null. However, if no user object was found and rulesEngine.throwObjectNotFoundException is set to true, this same rule would throw an exception. If this rule was used to determine the visibility of a page or portlet, the ultimate result would depend upon the value of the rulesEngine.visibilityDefault property, which would decide what occurs if an exception is thrown during processing of a rule in attribute based administration.

Procedure

1. Open the PersonalizationService.properties file. This file is located in the following directory:*wp_profile_root*`/PortalServer/config/config/services/PersonalizationService.properties`.
2. Find the rulesEngine.visibilityDefault property.
3. Set the value of this property to `show` to enable portlets or pages to render if an error occurs.
4. Fine the rulesEngine.throwObjectNotFoundException property.
5. Set the value of this property to `true` to throw an exception if the object is not found.

Rules:

Rules are used to define how your Web site interacts with individual and groups of Web site visitors. Rules are composed of easy-to-read logic statements that, in their final form, specify how to evaluate various conditions and what actions to take based on those conditions.

"Actions" on page 2251
Actions use simple evaluation statements to select content to use or display, or

to set information. Basic arithmetic calculations (addition, subtraction, multiplication, division) that follow order of operations can be used on either side of the evaluation; parentheses are not supported. Actions can be combined with profilers into bindings.

"Profilers" on page 2253
Profilers are typically used to categorize an individual (usually the current site visitor) according to his or her user properties.

"Bindings" on page 2256
Bindings combine actions and profilers to specify actions to perform when defined conditions are encountered. Returned content can be sorted or filtered prior to display or use. Actions can be set to be performed by *always*, *exclude*, and *otherwise* blocks. In addition, the total number of items used can be limited.

"Recommend Content" on page 2259
You use Recommend Content rules (also referred to as recommendation rules) to recommend content to your Web site visitors. Recommendation rules, powered by LikeMinds, recommend content based on users' past interactions with your Web site.

"Visibility Rules" on page 2260
Visibility rules determine what a user will see, or what has been targeted towards a user. Visibility rules can be assigned to pages and portlets and will be triggered automatically by the portal as needed.

"Rule elements" on page 2261
Learn about the options in the rule editor for the different types of rules.

"Email" on page 2269
View the prerequisites for creating an email action or promotion within the Personalization workspace.

"Email administration" on page 2270
View the steps you need to complete before your run time server can send personalized email.

Actions:

Actions use simple evaluation statements to select content to use or display, or to set information. Basic arithmetic calculations (addition, subtraction, multiplication, division) that follow order of operations can be used on either side of the evaluation; parentheses are not supported. Actions can be combined with profilers into bindings.

The following action items are supported:

Select actions
Select data or content. Select actions retrieve data from a data store, typically for display on a web page. Select actions also can be used within bindings to exclude certain content, that is, filtering a subset of returned content from a superset.

Update actions
Update content or objects on the request. Update actions cannot select content. Update actions are used to store content or data in the user profile, an application object, or other data stores.

Email actions
Send email messages using a web page as the body. Email actions cannot select content. An email action sends an email message to a recipient or list of recipients. An email action assigned to a content spot sends an email

message when the content spot is triggered. For example, at the time a website visitor views a page with the content spot.

The email action editor allows the fields that identify the recipients (primary, copied and blind copied), the subject line, and the sender to be identified by either explicit text or by resources attributes. The email body is a separate file, such as a text file, an HTML file, or a JSP, that must be accessible from the email server via a URI. An emailed JSP can contain content spots for personalizing the email message for the user who triggers the content spot.

Although email actions differ somewhat from email promotions, both have prerequisites that must be in place and working before email can be sent.

"Example: Simple select content action"
View an example for a simple select content action.

"Example: Simple update action"
View an example of an update action that is part of a Web site that allows visitors to manage certain information and preferences about themselves.

"Example: Simple email action" on page 2253
This email action rule example is typical of one that might be used after a website visitor submits a form indicating interest in an item or service.

Example: Simple select content action:

View an example for a simple select content action.

The select content action shown here, `Get Bank News By Role`, queries all records within a content resource entitled News and returns those marked as being for the current user's role.

The content resource YourCoNews represents news articles in the data store. Each record has several different fields (for example, Title, Abstract, Author, Body), including a field entitled `Role`. In the data store, this field is marked to indicate the role of the visitor to whom it applies.

Simple select content action

```
Select NewsArticle
       whose Role is current User.Role
        order as is
```

Example: Simple update action:

View an example of an update action that is part of a Web site that allows visitors to manage certain information and preferences about themselves.

When executed, the following update action will write to the fields (`Income Group`, `Role`) in the data store for the record associated with the current user (the current Web site visitor), using data contained in the current user's session variables, such as `incomeGroup` and `role`.

Update action

```
Update
        current Portal Users.Income Group set to current Session.incomeGroup
        current Portal Users.Role set to current Session.role
        current Portal Users.Last Name set to current Session.lastName
        current Portal Users.Title set to current Session.title
```

Example: Simple email action:

This email action rule example is typical of one that might be used after a website visitor submits a form indicating interest in an item or service.

The email action rule can be attached to a content spot that, when triggered by the visitor viewing the page with the spot, sends the email indicated by the **bodyURI** field to that visitor. This email is also blind copied to someone within the sample company.

Email action rule

```
To: current Portal Users.Email Address
 From: Rates@YourCo.com
 bcc: Mortgage_Broker@YourCo.com

 Subject: Today's Mortgage Rates
 Body URI /email/mortgage-rates.jsp
```

Profilers:

Profilers are typically used to categorize an individual (usually the current site visitor) according to his or her user properties.

Besides a user's properties, profilers can be used to define other conditions based on such factors such as the current date and time, the type of browser the visitor uses, or other implicit and explicit application object properties. Profilers can also make decisions based on the current user's session attributes and request attributes and parameters, along with category and action counts.

Profilers can be constructed to define the conditions of arbitrarily named profiles, or can be defined in terms of other profilers. For example, you can create a profiler that will evaluate as true if a profile is in any, all, or none of a group of other profiles.

"Example: Simple profiler" on page 2254
View an example of a simple profiler that determines whether confidential company news articles will be shown to the current Web site visitor.

"Example: Nested profiler" on page 2254
View an example of a nested profiler.

"Example: Category Count (implicit profiling)" on page 2254
Get an overview of implementing category counts from a profiler that will contain profile definitions for movies, cooking, and sports; this overview sets the profile for the category with the highest count.

"Example: Browser capability" on page 2255
The browser capability stock object allows you to profile the browser the current Web visitor is using to view your site. View an example profiler that checks the browser version to determine whether it is supported.

"Example: "Count of" (quantifiable condition)" on page 2255
View an example demonstrating the use of "Count of".

"Example: Request attributes and session attributes" on page 2256
Request values passed to the JSP or stored in the HTTP session can be referred to from rules. To refer to them in a rule, you must know the variables and their possible values.
"Example: Arithmetic operation" on page 2256
View an example of a profiler that uses arithmetic operations.

Example: Simple profiler:

View an example of a simple profiler that determines whether confidential company news articles will be shown to the current Web site visitor.

The profiler `User Clearance` is based on a user resource called `Personnel`. When the profiler was created, the name `User Clearance` and the settings, `Confidential` and `Regular`, were arbitrarily defined for later reference within bindings. One side of the comparison line (`current Personnel.Role`) refers to a user resource named `Personnel` created from a Personnel table in a database. `Role` is a mapped value, defined when the resource was created, that points to the Personnel.Role column in the Personnel table. The values in the Role column in the database are either Employee, Executive, or Manager.

This completed profiler is used within a binding as a means of determining whether confidential company news articles will be shown to the current Web site visitor.

Simple profiler

```
User Clearance is
       Confidential when
           current Personnel.Role is Executive or
           current Personnel.Role is Manager
      Otherwise Regular
```

Example: Nested profiler:

View an example of a nested profiler.

A nested profiler is true if any, all, or none of the profilers within the profiler are true. You can categorize a condition as a combination of other conditions. For example, a Web site visitor can be profiled as a young male if a pre-existing gender profiler classifies the visitor as male, and a pre-existing age profiler classifies as the visitor as being in his teens or twenties.

Nested profiler

```
AgeGenderProfiler is
       YoungMale when
           GenderProfiler is Male and
           AgeProfiler is any of Teenager or Twenties
      Otherwise NotInTargetAudience
```

Example: Category Count (implicit profiling):

Get an overview of implementing category counts from a profiler that will contain profile definitions for movies, cooking, and sports; this overview sets the profile for the category with the highest count.

For the Category Count example, assume a repository of articles on sports, movies, and cooking is available for the user to view. Each time the user views an article, a

record is logged to show his or her preference for that topic. For this to occur, each article must be a JSP that implements category beans. For example, the following code would appear on a sports article:

```
<jsp:useBean class="com.ibm.wcp.analysis.beans.Category" id="category"
scope="session">
</jsp:useBean>
<% category.log(request, "Articles/Sports"); %>
```

These values were typed into the Attribute text field during the creation of this profiler after selecting current Category Count.

Note: A complete version of this profiler will contain profile definitions for movies and cooking for the cases where those category counts are greater than sports and each other.

Category count

```
ArticlePreference is
        Sports when
            current Category Count.Articles.Sports is greater than current Category Count.Articles.Cooking and
            current Category Count.Articles.Sports is greater than current Category Count.Articles.Movies
```

Example: Browser capability:

The browser capability stock object allows you to profile the browser the current Web visitor is using to view your site. View an example profiler that checks the browser version to determine whether it is supported.

When using the browser capability stock object, there is a finite list of attributes available, but you must type the values for one side of the evaluation. The browser capability script files and the SinglePixel.gif image must be properly configured in the Web application.

The following example profiler checks the browser version to determine whether it is supported. Other possible checks include available plug-ins, whether Java is enabled, and whether cookies are enabled.

```
Check Browser is
        supported when
           (
             (
              current Browser Capability.BrowserType is Netscape and
              current Browser Capability.FullVersion is greater than or equal to 6.2
             ) or
             (
              current Browser Capability.BrowserType is Internet Explorer and
              current Browser Capability.FullVersion is greater than or equal to 6.0
             )
           )
       Otherwise unsupported
```

Example: "Count of" (quantifiable condition):

View an example demonstrating the use of "Count of".

A quantifiable condition profiler is similar to implicit profiling because a profile is defined according to numbers of items. Quantifiable condition profilers do not require the use of logging beans, but require attributes of resources that will be quantified to be organized uniformly.

In the following profiler, counts are made for items in the session object `shoppingCart` used by the user resource Shopper. Here, `shoppingCart` is analogous to a table in a database and `color` would be a column of data. Each item within the table would be a row. For example:

Table 343. Counts made for items in the session object `shoppingCart` used by the user resource Shopper

Item	quantity	size	color	price
Gadget	1	L	red	$1.99
Gizmo	3	S	green	$0.95

Quantifiable condition profiler for the session object `shoppingCart`

```
ColorPreference is
Red when number of items matching (Shopper.shoppingCart.color is red) is greater than 5
Green when number of items matching (Shopper.shoppingCart.color is green) is greater than 5
```

Example: Request attributes and session attributes:

Request values passed to the JSP or stored in the HTTP session can be referred to from rules. To refer to them in a rule, you must know the variables and their possible values.

The following example profiles news articles as read or unread by the current user, based on the page request generated by a form on a JSP.

Request attributes and session attributes

```
User News is
        ReadNews when
            current Request.ProcessNews is Read
        UnreadNews when
            current Request.ProcessNews is Unread
        UnreadAllNews when
            current Request.ProcessNews is UnreadAll
```

Example: Arithmetic operation:

View an example of a profiler that uses arithmetic operations.

To build an operation, select a combination of **Resource.Attribute** and other operands. You can do this on either side of the evaluation.

Order of operations is in effect but parentheses cannot be used

```
 AgeProfiler is
       Youth when
           current Date.Year - current User.BirthDate.Year is less than or equal to 25
       Adult when
           current Date.Year - current User.BirthDate.Year is between 25 and 65
       Senior when
           current Date.Year - current User.BirthDate.Year is greater than or equal to 65
```

Bindings:

Bindings combine actions and profilers to specify actions to perform when defined conditions are encountered. Returned content can be sorted or filtered prior to display or use. Actions can be set to be performed by *always*, *exclude*, and *otherwise* blocks. In addition, the total number of items used can be limited.

The always and exclude blocks will always be performed no matter what the outcome of the profiler execution, but the otherwise block will only be run if none of the profilers match. An otherwise block works the same as an always blocks in that it adds items to the results, but for an exclude block, you actually choose an action that defines items that you don't want to include in the results. For example, on a shopping site, you may want to exclude items that have already been purchased.

"Example: Simple binding"
Because bindings couple the conditional processing of a profiler with the functional power of an action, the simplest form of a binding works like a conditional "if-then" clause.

"Example: Multiple profilers and optional actions"
View an example that demonstrates the use of a conditional "if-then" with an additional clause.

"Example: Nested bindings (simple)" on page 2258
When creating a binding, it is possible to use a binding in any of the `do action` areas. This is known as a nested binding.

"Example: Nested bindings (advanced)" on page 2259
View an example that demonstrates advanced nested bindings.

Example: Simple binding:

Because bindings couple the conditional processing of a profiler with the functional power of an action, the simplest form of a binding works like a conditional "if-then" clause.

Consider a simple binding example. If the current user is not a previous customer, then show a limited number of current offers. If the current user is a known customer, then show offers appropriate to their status level.

For example, the profiler `Customer Type` is used to check whether the current user is a known customer. If the customer is not a known customer, the action `Get Limited Number of Offers` is run. If the profiler indicates that the user is a known customer with a status of Gold or Platinum, then a different action is run and different offers are retrieved for display.

Simple binding

```
When Customer Type is
        Not A Customer
           do Get Limited Number of Offers
        Gold or
        Platinum
            do Get Offers For User
        order as is
```

Example: Multiple profilers and optional actions:

View an example that demonstrates the use of a conditional "if-then" with an additional clause.

Consider an example: If the current user does not have Confidential status, then the action `GetNonConfidentialNews` is executed. The same results could be achieved in this example by placing the `GetNonConfidentialNews` action under `Otherwise` because these are the only two profiles possible within this profiler.

The action field under Otherwise remains as is. Since the UserClearance profiler places every user into one of two categories (Regular or Confidential), any action placed here would never be executed.

The GetSiteNews rule will always be executed. Any content the rule retrieves from the data store is added to the total return set.

The GetNewsAlreadyRead action works like any other action because it retrieves content from the data store. However, when the action is placed under Exclude, any content retrieved by this action is removed from the total return set.

Note: It must be possible to indicate an article has been read by a given user. When you click the Select Action menu, you will only see rules that are assigned a Select Action type. Binding rules are also Select Action type rules. Once a resourceCollectiontype is set for the binding, all of the action rules will be locked and will use the same collection type.

The order of the total return set is randomized and the number truncated to no more than 10 items. This effect takes place each time the rule is executed, so the news articles displayed on the Web page will change from page view to page view.

Conditional "if-then" with an additional clause

```
When UserClearance is
        Confidential
           do GetConfidentialNews
        Regular
           do GetNonConfidentialNews
       Always
            GetSiteNews
       Exclude
            GetNewsAlreadyRead
        order randomly
        show 10 items
```

Example: Nested bindings (simple):

When creating a binding, it is possible to use a binding in any of the do action areas. This is known as a nested binding.

In this example, the Always action (Get Top Products) in Get Products By Location is actually another binding. When the nested binding is placed with Always, it has the effect of the boolean operator or.

For example: The total rule returns content that meets the conditions in the earlier part of the binding or that meets the conditions in the later part.

Note: It is possible for a nested binding to contain nested bindings.

Get Products By Location:

Nested binding

```
When User Location is
        Lab
           do Get Test Products
        Factory
           do Get Available Products
        Field
           do Get All Products
       Otherwise
```

```
            do Get Future Products
        Always
            Get Top Products
         order as is

Get Top Products:
   When User Role is
         Manager
            do Get Top Selling Products
         Exec
            do Get Top Selling Products
         Employee
            do Get Top Overstocked Products
         order as is
```

Example: Nested bindings (advanced):

View an example that demonstrates advanced nested bindings.

This example is similar to the Nested bindings (simple) example, except for the addition of the binding `Get Top Products` to the actions done when the `User Location` profiler is `Lab`. Multiple actions can be grouped by selecting multiple actions or bindings simultaneously within the rule editor. Selecting multiple actions or bindings here has the effect of the boolean operator "and", which returns the intersection of the data sets.

For example: the current user location must be in the lab and an executive. Therefore, in addition to test products, executives and managers in the lab receives information about the best selling products, and employees at the lab gets the most popular overstocked items. Factory or field workers will not see either best selling or most popular overstocked products.

Modified `Get Products By Location`:

Advanced nested bindings

```
When User Location is
         Lab
            do Get Top Products and
            do Get Test Products
         Factory
            do Get Available Products
         Field
            do Get All Products
        Otherwise
            do Get Future Products
         order as is
```

Recommend Content:

You use Recommend Content rules (also referred to as recommendation rules) to recommend content to your Web site visitors. Recommendation rules, powered by LikeMinds, recommend content based on users' past interactions with your Web site.

When creating a Recommend Content rule, you specify one of three recommendation methods. The recommendation methods are:

how the current user navigated the site
: This method is associated with the LikeMinds Clickstream Engine.

preferences explicitly expressed by the user

Use this recommendation method to generate recommendations based on users' ratings of items. This method is associated with the LikeMinds Preference engine.

Items map to a piece of content and are represented by resources and resource collections. Your Web site captures ratings using the Rating bean. The Rating bean collects the rating, the item resource, and resource collection, and then logs the data for LikeMinds to use later.

association with content returned from a rule

Use this recommendation method to generate recommendations based on market-basket analysis. This method associates items that a current Web site user has interest in (such as an item in their shopping cart) with items that others users have had interest in or have purchased. This method is associated with the LikeMinds Item Affinity engine.

Item affinity rules make use of the LikeMinds transaction data being collected. They offer a method for generating recommendations from a known set of resources (actually the results of another rule returning the same resource type).

Notes:

- Before using Recommend Content rules, check with your system administrator to see which LikeMinds engines are configured and running on the production run-time server.
- To preview results, the production LikeMinds database must contain data, including items, users, and transactions (ratings or actions). The problem of initial data priming is commonly called coldstart.

Visibility Rules:

Visibility rules determine what a user will see, or what has been targeted towards a user. Visibility rules can be assigned to pages and portlets and will be triggered automatically by the portal as needed.

Visibility rules use any type of information, including LDAP attributes, time of day, or session information. For example, if you want to hide a portlet for an individual in a certain geography, store the location as an attribute in LDAP, and assign a visibility rule hiding the portlet. A user may have access to the revenue figures for all divisions the entire year, but these figures should not be displayed prominently except when they are first released. For a week after the figures are first released, the figures for the employee's division should show prominently on their home page. The visibility rule hides figures for divisions the employee is not in and only shows the employee's figures the week after they are released.

Visibility rules can be assigned to pages and portlets and will be triggered automatically by the portal as needed. Through the APIs, visibility rules behave like profiler rules where the only two possible profiles are **show** and **hide**. This allows visibility rules to be invoked programmatically and used in any custom application just as you would call a profiler rule. Visibility rules only apply to authenticated users.

"Example: Show page or portlet" on page 2261
View an example of a visibility rule, `Show Page` that shows the specified page or portlet only during the specified time period, and only to users in the Midwest. For all other dates and users, the page or portlet is hidden.

Related concepts:

"Attribute Based Administration" on page 2248
Attribute based administration provides a facility to customize the layout of a page for individual authenticated users by using rules to show or hide pages or portlets. This implementation tells the portal to show or hide pages and portlets based on dynamic characteristics that are determined at runtime. Attribute Based Administration is only available for authenticated users. For anonymous users, all pages are shown.

Example: Show page or portlet:

View an example of a visibility rule, `Show Page` that shows the specified page or portlet only during the specified time period, and only to users in the Midwest. For all other dates and users, the page or portlet is hidden.

Visibility rule

```
Show page or portlet when
        current Date.Date is between December 12, 2006 and December 19, 2006
        current LdapUsers.Geography is Midwest Region
     Otherwise hide
```

Rule elements:

Learn about the options in the rule editor for the different types of rules.

"Arithmetic expressions" on page 2263
Arithmetic expressions allow you to perform mathematical operations on resource attributes as part of your rule. When you choose this option, you can select multiple resource attributes, values, and operators (addition, subtraction, multiplication, or division) to use between them.

"Count of (quantifiable conditions)" on page 2263
Create an evaluation based on a count or tally of attributes that meet your criteria.

"Current Action Count or Action Name" on page 2263
Current action count, like **current category count**, is a way to base a profiler or rule on the number of times a Web site visitor has performed certain actions. These actions must be logged using the action logging beans in order to be accessible by the rule. **Current action name** inspects the names of the actions logged.

"Current Browser Capability" on page 2263
Browser Capability is an application object that allows you to profile a Web site visitor based on the attributes or capabilities of the browser being used. When applicable, it appears in the rule editor as an option when you select **Resource.Attribute**.

"Current Date" on page 2264
The **current Date** resource contains several attributes you can use for comparison (date, day, month, time, timestamp, weekday, and year). To set values, you may enter a specific value or reference the value of a specific attribute of the same type.

"Current Request Attributes" on page 2264
Use **current Request Attributes** to inspect request attributes which can be set on the current JSP. You must know the name of the request attribute to use it in a rule. This request is the request passed into the content spot executing the rule. For example, you would use the portlet request to set the current Request attribute for portlets. The portlet request is not shared among portlets. For jsps directly within a Web application, the current Request Attribute is the HTTP request of the Web application.

Arithmetic expressions:

Arithmetic expressions allow you to perform mathematical operations on resource attributes as part of your rule. When you choose this option, you can select multiple resource attributes, values, and operators (addition, subtraction, multiplication, or division) to use between them.

An example use of an arithmetic expression is a profiler that profiles Web site visitors according to age. In the data you record for each visitor, it is more practical to store date of birth (which does not change), than to store age. In the evaluation in the profiler, you can use an arithmetic expression to calculate the visitor's age by subtracting the current user's year of birth from the current year (`current Date.year`).

Arithmetic expressions are calculated according to traditional order of operations (multiplication and division are calculated before addition and subtraction. For example, 3+2*2–1/2 evaluates to 6.5). It is not possible to group expressions using parentheses.

Count of (quantifiable conditions):

Create an evaluation based on a count or tally of attributes that meet your criteria.

In the Specify a Resource Attribute drop down, you have the option to select **Use Number of Items in List**. Selecting this option allows you to create an evaluation based on a count or tally of attributes that meet your criteria. When you select this option, you must select a resource and the attribute of that resource that are to be tallied when the rule executes.

Note: This option can only be used in profiler and visibility rules.

Because the tally is made at the time the rule is triggered, it could produce different results at different times during the session if used on an application object or a current resource. For example, you might profile a visitor's color preference as red by creating an evaluation that checks to see if the number of red items in the user's shopping cart is greater than 5. The rule syntax for this evaluation could be:

```
Count of (shoppingCart.item.color is red) is greater than 5
```

Although you can make counts of any data type, the tally must be compared against a value or resource attribute that has a data type of number, decimal number, or integer.

Current Action Count or Action Name:

Current action count, like **current category count**, is a way to base a profiler or rule on the number of times a Web site visitor has performed certain actions. These actions must be logged using the action logging beans in order to be accessible by the rule. **Current action name** inspects the names of the actions logged.

Current Browser Capability:

Browser Capability is an application object that allows you to profile a Web site visitor based on the attributes or capabilities of the browser being used. When applicable, it appears in the rule editor as an option when you select **Resource.Attribute**.

Purpose

Browser Capability currently supports these attributes:

AcceptLanguage
Returns the value of the header 'accept-language' from the request object.

AcceptMimeTypes
Returns the value of the header 'accept' from the request object.

Agent Returns the value of the header 'user-agent' from the request object. This is a lowercase string that contains information about the client software, usually the browser name or version.

BrowserType
Returns the browser type. Choices are available for supported browsers.

FullVersion
Returns the version of the browser to one point of precision. For instance, 6.1 and 6.1.1 are both returned as 6.1.

MajorVersion
Returns the first digit of the browser version. For instance, 6.0, 6.1 and 6.1.1 are all returned as 6.

Current Date:

The **current Date** resource contains several attributes you can use for comparison (date, day, month, time, timestamp, weekday, and year). To set values, you may enter a specific value or reference the value of a specific attribute of the same type.

Current Request Attributes:

Use **current Request Attributes** to inspect request attributes which can be set on the current JSP. You must know the name of the request attribute to use it in a rule. This request is the request passed into the content spot executing the rule. For example, you would use the portlet request to set the current Request attribute for portlets. The portlet request is not shared among portlets. For jsps directly within a Web application, the current Request Attribute is the HTTP request of the Web application.

Consider the following code that can be inserted into a JSP to set a request attribute:

```
<%
 request.setAttribute("user", userObject);
%>
where userObject is of any Object type
```

An example rule condition constructed to evaluate the previous example might be:

```
when current Request Attributes.user is equal to rob
```

All data types are supported.

Current Request Parameters:

Use **current Request Parameters** to inspect data contained within the query string (the variables and values that appear after a question mark on a URL).

To understand current Request parameters, consider the example URL `http://hostname/page.jsp?var1=rob&var2=expert`. In this example, the request parameters are `var1` and `var2`. Typically these are passed by GET and POST methods associated with forms. You must know the name of the request parameter that is passed by the page to use it in a rule.

Given the following <jsp:forward> command:

```
<jsp:forward page="/servlet/login">
 <jsp:param name="user" value="rob" />
</jsp:forward>
```

an example rule condition constructed to evaluate this example might be:

```
when current Request.user is rob
```

Only data types Text and List are supported.

Current Session Attributes:

Use **current Session Attributes** to inspect parameters stored within the current session object for the Web site visitor. You must know the name of the parameter to use it in a rule. All data types are supported. The current session object is the session associated with the request passed into the content spot executing the rule. For example, the current session object is the portlet session, which is unique to the portlet. For jsps within a WAR, the current session object is the the http session.

do Action:

Within a binding, you can couple actions with profilers so certain tasks are performed when certain conditions are met. You can also indicate actions to be done under other conditions. Use the **Do action**, **Otherwise do action**, **Always do action**, and **Exclude do action** elements.

Do action allows you to choose one or more actions in your project. You can also select another profiler and profile to define a combination of conditions to evaluate. These actions run when the condition in the preceding profile (or set of profiles) are met.

Note: If there are multiple actions in a binding, they must all work with resources of the same type.

Otherwise do action allows you to choose one or more actions that run when none of the preceding conditions in the profile (or set of profiles) are met. Within the otherwise clause, you can also select another profiler and profile to define a combination of conditions to evaluate.

Always do action allows you to choose one or more actions in your project that will execute whether or not any of the preceding conditions are met.

Exclude do action allows you to identify one or more actions in your project that will execute, and whose results returned will be removed from the result set generated by the other actions in the binding.

Note: Exclude takes precedence over Always.

Include Only:

Include Only is a choice within the Select Action and Recommendation Rule structures. You can select action or binding rule to be used as the include only cause. When the content is selected for the main select action or recommended rule, it is only returned if it would be selected by the Include Only clause's action rule.

is:

Select **is** to evaluate the relationship between two sides of a conditional statement.

When using **is**, either side of the conditional statement can typically be the content returned by a resource attribute, value, or arithmetic expression. If the resource attribute is of the data type List (array, vector, or enumeration), the available evaluations become `includes` and `includes any of`. Otherwise, the choices are:

- includes
- includes any of
- is between
- is between but not equal to
- is empty
- is
- is greater than
- is greater than or equal to
- is included in
- is less than or equal to
- is less than
- is not empty
- is not

Is Empty/Is Not Empty

The evaluations `is empty` and `is not empty` allow a rule to check for the existence of a null value or an empty list. When using either of these evaluations, one side of the evaluation is unnecessary and is removed.

Table 344. Examples of `Is Empty` or `Is not Empty` evaluations

One side of Evaluation	Evaluation	Result
Resource Attribute (non-list type)	is empty	true if attribute is null, otherwise false
Resource Attribute (non-list type)	is not empty	false if attribute is null, otherwise true
Resource Attribute (list type)	is empty	true if list is empty, otherwise false
Resource Attribute (list type)	is not empty	false if list is empty, otherwise true
Request Attributes or Session Attributes (non-list type)	is empty	false if attribute/parameter exists and value is not null; true if attribute/parameter does not exist or value is null

Table 344. Examples of `Is Empty` or `Is not Empty` evaluations (continued)

One side of Evaluation	Evaluation	Result
Request Attributes or Session Attributes (non-list type)	is not empty	true if attribute/parameter exists and value is not null; false if attribute/parameter does not exist or value is null
Request Attributes or Session Attributes (list type)	is empty	true if attribute/parameter does not exist or list is empty; false if attribute/parameter exists and list has data
Request Attributes or Session Attributes (list type)	is not empty	false if attribute/parameter does not exist or list is empty; true if attribute/parameter exists and list has data

Profiler evaluations

If you choose to evaluate a profiler instead of a resource attribute in the Specify a Resource Attribute window, the available evaluations are:

- is
- is all of
- is any of
- is not
- is not any of

On one side of the evaluation, the possible choices are the profiles that are defined within that profiler. You may select one or more profiles for the result of the evaluation.

order as is:

Order as is is used to specify the order you want selected content to be returned and used. The default, order as is, will return data in the order it is stored in the repository. By clicking the order as is link, you can also choose **order randomly** or **order by**.

Order by allows you to sort content by any of its attributes, sort by more than one attribute (and specify the order the attributes are used to sort), and specify whether you want each attribute in ascending or descending order. Order randomly returns data in a different order each time the rule executes.

Profile:

Profile is an arbitrary name (of your choice) that provides information about the Web site visitor, the date and time the visit occurs, or other circumstances or conditions.

To better understand profiles, consider an example. Suppose you want to differentiate your Web visitors according to whether they are able to view confidential information. You might use two profiles in this scenario: Confidential and Regular.

When you create a profile within a profiler, type an arbitrary, but descriptive name. Be as accurate as possible to avoid duplication or confusion with other profiles.

When selecting a profile (for example, within a binding), you choose from a list of available profile names that match the profiler rule.

Profiler:

Profiler is a choice within the binding rule structure, and within the Specify a Resource Attribute window when constructing a profiler. Within a binding, you identify specific actions to perform that are based on the one profile within a profiler that evaluates as true.

You may also select quick profiler and specify a simple evaluation in-line instead of using a separate profiler.

Selecting **Profiler** within a profile allows you to identify other profilers (in effect, nesting profilers within one another) in order to create a profiler that can evaluate as true when multiple profilers or other evaluations are true.

Quick Profiler:

Quick profilers are created within bindings to perform simple evaluations. By using a quick profiler, you can avoid creating simple profilers as separate rules.

When you select the profile link within a binding and choose the quick profiler option, the structure for the line will change to an evaluation. The subsequent line of the binding will be the action to perform if the quick profiler evaluates as true.

sender:

sender must be a valid email address, list of email addresses (comma separated), or a resource attribute containing valid email addresses to whom the email will be sent.

set to:

Learn about the **set to** action and alternatives to **set to**.

Set to is the default action within an update action rule. Set to will modify the attribute of a resource, request object, or session object according to the value you specify in the expression.

Alternatives to set to include:

- append
- decrement by
- divide by
- increment by
- multiply by
- prepend
- remove
- remove all

value:

`Value` is the placeholder for the result of an evaluation. This value can be one you enter, the value of another resource attribute, or an arithmetic expression.

The value must be compatible with the data type of the other side of the expression or evaluation. For example, if you are evaluating an attribute that has the type Number, you can only compare it to resource attributes of the type Number or Decimal Number. The rule editor prevents you from choosing other resource attributes with incompatible types.

Note: Making comparisons against resources in a database respects the column type and size. Therefore, to compare a value to a column typed as CHAR(10), you must include all 10 characters. For example, assume you have a table with a column named DAY that is typed as CHAR(10). A row in the table has the value of 'Monday ' rather than 'Monday' in the DAY column because DAY is compared against a profiler condition, and must have all 10 characters defined. However, if the column is typed as VARCHAR, the value in the profiler condition can be 'Monday' (without the four additional blanks).

Mapped values

Resources may be created using mapped values instead of actual values specified in the data store. This facilitates the creation of rules that are easier to understand. For example, if a column in the database held the integer values of 1, 2, or 3 indicating Yes, No, or Maybe, the resource can be configured to map integer values to words. If mapped values have been created for a resource, the mapped values will be used in the rule editor instead of the actual values. For more information on creating value mappings, refer to the documentation in Rational Application Developer for creating resources using the Personalization resource wizard.

Dynamic properties

In addition to predefined resource properties, you can enter properties of a resource that are not in the list. If you know the resource to handle dynamically, specify the name of the property. If the resource manages properties dynamically, the values are retrieved when the rule is evaluated.

Email:

View the prerequisites for creating an email action or promotion within the Personalization workspace.

An email promotion is an email message automatically sent to a defined list of recipients by a running rule. Email promotions can be sent once or repeatedly on regular intervals. The body of the email message is derived from a file on the server, such as a text file, an HTML file, or even a JSP containing content spots for rules. This file can be chosen from the authoring repository. The list of recipients can be derived dynamically from a rule. Email promotions are implemented by using a rule event to trigger an email rule on a schedule.

Before you can create an email action or promotion within the Personalization workspace, you need the following:

- A user resource: This resource contains information about potential email recipients, and can be created with the Personalization resource wizard in Rational Application Developer. The resource must include a string that represents the email address of the recipients (in the form "username@domain"). The string must be published to the workspace server and to the run time environment.

- An email body: The body of the email is a flat text, HTML or JSP file that must exist on a server accessible from the run time environment. Typically, this file is created in Rational Application Developer. The location of the file in the run time environment must be specified as a URI when you create the email rule. The email body HTML or JSP page must be on the server, which is sending the email.
- An email rule: The email rule specifies to whom the email must be sent, who is sending it, and identifies the email body as a URI.
- A rule to determine recipients (for emails that are triggered on a schedule or periodically, optional for email actions): This rule can be a select content action or a binding, but must return a collection of recipients from the user resource that was previously mentioned. The action or rule you create becomes an option of the **To** list. If your actions or rules are not properly defined, the **To** list displays "No Matching Rules".

  It is possible to create email actions or promotions that are sent to a predefined address or list of addresses. This task is done by typing them into the **To** field when you create the email action or promotion.
- A rule event (for emails that are triggered on a schedule or periodically): The rule event binds the email rule to the rule, which determines the recipients. The rule event says that at a given time or times in the future, a specific rule must be run once for each user in a list. That list is determined by the rule to determine recipients.

For more information about configuring email activities, see *configuring email activity accounts*.

Email administration:

View the steps you need to complete before your run time server can send personalized email.

Before your run time server can send personalized email:

- Verify that the `pznscheduler.ear` is as an Enterprise Application.
- Have a properly configured and operating SMTP email server.

  JavaMail provides the SMTP required to send email. You can manage email responses from customers and outgoing error conditions (such as an unknown email address) using a standard email client.
- Configure a Mail Provider using the WebSphere Integrated Solutions Console.
  1. Click **Resources** > **Mail** > **Mail Providers**.
  2. Create a mail session to use with Personalization. By default, Personalization looks for a mail session in `mail/personalizationMailSession/jndi`. The JNDI name used is configurable in the `PersonalizationService.properties` file if you want to use Personalization with an existing mail session you have configured. If you are creating a new mail session, you must specify a Mail Transport Host. This is the mail server Personalization uses to send email. If your mail server is secured, you must specify a Mail Transport User ID and Mail Transport Password.
  3. Restart the server on which the email rules execute for the changes to take effect.
- Additional configuration is available through the `PersonalizationService.properties` file. Using this file, you configure how

often Personalization checks for rule events that run scheduled or repeating emails. You can specify what port an email rule will try to connect to when retrieving the bodyuri of the rule. You can also configure the mail session being used.

Content spots:

A content spot is a placeholder or slot for a rule on a Web page. When the page is viewed, the content spot uses its rule mapping to determine which rule to execute. When the rule is executed, any actions defined within the rule take place. Each content spot has a unique name. A content spot's content type must be defined when it is created and should not be changed.

Content spots are created by developers using the Content Spot wizard in Rational Application Developer and also in the Personalization workspace by selecting **New > Content Spot**. After creating the spot, the developer can place it on a JSP, or invoke it programmatically from any Java class.

To make the spot available to the Personalization engine, it should be on the classpath of any application which invokes it. If you are using a portlet or Web project in Rational Application Developer, the classpath information updates automatically when you deploy the application.

To make the content spot available to the Personalization authoring portlets, the content spot must be created in the workspace by selecting **New > Content Spot**. The name given to the content spot in the authoring portlet should match the display name given to it in the Rational Application Developer wizard or the name by which it is invoked using the com.ibm.websphere.personalization.ContentSpot programming interface. Content spots may be placed into folders by either using a display name which fully qualifies this folder, or by setting the execution scope to match the folder at runtime. So, if you want your content spot to be called `MyDataSpot` in a folder called `ProductData`, then the content spot's display name should be specified in the wizard as `ProductData/MyDataSpot`.

Users of the Personalization workspace specify which rule to place in a content spot. This is also known as mapping the rule to the content spot, or creating a rule mapping. When finished, a workspace user with authority to publish rules and rule mappings publishes them from the workspace server to the run-time environment. Publishing is optional, and is used to move objects between servers. Content spots, rules and all other objects created in Personalization are live as soon as they are created. Rule mappings can be changed at any time and are effective immediately upon publication, or upon the rule mapping start date, whichever comes later. Rule mappings expire on the rule mapping end date.

Content spots can be accessed in the workspace through the Personalization authoring portlets. You can see a list of all the content spots in the project, along with their content type and the name of their mapped rules, by navigating the browser view.

Use of content spots is optional. The com.ibm.websphere.personalization.ContentSpot class can be used to directly execute a rule by the rule name.

Rule spot mappings:

For a rule to be used on your Web site, it must be mapped to an existing content spot. A rule spot mapping is merely an association between a content spot and a rule. Changing the rule that is executed in the run-time environment is as easy as mapping a different rule to a content spot.

You create rule spot mappings within the Personalization workspace. There are two views for rule mappings: **Rule Mappings by Campaign** and **Rule Mappings by Content Spot**. The **Rule Mappings by Campaign** view shows all the rule mappings under a selected campaign from a drop-down menu, and their mapped content spots and rules. This view includes the Default Mappings option which simply shows all the default mappings of each content spot. The **Rule Mappings by Content Spot** view shows all the rule mappings under a particular content spot, including the default mapping and any mappings under campaigns. You can change the personalization behavior of your Web site by mapping a different rule to a given content spot.

Although only one rule is executed when a content spot bean is invoked, you can have multiple rules simultaneously mapped to a content spot by using campaigns. When you create a campaign, you can create a separate set of rule spot mappings for any or all of the content spots in your project.

When multiple campaigns are simultaneously active, campaign priorities and splits are used to determine the rule to execute. When multiple active campaigns have the same priority, the splits are used to calculate a percentage chance that one mapping will be used instead of the others.

Splits can be changed for each rule spot mapping.

Rule spot mappings can be duplicated and moved from one campaign to another. The start and end date of the rule spot mapping may both be modified if they fall outside the range of dates for the campaign to which the spot mapping is moved. Multiple mappings can be added to the same spot within a campaign.

Campaigns:

Campaigns are a means of organizing and implementing sets of personalization behavior. A useful analogy is an advertising campaign, which targets specific audiences with high-priority information for a specified period of time. Campaigns achieve this by allowing you to preferentially display campaign-related content in the content spots of a Web site. To accomplish such a goal, a campaign contains a set of rule-to-content spot mappings, start dates, and stop dates.

Users can create and manage campaigns through the Personalization Authoring Portlet. Campaigns are live as soon as their start date is reached and they may be published to other servers together with rules. To create a campaign, select **New** > **Campaign**. To add rule mappings to a campaign, select the campaign, and select **New** > **Rule Mapping**.

When a campaign is active in the run-time environment, the rule mappings take precedence over the default rule mappings for content spots the campaign references. For example, a seasonal campaign might contain certain rule mappings that result in the display of special offers to a Web site visitor. A campaign can contain rule mappings for some or all of the content spots on a site.

It is possible to have multiple campaigns active simultaneously. When this happens, the priority settings of the active campaigns dictate which campaign's rule mapping will be used. The campaign with the highest priority 'wins' and its rule mappings are used. In the event that multiple active campaigns have the same priority setting, the rule mapping used for a given content spot is determined randomly according to the relative split ratios.

Application object:

An application object is a java object existing at a known location in the request context. Defining an application object involves specifying the object's class name (as a Java class), and specifying a key (string key into a session attribute) to find it in the request context. Personalization calls methods on these objects during rule execution and uses their results in its decision making. Application Objects that implement the SelfInitializingApplicationObject interface are automatically instantiated as needed by Personalization.

"Device application object" on page 2274
The Device application object displays content by device class or by location (city, country, latitude, and longitude).

"Referrer application object" on page 2284
You can target your content to users based on what site the user came from before the user accessed your site. You can also target your content by the search parameters that are entered by users in a search engine.

"Public Render Parameters application object" on page 2288
The Public Render Parameter application object provides read and write access to public render parameters. Public render parameters allow portlets to share navigational state information and preserve this information across requests. Use this object in rules when you need your site to store a user's selection as a public render parameter during the action phase and have other portlets read this public render parameter during the render phase.

"Shared Data application object" on page 2291
The Shared Data application object is used in rules to share complex data between web applications and IBM WebSphere Portal Express in a user's session.

Installed application objects:

The Device, Referrer, Public Render Parameter, and Shared Data application objects are installed by default. By using installed application objects, you can skip the process of defining and registering application objects.

When you use application objects that are not installed, you must define the application objects by using a set of Personalization wizards that are provided with IBM Rational Application Developer or develop application objects according to a set of public programming interfaces. After you define the application objects, the application objects are registered to the Personalization server through the Personalization browser. When you use the installed application objects, you do not have to define or register the application objects.

The Device, Referrer, Public Render Parameter, and Shared Data application objects are installed and enabled with 8.5.

Optional: To enable the Content Targeting Dialog in virtual portals, use XML access to manually create the hidden Content Targeting Dialog page for each virtual portal. From the *wp_profile_root*/ConfigEngine directory, run the following task:

- Linux : ./xmlaccess.sh -in *PortalServer_root*/pzn.ui/wp.pzn.ui.actions/config/templates/DeployPages.xml -url http://*localhost*:10039/wps/config/*your_virtual_portal_context* -user *admin_user_id* -password *admin_password*
- IBM i: xmlaccess.sh -in *PortalServer_root*/pzn.ui/wp.pzn.ui.actions/config/templates/DeployPages.xml -url http://*localhost*:10039/wps/config/*your_virtual_portal_context* -user *admin_user_id* -password *admin_password*
- Windows: xmlaccess.bat -in *PortalServer_root*\pzn.ui\wp.pzn.ui.actions\config\templates\DeployPages.xml -url http://*localhost*:10039/wps/config/*your_virtual_portal_context* -user *admin_user_id* -password *admin_password*

The following topics contain an overview of the installed application objects. This overview includes descriptions and examples of using the application objects in rules that you create. To select the attributes that are used in the examples, you must enable the application objects. Instructions for enabling the location attributes associated with the Device application are also included in this section.

Device application object:

The Device application object displays content by device class or by location (city, country, latitude, and longitude).

"Device application object: Device class attribute"
Site content can display differently for a smartphone, desktop, or other device by using the Device application object in rules. You do not have to restrict your content to fit across all devices. Use this object to enable your site to recognize the device that accesses your site and to target content that best displays for that device.

"Device Application Object: Location attributes" on page 2279
You can use location to tailor the content that displays. The Device application object contains five location attributes that you can use in rules that you create: latitude, longitude, country, state, and city.

Device application object: Device class attribute:

Site content can display differently for a smartphone, desktop, or other device by using the Device application object in rules. You do not have to restrict your content to fit across all devices. Use this object to enable your site to recognize the device that accesses your site and to target content that best displays for that device.

"Defining your device classes"
When you target content to a segment based on device classes, ensure that the device classes are installed and enabled in portal.

"Example: Creating a segment by device class" on page 2277
Learn more about the Device application object through an example. In this example, you are creating two segments by using a profiler rule: Smartphone User and Tablet User. Each segment views content through different devices.

Defining your device classes:

When you target content to a segment based on device classes, ensure that the device classes are installed and enabled in portal.

About this task

By default, the smartphone and tablet device classes are already defined for you. You can use these device classes in rules that you create. If your mobile device is not recognized by using the default smartphone or tablet device classes, you can add your device as a client to these default classes. To add your device go to **Add new client**. Click the **Administration menu** icon. Then, click **Portal Settings** > **Supported Clients**. Then, click **Add new client**. You can also create an XML script to add your device.

When you add your device to the default classes, your device inherits and uses the responsive web design theme when it displays content. You can import the XML file. Click the **Administration menu** icon. Then, click **Portal Settings** > **Import XML**. You can also run the XML access directly to import the XML file.

You can also create custom device classes rather than using the default classes. Clients that are assigned to custom classes use the desktop theme. For custom classes to have a responsive theme based on the type of device, you must develop custom themes for your class. For more information, see the *Responsive Web Design* section.

To add a client to a device class, you need, at a minimum, the following information about your device:

- User-agent pattern
- Manufacturer
- Model
- Client capability

Use the table to learn more about the options available to you for defining device classes.

Table 345. Define device classes to use later with the Device application object in rules that you create. Select one of the following options to define device classes.

Option	Description
Add client definitions to already defined device classes. The smartphone and tablet device classes are examples of device classes that are provided to you by default.	1. Click the **Administration menu** icon. Then, click **Portal Settings** > **Supported Clients**.Then, click **Add new client** to enter information about the client. **Note:** Refer to the product help for more detailed instructions for adding new clients. 2. In the **User Agent** field, enter the name of the client. For example, enter `*.useragent.*` 3. In the **Manufacturer** field, enter the name of the company that manufactured the client. 4. In the **Model** field, enter the model number or name of the client. 5. In the **Capabilities** field, enter the specific capabilities of the client, and click **Add**. To add tablet capabilities, enter the following information: `com.ibm.portal.devicesupport.deviceclass=tablet HTML_4_0` To add smartphone capabilities, enter the following information: `com.ibm.portal.devicesupport.deviceclass=smartphone HTML_4_0` 6. From the **Position** menu, select the order in which you want this client to be entered in the client registry. It is recommended to place the most specific user agent patterns at the beginning of the list. 7. Click **OK** to save the new client that you added.
Create client definitions, and add to existing device classes.	You can also create client definitions through an XML file that contains the device information. For more information, see the *Device classes* topics in the *Developing Themes and Skins* section for more information and examples.
Create custom class definitions, and add client information to your class definitions.	Class definitions might also be created through an XML file that contains the class information. After you create your device class, you must add appropriate clients by using XML. You might need to create a custom theme for this class. For more information, see the *Device classes* topics in the *Developing Themes and Skins* section for more information and examples.

Example: Creating a segment by device class:

Learn more about the Device application object through an example. In this example, you are creating two segments by using a profiler rule: Smartphone User and Tablet User. Each segment views content through different devices.

About this task

Procedure

1. Click **Applications** > **Personalization** > **Business Rules**.
2. From the Personalization Navigator, click **New** > **Rule**.
3. For Rule Type, select **Profiler**. The profiler rule groups a user into one or more segments. Segments are profiles.
4. The numbered screen capture, along with the corresponding table, provides the values and selections that are used in this example. Use these example values and selections to guide you in creating a profiler rule by using the device class attribute.

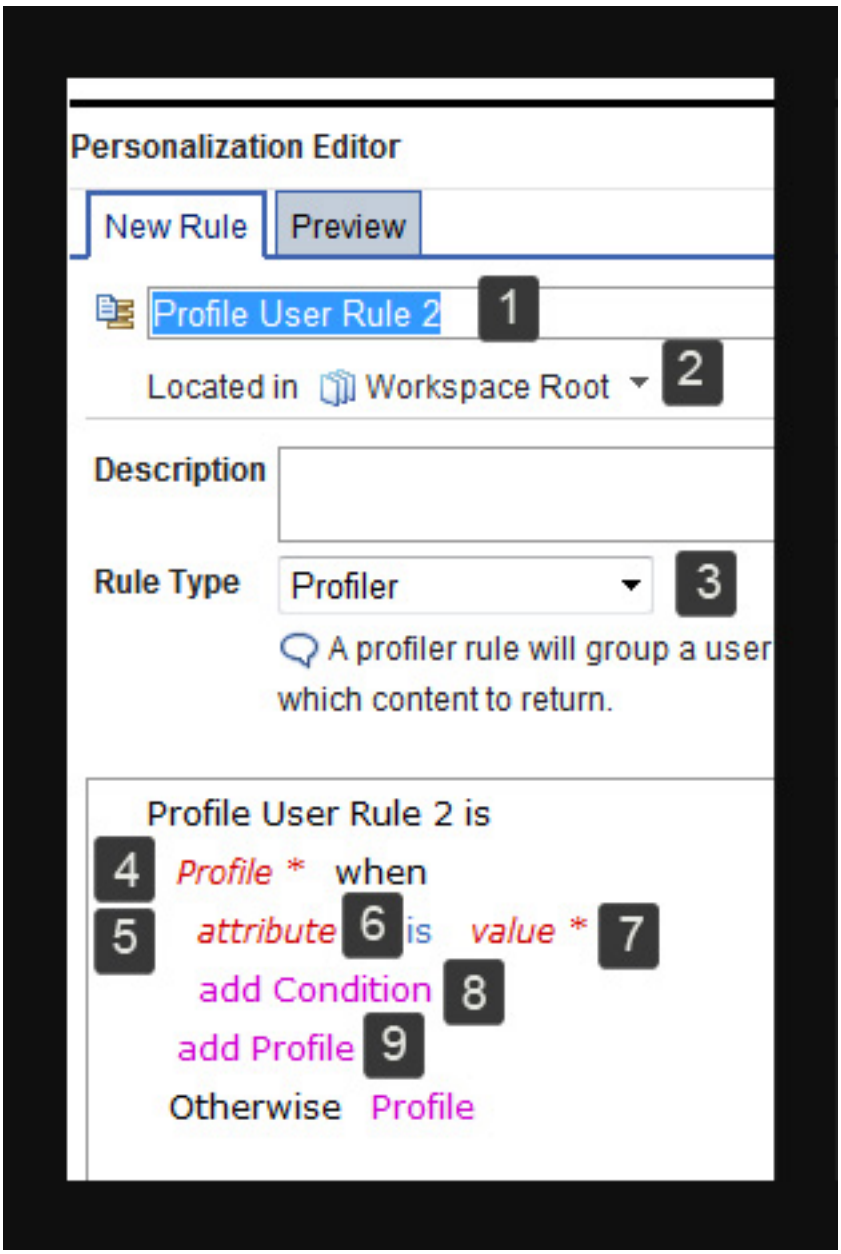

Table 346. Creating segments (profiles) in a profiler rule

Numbered item in screen capture	Description
1	Type `User by device` as the name for your rule.
2	By Located in, use the default folder to store your rule for this example.
3	For Rule Type, select **Profiler**. A segment is another word for profile in the profiler rule.
4	Click **Profile**, and enter `Smartphone User` as the name for your segment. Click **Submit**.

Table 346. Creating segments (profiles) in a profiler rule (continued)

Numbered item in screen capture	Description
5	In this example, you are defining a segment that is based on device class used. Define attributes and values for the Smartphone User segment. Click **attribute**, and select **Device** > **Device Class**. The attribute label changes to current Device.Device Class.
6	In this example, continue to use **is** as the comparison operator.
7	Click **value**, and select **smartphone** as the value for the condition.
8	In this example, you are not setting up another condition for the Smartphone User. Skip to add Profile.
9	Click **add Profile** to add another segment to the profiler rule. Enter `Tablet User` as the name for your segment. Click **Submit**.
Not shown in screen capture	Define attributes and values for the Tablet User segment. Click **attribute**, and select **Device** > **Device Class**. The attribute label changes to current Device.Device Class.
Not shown in screen capture	In this example, continue to use **is** as the comparison operator.
Not shown in screen capture	Click **value**, and select **tablet** as the value for the condition.

5. Click **Save**.

Results

The segments in this saved profiler rule appear in the Add Segment view when you create targeting rules. You can add these segments to content in a targeting rule or use these segments in other types of rules.

Device Application Object: Location attributes:

You can use location to tailor the content that displays. The Device application object contains five location attributes that you can use in rules that you create: latitude, longitude, country, state, and city.

About this task

To receive latitude and longitude information from a user's device:

- You must enable the geolocation theme module on IBM WebSphere Portal Express.
- The user that accesses your site must use a device that is location aware and selected to share location information about their device to your site.
- The client software on the device (the browser) must support HTML5.

Country, state, and city attributes are resolved from the latitude and longitude coordinates of the user's device or from the IP address that is obtained by using a reverse geocoding service. A reverse geocoding service is not provided with WebSphere Portal Express. Use the geolocation interface and registration mechanism that is provided with WebSphere Portal Express to define how to deploy the service you use.

"Enabling the geolocation theme module"
Unlike the other application objects that are installed by default, the geolocation features of the Device application object are not enabled after you run the ConfigEngine **enable-content-targeting-extension** task. To enable the geolocation features, you can modify the JSON profiles to include the geolocation theme module, provide a resolver JAR, or use both methods.

"Retrieving the location of users or devices" on page 2281
To implement the geolocation interface, you must provide methods to resolve coordinates or IP address to one or more of the location attributes (country, state, or city). You can determine the location of a device by using reverse geocoding or by using service providers. Reverse geocoding converts latitude and longitude coordinates into a location (such as country, state, or city) by using a geolocation JAR that you provide or by using an external geolocation service provider.

"Example: Creating a segment that uses the state attribute" on page 2282
Learn more about the Device application object through an example that uses a location attribute (state). In this example, you are creating two segments by using a profiler rule: North Carolina and California. Each segment views content that is based on the location of the device.

Enabling the geolocation theme module:

Unlike the other application objects that are installed by default, the geolocation features of the Device application object are not enabled after you run the ConfigEngine **enable-content-targeting-extension** task. To enable the geolocation features, you can modify the JSON profiles to include the geolocation theme module, provide a resolver JAR, or use both methods.

About this task

The new geolocation theme module adds JavaScript to every portal page to check that the HTML5 geolocation API is available on the client. When the HTML geolocation API is available, the latitude and longitude of the device that accesses portal is returned to the portal.

Procedure

1. Connect to WebDav client, and go to the `/profiles` directory. For example, follow this path to the `/profiles` directory: `http://server_name/wps/mycontenthandler/dav/themelist/ibm.portal.85Theme/profiles/`
2. By default, four JSON profiles are in this directory. Add the Geolocation theme module ID to the moduleIDs section of every JSON file. The value for the Geolocation theme module ID is `wp_pzn_geolocation`. For example:

```
"moduleIDs": [
  "wp_theme_portal_85",
  "wp_pzn_geolocation",
  "wp_portlet_css",
  "wp_one_ui",
```

```
"wp_one_ui_dijit",
"wp_legacy_layouts",
"wp_client_ext",
...
```

3. Use the Theme Opt Analyzer portlet to invalidate the cache. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Theme Analyzer**. Then, click **Utilities** > **Control Center** > **Invalidate cache**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities. You do not need to restart the server.

Retrieving the location of users or devices:

To implement the geolocation interface, you must provide methods to resolve coordinates or IP address to one or more of the location attributes (country, state, or city). You can determine the location of a device by using reverse geocoding or by using service providers. Reverse geocoding converts latitude and longitude coordinates into a location (such as country, state, or city) by using a geolocation JAR that you provide or by using an external geolocation service provider.

About this task

Key concepts for determining the location of a device:

- The new geolocation theme module checks to see that the HTML5 geolocation API is available on the client. When the HTML geolocation API is available, the latitude and longitude of the device that accesses your site is returned to the portal.
- When latitude and longitude information is returned to your portal, Personalization calls the API method `getAddressFromCoords()` to return the corresponding country, state, or city information.
- If latitude and longitude are not returned to portal, Personalization calls the API method `getLocation()`. This method typically resolves the IP address to a country, and other location attributes are not set. Examples of when latitude and longitude are not available are as follows:
  - The client does not support HTML5. For the location-based services to work correctly, the clients (browsers) must support HTML5.
  - The user does not want to share location information about their device.
  - The device does not have location awareness.
- You can also use the geolocation theme to add JavaScript. When the latitude and longitude coordinates are received on the client, these coordinates are resolved to country, state, or city location information that uses a call from the client to an external resolver service. The location attributes (latitude, longitude, country, state, or city) are returned to your portal. The `getLocation()` method resolves the request parameters and returns these parameters.

Procedure

1. Enable the reverse geocoding class in the `PersonalizationService.properties` file to receive the latitude and longitude coordinates of the client that accesses your portal.
   a. Locate the `PersonalizationService.properties` in the following directory: *wp_profile_root*`/PortalServer/config/config/service`
   b. Create a backup copy of the `PersonalizationService.properties` file.
   c. Add the class name to the key. For example:
   `pzn.externalGeolocation=com.acme.geolocation.ReverseGeolocationExample`

2. Create a JAR file, and place this file on the portal server class path. For example, place your JAR file in the following directory: *PortalServer_root*/shared
3. Restart the WebSphere Portal Express server.

Example: Creating a segment that uses the state attribute:

Learn more about the Device application object through an example that uses a location attribute (state). In this example, you are creating two segments by using a profiler rule: North Carolina and California. Each segment views content that is based on the location of the device.

About this task

Procedure

1. Click **Applications** > **Personalization** > **Business Rules**.
2. From the Personalization Navigator, click **New** > **Rule**.
3. For Rule Type, select **Profiler**. The profiler rule groups a user into one or more segments. Segments are profiles.
4. The numbered screen capture, along with the corresponding table, provides the values and selections that are used in this example. Use these example values and selections to guide you in creating a profiler rule that uses the device class attribute.

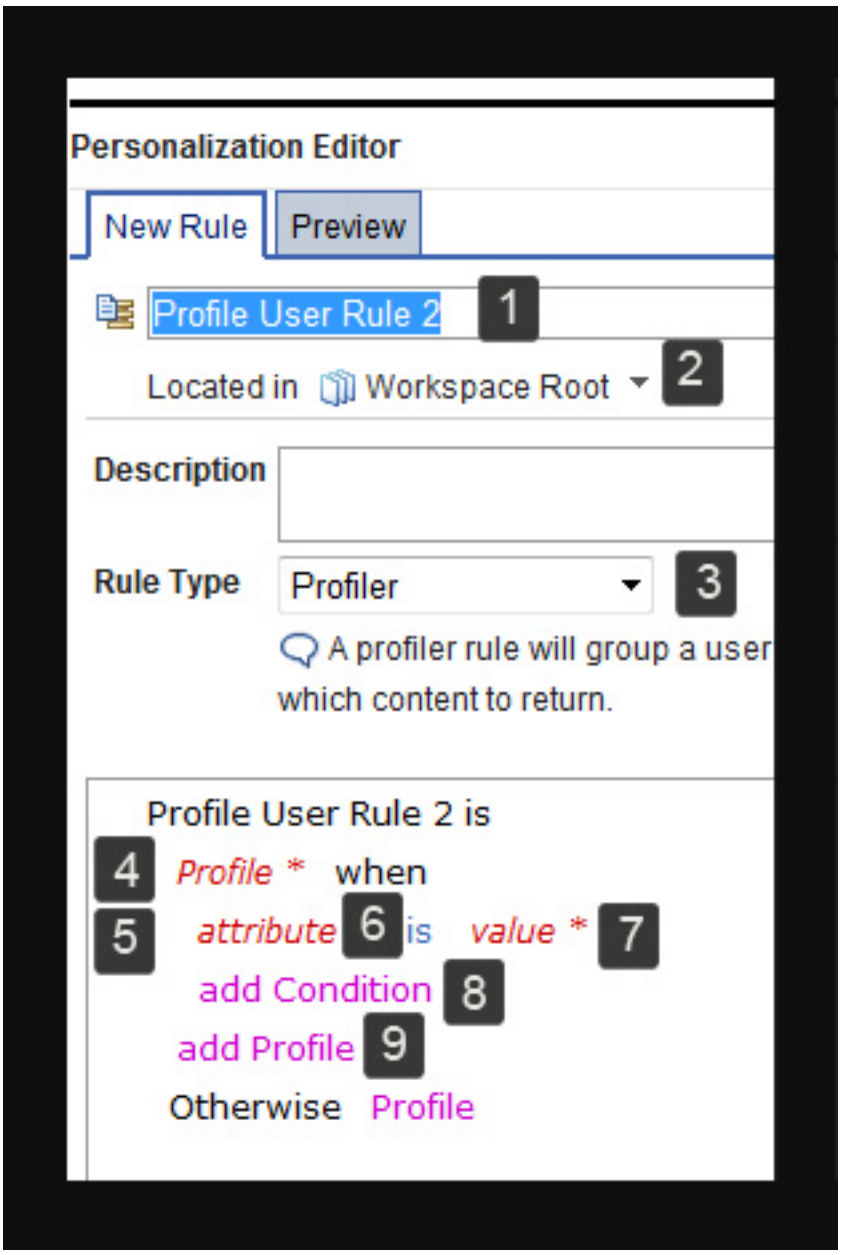

Table 347. Creating segments (profiles) in a profiler rule

Numbered item in screen capture	Description
1	Type `Device segments by state` as the name for your rule.
2	By Located in, use the default folder to store your rule for this example.
3	For Rule Type, select **Profiler**. A segment is another word for profile in the profiler rule.
4	Click **Profile**, and enter `North Carolina` as the name for your segment. Click **Submit**.

Table 347. Creating segments (profiles) in a profiler rule (continued)

Numbered item in screen capture	Description
5	In this example, you are defining a segment that is based on the state the device is located in. Define attributes and values for the North Carolina segment. Click **attribute**, and select **Device** > **State**. The attribute label changes to current Device.State. **Note:** • You can also create other segments that are based on location by selecting Country, Latitude, or Longitude.
6	In this example, continue to use **is** as the comparison operator.
7	Click **value** to enter `North Carolina` as the value for the condition. Click **Submit**.
8	In this example, you are not setting up another condition for the North Carolina segment. Skip to add Profile.
9	Click **add Profile** to add another segment to the profiler rule. Enter `California` as the name for your segment. Click **Submit**.
Not shown in screen capture	Define attributes and values for the California segment. Click **attribute**, and select **Device** > **State**. The attribute label changes to current Device.State.
Not shown in screen capture	In this example, continue to use **is** as the comparison operator.
Not shown in screen capture	Click **value** to enter `California` as the value for the condition. Click **Submit**.

5. Click **Save**.

Results

The segments in this saved profiler rule appear in the Add Segment view when you create targeting rules. You can add these segments to content in a targeting rule or use these segments in other types of rules.

Referrer application object:

You can target your content to users based on what site the user came from before the user accessed your site. You can also target your content by the search parameters that are entered by users in a search engine.

About this task

The Referrer application object supports the following search engines:

- Google
- Yahoo
- AOL

- Ask
- Bing

  "Example: Creating a visibility rule that uses the referral host and search attributes"
  Learn more about the Referrer application object through an example. In this example, you are creating a visibility rule that uses the referral host and search attributes. These attributes are only used in rules to display ski related vacation information for users that search on ski trips in Google.

Results

Example: Creating a visibility rule that uses the referral host and search attributes:

Learn more about the Referrer application object through an example. In this example, you are creating a visibility rule that uses the referral host and search attributes. These attributes are only used in rules to display ski related vacation information for users that search on ski trips in Google.

About this task

This rule prevents other types of information, such as beach or mountain vacation information, from displaying when users search on ski trips.

Procedure

1. Click **Applications** > **Personalization** > **Business Rules**.
2. From the Personalization Navigator, click **New** > **Rule**.
3. For Rule Type, select **Visibility Rule**.
4. The numbered screen capture, along with the corresponding table, provides the values and selections that are used in this example. Use these example values and selections to guide you in creating a visibility rule that uses the referral host and search attributes.

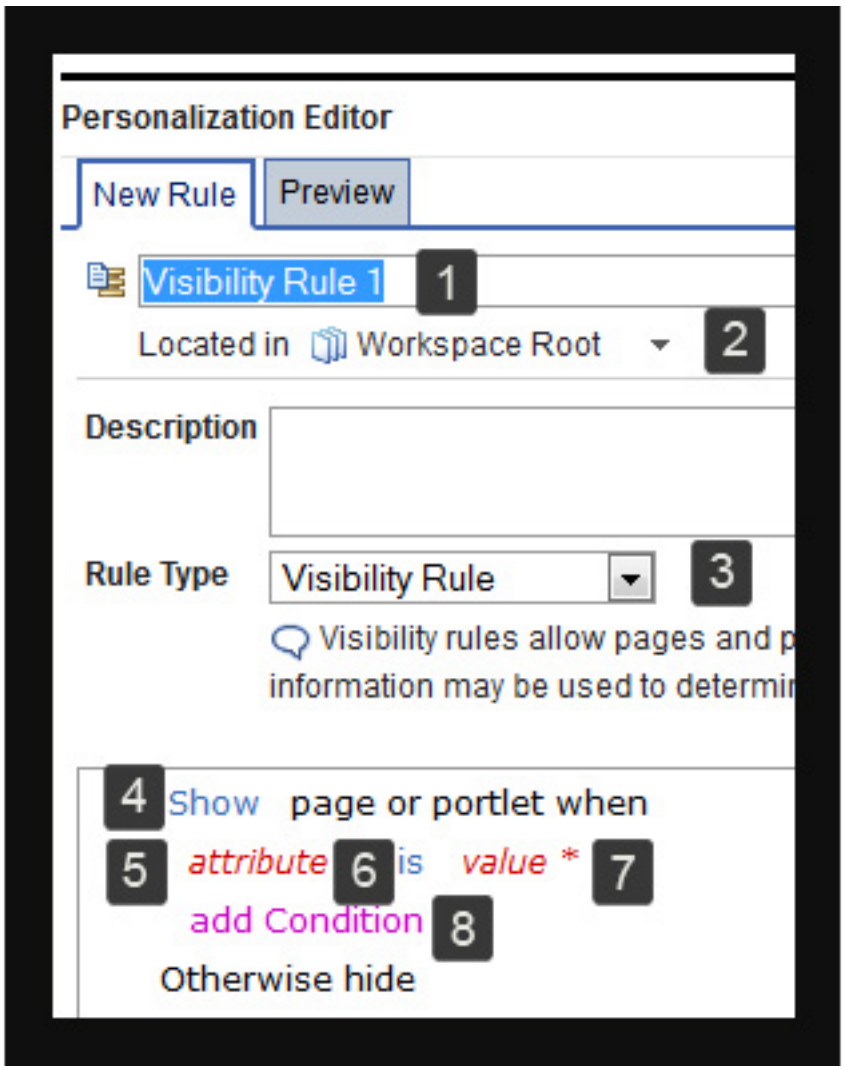

Table 348. Creating a visibility rule that uses the referral host and search attributes for the Referrer application object

Numbered item in screen capture	Description
1	Type `Ski vacation information` as the name for your rule.
2	By Located in, use the default folder to store your rule for this example.
3	For Rule Type, select **Visibility Rule**.
4	Continue to use **Show** in this example to show a page or portlet that is based on the conditions that you define in this rule.
5	Click **attribute** > **Referrer** > **Referral Host**. The attribute label changes to current Referrer. Referral Host. **Note:** The Referral URL attribute is another attribute available to you with the Referrer application object. Use the Referral URL attribute when a user is referred to your site from a search engine other than the supported search engines. Use the Referral Host attribute, as shown in this example, when a user is referred to your site from the supported search engines.
6	In this example, continue to use **is** as the comparison operator.

Table 348. Creating a visibility rule that uses the referral host and search attributes for the Referrer application object (continued)

Numbered item in screen capture	Description
7	Click **value** * to enter `www.google.com` as the value for the condition. Click **Submit**.
8	Click **add Condition** > **Referrer** > **Search Keywords**. The attribute label changes to current Referrer. Search Keywords. **Note:** You can provide a value for the Referrer. Search Keywords only when a user is arriving to your site from one of the supported search engines.
Not shown in screen capture	Click **value** * to enter `skiing` as the value for the condition. Click **Submit**.

5. Click **Save**.

You successfully created your visibility rule. You can add your rule to a page or portlet from the Manage Pages area of your site.

Note: Visibility rules do not hide pages or portlets for anonymous users.

6. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
7. Click **Content Root**.
8. Go to the page that you want to use your rule. For example, you might have a page that is named Ski Vacations in the Home area of your site. To locate the Travel page, click **Home** > **Ski Vacations**
9. After you locate your Travel page, follow the instructions for adding your rule to a page or for adding your rule to a specific portlet.

Option	Description
Instructions for adding your rule to a page	1. Click **Edit Page Properties**. 2. Expand **Advanced options**. 3. Click the arrow by Show or Hide page rule, and click **Select Rule**. 4. Select the check box by a rule you want to add to your page. Click **OK**. 5. Click **Done**
Instructions for adding your rule to a portlet	1. Click **Edit Page Layout**. 2. Make sure that Show portlet rule mapping is enabled. When this option is enabled, you see a Hide Portlet Rule Mappings link. 3. Click the arrow by **No rule mapped** for a portlet on this page, and click **Select Rule**. 4. Select the check box by a rule you want to add to your portlet. Click **OK**. 5. Click **Done**.

Public Render Parameters application object:

The Public Render Parameter application object provides read and write access to public render parameters. Public render parameters allow portlets to share navigational state information and preserve this information across requests. Use this object in rules when you need your site to store a user's selection as a public render parameter during the action phase and have other portlets read this public render parameter during the render phase.

About this task

You can write public render parameters from preprocessors and portlets (JSR 168, JSR 286, and legacy IBM portlets) during the action phase. Render parameters are read from anywhere, including preprocessors, themes, dynamic assembly transformation, and portlets, during all phases.

Let's apply an example to this definition to highlight how you can use the public render parameters application object in rules that you create on your site. For example,

- You select a travel destination from an airline website.
- Your selection is saved by a portlet as a public render parameter during the action phase.
- Portlets can read your destination during the render phase, and your destination is available in bookmarks that you create. For example, you have a portlet that provides ticket rates that are based on the destination selected.
- A visibility rule that uses the Public Render Parameters application object displays content in the site that is based on your destination selection.

Note: You cannot write public render parameters from themes or from update rules.

Use the table to learn more about the Public Render application object

Table 349. Feature highlights for the Public Render application object

Description	Public Render Parameter application object
Type of data stored	Strings and arrays of strings. Since these parameters are encoded in your portal URLs, it is recommended that you use string values that are not long in length.
Location of stored data	Public render parameters are encoded in all portal URLs. Public render parameters remain available when a user remains in the same browser tab or opens a new tab by using a link from the original tab.
Duration of storage	Data is not connected to a user session. Data is available in the same browser tab, window, or bookmarks.
Supported user types	You can use this object for all users. For example, supported user types include authenticated users and anonymous users, with and without sessions

Note: The Shared Data application object is also used in rules to share data between portal web applications. Use the Shared Data application object, instead of the Public Render Parameters application object, when you need to share complex data.

"Example: Creating a visibility rule that uses travel destination as your public render parameter"
Learn more about the Public Render Parameter application object through an example. In this example, create a visibility rule that uses your travel destination as the public render parameter used in the rule.

Example: Creating a visibility rule that uses travel destination as your public render parameter:

Learn more about the Public Render Parameter application object through an example. In this example, create a visibility rule that uses your travel destination as the public render parameter used in the rule.

Procedure

1. Click **Applications** > **Personalization** > **Business Rules**.
2. From the Personalization Navigator, click **New** > **Rule**.
3. For Rule Type, select **Visibility Rule**.
4. The numbered screen capture, along with the corresponding table, provides the values and selections that are used in this example. Use these example values and selections to guide you in creating a visibility rule that uses a public render parameter.

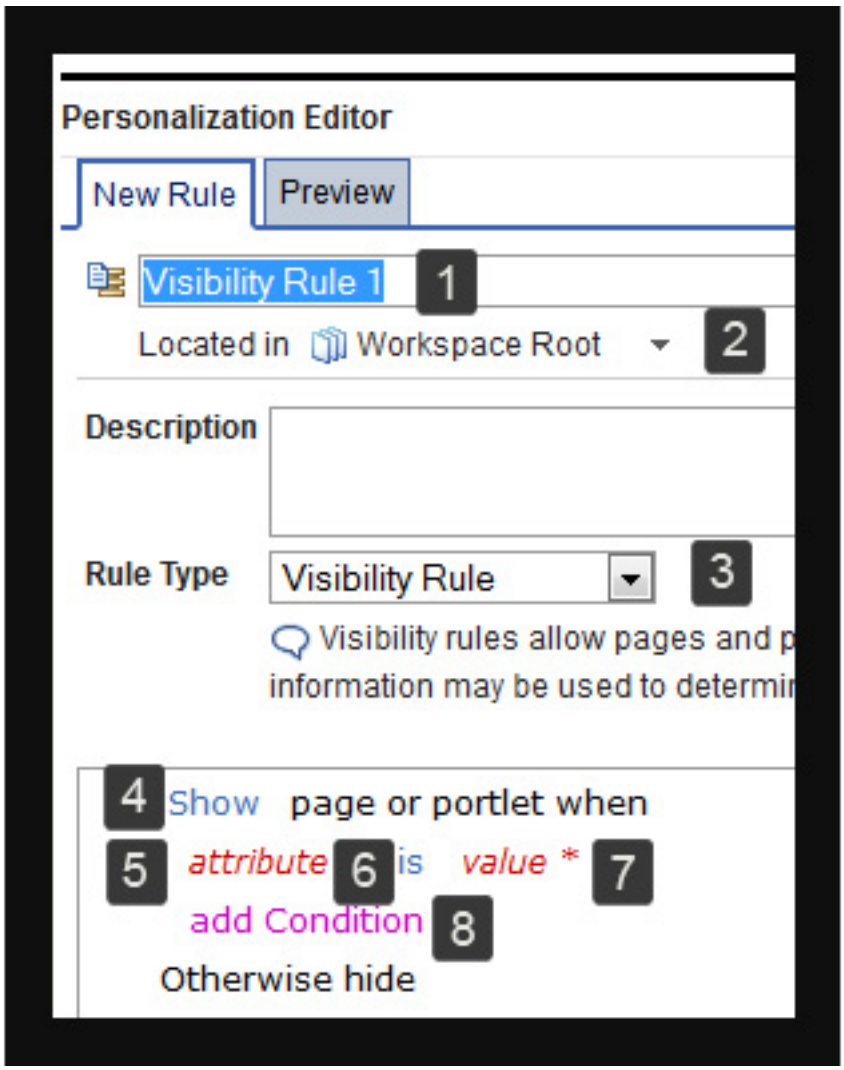

Table 350. Creating a visibility rule that uses travel destination as your public render parameter

Numbered item in screen capture	Description
1	Type `Show Shops in Paris` as the name for your rule.
2	By Located in, use the default folder to store your rule for this example.
3	For Rule Type, select **Visibility Rule**.
4	Continue to use **Show** in this example to show a page or portlet that is based on the conditions you define in this rule.
5	Click **attribute** > **Public Render Parameters** > **Travel Destination**. **Note:** • Travel Destination must exist as a parameter to select this option. • If Travel Destination does not exist, click **attribute** > **Public Render Parameters** > **Manage Properties** to create this parameter. • You must know the name of the parameter that the portlet or preprocessor is using to set the value for public render parameters in Manage Properties.

Table 350. Creating a visibility rule that uses travel destination as your public render parameter (continued)

Numbered item in screen capture	Description
6	In this example, continue to use **is** as the comparison operator.
7	Travel Destination is the public render parameter that is read by portlets on the site during your session and is used to display targeted content. Click **value** * to enter `Paris` as the value for the condition. Click **Submit**.
8	In this example, you are not setting up another condition.

5. Click **Save**.

You successfully created your visibility rule. You can add your rule to a page or portlet from the Manage Pages area of your site.

Note: Visibility rules do not hide pages or portlets for anonymous users.

6. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
7. Click **Content Root**.
8. Go to the page that you want to use your rule. For example, you might have a page that is named Travel to contain portlets that use the Travel Destination public render parameter in the Home area of your site. To locate the Travel page, click **Home** > **Travel**
9. After you locate your Travel page, follow the instructions for adding your rule to a page or for adding your rule to a specific portlet.

Option	Description
Instructions for adding your rule to a page	1. Click **Edit Page Properties**. 2. Expand **Advanced options**. 3. Click the arrow by Show or Hide page rule, and click **Select Rule**. 4. Select the check box by a rule you want to add to your page. Click **OK**. 5. Click **Done**
Instructions for adding your rule to a portlet	1. Click **Edit Page Layout**. 2. Make sure that Show portlet rule mapping is enabled. When this option is enabled, you see a Hide Portlet Rule Mappings link. 3. Click the arrow by **No rule mapped** for a portlet on this page, and click **Select Rule**. 4. Select the check box by a rule you want to add to your portlet. Click **OK**. 5. Click **Done**.

Shared Data application object:

The Shared Data application object is used in rules to share complex data between web applications and IBM WebSphere Portal Express in a user's session.

About this task

Use the table to learn more about the Shared Data application object.

Table 351. Feature highlights for the Shared Data application object

Description	Shared Data application object
Type of data stored	Any type of data.
Location of stored data	Encoded in all portal URLs.
Duration of storage	Data is tied to a user's session and is available only for the user's session.
Supported user types	This object is only used to store data for users with an active session.

Note: The Public Render Parameters application object is also used in rules to share data between portal web applications. Use the Public Render Parameters application object, instead of the Shared Data application object, when you are sharing string data that is not restricted to a user's session.

"Example: Creating a visibility rule to track your order history"
Learn more about the Shared Data application object through an example. In this example, create a visibility rule that uses your order history as the parameter used in the rule. A user would need to sign in to the site to view a summary of their order history and know the tracking number.

Example: Creating a visibility rule to track your order history:

Learn more about the Shared Data application object through an example. In this example, create a visibility rule that uses your order history as the parameter used in the rule. A user would need to sign in to the site to view a summary of their order history and know the tracking number.

Procedure

1. Click **Applications** > **Personalization** > **Business Rules**.
2. From the Personalization Navigator, click **New** > **Rule**.
3. For Rule Type, select **Visibility Rule**.

   Note: In this example, a parameter is set in an application and read in a Visibility rule. You can also use an Update rule to set your parameter for a Visibility rule to reference.
4. The numbered screen capture, along with the corresponding table, provides the values and selections that are used in this example. Use these example values and selections to guide you in creating a profiler rule that uses the device class attribute.

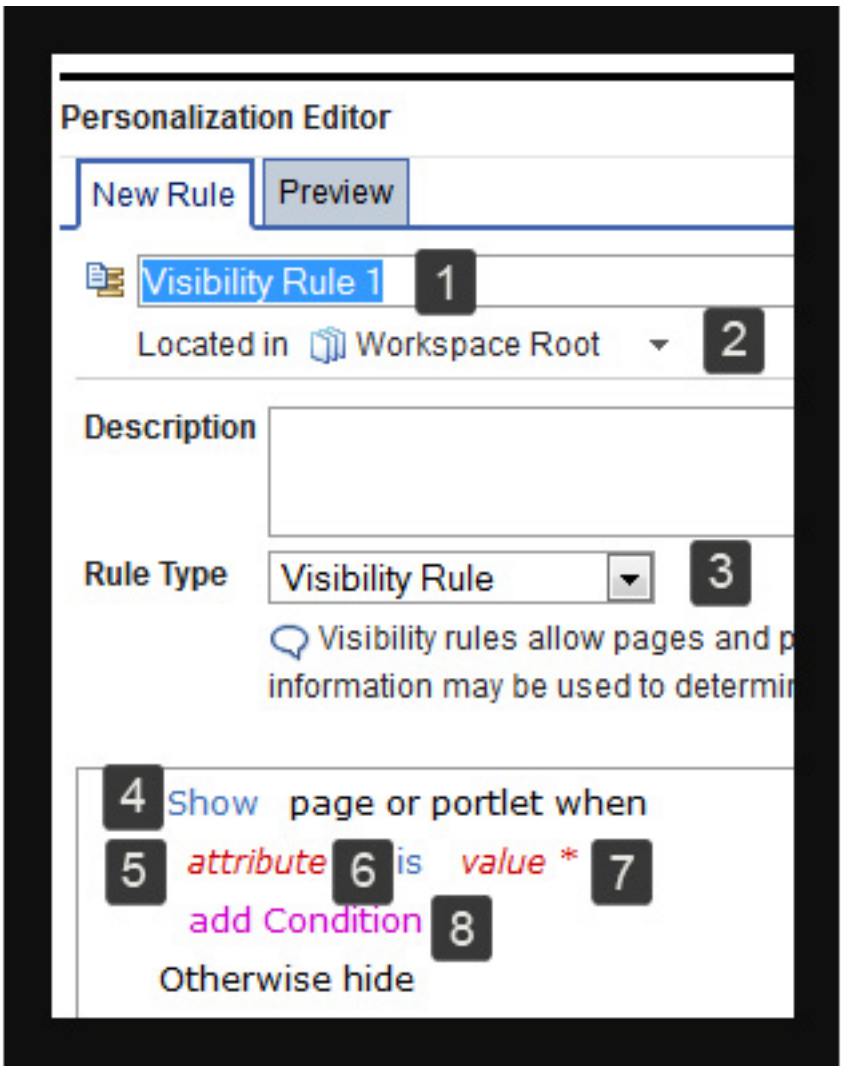

Table 352. Creating a visibility rule that uses order history as parameter used in the Shared Data application object.

Numbered item in screen capture	Description
1	Type `Show Order Tracking` as the name for your rule.
2	By Located in, use the default folder to store your rule for this example.
3	For Rule Type, select **Visibility Rule**.
4	Continue to use **Show** in this example to show a page or portlet that is based on the conditions you define in this rule.
5	Click **attribute** > **Shared Data** > **Order Number**. **Note:** • Order Number must exist as a parameter to select this option. • If Order Number does not exist, click **attribute** > **Shared Data** > **Manage Properties** to create this parameter. • You must know the name of the parameter that the portlet or preprocessor is using to set the value for parameters in Manage Properties.

Table 352. Creating a visibility rule that uses order history as parameter used in the Shared Data application object. (continued)

Numbered item in screen capture	Description
6	In this example, continue to use **is** as the comparison operator.
7	In this example, Order Tracking is the parameter that is read by portlets on the site during your session and is used to display targeted content. Click **value** * to enter `248761` as the value for the condition. Click **Submit**. **Note:** In this example, `248761` is your order number for a recent purchase.
8	In this example, you are not setting up another condition.

5. Click **Save**.

You successfully created your visibility rule. You can add your rule to a page or portlet from the Manage Pages area of your site.

Note: Visibility rules do not hide pages or portlets for anonymous users.

6. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
7. Click **Content Root**.
8. Go to the page that you want to use your rule. For example, you might have a page that is named Orders in the Home area of your site. To locate the Orders page, click **Home** > **Orders**
9. After you locate your Travel page, follow the instructions for adding your rule to a page or for adding your rule to a specific portlet.

Option	Description
Instructions for adding your rule to a page	1. Click **Edit Page Properties**. 2. Expand **Advanced options**. 3. Click the arrow by Show or Hide page rule, and click **Select Rule**. 4. Select the check box by a rule you want to add to your page. Click **OK**. 5. Click **Done**
Instructions for adding your rule to a portlet	1. Click **Edit Page Layout**. 2. Make sure that Show portlet rule mapping is enabled. When this option is enabled, you see a Hide Portlet Rule Mappings link. 3. Click the arrow by **No rule mapped** for a portlet on this page, and click **Select Rule**. 4. Select the check box by a rule you want to add to your portlet. Click **OK**. 5. Click **Done**.

Request Context:

This is the interface used to access various attributes for rules. For HTTP contexts, it provides access to the HttpRequest and HttpSession attributes. For non-HTTP contexts, it provides the same interface to a surrogate for the request and session.

The request context, and any request values accessed via the request context, are only valid for the life of the request.

The Request Context string is used in caching lookups. The lookup is created by using a user-specified string combined with query values as the lookup key. The user-specified string should uniquely represent the current Request Context. This key is stored under ibm.wcp.cache.user.key as a request attribute or as a session attribute with the request attribute taking precedence.

Accessing the Request Context

The Request Context provides the Personalization rules engine with the data and environmental information needed for rules processing. In other words, the Request Context contains all the input to execute Personalization content spots and rules. This includes simple inputs like request and session data, and more advanced input like the user object.

You can access the Request Context from a content spot by first using the setRequest method of the content spot to back the content spot with a request, and then by calling getContext to retrieve the context. You can also use the Request Context to call directly into the ResourceDomain3 and ResourceManager3 APIs.

The Request Context allows you to retrieve session, request, portlet attribute, date, cookie, and other data and environmental information from the resource layer.

The Request Context includes:

- Session

  The session information identifies the HttpSession object that is associated with the current user.
- Request date

  This request date is the date the HTTP request was received. This information supports rules that have date-dependent actions.

Since Personalization uses the Request Context to contain all the rule input, the Request Context must be set onto the content spot prior to rule execution. The code with the content spot's useBean tag must be similar to:

```
<jsp:useBean id="gold_promo_bean"
class="yourco.goldpromo.BannerSpot" />
<% gold_promo_bean.setRequest (request); %>
```

In the previous section, the jsp:useBean tag constructs the yourco.goldpromo.BannerSpot class and stores an instance of that class into the local variable gold_promo_bean. The next line calls setRequest to put the HttpServletRequest or PortletRequest onto the newly constructed content spot bean. The content spot then implicitly constructs a Request Context which is backed by the given HttpServletRequest or PortletRequest. This Request Context then provides access to that request's parameters and attributes and attributes of the session through the com.ibm.websphere.personalization.RequestContext interface.

In some cases, it may be useful to call into a content spot without having access to an HttpServletRequest or PortletRequest. The interface com.ibm.websphere.personalization.PznRequestObjectInterface can be used in these situations. A implementation of this class called com.ibm.websphere.personalization.PznRequestObjectImplementor is provided for convenience.

Query framework:

The query framework is an object representation of a query. The framework is not specifically oriented toward querying either object or relational databases. A set of common operators is defined, but what an attribute represents is determined by the interpreter of the query.

Since the framework makes no assumptions about how the name of an attribute is translated to the object it represents, object trees and graphs, relational models, or almost any other data structure could be queried with the framework. The query framework is used to pass query information from the runtime engine into the resource engine. It is up to the resource collection to interpret the query. Traditionally, this interpretation of the query object is done through a callback class, which is essentially a translator from the query framework into a protocol-specific query language.

The Personalization interface

The Portal Personalization user interface consists of three portlets: the Personalization Navigator, Personalization Editor, and the Personalized List.

These portlets are automatically installed with IBM WebSphere Portal Express. Although personalization services can be used in portlets supporting remote WSRP services, the personalization portlets do not support being used as a remote WSRP service.

Personalization Navigator

The Personalization Navigator is the main navigation interface. Users explore the repository with a tree structure--directories display on one side of the window, and elements within a selected directory display in the other part of the window. The view can be modified to eliminate the side of the window with the tree structure, and instead list all directories and elements in a hierarchical list. A drop-down list enables users to show all elements in Personalization, or filter the view to display a single element type (such as rules or campaigns). The following table shows which views are available:

Table 353. Available views in the Personalization Navigator

List view	Description	Properties shown
Browse Personalization Resources (tree)	This tree view will show only artifacts created by Personalization. For example, rules, campaigns, resource collections.	Name, Creator, Last Modified, Node Type
Browse Rules (tree)	This tree view will show only Personalization rules. This view will also show the type of each rule; for example, Select Action or Profiler.	Name, Creator, Last Modified, Return Type, Rule Type

Table 353. Available views in the Personalization Navigator (continued)

List view	Description	Properties shown
Campaigns (list)	Campaigns will be a specialized list view. In the action bar for the view, there will be a scope drop down. The scope drop down will allow the user to pick an execution scope. The campaigns from the scope context of that execution scope will be shown. When the scope setting is global as by default, there will be no drop down and all campaigns will be shown. As with all views, the Edit Mappings action will be available when a campaign is selected.	Name, Priority, Split, Start Date, End Date
Rule Mappings by Campaign (list)	This view is launched either by the drop down for selecting a view, or by the Edit Mappings action for a campaign. The view shows a list of mappings for a given campaign.	Spot Name, Rule Name, Content Type, Split, Start Date, End Date
Collections (list)	This view will allow a user to see all resource collections and application objects created under a collection.	Collection Name, IBM Java Content Repository(True / False), Collection Type (User / Content)
Events	This view will allow a user to see all rule events on the system.	

In addition to navigation, the Personalization Navigator is where users control the repository content. Users can move, copy, import and delete elements, and create new elements. When users create a new element (by selecting **New** from the Personalization Navigator menu), they are automatically taken to the Personalization Editor.

You can also access the Resource Permissions portlet to set access control on individual personalization items from the Personalization Navigator by clicking **Edit Access** > **Extra Actions**.

Personalization Editor

This portlet is where users edit element content or information. Selecting a new element from the Personalization Navigator activates the edit mode, where users enter data, depending on the element chosen. To edit an existing element, users highlight the item in the Personalization Navigator. They return to the Personalization Editor and click **Edit** on the Edit item tab.

Personalized List

The Personalized List portlet allows a user to display personalized content without having to build a custom JSP portlet. Each portlet can display a list of resources and show details for each returned resource. Groups of related resources may be categorized for easy viewing. When a more detailed view of a piece of content is required, a custom detail JSP may be specified. Different instances of the portlet may be used across WebSphere Portal Express to quickly and easily deploy customized information to users.

Publishing personalization rules overview

WebSphere Portal Express Personalization sends published rules across HTTP to a servlet which resides on each personalization server. This servlet can receive publishing data or initiate new publishing jobs. When a user begins a publishing job from the personalization authoring environment, the local servlet is provided with the set of information necessary to complete the job. The local servlet contacts the destination endpoint servlet (which could be the same servlet) and sends its data to it. The destination servlet reports success or failure.

1. "Publishing considerations"
   If you are publishing personalization rules in a clustered server configuration, to an IPv6 host, or using Web Content resource collection classes, there are unique considerations that you should be familiar with.
2. "Publishing personalization rules" on page 2300
   After developing personalization rules, you publish the rules.
3. "Publishing and deleting personalization rules using a script" on page 2303
   You can use a WebSphere Portal Express Personalization provided script, pznload, to export, publish, and delete Personalization rules on local or remote servers. You can script the delivery of rules and campaigns from staging to production, or the offline publishing between disconnected systems (such as when production servers are secured behind a firewall). You can use this function to quickly revert production servers to an earlier state.
4. "Publishing personalization rules over SSL" on page 2305
   WebSphere Portal Express Personalization uses the built-in SSL capabilities of WebSphere Application Server to provide secure publishing across unprotected networks. Your personalized portal can benefit from the full range of authentication repositories supported by WebSphere Application Server security.
5. "Monitoring the status of publishing" on page 2307
   After you start a job to publish a personalization rule, you can monitor the status to make sure the publish completes successfully.

Publishing considerations:

If you are publishing personalization rules in a clustered server configuration, to an IPv6 host, or using Web Content resource collection classes, there are unique considerations that you should be familiar with.

Clusters

Publishing to or from a clustered environment requires no special configuration. The specific cluster member that will perform the publishing task is chosen by the same rules that apply to incoming Web requests (because the publishing mechanism uses HTTP messages). At the end of a successful publishing job, Personalization flushes its caches for that workspace to ensure that any subsequent personalized content will be as current as possible.

When you first used the Personalization authoring portlets on a cluster to publish objects, the Publish Status dialog (accessed through **More Actions** > **Publish** > **View Status**) only shows information about the publish jobs initiated on that cluster member. To make all publishing jobs visible, set the **pzn.publishServlet.url** parameter described previously to be a specific cluster member. Set the URL to point to a single machine at the internal HTTP port: The default port number for HTTP is *10040*, and the default port number for HTTPS is *10035*.

For example, supposed the cluster head is visible at `http://intranet.yourco.com`, and the cluster members are accessible at `http://intranet01.yourco.com` and `http://intranet02.yourco.com`. If you set the publish servlet URL parameter to `http://intranet01.yourco.com:10040/wps/pznpublish/pznpublishservlet` you force all publishing requests to run on this single machine.

Note: Publish to a single node in the cluster as opposed to the cluster head, making sure you do not pass through a Web server.

IPv6 hosts

The server which initiates the publish command must have the IPv6 protocol stack installed and available. When publishing from the command line using pznload to an IPv6 host, you may need to set the system environment variable IBM_JAVA_OPTIONS to a value of *-Djava.net.preferIPv4Stack=false -Djava.net.preferIPv6Addresses=true* on the system where pznload is run.

Resource collection classes

You use resource collections in Personalization to access LDAP, IBM Content Manager, the Portal user object, or other custom sources of data.

The DB2 Content Manager run-time edition and the WebSphere Portal Express user resource collection classes are installed in the Personalization shared library. Therefore, you do not need to move these classes between systems because they are already installed with Personalization.

For LDAP resources, Rational Application Developer provides a wizard to generate classes which implement the resource collection interfaces.

To use the authoring portlet, all resource collection classes must be in the class path of the Personalization authoring portlet. The rule editor uses these classes to display the list of attributes belonging to the collection. If the resource collection classes are not found by the rule editor, you could see the following message in a JavaScript alert.

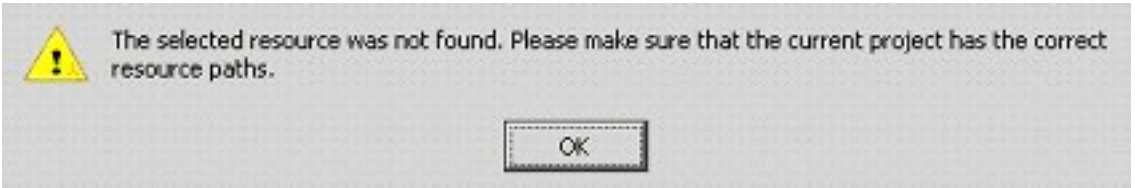

Figure 22. Message displayed when resource classes cannot be found

The resource collection classes must also exist on the class path of the application invoking the Personalization rules. The Personalization rules engine finds the

resource collection classes using the class path of the application which invokes the rules. If you use the Personalized List portlet to display rule results, this application is the Personalized List application `pznruleportlet.war` in the Personalization `Lists.ear`.

So, the classes should be accessible to both the rule editor and the personalized application. An application server shared library is the easiest way to accomplish this. You can configure the shared library using the WebSphere Integrated Solutions Console. For more information, see the sections on the shared library in the WebSphere Application Server Information Center.

You handle updates and additions to the resource collection classes just as you would handle updates to any application binary or JSP. These classes are not affected by Personalization publishing. The definition of the resource collection which Personalization uses to associate a resource collection with its classes is stored in the Content Manager repository. Initially represented by the .hrf file, this definition is published along with the rules and campaigns.

Publishing personalization rules:

After developing personalization rules, you publish the rules.

Procedure

1. To begin publishing personalization rules, you create an object in the authoring environment which describes the target endpoint. This endpoint definition is referred to as a publish server and is created and managed in a manner similar to creating and managing rules and campaigns.

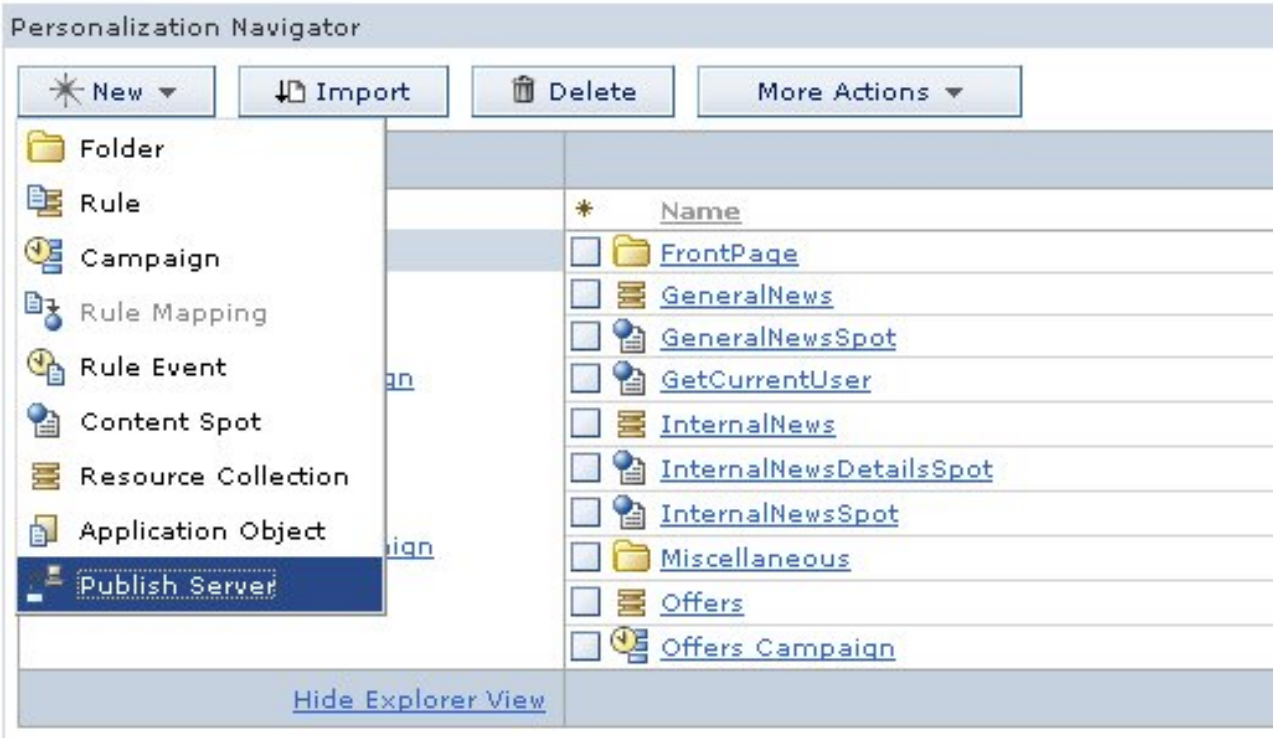

Figure 23. Creating a new publish server

The server requires one field, which is the URL associated with the publish servlet for that endpoint. The publish server may also define which workspace

will receive publishing data. Personalization operates in the default Content Manager run-time edition workspace after installation. If the target workspace field is empty, then the publish server uses the default workspace. (You need to set the workspace field if you are configuring scenario three described previously.)

The last option is whether or not to delete remote objects that have been deleted on the local system. The default is Smart Delete, which simply removes items that are no longer present. If you do not have delete permission on the remote server you could select the Leave deleted resources on server option.

2. After you create a publish server, you can publish either the entire workspace or a set of objects within it. You specify either of these options by selecting the **More Actions** > **Publish submenu**

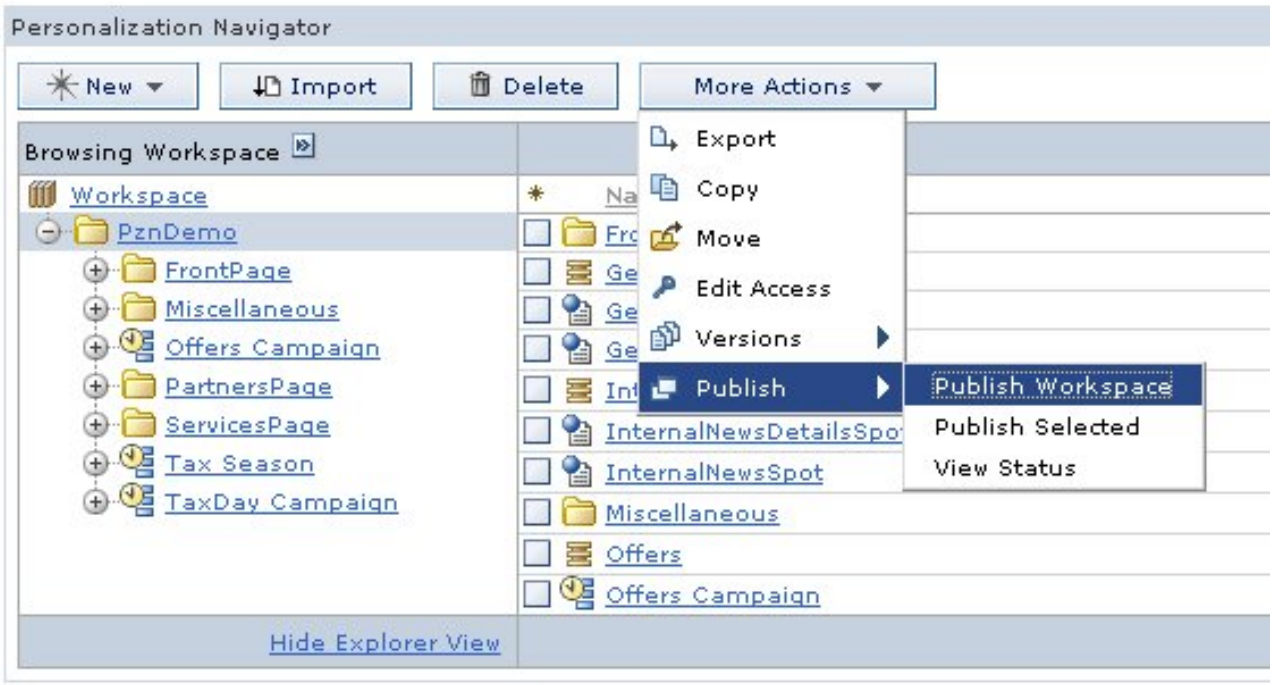

Figure 24. Start a publish job

The Publish page displays what will be published. This page requires the user to choose a destination publish server and any necessary authentication information. If the remote system is secured and is not a member of the current server's Single Sign-On domain you can enter a user name and password in the provided fields. The values for user and password are stored in the WebSphere Portal Express credential vault and are not accessible to any other user.

3. Finally, click **Publish** to launch the publish job.

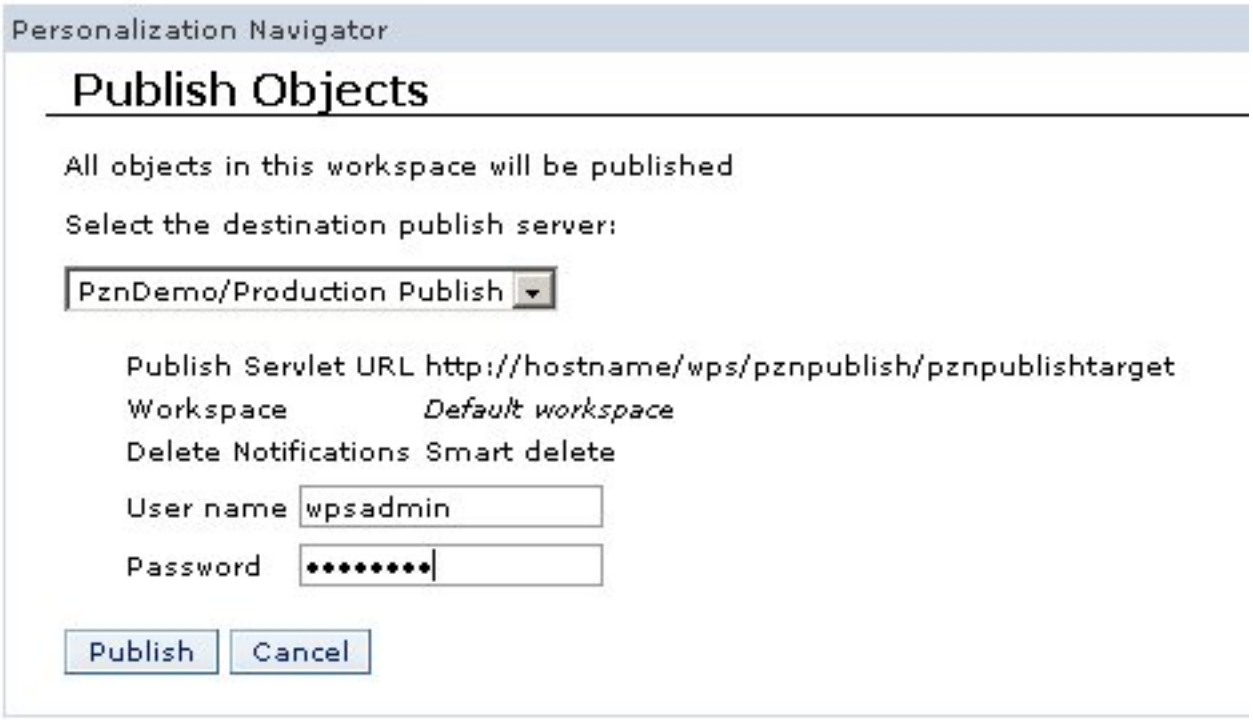

Figure 25. Publish page

If the local system is able to locate and authenticate with the remote publish server, you are returned to the main navigator view, and you see the Personalization message `EJPVP20001I`. Then, the publish job runs as a background process on the local server.

4. Click the **View the details of this job** link to open the publish status window to see information about the progress and success or failure of the publish job.

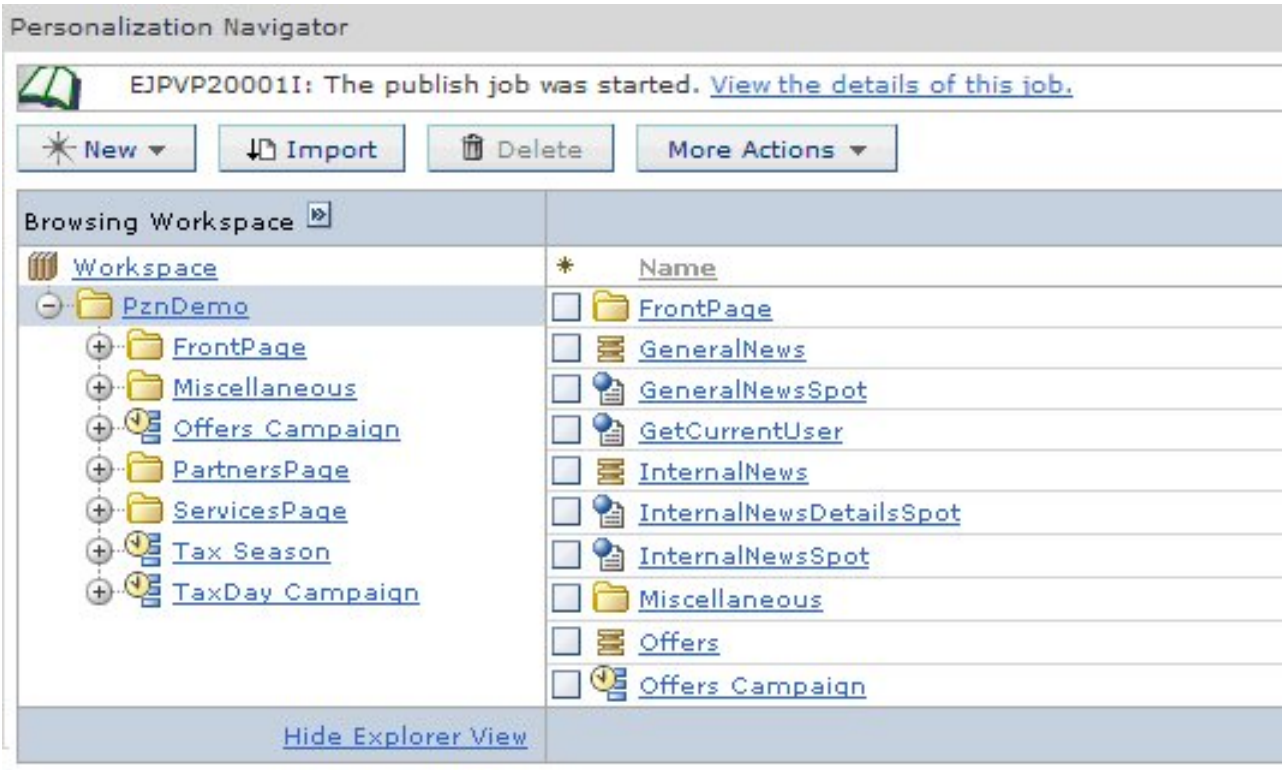

Figure 26.

Publishing and deleting personalization rules using a script:

You can use a WebSphere Portal Express Personalization provided script, pznload, to export, publish, and delete Personalization rules on local or remote servers. You can script the delivery of rules and campaigns from staging to production, or the offline publishing between disconnected systems (such as when production servers are secured behind a firewall). You can use this function to quickly revert production servers to an earlier state.

Before you begin

In order to run the pznload script, you must first run the `setupCmdLine` batch file to set up the WebSphere Application Server parameters. The `setupCmdLine.bat` file is in the `wp_profile\bin` directory.

About this task

Publishing through the command line is a two-step process. First, you export the personalization rules that you want to transfer from the authoring environment to a remote system. After you are done exporting and saving the required objects, you use the pznload script to send this data to the appropriate server.

Tip: For extra help on using the pznload script, run the `--help` command.

Procedure

1. You can export the personalization rules on the site or you can run the pznload command. Select one of the following methods to export personalization objects from the site:

- Click **More Actions** > **Export** in the Personalization Navigator. You are prompted for a location to save a nodes file. This file contains an XML representation of all the currently selected personalization objects. You can export entire folders.

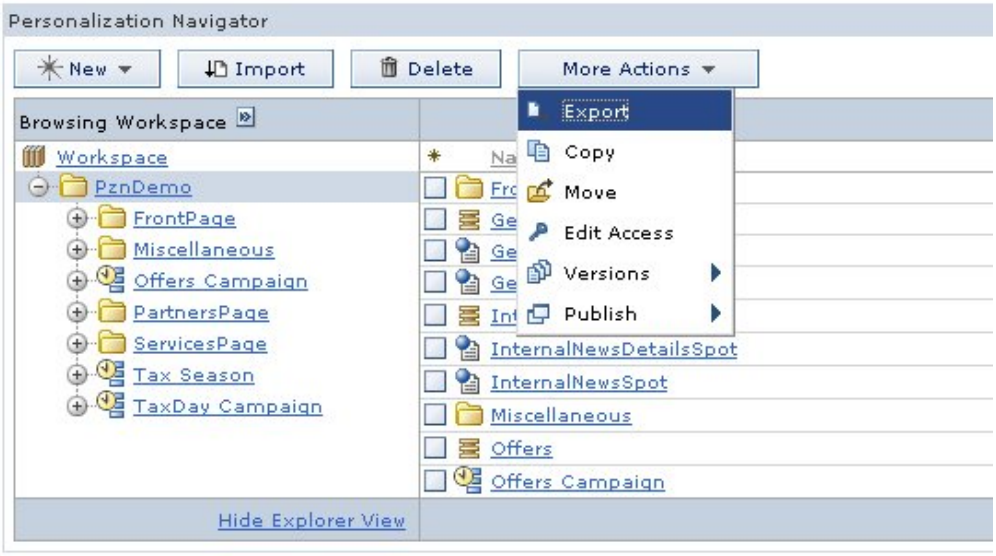

Figure 27. Exporting a folder to the file system

- Open a command prompt and run the following command, where `out` designates the location of the exported data on your local system and `targetpath` is the object (and child) that is exported:

  `pznload --export --out filename --serverurl` *`url`* `--targetpath` *`path`* `--targetworkspace` *`workspace`* `--username` *`username`* `--password` *`password`*

2. Choose the appropriate option to send this data to the appropriate server:

   The **`pznload`** script is in the *PortalServer_root*`/pzn/prereq.pzn/publish/` directory.

   Tip: This program accepts a number of command-line options and a set of nodes files to publish. Start `pznload` with the - help option to see a list of all options. The most important arguments are described here:

   serverurl
   The URL of the remote publish servlet. If you do not specify a value, the program attempts to connect to a WebSphere Portal Express server that is running on the local machine.

   targetworkspace
   The name of the workspace to publish to. The default workspace name on all IBM Content Manager run time edition installations is *ROOTWORKSPACE*.

   targetpath
   The location in the target workspace, which is the parent for the published nodes. The target path must exist before publishing. Example: If the export function was used on the folder `/Projects/HR` website, then the target path is specified as `/Projects`. So that the published resources are once again in `/Projects/HR` website.

username
A valid user on the target system with sufficient access rights.

password
The password for the user.

- Linux: `./pznload.sh --serverurl url --targetpath path --targetworkspace workspace --username username --password password`
- IBM i: `pznload.sh --serverurl url --targetpath path --targetworkspace workspace --username username --password password`
- Windows: `pznload.bat --serverurl url --targetpath path --targetworkspace workspace --username username --password password`

3. To delete objects, run the following command where `targetpath` is the object (and all associated child) that is deleted.

   `pznload --delete --username username --password password --targetpath path`

   Note: To force the deletion of a personalization rule without having to respond to a confirmation message, insert the `--force` flag after the delete command. For example, `pznload --delete --username username --password password --targetpath path --force`

Results

After a publish is started, you see status messages in the command console.

Publishing personalization rules over SSL:

WebSphere Portal Express Personalization uses the built-in SSL capabilities of WebSphere Application Server to provide secure publishing across unprotected networks. Your personalized portal can benefit from the full range of authentication repositories supported by WebSphere Application Server security.

About this task

In some environments even SSL publishing may not be secure enough. The pznload command-line program lets you fully control the transportation of the rules and campaigns during publish. You can encrypt the exported .nodes file and send it using email, or you can use another secure channel such as physical media transported between the staging and production servers.

Procedure

1. Enable SSL between the personalization servers. To enable Personalization publishing over SSL, see the Personalization Navigator's inline help: click the question mark, and scroll down to the end of the page to locate the link to the help topic on publishing.
2. Alter the publish servlet URL for secure publishing. If the remote server is not using the default HTTPS port of 443, modify the URL by adding a colon and the port number immediately after the host name.

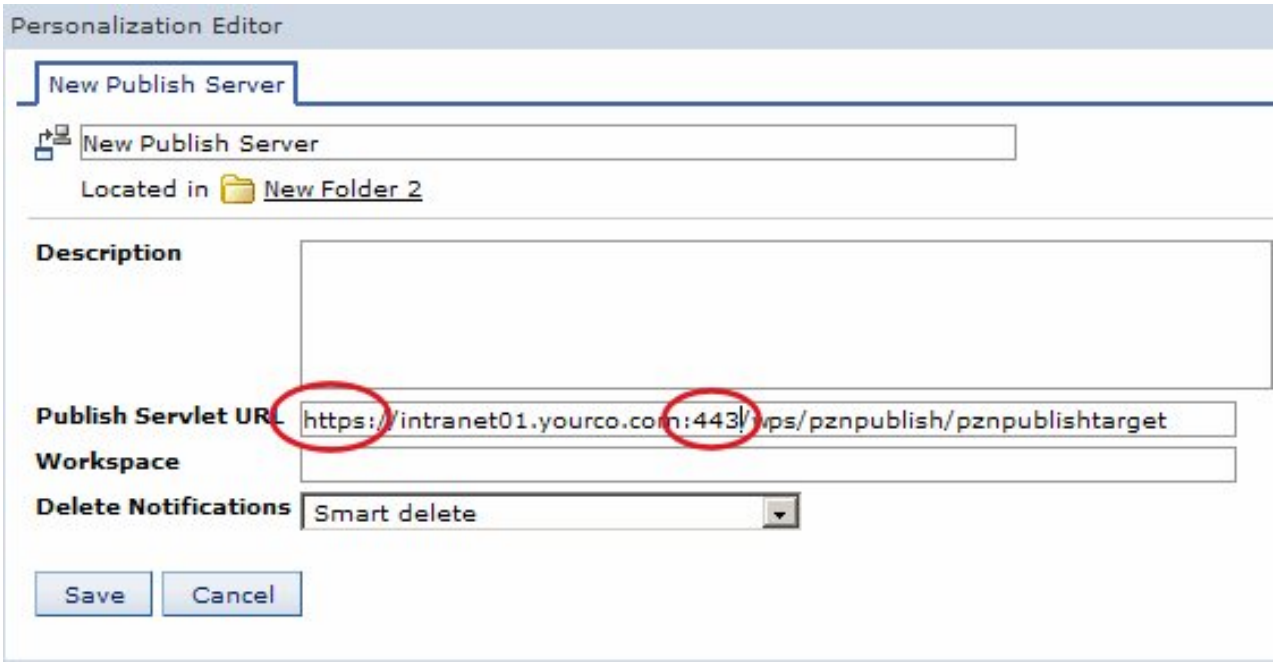

Figure 28. Altering the publish servlet URL for secure publishing by adding a colon and the port number after the host name for remote servers not using the default HTTPs port of 443.

3. Configure the personalization server from which you will be publishing to use the HTTPS protocol. To determine whether a particular URL is valid, point your browser to that location and enter your username and password for the system. If you see the message Publish servlet available and all SSL certificates have been properly imported, you should be able to publish. You can change this URL to redirect all publish jobs through a specific cluster member. If you encounter an error message that indicates the publish service was not available, the local publish servlet may not be configured correctly. To configure the local publish servlet URL:
   a. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
   b. Locate the Personalization Navigator portlet in the list.
   c. Click **Configure portlet** to configure the portlet.
   d. Add a new portlet parameter whose name is **pzn.publishServlet.url** and specify the appropriate value.

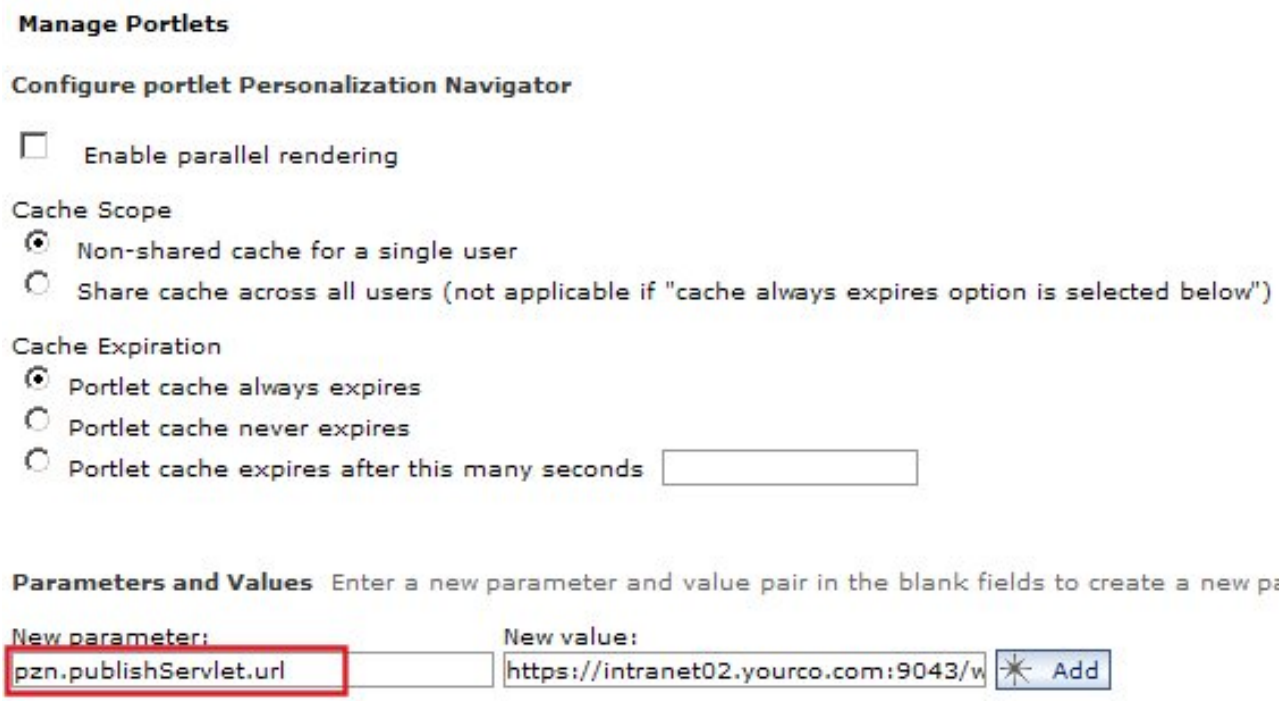

Figure 29. Configuring the local publish service

Results

If a Personalization server is configured to use a nonstandard HTTPS port or context root, or if you see messages such as `EJPVP20002E: The local publish service was not available` when publishing from the authoring environment, the local publish servlet URL might be incorrect.

Monitoring the status of publishing:

After you start a job to publish a personalization rule, you can monitor the status to make sure the publish completes successfully.

About this task

All publish jobs that are currently running or have been completed are displayed in the status view. If an error occurs, to get more information, turn on the Java Run time Environment tracing for WebSphere on the client system or examine the error and trace logs on the server system.

Procedure

1. To see the status of all current publish jobs, select **More Actions** > **Publish** > **View Status**.

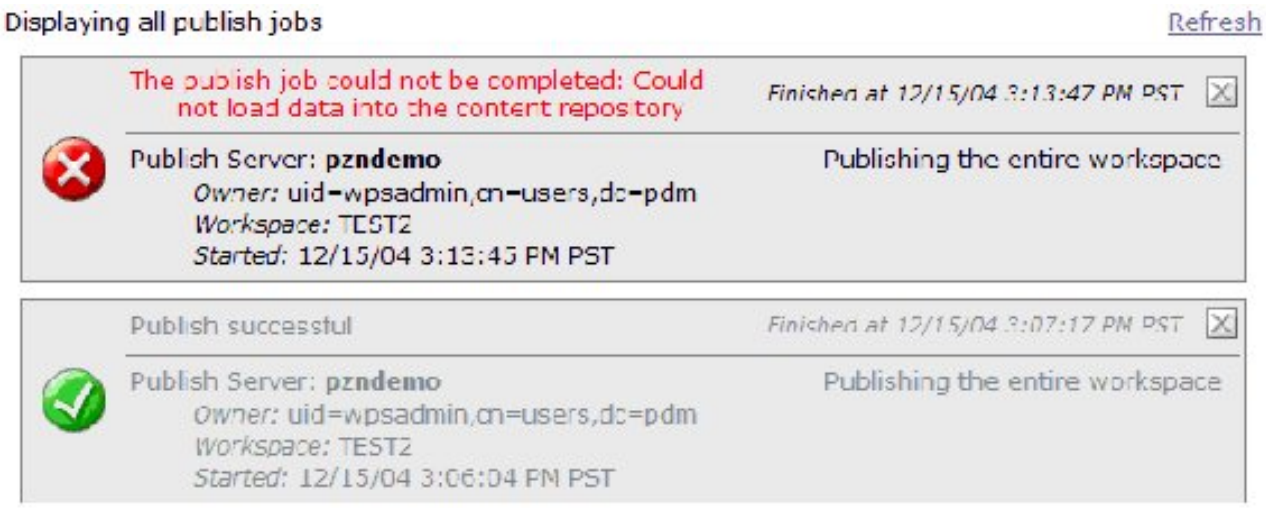

Figure 30. Publish status window

2. After a job has completed (successfully or otherwise) a close icon displays that you can click to remove the job from the list of monitored jobs. If you click this icon, you can no longer view the status of that job.

The Web Content resource collection

The Web Content resource collection is installed and configured out of the box. This predefined collection allows you to write rules that select lists of content from IBM Web Content Manager. Rules specify which Web content to show in a Portal Personalization component in Web Content Manager.

The Personalization component is similar to a menu component in that its content is decided by a rule. The Personalization component specifies how the content returned from the rule is presented and points to a rule to decide what content to display. That rule may make use of the Web Content resource collection to select a list of Web content.

Personalization rules that you create using the Personalization editor are not managed in Web Content Manager and so are not available for versioning or included in syndication. These rules must be published using pznload or by publishing with Personalization.

The Web Content resource collection allows rules based on the following attributes:

Table 354. Attributes used in Personalization rules for Web Content resource collections. The names and descriptions of Web Content attributes that you can use in Personalization rules

Attribute	Description
Author	The author of the content as set in Web Content Manager. This attribute value is stored as a Distinguished name; for example, `uid=wpsadmin,o=defaultWimFileBasedRealm`.
Authoring template	The authoring template used to create the Web content. The value may be selected using an authoring template picker.
Authoring Template Properties	All authoring template properties that are available to be used within rules.

Table 354. Attributes used in Personalization rules for Web Content resource collections (continued). The names and descriptions of Web Content attributes that you can use in Personalization rules

Attribute	Description
Category	The categories to which the piece of Web content belongs. If you are matching this attribute to a value from another resource collection or application object, the format for the value should be `/parentcategory/childcategory`.
Creation date	The date the piece of Web content was created.
Creator	The person who first created this piece of Web content. This attribute value is stored as a Distinguished name; for example, `uid=wpsadmin,o=defaultWimFileBasedRealm`.
Description	The description provided for the piece of Web content.
Expiration date	The date the content is set to expire in Web Content Manager.
Full text	Use this attribute to search the full text of a piece of Web content. It should be used sparingly. This attribute may not perform as quickly as other attributes when used in rules, especially when used in conjunction with other attributes.
Keywords	The keywords stored on the piece of Web content.
Last modified date	The date a modification last occurred on the piece of content.
Last modifier	The last person to modify the piece of content. This attribute value is stored as a Distinguished name; for example, `uid=wpsadmin,o=defaultWimFileBasedRealm`.
Name	The name of the piece of Web content as specified in Web Content Manager. This property uses case-insensitive matching. For example, a piece of content with a name of "SampleContent" matches "SampleContent," "samplecontent," "SAMPLECONTENT," and other variations.

Table 354. Attributes used in Personalization rules for Web Content resource collections (continued). The names and descriptions of Web Content attributes that you can use in Personalization rules

Attribute	Description
Position	The zero-based numeric position of the piece of content among its siblings in the nodes of the content hierarchy. Web Content resource collections use absolute positioning and relative positioning to support the ordering of content items. The algorithm used to generate position numbers results in fractional and negative values that control the display order of a set of child content items under a given area of a site. For more information, refer to the description of the position attribute in the *Command reference for the Portal Scripting Interface*.
Publish date	The publish date as specified in Web Content Manager.
Location	The document library or site area from which to select content. If specified as a string, it should be in the format `/Library/Site/SiteArea`. You can also specify `*/Site/SiteArea` to search by site area in all document libraries. Rules from previous versions with the Site Area attribute will automatically reference Location. If the site area was specified as a string, ensure the string starts with `/Library` or an asterisk (*).
Title	The display title as specified in Web Content Manager.
Unique Identifier	Use this attribute to select pieces of Web Content.

When a text, short text, numeric, or date component is added to an authoring template in Web Content Manager, that component will appear as an attribute on the resource collection under the Authoring Template Properties menu item. For example, if an authoring template is created for "Benefit Announcement" which includes an "enrollment begin" date component, you will have an "Enrollment begin" attribute on the Web Content resource collection. This new attribute would appear under a submenu for "Benefit Announcement". This will allow you to write rules based on custom metadata you attach to Web content. The performance of the standard metadata will do better compared to the performance of rules using attributes added to authoring templates. The use of keywords and categories should be considered since these are part of the standard metadata of Web content. If you are running a rule that uses the **`Name`** property as a sort by attribute, you might experience processing delays of up to 10 minutes. For best processing performance, sort by the **`Title`** property instead.

If too many authoring template properties have been designed, the Authoring Template Properties menu may become to large to be easily used. Once there are more than 15 authoring template properties, they are replaced with a chooser to

select properties. This threshold can be adjusted by changing the value of wcm.authoringTemplate.menu.threshold in *wp_profile_root*/PortalServer/config/config/services/PersonalizationService.properties.

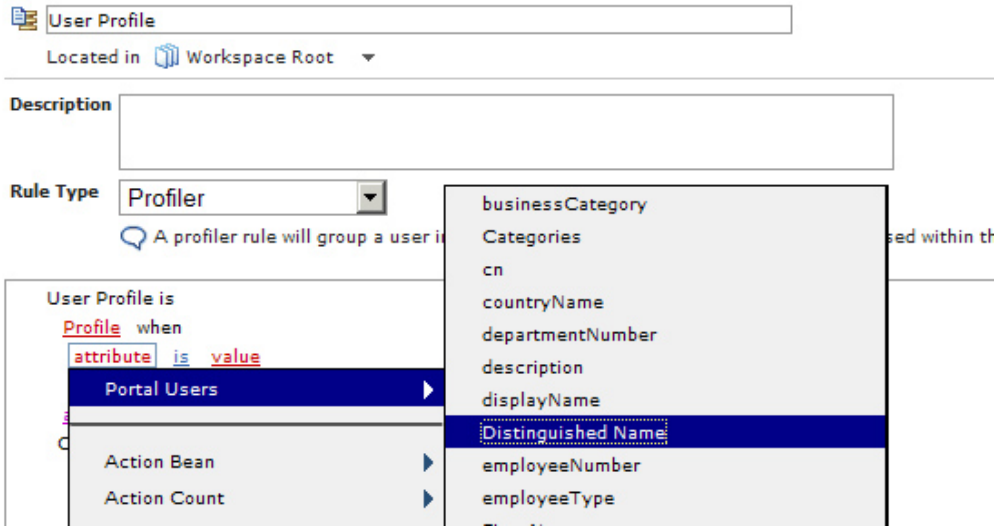
Personalization rules querying on short text run faster than those querying on text. Short text components can only store 254 characters. Text components can store an unlimited number of characters, but personalization rules will only see the first 254 characters. Anything after that is ignored when the rule runs.

Note: All attributes which store a reference to a person are stored as distinguished names. This format will match against the value of the Distinguish Name attribute on the Portal User resource collection. For instance, to select all documents authored by the user viewing the portlet, you would write, "Author is current Portal Users.Distinguished Name."

The Portal User resource collection

Portal Personalization comes with a Portal User resource collection. This collection uses public APIs provided by IBM WebSphere Portal Express to access user information.

The collection allows rules to be written based on all properties of the WebSphere Portal Express user.



You can also use the Portal User resource collection to profile based on the property extension database. Use the **Manage Properties** menu option in the rule editor to add or remove dynamic or Lookaside properties from the collection. You may add any properties to this collection, but for them to function at runtime some values must be stored in Virtual Member Manager for the properties being used and the user executing the rule. The Manage Properties screen can also be used if the server on which you author rules has a different Virtual Member Manager configuration than the one on which the rules are deployed.

The resource collection is not new to WebSphere Portal Express Version 8.5, but it now shows the list of Portal User attributes automatically. You no longer have to add each WebSphere Portal Express property you want to use as a dynamic property in the Personalization rule editor. You do not need to generate Java code to use this collection or configure a security ID translator as is often required for

Personalization User collections. You cannot currently write rules to select or recommend a list of users from this collection. This collection works with update rules as long as your repository allows writes. The collection works as if it is an LDAP collection that is automatically configured for the LDAP server.

You may continue to use your existing LDAP or custom user resource collections, and even use them in the same rules as the Portal User Collection. This is useful if you have multiple user repositories, you a have repository that is generally not used for Portal and only used for Personalization rules, or you requirements for attribute value translation ('CHI' should be interpreted as 'Chicago' for instance).

Using the Groups Attribute

The Groups attribute on the Portal User object exposes the distinguished names (dn) of the groups. An example of a distinguished name of a group is `cn=wpsadmins,o=defaultWimFileBasedRealm`, though the exact form will vary by your installation. Using distinguished name allows for more exact matching of groups, since it is possible for two groups to share a common name, such as `wpsadmins`. The `includes` operator may be used for inexact string matching, but will perform slightly slower. When possible, use the `is` operator and match to the distinguished name of the group.

Adding and extending user attributes

You can make attributes from your user registry available to the personalization portlet as required. However, in most cases the schema for your user registry does not match the default schema for Virtual Member Manager (VMM). For this reason, you must first extend the default VMM schema by adding attributes that you must then map from the VMM schema to your user registry.

Do the following to make user attributes available:

1. Extend the default VMM schema by adding attributes that you can map to your user registry. For instructions, see the following topic in the Installation section of this Information Center: *Adding attributes*. Refer to the topic that corresponds to your operating system and environment configuration.
2. Map the attributes you added to the VMM schema to the attributes in your user registry. For instructions, see the following topic in the Installation section of this Information Center: *Mapping attributes*. Refer to the topic that corresponds to your operating system and environment configuration.

Configuring which properties show up for the Portal User Collection

The Personalization rule editor discovers the list of properties to show in rules through a public API (`com.ibm.portal.um.PumaProfile`). The list exposed by this API is configurable in your Member Manager configuration.

You may have a long list of properties that are available on the portal user, but do not want all of them to show up in the Personalization rule editor. For this purpose, set the property **`wmm.property.hide`** in the file *wp_profile_root*`/PortalServer/config/config/services/PersonalizationService.properties` as illustrated in this example:

```
# Use this configuration property to control which WMM properties show
# in the Personalization rule editor. wmm.property.hide will only
# hide those properties which are introspected from the WMM configuration.
wmm.property.hide=mobile,pager,roomNumber,secretary,carLicense,telephoneNumber,
facsimileTelephoneNumber,seeAlso,userPassword,ibm-firstWorkDayOfWeek,
```

```
ibm-alternativeCalendar,ibm-preferredCalendar,ibm-firstDayOfWeek,ibm-primaryEmail,
ibm-otherEmail,ibm-generationQualifier,labeledURI,createTimestamp,
modifyTimestamp,ibm-middleName,ibm-timeZone,initials,jpegPhoto,WCM\:USERDATA,groups
```

The Portal User collection and the Personalization Server installed without Portal

The Portal User collection can only be used in rules running within a WebSphere Portal Express installation. The system will not prevent you from publishing rules using this collection to a Personalization Server installed outside of WebSphere Portal Express, but the rules will not function in this environment since Virtual Member Manager is not available. When WebSphere Portal Express is installed, the security context of the logged in user must have access (through Portal resource permissions) to the user information being accessed through the collection.

LikeMinds Recommendations

Personalization contains a dynamic recommendation system based on LikeMinds. LikeMinds is software that is used with your e-commerce applications. LikeMinds analyzes user interactions that occur on your Web site and generates real time predictions and recommendations to your Web site users.

Real time predictions are generated by three LikeMinds engines using recommendation rules within Personalization. These rules, called recommend content, base their predictions on transactions logged through Personalization's rating and action beans.

When a user visits your Web site, rating and action beans log captured transactional data. If your e-commerce Web site is set up so that users can rate content (or products), you use Rating beans to capture rating data. Similarly, if you use shopping cart technology, you use action logging beans to capture content affinity behavior to capture shopping activity. Both rating and action data is stored in your database. For example, the following types of transactions may be recorded:

- Products a user has purchased
- Items added or removed from a shopping basket
- A history of the user's navigation throughout the application
- Products that go best with a product that the user has already selected
- Any action or series of actions that are meaningful for a site

Using recommend content rules, LikeMinds surfaces results through a set of recommendation engines. These engines predict relevant content for users based on their past Web browsing habits.

Typically, after a user has rated a minimum number of items or completed a minimum number of transaction activities, that user is assigned a set of mentors. A mentor is a specially designated user who has visited the e-commerce application a number of times, and whose profile is similar to the user's. LikeMinds uses a technique called collaborative filtering to build a mentor's profile for each user to predict how much a user will like particular items and which items that user will enjoy, buy, or add to their shopping cart.

Predicting a matching product to go with a user's selected product, independent of actual user preferences, is accomplished by the discovery of probable pairs of product matches to be recommended. This concept is called *item affinity* and uses a family of algorithms different from collaborative filtering. While collaborative

filtering uses its algorithms to discern the highly variable affinities between individual Web-surfers, the item affinity approach looks at relationships that can exist between items.

You can use LikeMinds in a variety of situations, including:

- eRetailer promotion and personalization Web sites
- Financial portal content recommendation and personalization Web sites
- Help desk and/or on-line technical support content recommendation Web sites
- Gift recommendations for eRetailer
- Music, movie, book, or other product rating and recommendations
- Travel bureau trip planners

Get an overview of the functioning and architecture of the LikeMinds Recommendation Engine. In order to build your own recommendation application you need to customize the LikeMinds Recommendation Engine settings to work with your database and Web applications.

LikeMinds Recommendation Engine architecture:

Get an overview of the functioning and architecture of the LikeMinds Recommendation Engine. In order to build your own recommendation application

you need to customize the LikeMinds Recommendation Engine settings to work with your database and Web applications.

The LikeMinds Recommendation Engine captures data based on user actions. From this set of actions, LikeMinds bases its construction of mentor sets and subsequent predictions. User actions can include:

- A history of the user's navigation throughout the application
- Products that go best with a product that the user has already selected
- Products purchased
- Items added to or removed from a shopping basket

The current user preferences are collected by the engine in the so-called rating vector and used to identify those people most like the current user.

People with a behavior similar to the current user become mentors for that user. The LikeMinds Recommendation Engine assigns a numeric weight to each mentor based on the level of similarity of the rating vector to yours. The more the mentor's rating values resemble a user and the more products the mentor has rated, the greater the weight.

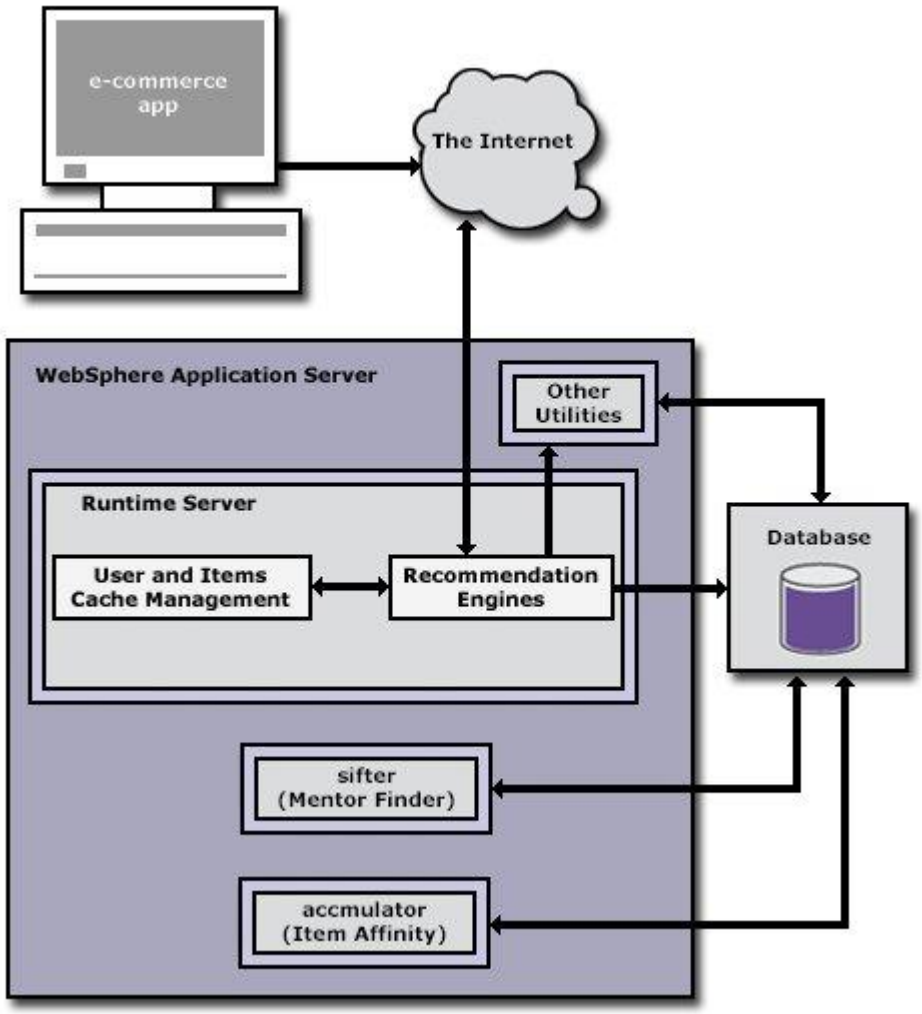
The LikeMinds Recommendation Engine assembles a set of recommendations by finding the products each mentor recommends and creating a prediction vector containing the predicted rating of each product. With each predicted rating, it also stores a numeric value representing the confidence for the rating.

The confidence values determine the quality of predictions. The LikeMinds Recommendation Engine assigns a confidence level to each recommendation based on how many users have rated the recommended item and how similar the ratings are to each other.

A user is assigned a set of mentors only after he has rated a minimum number of items or completed a minimum number of transaction activities.

If you want your application to predict a matching product to go with a user's selected product, you can configure probable pairs of product matches to be recommended. This concept is called item affinity.

Depending on the type of recommendation you want to extract, the specific engines must be configured, such as the Preference Engine or Item Affinity Engine. The following image shows the details of the overall LikeMinds Recommendation Engine architecture.



How LikeMinds generates recommendations:

Learn how LikeMinds generates recommendations when a user logs on and navigates through your web site.

When a user logs on and navigates through your Web site, LikeMinds follows these steps to generate recommendations for that user:

1. Personalization Rating beans and action logging beans create a record for new users in the Lps_User_Data table. The Lps_User_Data table stores the following types of information about the user: the user's resource ID, a user ID, the number of items the user has rated or selected, and so on.
2. The Personalization Rating beans and action logging beans log data for that user as that user navigates your Web site.

   The profile data is first stored in the server's cache, then the server writes all the new data to the database. The Lps_User_Rating table stores the user's explicit preferences; the Lps_User_Trx table stores the user's clickstream and purchase behavior. The Lps_User_Trx table also stores item affinity input data.
3. The application can then query LikeMinds for recommendations. Recommendation queries are transaction data-specific.

- Preference recommendations are surfaced by the recommend content rule. To receive Preference recommendations, your application must record users' explicit preferences (ratings) using the Rating bean.
- Clickstream recommendations are surfaced by the recommend content rule. To receive Clickstream recommendations, your application must record users' clickstream behaviors (that is, product detail views, shopping basket inserts, and so on) using the Action bean.
- Item Affinity recommendations are in the form: "`this mouth guard is a likely product to go along with the hockey puck the user has just added to his or her shopping cart`". To receive Item Affinity recommendations, your application must record users' likely product pair matches. In other words, your application must capture the current "content/product" context using the Action bean, in order to return those items most associated with that "content/product".

4. Depending on the engine you are using, the following step occurs next:
   - **Preference and Clickstream engines**: For a new user, if your application queries LikeMinds for recommendations before mentors have been assigned for that type of data (that is, Preference, Clickstream, or Item Affinity), the server will assign mentors from a cached pool of mentors.

     If the server is unable to, for lack of profile data, match cached mentors to this user, the server will provide an empty set of recommendations. An important distinction, profile data means the transaction data for the current user and not the attributes of that user.
   - **Item Affinity engine**: If your application is predicting item affinity product pair matches, it will collect data based on a set of definitions that you create, called an item affinity set. For input data, the item affinity set uses transactions from a specified input table.
5. Depending on the engine, the following step occurs next:
   - **Preference and Clickstream, engines**: Once a user's profile is stored in the database, the `sifter` utility can calculate mentors for that user. The `sifter` is a background utility which assigns a set of mentors to each user.
     - Mentor assignments are specific to each type of data.
     - Mentor assignments are stored in the mentor table associated with this type of data.
   - **Item Affinity engine**: The `accumulator` generates item affinity product pair matches by analyzing data in the item affinity set (same as transaction table) and recording its findings to an output table.
6. Depending on the engine, the next step is as follows:
   - **Preference and Clickstream engines**: As new transaction data is recorded for a user, the user is prioritized for reprocessing by the `sifter` to calculate new mentor assignments. Users are prioritized by a calculated 'sift priority', reflecting the percentage of new or changed profile data for that visitor.
   - **Item Affinity engine**: As new product selection behaviors are recorded in the transaction input table specified in the item affinity set definition, the `accumulator` uses this data to calculate new item affinity recommendations.
7. When your application runs LikeMinds rules, the following occurs, depending on the engine:
   - **Preference and Clickstream engines**: LikeMinds looks up that user's mentors, and calculates recommendations.
   - **Item Affinity engine**: LikeMinds calculates the most likely item-content pairs based on accumulated item transaction history.

The LikeMinds Recommendation Engines:

LikeMinds Recommendation Engines communicate with a relational database and generate recommendations. Learn about the three types of recommendation engines, Preference engine, Clickstream engine, and Item Affinity engine.

Following is a description of the three types of recommendation engines:

- **Preference engine**: This engine generates recommendations using patented collaborative filtering algorithms based on users' item ratings.
- **Clickstream engine**: This engine, which also accesses transaction information, generates recommendations based on users' actions as they navigate a Web site; that is, the history of user "clicks" during website visits, and the items that users view, click, and add to their shopping carts.
- **Item Affinity engine**: This engine generates recommendations based on the history of the user's site browsing activity. It matches a currently selected product with a second product that the user would most likely want to purchase along with the first product. For example, if a user is purchasing groceries and adds French onion soup to the shopping cart, the Item Affinity engine could recommend Gruyere cheese to go with it.

  "Preference Engine"
  The Preference Engine uses explicitly stated user preferences to make highly accurate recommendations for products and content that your website visitors like.

  "Clickstream Engine" on page 2319
  Based on navigational data gathered as customers browse your Web site, the Clickstream Engine tracks clickstream (or rating) behavior and generates recommendations based on mentors who exhibit similar content/product affinities.

  "Item Affinity Engine" on page 2319
  The Item Affinity Engine generates recommendations based on any transactional history available, such as shopping cart activity, external legacy transactions, and web transaction completely unrelated to shopping cart activity (page views, product inquiries, searches, and so on).

Preference Engine:

The Preference Engine uses explicitly stated user preferences to make highly accurate recommendations for products and content that your website visitors like.

The Preference Engine enables customers get exposure to items they might otherwise miss. For example, users shopping for gifts can get recommendations based on the gift recipient's shopping preferences.

The shipped with the LikeMinds Recommendation Engine presents a typical implementation of the Preference Engine:

- A user can rate a movie and LikeMinds returns a predicted rating for that movie.

  For example, a user can assign the movie *Fantasia* with a rating such as "I loved it". Internally the rating corresponds to a numerical value.
- A user can ask for a recommendation about the best bet, which is provided by a LikeMinds rule. This corresponds to asking which movie a user would like the most among all available movies.

Clickstream Engine:

Based on navigational data gathered as customers browse your Web site, the Clickstream Engine tracks clickstream (or rating) behavior and generates recommendations based on mentors who exhibit similar content/product affinities.

The Clickstream Engine tracks the pages that users have looked at. After analyzing all users' traffic patterns, it then makes content recommendations for each specific user, using data from relevant subsets of the user base.

Item Affinity Engine:

The Item Affinity Engine generates recommendations based on any transactional history available, such as shopping cart activity, external legacy transactions, and web transaction completely unrelated to shopping cart activity (page views, product inquiries, searches, and so on).

An Item Affinity Engine can, for example, predict that a user who purchases a digital camera would likely want to purchase compact flash cards or a USB card reader. The Item Affinity Engine also spots the less obvious connections—that users who purchase beer are likely to purchase diapers at the same time, for example.

The Item Affinity engine lets you track more than mere purchases measured at check-out time. It can identify items the user only considered for purchase. For example, it can know when a user only considered purchasing rye bread rather than actually purchasing the rye bread. (This is measured by a shopping cart add, followed by a shopping cart drop, of the rye bread.) In this case, the grocer could not possibly know that the user considered purchasing rye bread during the shopping session, since the rye bread was not in the shopping cart at check-out time. Even though a considered purchase does not necessarily imply the same level of item affinity as a completed purchase, it does convey item affinity information.

Unlike the other engines, Item Affinity Engine recommendations are based on Market Basket Analysis statistics, not collaborative filtering. Market Basket Analysis enables content affinity predictions even when cold-start situations obscure the relevance of collaborative filtering. The Item Affinity Engine can be used to provide improved automated recommendations, such as cross-sells, even for first time visitors to the Web site.

The LikeMinds utilities:

Get an overview of `sifter`, `buildstats`, `buildvisit`, and `accumulator`, the utilities that support running of background processes along with the LikeMinds server.

The following utilities support the background processes operating on the database when the LikeMinds server is running:

- `sifter`: This utility runs continuously to identify mentors for new users and recomputes the best set of mentors for existing users. The mentor set for a user may change as the sifter gathers more information about the user or the mentors. The `sifter` identifies mentors for the Preference, and Clickstream engines.
- `buildstats`: This utility runs once a day to update statistics for each item, such as the number of ratings or transactions, the average rating, the standard

deviation in the average rating, and the default recommendation information. The Clickstream and Preference engines use `buildstat`. The Item Affinity engine does not.

- `buildvisit`: This utility, which the Preference engine uses, runs daily to construct lists of items to be presented to users for rating. If your applications do not use the Preference engine, `buildvisit` is not necessary.
- `accumulator`: For the Item Affinity engine, the `accumulator` (listed as `lpsIAA` in the `util` directory) accumulates the number of times every possible item-to-item combination occurs and writes its findings to an output table specified by the item affinity set. An item affinity set defines the type of data required to build an item-to-item combination.

Configuring LikeMinds:

Use a suitable database modification tool or edit the `likemindsdb.properties` file to configure your LikeMinds server installation.

Set the following general **`lps_cfg`** parameter information for the LikeMinds server installation:

- Basic server information
- Scheduling LikeMinds events
- Server load management
- Cache behavior
- Recommendation behavior

All these parameters are set in the `likemindsdb.properties` file. This file is in the directory *`wp_profile_root`*`/pzn/config/runtime/likemindsdb.properties`. The file is in ASCII. To edit it, use an ASCII editor.

LikeMinds stores its configuration information in the lps_cfg table of its database, which is initialized with the data in the `likemindsdb.properties` file. To update this configuration, you can update this file and reload the configuration data, or you can use any database modification tool, to modify the LikeMinds configuration parameters. To update configuration values, complete these steps:

1. Stop the WebSphere_Portal server.
2. Edit the `likemindsdb.properties` file.
3. Choose the appropriate task to update the configuration:
   - Linux : `./ConfigEngine.sh likeminds-load-config -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh likeminds-load-config -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat likeminds-load-config -DWasPassword=`*`password`*
   - Use the DB modification tool to update the configuration directly.
4. Start the WebSphere_Portal server.

"Estimating database size" on page 2321
The size of your database depends on your application, as well as the number of users and items. View some general guidelines for estimating the size of your database, but your results may vary.

"Database performance" on page 2322
View some guidelines for performance optimization in your LikeMinds database.

"Scheduling LikeMinds Events" on page 2322
Use the `lps.schedule` setting to schedule events to be fired at specific dates and times.

"Configuring the LikeMinds engines" on page 2324

"Specifying recommendation behavior" on page 2336
You can configure several parameters that affect the way the LikeMinds server generates recommendations.

Estimating database size:

The size of your database depends on your application, as well as the number of users and items. View some general guidelines for estimating the size of your database, but your results may vary.

A database containing the seed data supplied with the Movie Site application may use just 250 MB, while the LikeMinds tables for a large site with millions of users may take up 10 GB. Following are some general guidelines:

The tables that contribute the most to the size of the database are as follows:

- **Lps_User_Rating**: This table normally dominates your space considerations. Users typically average 50 to 100 ratings. The seed users supplied with Movie Site average about 500 ratings.
- **Lps_User_Trx**: This table can grow very large, depending on the number of item affinity, clickstream, or purchase activities recorded from your applications.
- **Lps_MBA_Scored**: This table can grow quite large, depending on the number of products your site sells and the number of relationships you want to configure for each product. For example, if you have 1000 products listed in your Lps_Item_Data table, and you want to store 10 relationships for each product, an Lps_MBA_Scored table can grow to 10,000 rows.
- **Lps_User_Mentor**: The size of this table depends on the number of users and the number of mentors associated with each user (50 by default).
- **Lps_User_Data**: This table may contribute a large portion of the database size if you have large numbers of users who each have few ratings. This table is heavily indexed, which can affect performance.
- **Lps_Item_Data**: This table is normally fairly small, but may be significant if you store large amounts of data about each item.

The remaining tables are typically less than 100 KB each.

The following table gives typical numbers of rows, row sizes, and index sizes for a "typical" Microsoft SQL Server database with 5000 items and 100,000 users. The row sizes include only the fields required by LikeMinds, and they account for typical null fields and clustered index overhead. Sizes will vary for other database systems, especially for indexes.

Table 355. Example Table Sizes for a Typical Database

Table	Rows in Typical Site	Row Size (Bytes)	Total Size	Index Size (Bytes Per Row)	Total Size
Lps_User_Rating	8,000,000	25	200 MB	about 20	160 MB
Lps_User_Trx	8,000,000	32	256 MB	about 20	160 MB
Lps_User_Mentor	5,000,000	25	125 MB	about 20	100 MB

Table 355. Example Table Sizes for a Typical Database (continued)

Table	Rows in Typical Site	Row Size (Bytes)	Total Size	Index Size (Bytes Per Row)	Total Size
Lps_User_Data	100,000	typical: 100 maximum: 400	100-400MB	about 100	10 MB
Lps_Item_Data	5000	136 (for required fields only)	68 MB	4	2 MB
Lps_MBA_Scored	10,000	32	32 MB	about 20	1MB
Lps_Genre_Data	10-1000	116	1160 KB-116 MB		N/A
Lps_Item_Genre	5000-20,000	12	60-240MB		N/A
Lps_User_Selector	25,000-100,000	12	30-120MB	4	100-400 MB

In your size estimate, remember to include space for transaction logging and rollback areas. Because the LikeMinds server commits frequently, the rollback area need not be especially large relative to the database. Allow space equal to the size of the database for transaction logs, since the LikeMinds server performs frequent updates.

Database performance:

View some guidelines for performance optimization in your LikeMinds database.

How you configure your database during installation has a significant impact on performance. Use the following guidelines to achieve the maximum performance in your LikeMinds database:

- **Hardware setup**: Ideally, you should have one machine (with two CPUs), preferably the fastest, dedicated to the database, and the WebSphere Portal software on a separate machine. See the system requirements in the WebSphere Portal Information Center for more information.
- **load distribution**: You can install the LikeMinds utilities onto separate machines to distribute load. Refer to the documentation for information about installing utilities to multiple machines.
- **sifter configuration**: You can configure the `sifter` to accommodate heavy loads or busy sites. Be aware that the `sifter` has heavy memory usage.
- **accumulator configuration:** As with the `sifter` , the `accumulator` has heavy memory usage, so you should schedule it to run during off-peak hours.

Scheduling LikeMinds Events:

Use the `lps.schedule` setting to schedule events to be fired at specific dates and times.

The syntax for using the `lps.schedule` setting is as follows:

```
lps.schedule.<event name> = <schedule><event type><event args>
```

where:

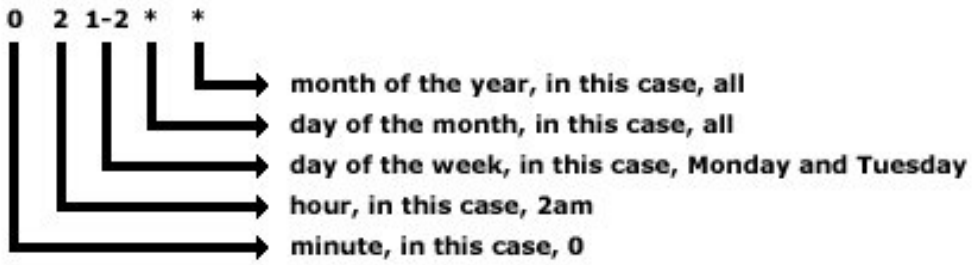
`event name`: Refers to a unique name for the event.

`schedule`: Refers to the scheduling time, in five fields separated by spaces or tabs, and are integer patterns. These fields are:

Table 356. Schedule Time Values

Field	Values
minute	0–59
hour	0–23
day of the week	0-6, with 0 being Sunday
day of the month	1–31
month of the year	1–12

To specify all values of a particular field (for example, to schedule events every day of the week), use an asterisk (*), in the order listed in this table. For example:



When you do specify actual values, you can enter either the value itself (such as 1 to schedule an event on Monday) or a range of values (for example, 1-2 to schedule events for Monday and Tuesday). When you want to specify days, you need to include both the day or the week field and the day of the month field. For examples of using these values, see

`event type` and `event args`: Refer to any of the following events and their arguments:

Table 357. Event Types and Arguments

Event type	Argument	Description
`lazyDBWrite`	N/A	Specifies when all the changed information since the last read is written to the database. The default setting is: `12,24,36,48,00 **** lazyDBWrite`
`purgeUserCache`	`timeval`	Specifies the time in seconds after permanent users have not been used before purging them from cache. If timeval is not specified, the setting from `db.tune.user_cache_age_time` is used.
`purgeItemCache`	`timeval`	Specifies the time in seconds after items have not been used before purging them from cache. If `timeval` is not specified, the setting from `db.tune.item_cache_age_time` is used.

Table 357. Event Types and Arguments (continued)

Event type	Argument	Description
syncCache	user	Refreshes all permanent user objects in cache.
	item	Refreshes all item objects in cache.
	engine	Refreshes all engine cache.
runBuildstats	verbose	Runs the buildstats utility. If verbose is specified, additional information is printed to the trace log.
runBuildvisit	verbose	Runs the buildvisit utility. If verbose is specified, additional information is printed to the trace log.
runAccumulator	verbose	Runs the accumulator utility. If verbose is specified, additional information is printed to the trace log.

Configuring the LikeMinds engines:
You can configure your LikeMinds recommendation engines to control aspects such as predictability, number of mentors used, which rating, transaction, or mentor set to use, and so on, for the recommendations returned.

The Preference and Clickstream engines rely on the `sifter` utility to assign mentors to users. The Item Affinity Engine uses the `accumulator` utility to collect item affinity data.

"Configuring the Preference Engine"
"Configuring LikeMinds utilities" on page 2327
"Configuring the Clickstream Engine" on page 2333
"Configuring the Item Affinity Engine" on page 2335

Configuring the Preference Engine:
The Preference Engine generates recommendations based on users' ratings of items. You can configure the following settings for the Preference Engine.

"Number of mentors to use"
"Mentors to look for in cache"
"Use of "average user" to improve recommendation confidence" on page 2325
"Archetypes" on page 2325
"Guidelines for configurable recommendation dynamics" on page 2325
"Setting the number of archetypes in cache" on page 2325
"Enabling or disabling the use of archetypes" on page 2325
"User predictability" on page 2325

Number of mentors to use:
Set `<eng_instance_name>.db.engine.tune.num_mentors` to the maximum number of mentors to assign to a given user. The default is 50. For example:

```
movie_pref.db.engine.tune.num_mentors = 60
```

If you do not set this parameter, then the Preference Engine uses the value set for `<mentor_set>.max_mentors = <number>`.

Mentors to look for in cache:

If a user requests recommendations before the sifter has found mentors for that user, the Preference Engine checks the cache for mentors for the user. Set `<eng_instance_name>.db.engine.tune.max_cached_mentors` to the number of potential mentors which it should consider for a given user. The default is 500. For example:

```
movie_pref.db.engine.tune.max_cached_mentors = 600
```

Use of "average user" to improve recommendation confidence:
The Preference Engine can use an "average user," whose ratings are the average of all users' ratings. The `buildstats` utility computes the average ratings. Configuring an average user improves the confidence level of recommendations for that user. To do so, set *`eng_instance_name`*`.db.engine.tune.disable.avg_user` to `false`.

However, remember that this feature can be costly in system resources. To disable it, set it to `true`. (The default setting is `true`.)

Archetypes:
To generate recommendations for items that no mentors have rated, the Preference Engine uses synthetic users called "archetypes." These users possess a particular characteristic very strongly. For example, an archetype who only likes action movies might rate all action movies very highly. Recommendations from archetypes are added to recommendations produced by mentors.

Guidelines for configurable recommendation dynamics:
You can use the following configuration parameters to control, or at least balance, effects of external factors.

- The number of mentors to use in making recommendations, using the following configuration parameters:
  - `<mentor_set_name>.min_mentor_ratings`
  - `<mentor_set_name>.max_mentor_ratings`
  - `<mentor_set_name>.min_mentor_transactions`
  - `<mentor_set_name>.max_mentor_transactions`
- Balancing the mentor selection process with the following configuration parameters:
  - `<mentor_set_name>.mentor.pool.size`
  - `<mentor_set_name>.max_mentors`

Setting the number of archetypes in cache:
The list of archetypes is kept in the cache for a specified number of uses before it is reloaded. To change the number of users, set `<eng_instance_name>.db.engine.tune.max_archetype_list_use` . The default is 100000.

For example:

```
movie_pref.db.engine.tune.max_archetype_list_use = 150000
```

Enabling or disabling the use of archetypes:
To turn on or off the use of archetypes, set `<eng_instance_name>.db.engine.tune.consult.archetype_for_list` to `true` or `false` . The default is `false` . For example:

```
movie_pref.db.engine.tune.consult.archetype_for_list = true
```

User predictability:
This section contains the following information regarding user predictability:

Maximum number of mentors assigned to each user:
Use the following setting to specify the number of mentors to be assigned to each user. The number of actual mentors can be less than the maximum setting but never greater than the value specified. For example:

```
<mentor_set_name>.max_mentors = 50
```

Note: Use a value between 50-100. See "Maximum ratings a user needs before becoming a mentor" for guidelines on setting `<mentor_set_name>.max_mentors`

Maximum ratings a user needs before becoming a mentor:
The following setting specifies the maximum number of ratings a user can have to become a mentor. The `sifter` uses this setting if the Preference Engine is using that mentor set. You can specify the value as one of the following:

- A percentage of the total number of items in the database. For example:

  ```
  <mentor_set_name>.max_mentor_ratings = 75%
  ```

- The maximum number of ratings (that is, without a percentage). For example:

  ```
  <mentor_set_name>.max_mentor_ratings = 18
  ```

Use the following guidelines for setting `<mentor_set_name>.max_mentor_ratings:`

Table 358. Guidelines for Setting the Maximum Ratings

Total Number of Items in Database	Suggested Setting
< 1000	<= 100
1000–5000	<= 500
5000–10,000	<= 1500
10,000+	<= 1500

Note: For more information on how the `sifter` makes use of `<mentor_set_name>.max_mentor_ratings`, see "Maximum number of mentors assigned to each user."

Maximum transactions a user needs before becoming a mentor:
The following setting specifies the maximum number of transactions a user can have before becoming a mentor. The `sifter` uses this setting if the Purchase or Clickstream Engine is using that mentor set. You can specify the value as one of the following:

- A percentage of the total number of items in the database. For example:

  ```
  <mentor_set_name>.max_mentor_xactions = 75%
  ```

- The maximum number of transactions (that is, without a percentage). For example:

  ```
  <mentor_set_name>.max_mentor_xactions = 18
  ```

Use the following guidelines for setting
<mentor_set_name>.max_mentor_transactions

Table 359. Guidelines for Setting the Maximum Transactions

Total Number of Items in Database	Suggested Setting
< 1000	<= 100
1000–5000	<=500
5000–10,000	<= 1500
10,000+	<= 1500

Minimum number of ratings for user recommendations:
Set <eng_instance_name>.engine.titan.predictable.min_ratings_cutoff to the minimum number of ratings a user must make before the Preference Engine will make recommendations for that user. The default is 2. For example:

```
movie_pref.engine.titan.predictable.min_ratings_cutoff = 3
```

Recomputing Preference Engine predictions:
The <eng_instance_name>.engine.titan.recomputation_bound configuration parameter specifies the percentage change allowed in a user's ratings before the LikeMinds server recomputes the user's predictions. For example:

```
music_pref.engine.titan.recomputation_bound = 10.0
```

Ordinarily, the LikeMinds server generates predictions based on a user's mentors, which the sifter computes and makes available to the database. When a user has no mentors, perhaps because he or she has just arrived at the site, or when the user's ratings or transactions have changed beyond the percentage specified here, the LikeMinds server selects mentors from a reduced set of candidates and recomputes the user's predictions.

Use this setting with caution, as selecting mentors is a relatively expensive operation: a low percentage setting can lead to excessive CPU load with little or no gain in prediction quality. A higher setting will improve performance, but predictions may be less accurate.

Default Preference Engine recommendations:
The Preference Engine reads the value from the score field in the Lps_Item_Data table to determine which items are popular. Hence, a higher score means that the item is more popular. When buildstats runs, it updates the score field to the average rating for that item; it generates this value based on the rating set defined in the db.applic.rating.source parameter. To get reliable default recommendations, run the buildstats utility on a regular basis. By default, the installer sets buildstats to run once a day. Some applications use their own business logic to assign the score to items. If you want to override the score field value to use your application's scoring instead, run buildstats using the -noscore argument.

Configuring LikeMinds utilities: You can configure the following settings for the buildstats and buildvisit background utilities:

- Ratability parameters
- Repeated items in the visit list

You can use the `buildstats` utility for all of the Recommendation engines except for the Item Affinity Engine. The `buildvisit` utility is only used for the Preference Engine.

"Configuring the sifter for mentor selection"
"Ratability parameters" on page 2332
"Repeated items in visit list" on page 2333

Configuring the sifter for mentor selection:
The sifter finds mentors for users, using the information from the rating or transaction data for the LikeMinds server engines. The sifter is used by all of the LikeMinds server engines except for the Item Affinity Engine, which uses the `accumulator` utility Figure 31 illustrates how the sifter works:

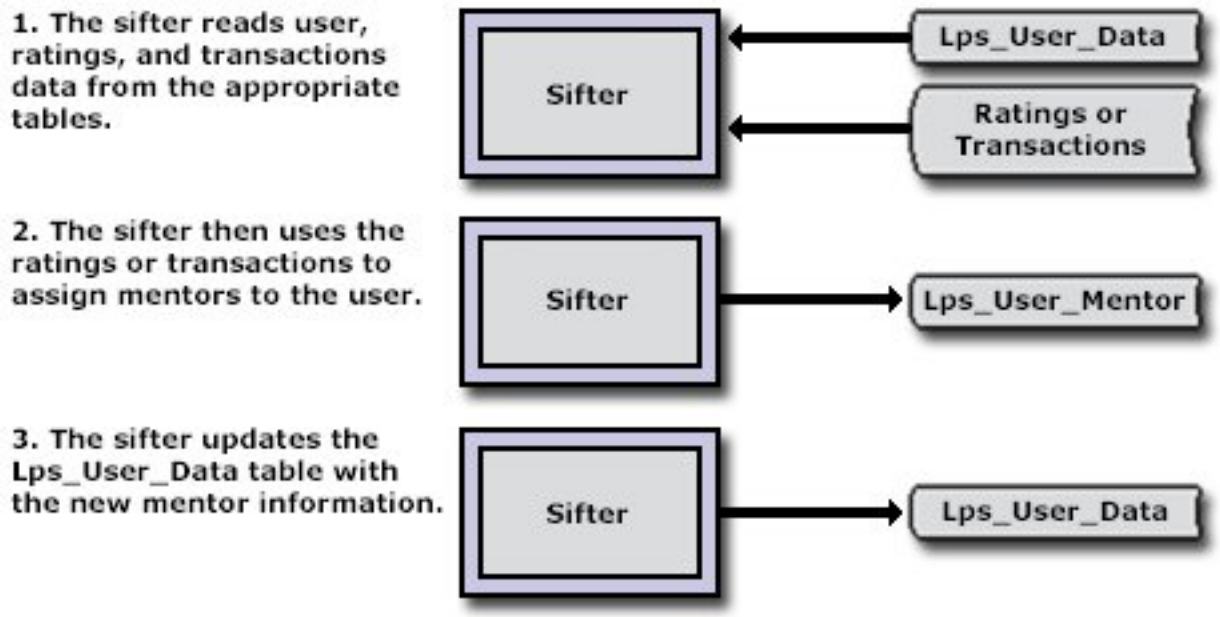


Figure 31. How the Sifter Works

"Sifter-specific mentor set configuration"
"How the mentor selection process works" on page 2329
"Sifter performance considerations" on page 2330
"Recomputing (rebuilding) the mentor pool" on page 2331
"Running multiple sifters" on page 2331
"Preventing multiple sifters from sifting the same user" on page 2332
"Number of threads to sift users" on page 2332
"Sifter sleep time when the Lps_User_Data sift_pri field Is 0" on page 2332
"Time interval for checking sift priority" on page 2332

Sifter-specific mentor set configuration:
You can specify the following categories of `sifter`-specific configuration parameters for mentor sets:

- The engine to be used for mentor tables to be rebuilt
- Time interval for checking the sift priority
- Number of sift priority users per batch

- Maximum number of mentors assigned to each user
- Minimum ratings a user must have before becoming a mentor
- Maximum ratings a user must have before becoming a mentor
- Minimum transactions a user must have before becoming a mentor
- Maximum transactions a user must have before becoming a mentor
- How to set the mentor pool size
- `sifter` sleep time for when the Lps_User_Data table sift_pri field is 0
- Running multiple `sifters`
- Number of threads to sift users
- Recomputing (rebuilding) the mentor pool
- Pausing the `sifter` during heavy database access

How the mentor selection process works:
In order to fully understand the `sifter`, it is important to have a clear idea of how the mentor selection process works, and how to set configuration parameters that increase the accuracy of your recommendations. You should understand the following terms before proceeding:

- **Collaborative Filtering** -- Collaborative filtering (CF) is a technology that calculates the similarity between users. It uses the behaviors of those who most closely resemble any given user as a functional basis for making predictions and recommendations for that user. Given that definition, the process by which "...the entire population of users is analyzed, their fitness as mentors is calculated, and they are assigned as mentors to individual users..." is critically important to the ultimate recommendations that come from the collaborative filtering approach. All of the LikeMinds server engines, except the Item Affinity Engine, use collaborative filtering.

  The data used to decide on the levels of similarity can come in a variety of forms. From a stream of self-supplied ratings made explicitly to get recommendations back, to clickstream events that comprise the sequence, duration, and outcome of a Web-surfer's session, to data from a company's legacy databases (such as transactions, demographics, or credit events)--all can form the necessary basis for making similarity calculations. From those similarity measures, this data can result in the measured recommendations from those users deemed most similar to any given user.
- **Mentor** -- A like-minded user that is used as the basis for recommendations for new users. Every user is assigned mentors by the `sifter` program, whose stored preferences are judged to be like-minded to the new user.
- **Mentor Pool** -- While the purpose of mentors is to form the basis for recommendations for those users deemed most similar to them, in its most basic form the mentor pool should reflect a representative sample of users in the transaction set for which the recommendations are required. And despite the clearly required emphasis on similarity, no recommendation process can make lucid suggestions without a concomitant space of dissimilarity. We might base our final recommendations on the similar, shared tastes discovered in our analysis of the users being considered for entry to the mentor pool, but it is truly the confluence of similarity in purchases with some difference in the items purchased that make the LikeMinds server collaborative filtering-based recommendations possible.
- **Sifter** -- Creates mentors by analyzing stored user transactional data. The `sifter` runs in the background when you run the LikeMinds server.
- **Coverage** -- The volume or number of items rated or transactions performed.

"Mentor selection and assignment" on page 2330

"Number of sift priority users per batch"

"Pausing the sifter during heavy database"

Mentor selection and assignment:
Several factors determine the fitness of any user as a mentor. Similarity to any other user is the final arbiter of any mentor's fitness to make recommendations for a specific user. Yet it is **coverage** (the volume of number of items rated or transactions performed) that is most important when forming the mentor pool. (The mentor pool is a superset of the final mentors chosen to make the recommendations.) Although a case could be made for using the extent of the unshared purchase space as another dimension of dissimilarity, the shared space is where we find the most data (and the most predictive data) for making the required similarity distinctions within the user population.

In a nutshell, while similarity to the user is important, it is the ability of a mentor to contribute items outside of any user's typical purchasing space into the final pool of possible recommendations that qualifies the user as a possible mentor.

For this purpose, the first step the `sifter` uses in mentor assignment is to periodically create a new mentor pool (see `lps_rtg_pool` and `lps_trx_pool`) in an effort to collect a representative sample of experienced users who will then be considered as potential mentors for any user who requires recommendations.

The second step in the mentor selection process is to assign mentors from the mentor pool to be mentors for specific users. The challenge is to create a fair balance between the similarity and the coverage of users being considered as mentors. You can configure the `sifter` to emphasize similarity, coverage, or to automatically determine which dynamic to emphasize for each user in the final assignment of mentors to users.

Number of sift priority users per batch:
To specify how many users to sift during a single batch; for example:

```
<mentor_set_name>.pri_list_size = 10
```

Pausing the sifter during heavy database:
You can pause the `sifter` during times of heavy database access. This frees up database resources for other activities during heavy database activity. For example, to put the `sifter` asleep at 11 a.m.:

```
<mentor_set_name>.pause_sifting_at= 0 11 * * *
```

If you set `<mentor_set_name>.pause_sifting_at`, use the following setting to wake up the `sifter` afterwards. For example, to wake the `sifter` up at 4 p.m.:

```
<mentor_set_name>.resume_sifting_at= 0 16 * * *
```

Sifter performance considerations:
The *sifter* places high processing demands on the system running it. For this reason it is important to tune it with consideration of its usage and environment. Use the following simple guidelines when tuning the sifter:

- Schedule the sifter to build the mentor pools during hours of the day when there is low traffic volume, for example, at 3 a.m.
- Tune the number of processing threads used by the process. You can configure this setting for each mentor set.

  To optimize the resource utilization of the sifter, set the number of threads to spawn to twice the number of CPUs in the machine that the accumulator is

running on. The LikeMinds Recommendation Engine configuration value that controls this is *item_affinity_set*`.item_affinity.num_threads`.

- Distribute the sifter onto a separate server from the LikeMinds Recommendation Engine.
- Run multiple sifter processes distributed across multiple machines for greater scalability.

Recomputing (rebuilding) the mentor pool:
For better recommendations, you must recompute, or rebuild, the mentor pool at least once a day, ideally at a time when the database has little usage. This allows new users to become mentors and removes current mentors who are no longer good mentors. If you are running multiple instances of the `sifter`, use the following procedure to recompute the mentor pool:

1. Disable all instances of the `sifter` except for one, which you will use as the master `sifter` instance. Rebuilding the mentor pool uses a large amount of database resources, so it is better to use only one `sifter` to rebuild the mentor pool.

   For the `sifter` instance to be used as the master, type the following:

   ```
   <mentor_set_name>.disable_build_mentor_pool = false
   ```

   For each `sifter` instance to be disabled, type the following:

   ```
   <mentor_set_name>.disable_build_mentor_pool = true
   ```

2. Rebuild the mentor pool on the master `sifter` instance by specifying a time for the recomputation to take place.

   Because rebuilding the mentor pool requires heavy database access, schedule it for a time when the database has little usage. For example, the following setting is for 2 a.m.:

   ```
   <mentor_set_name>.build_mentor_pool_at = 0 2 * * *
   ```

   The times are interpreted as follows:

   

3. For each `sifter` instance you disabled, set a time to reload the mentor pool after it has been rebuilt.

   The `sifter` will destroy the current mentor pool and reload the pool from the mentor pool table specified in the `<mentor_set_name>.mentor_pool.table` setting. Usually, you should set it for about an hour after the `sifter` instance has been reloaded.

   For example, to reload the mentor pool at 3 a.m.:

   ```
   <mentor_set_name>.reload_mentor_pool_at= 0 3 * * *
   ```

Running multiple sifters:
Use the following settings to run multiple instances of the `sifter` and have all the `sifters` share some configuration parameters and override others. Running multiple `sifters` simultaneously allows you to distribute load on very large systems.

To override a particular default parameter, add a prefix to the parameter. For example, to reload the mentor pool for the MovieSift `sifter` instance at 4 a.m.:

```
MovieSift.<mentor_set_name>.reload_mentor_pool_at = 0 4 * * *
```

If you run a `sifter` with the following setting,

```
sifter -config MovieSift -conf <lps config file>
```

that `sifter` will use the`MovieSift.<mentor_set_name>. reload_mentor_pool_at = 0 3 * * *` setting.

Preventing multiple sifters from sifting the same user:
When you run multiple `sifters` simultaneously to distribute load, use the following setting to prevent multiple `sifters` from sifting the same user in the Lps_User_Data table. This setting limits the `sifter` to look at only a certain group of users, or eliminates a group of users from being sifted. For example, to allow the `sifter` to sift only users whose IDs are greater than 100000, and to ignore users whose IDs are less than 100000:

```
<mentor_set_name>.constraint = user_id > 100000
```

You can specify any field in the Lps_User_Data table for this parameter. For example, assuming there is an age column in the Lps_User_Data table, you could use the following setting to constraint the `sifter` to look at all users whose IDs are greater than 10000 and who are over 25 years of age:

```
<mentor_set_name>.constraint = user_id > 100000 and age > 25
```

Number of threads to sift users:
To set the number of threads to use for sifting users in `lpsconfig`:

```
<mentor_set_name>.num_sift_threads = 3
```

Sifter sleep time when the Lps_User_Data sift_pri field Is 0:
The Lps_User_Data sift_pri field values must be greater than 0 in order for the `sifter` to get useful data (that is, updated mentors) for users. If set to `true`, the following setting causes the `sifter` to sleep for the specified number of seconds by `<mentor_set_name>.pri_check_interval` if the sift_pri field values in the Lps_User_Data table are 0. If you set the parameter to `false`, the `sifter` sifts random users when there are no users with sift_pri greater than 0.

```
<mentor_set_name>.sleep_on_no_sift_pri = true
```

Time interval for checking sift priority:
To specify the interval in seconds for the `sifter` to check the sift priority value for a user, use the following setting. The default is 20 seconds.

```
<mentor_set_name>.pri_check_interval = 40
```

Note: You can also use this setting when you are setting the time for the `sifter` to sleep during busy periods of database access. See "Sifter performance considerations" on page 2330.

Ratability parameters: The `buildvisit` background utility computes a ratability value for each item in the database. It is only used for the Preference Engine. The LikeMinds server presents items for rating in decreasing order of ratability; items with the same ratability are presented in random order.

The ratability value is computed as

ratability = $A_i+B_i+C_i$

where A_i is the popularity of item $_i$:

$A_i=Kx(\log_{10}(num\_rating))^{rpow}$

num_rating is the number of ratings for the item.

To specify K, set `db.ratability.num_rating.coefficient` (default is 1.0):

```
db.ratability.num_rating.coefficient = 1.0
```

To specify rpow, the rating power, set `db.ratability.num_rating.power` (default is 1.0):

```
db.ratability.num_rating.power= 1.0
```

B_i is a measure of how controversial the item is:

$B_i=Kx(rating\_std\_dev)^{sdpow}$

rating_std_dev is the standard deviation of the ratings for the item.

To specify K, set `db.ratability.stddev.coefficient` (default is 1.0):

```
db.ratability.stddev.coefficient = 1.0
```

To specify stdpow, the standard deviation power, set `db.ratability.stddev.power` (default is 1.0):

```
db.ratability.stddev.power= 1.0
```

$C_i$is a weight based on the age of the item:

$C_i=Kxexp(-(current\_year - release\_year))\ exp\ \hat{}\ apow$

release_year is the value of the year field in the `Lps_Item_Data` table for the item.

To specify K, set `db.ratability.age.coefficient`. You can set this to zero if you do not want to consider age in determining ratability (default is 2.7):

```
db.ratability.age.coefficient = 2.7
```

To specify ^{apow}, set `db.ratability.age.power` (default is 0.5):

```
db.ratability.age.power= 0.5
```

Repeated items in visit list: To specify whether the `buildvisit` utility should repeat an item in the visit list to be shown to a user, set `db.visitlist.ratability.duplication_threshold.` Items with ratability values greater than this threshold may be repeated.

For example:

```
db.visitlist.ratability.duplication_threshold = 6
```

Configuring the Clickstream Engine:
The Clickstream Engine generates recommendations based on a record of user shopping behavior as the user navigates through a Web site; that is, a history of user "clicks" during the user's website visit. It uses data such as the items the users view, click, and add to their shopping carts.

You can use the “User predictability for the ClickStream Engine” on page 2334 setting to specify recommendation behavior for the Clickstream Engine.

“User predictability for the ClickStream Engine” on page 2334

User predictability for the ClickStream Engine:
This section contains the following information regarding user predictability:

- The minimum number of clickstream activities required for a user before he or she can receive recommendations .
- The number of mentors the Clickstream Engine will examine before it checks to see whether the user is predictable.
- The percentage change allowed in a user's transactions before the LikeMinds server recomputes the user's predictions.
- Default recommendations.

"Minimum number of Clickstream activities for a user"

"Minimum mentors the engine examines for predictability"

"Recomputing Clickstream Engine predictions"

"Default Clickstream Engine recommendations" on page 2335

Minimum number of Clickstream activities for a user:
Set `<eng_instance_name>.engine.saturn.tune.predictable.min_xactions_cutoff` to the minimum number of transactions a user must make before the Clickstream Engine will make recommendations for that user. The default is 10.

For example:

```
movie_click.engine.saturn.tune.predictable.min_xactions_cutoff = 2
```

Minimum mentors the engine examines for predictability: When it determines whether it can make recommendations for a given user, the Clickstream Engine must examine the user's mentors.
`<eng_instance_name>.engine.titan.predictable.loop_check_cutoff` specifies the number of mentors the Clickstream Engine will examine before it checks to see whether the user is predictable. The default is 10.

For example:

```
movie_pref.engine.titan.predictable.loop_check_cutoff = 12
```

If the user is not predictable, the engine will examine another group of `<eng_instance_name>.engine.titan.predictable.loop_check_cutoff` mentors, and then check to see whether the user is predictable. It will continue until it finds that the user is predictable or it runs out of mentors.

Recomputing Clickstream Engine predictions:
The `<eng_instance_name>.engine.saturn.recomputation_bound` configuration parameter specifies the percentage change allowed in a user's transactions before the LikeMinds server recomputes the user's predictions. For example:

```
music_click.engine.saturn.recomputation_bound = 10.0
```

Ordinarily, the LikeMinds server generates predictions based on a user's mentors, which the `sifter` computes and makes available to the database. When a user has no mentors, perhaps because they have just arrived at the site, or when the user's ratings or transactions have changed beyond the percentage specified here, the LikeMinds server selects mentors from a reduced set of candidates and recomputes the user's predictions.

Use this setting with caution, as selecting mentors is a relatively expensive operation: a low percentage setting can lead to excessive CPU load with little or no gain in prediction quality. A higher setting will improve performance, but predictions may be less accurate.

Default Clickstream Engine recommendations:
The Clickstream Engine uses transaction data stored with a special user to generate default predictions. The `buildstats` utility generates clickstream transaction data, based on the transaction set named in the `db.applic.transaction.source` parameter. This transaction data is a summary of all clickstream transaction data for users, based on transaction data from all configured transaction sets. `buildstats`, the LikeMinds server, and other utilities identify the special user as one whose Lps_User_Data `mentor_type` field is set to "z". There should be exactly one user with this setting, not more. `buildstats` will automatically generate this user if custom IDs are not configured; otherwise, you need to create the user by hand, since `buildstats` cannot know what restrictions apply to the custom IDs.

Run the `buildstats` utility on a regular basis. By default, the installer sets `buildstats` to run once a day. Some applications use their own business logic to assign the score to items. If you want to override the score field value to use your application's scoring instead, run `buildstats` using the `-noscore` argument.

Configuring the Item Affinity Engine:
For every cross-selling transaction in the user's shopping history, the Item Affinity Engine derives its calculations from the following statistics:

- **Support**: This is the number of times an item pair is involved in the item affinity set you defined, divided by the total number of paired item affinity events. Item affinity events can be critical page views, purchases, shopping cart adds or drops, or combinations of these events. In other words, the support is the percentage of the time that the item pair occurred together, relative to all transactions.
- **Prediction**: Using the support statistic as a basis, the prediction is the number of times an item-to-item pair occurs together, divided by the singular support of the first item of that item pair. In other words, the prediction is the probability of the item pair, given the first item in the pair.
- **Confidence**: Using the prediction statistic as a basis, confidence is the prediction divided by the singular support of the second item of the pair for which the prediction is computed. That is, the confidence is the probability of the item pair given the first and second item in the item pair.

In general terms, you use the Item Affinity Engine as follows:

1. Define the shopping cart analysis requirements.

   This refers to the scope and filters for predictions you plan to use for the shopping cart analysis. This definition is very flexible. For example, the shopping cart can be based on the user's entire shopping history, on seasonal product sales, on the user's current session, user page views critical to an item's purchase, and so on.

   The type of purchases you expect from your users will determine the type of shopping basket you define. For example, a session-based shopping cart would be suitable for a grocery store site, where users tend to purchase a variety of items at once. A lifetime shopping cart is suitable for a site where users tend to purchase one large item occasionally, such as expensive electronic equipment.
2. Configure an item affinity set for the shopping cart analysis.

   The item affinity set defines your shopping cart analysis requirements. Similar to mentor sets or transaction sets, the item affinity set defines the type of data you want to collect. The item affinity set starts by collecting transactions from a transactions input table similar to Lps_User_Trx. You can include filters to query fields in the input table, specify the types of transactions to query, the number of highly associated items to consider, and so on, for the shopping cart

definition. Finally, you specify an output table to which the results of the analysis are written. The output table must have the same fields and datatypes as the Lps_MBA_Scored table.

3. Run the `accumulator` utility to collect the item affinity set data and populate it into the output table specified in the item affinity set.

   Similar to the `sifter`, which is used for the other LikeMinds server engines, the `accumulator` uses the item affinity set data to make the support, prediction, and confidence calculations (described earlier). It writes its findings to the output table specified in the item affinity set.

   You should configure the `accumulator` to run at times of low database usage, since it can make heavy use of system resources.

Specifying recommendation behavior:

You can configure several parameters that affect the way the LikeMinds server generates recommendations.

You can set the following recommendation behavior:

- Allowable rating values
- Allowable confidence levels
- Prediction quality
- Best bets

The parameters in this section affect the way the LikeMinds server generates recommendations. If you change them, be sure that the results will still be appropriate for your application. Because the Movie Site application expects these parameters to be set to their default values, Movie Site application developers should use extreme caution when modifying them. Parameters that apply to the background applications can also affect the way recommendations are generated.

"Allowable rating values"
Learn about the parameters that govern the allowable range of ratings.

"Allowable confidence levels" on page 2337
The LikeMinds server assigns a confidence level to each recommendation based on how many users have rated the recommended item and how similar the ratings are to each other. "Confidence" refers to the accuracy of the prediction. Learn how to set allowable confidence levels.

"Prediction quality values" on page 2337
The "quality" value refers to the degree a user will like an item. The LikeMinds server presents predictions in decreasing order of quality.

"Best Bets values" on page 2338
The LikeMinds server generates recommendation vectors that include all recommendations for a given user in order from best quality to the least. You can configure the number of items to be returned as Best Bets and the maximum percentage of the total recommendation vector to include in the Best Bets list.

Allowable rating values:

Learn about the parameters that govern the allowable range of ratings.

Specify the allowable range of ratings by setting `db.applic.param.lowestrating` (default is 0) to the lowest allowable rating and

db.applic.param.numberratingvalues(default is 13) to the number of possible ratings. This setting also determines the recommendation value. This example specifies a rating scale of zero to twelve:

```
db.applic.param.lowestrating = 0
db.applic.param.numberratingvalues = 13
```

The parameters db.applic.param.wontrate (default is -1) and db.applic.param.unrated (default is -2) set special allowable rating values that are not part of the normal rating scale. Setting an item to unrated marks the rating for deletion. wontrate means that a user has specifically indicated that he or she does not plan to rate the item.

```
db.applic.param.wontrate = -3
db.applic.param.unrated = -2
```

The LikeMinds server ignores ratings which are neither in the specified range of rating values nor equal to db.applic.param.wontrate or db.applic.param.unrated.

Note: You can use these parameters for all of the Recommendation engines except for the Item Affinity Engine.

Allowable confidence levels:

The LikeMinds server assigns a confidence level to each recommendation based on how many users have rated the recommended item and how similar the ratings are to each other. "Confidence" refers to the accuracy of the prediction. Learn how to set allowable confidence levels.

You can specify the range of confidence values by setting db.applic.param.lowestconfidence (default is 1) to the lowest confidence level and db.applic.param.numberconfidenceLevels (default is 4) to the number of confidence levels. You can set confidence levels for all of the Recommendation engines.

```
db.applic.param.lowestconfidence = 1
db.applic.param.numberconfidencelevels = 4
```

Prediction quality values:

The "quality" value refers to the degree a user will like an item. The LikeMinds server presents predictions in decreasing order of quality.

Recommendation quality is calculated using this equation:

quality = $\text{confidence}^{\text{mpow}}$x (pred rating —mean pred rating) + K x $\text{confidence}^{\text{pow}}$

where:

- **confidence** is the confidence value for the recommended item.
- **pred rating** is the predicted rating for the item.
- **mean pred rating** is the mean recommended rating for all items for the user.

To specify $^{\text{mpow}}$, set db.applic.param.BestBets.MultPower:

```
db.applic.param.BestBets.MultPower = 0.5
```

To specify K, set db.applic.param.BestBests.Coefficient:

```
db.applic.param.BestBets.Coefficient = 0
```

To specify pow, set db.applic.param.BestBets.Power:

```
db.applic.param.BestBets.Power = 1.0
```

Note: You can use these parameters for all of the Recommendation engines except for the Item Affinity Engine.

Best Bets values:

The LikeMinds server generates recommendation vectors that include all recommendations for a given user in order from best quality to the least. You can configure the number of items to be returned as Best Bets and the maximum percentage of the total recommendation vector to include in the Best Bets list.

The LikeMinds server produces Best Bets by beginning with the highest-quality item in the recommendation vector and listing items in decreasing order of rating quality.

To specify how many items the LikeMinds server should return as Best Bets, set db.applic.param.BestBets.Threshold. The default value of this parameter is the number of rating levels (specified by the db.applic.param.NumberRatingValues parameter) divided by 2. For example, if db.applic.param.NumberRatingValues were set to 12, the default would be 6. You can specify a different value, for example:

```
db.applic.param.BestBets.Threshold = 7
```

Set db.applic.param.BestBets.list.cutoff to the maximum percentage of the total recommendation vector to include in the Best Bets list. For example:

```
db.applic.param.BestBets.list.cutoff = 50
```

MovieSite Sample:

The MovieSite documentation focuses on six aspects of LikeMinds capabilities:

Best Bets
: The Best Bets task provides a list of recommended movies for each user. These recommendations are calculated based on a user's previous ratings, as well as the ratings of other similar users, using collaborative filtering. The system determines users' similarities by comparing their ratings history among all users. For example, if both user A and user B have many similar ratings, but user B has rated many more different movies; user B might make a great mentor for user A. It is from the set of mentors (user B and other similar users) that LikeMinds makes recommendations, in this case a movie recommendation for user A.

Get Items to Rate
: The Get-Movies-to-Rate task retrieves movies, which the user has not yet rated, from the database. These movies are selected based on the impact that a rating from the user would have on LikeMinds' ability to recommend movies (Best Bets). (See the task example.)

View the User's Previous Ratings
: This task retrieves ratings that a user previously entered from the LikeMinds database. An item that has previously been rated can always be given a different rating. (See the task example.)

Log Item Ratings
