WebSphere Portal Express v8.5

Version 8 Release 5

Contents

Chapter 17. Troubleshooting 3537

Chapter 1. Overview

IBM® WebSphere® Portal Express® provides a single access point to web content and applications, while it delivers differentiated, personalized experiences for each user.

Multiple solutions are available to fit your needs.

WebSphere Portal Server

This foundation offering provides a single access point to web content and applications and delivers socially infused, differentiated, personalized experiences for each site visitor. WebSphere Portal Server supports workflows, limited content management, simplified usability and administration, development tools and Web 2.0, open standards, security, and scalability. The result delivers exceptional web experiences across multiple channels, in context with the correct business applications and data, to engage and collaborate effectively, improve business productivity, and deliver better business results.

WebSphere Portal Enable and Extend

These offerings add capability on to the foundation WebSphere Portal Server offering. The Enable and Extend offerings add web content management capabilities. The offerings deliver the correct information to the correct audience. They include rich text editing tools, web content templates, workflow, advanced enterprise search, and personalization services. Used together, these features help you build rich websites that can deliver highly targeted and dynamic content to customers, partners, and employees in more relevant ways.

IBM Web Content Manager and Standard EditionIBM Web Content Manager

IBM Web Content Manager increases efficiency and accuracy of website deployments. This is achieved by placing content creation in the hands of content experts to create, maintain, and deliver online content while IT retains control.

WebSphere Portal Express

WebSphere Portal Express offers application integration, document management, web content management, and collaboration capabilities in a single, easy-to-deploy solution that is targeted at small, and medium businesses. WebSphere Portal Express can help your small and midsize business, or large department, easily deploy and customize websites, achieving faster time to value.

For additional information about WebSphere Portal solutions visit:
http://www.ibm.com/software/websphere/portal/

"What's new" on page 2
IBM WebSphere Portal Express provides new features for administrators, developers, and content authors. Start with Version 8.5 to leverage these new features on your site and then continue to get fixes, improvements, and new features with the latest cumulative fix. Use this section to get the quick highlights on these features and improvements.

"Product capabilities" on page 21
IBM WebSphere Portal Express capabilities let you quickly implement web experiences that are engaging, flexible, and high performing.

"Types of websites" on page 45
Different types of websites require different solutions and use different applications and features. These examples describe details of different websites and the types of applications and features that are required to deliver them.

"Accessibility features" on page 51
Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use software products successfully.

What's new

IBM WebSphere Portal Express provides new features for administrators, developers, and content authors. Start with Version 8.5 to leverage these new features on your site and then continue to get fixes, improvements, and new features with the latest cumulative fix. Use this section to get the quick highlights on these features and improvements.

"What's new in the combined cumulative fixes"

What's new with CF07

This Combined Cumulative Fix includes new features and improvements.

Some features are ready for immediate use when you apply the latest combined cumulative fix. Other features require extra configuration or a procedure to enable the feature.

Documentation resource: "Roadmap: Applying maintenance" on page 88

Updates to Dojo 1.9 modules

Use new theme modules to write Dojo dijits. The Dojo 1.9 Claro Theme Artifacts module, **dijit_theme_basic_19**, contains basic styles to render dijits. The Dojo 1.9 Basic Theme Artifacts module, **dijit_theme_claro_19**, contains the Claro theme from Dojo.

Documentation resource: “Modules that are provided with the modularized theme” on page 2608

Worklight is now IBM Worklight®

MobileFirst replaces Worklight to provide multi-channel support to your web communities and is now supported by the v7.0 server.

Documentation resource: “Integrating with IBM MobileFirst” on page 1002

Improved manual syndication options

Manual syndication has been improved to give users more choice when updating a syndication relationship to include a **Rebuild with mirror** option. If you select the mirror option, all items on the subscriber are reset to mirror the syndicator. All items that are newer on the syndicator are sent to the subscriber. Items that are newer on the subscriber are overwritten with the older version from the syndicator. Items that are created on the subscriber that do not exist on the syndicator are removed from the subscriber. Version history is not syndicated.

Documentation resource: Manually syndicating items

Page template mappings

The selection of a presentation template is now optional when creating template mappings for Page templates:

Documentation resource: Defining page item properties

The ML Translations text element is now hidden on forms

The **ML Translations** text element is displayed in the content item form only if the Multilingual Solution is enabled. Otherwise, this element is hidden in the content item form, but still visible in the Manage Elements dialog.

Documentation resource: “Edit-time navigation creation extension” on page 2464

Text provider strings can now be stored in content items and site areas

Previously, the strings used by the text provider plug-in had to be stored in a custom plug-in. Now they can be stored in content items and site areas, allowing users to create and maintain text provider strings from within Web Content Manager.

Documentation resource: “How to store translated text in a content item or site area” on page 1848

Additional rendering modes for web content

Additional rendering modes for web content have been added to allow users to define separate presentation templates for different media, such as JSON, XML, HTML, plus a summary mode.

Documentation resource: “Rendering modes for web content” on page 2093

Web content tag behavior and enhancements

Web content tag enhancements have been added to simplify and improve tag creation and usage.

Documentation resource: "Web content tag behavior and enhancements" on page 1833

Project template updates

You can now select a project template as the default project template. You can now hide the **Editors and viewers** selection tool within the **Publish Options**, **Approval Settings**, and **Custom Action** sections of the project form.

Documentation resource: Creating project templates

What's new with CF06

This Combined Cumulative Fix includes new features and improvements.

Some features are ready for immediate use when you apply the latest combined cumulative fix. Other features require extra configuration or a procedure to enable the feature.

Documentation resource: "Roadmap: Applying maintenance" on page 88

Configuration wizard supports database transfer to multiple databases for Oracle

Use the Database Transfer configuration option using the configuration wizard to transfer your Oracle database to multiple databases or schemas. The multiple databases or schemas option can configure multiple databases with different data sources and different users per schema. You can also use the multiple database option to configure a single database with different data sources and different users.

Documentation resource: Database Management Systems; then go to **Oracle: Database transfer** > **Oracle: Oracle worksheet: Transfer to multiple databases**.

Improving page loading performance with asynchronous web content rendering

You can now increase page loading performance by separating portal page content delivery from web content rendering.

Documentation resource: "Improving page loading performance with asynchronous web content rendering" on page 2065

Integrating remote JSON data by using the Digital Data Connector

Starting with CF06, the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework provides a generic JSON DDC plug-in that is ready to use for integrating external JSON data of your choice. You can use this plug-in to render external JSON data on your portal pages without having to write custom Java code.

Documentation resource: "Integrating remote JSON data" on page 3286

Web Application Bridge support for SAML

Starting with CF06, the Web Application Bridge now supports single sign-on using Security Assertion Markup Language (SAML).

Documentation resource: Content provider policy single sign-on

WSRP

You can now configure the WSRP Consumer to invalidate the remote session when a user explicitly logs out of the Consumer portal.

Documentation resource: "Configuring remote session invalidation" on page 1493

Updates to the Web Content Manager REST service

The Web Content Manager REST service now supports creating and updating authoring templates.

Documentation resource: "How to use REST with authoring templates" on page 3337

Updates to image and file elements

Image components and file components can now be selected when using image elements in content items and site areas:

Documentation resource: Adding a file resource element to an item

Documentation resource: Adding a file resource element to a template

Documentation resource: Adding an image element to an item

Documentation resource: Adding an image element to a template

Updates to custom search box in the portal theme

You can now redirect search requests issued by a custom search form to the Search Center.

Documentation resource: "Redirecting search requests from a custom search form to the Search Center" on page 645

OneUI is deprecated

OneUI styles were deprecated in the theme profiles of the default Portal 8.5 theme in this combined cumulative fix. It simplifies theme development and CSS content by excluding OneUI styles from the default theme. Core components that are embedded in your customer theme, such as the Web Content Viewer or inline editing, do not depend on OneUI styles any more. However, existing themes and applications continue to work with the OneUI theme. Some static resources were replaced with new `.css` and `.js` files. You might also need to remove old social rendering libraries and deploy the new ones.

Documentation resource: "Static resources" on page 2522

Documentation resource: "Removing the previous version of social rendering" on page 2135

Documentation resource: "Enabling social rendering in a virtual portal" on page 2133

Document Services feeds for Federated Documents

Support for Document Service feeds for Federated Documents are now disabled by default, but can be enabled using the `wp.federated.documents.document.services.enabled` configuration setting.

Documentation resource: “Configuring the federated documents feature” on page 407

The textbox.io feature for Ephox is now supported

The textbox.io feature for Ephox is now supported. For further information, and to obtain the application, visit the Ephox website.

What's new with CF05

This Combined Cumulative Fix includes new features and improvements.

Some features are ready for immediate use when you apply the latest combined cumulative fix. Other features require extra configuration or a procedure to enable the feature.

Documentation resource: “Roadmap: Applying maintenance” on page 88

Updating the content menu to open on click instead of on hover

This feature allows you to change the behavior of the content menu.

Documentation resource: “Updating the content menu to open on click instead of on hover” on page 2783

IBM UX Screen Flow Manager

Screen Flow Manager works like a wizard and uses screens to represent steps for a task. Starting with CF05, Screen Flow Manager provides you with several options to configure transitions between portlets, pages, and dialogs within a screen flow. The Screen Flow Manager also provides the dialog chaining and nesting option. You can configure another dialog to start after the current dialog ends or after the current dialog pauses. For example, in a travel site, you can configure the Car booking dialog to start after the Flight booking dialog ends or to start by pausing the Flight booking dialog.

Documentation resource: “Transitions” on page 3487

Documentation resource: “Dialog chaining and nesting” on page 3494

Project publish and validation updates

The process of publishing and validating projects is improved in CF05 to make it easier to monitor and manage projects.

Documentation resource: “Project Publishing” on page 1925

Documentation resource: “Project Validation” on page 1927

Folder updates

Folders can now be workflowed, and added to projects.

Syndication modes

The syndication user interface has been updated to allow for the selection of different modes of syndication.

Documentation resource: Creating a syndication relationship

SmartCloud for Social Business integration by using Active Directory Federation Services (ADFS)

Integration between WebSphere Portal Express and IBM Connections in SmartCloud for Social Business can now be completed by using Active Directory Federation Services (ADFS), which supports single sign-on. Integration with Tivoli Federated Identity Manager (TFIM) is still supported.

Documentation resource: "Configuration settings for Active Directory Federation Services (ADFS)" on page 3048

Searching in a multilingual environment

If your site is multilingual, you can now enable search for users in languages other than their preferred language.

Documentation resource: "Configuring search for multilingual sites" on page 684

Content as a Service pages

Use Content as a Service pages to render content that is managed by your IBM Web Content Manager in different data formats such as JSON or XML. Content as a Service pages allow the content that is centrally authored and maintained on your website, to be accessed by the other data clients in raw data formats.

Documentation resource: "Content as a Service pages" on page 1881

WSRP

The WSRP Consumer markup caching feature now offers better performance. You can now use WSRP markup caching without enabling the portlet container fragment caching. With a new configuration parameter, you can enable and disable markup caching specifically for selected remote portlets or for all remote portlets of a Consumer portal.

The WSRP Consumer provides multiple new configuration parameters for defining two-phase rendering behavior, WSRP response timeouts, and a limit for the size of file uploads.

Documentation resource: "WSRP Markup Caching" on page 1499

Updating the content menu to open on click instead of on hover

The content menu opens when a user hovers over a portlet containing IBM Web Content Manager items. In Combined Cumulative Fix 05, you can set the content menu to open when a user clicks an icon in the portlet skin instead.

Documentation resource: Updating the content menu to open on click instead of on hover

What's new with CF04

This Combined Cumulative Fix includes new features and improvements.

Some features are ready for immediate use when you apply the latest combined cumulative fix. Other features require extra configuration or a procedure to enable the feature.

Documentation resource: "Roadmap: Applying maintenance" on page 88

Validation improvements for the Configuration Wizard

Prevent a possible database transfer failure by validating your entries in the wizard. When you chose to validate settings for the Database Transfer option, field syntax and database connection validations are performed before you run the configuration. Examples of fields that are validated can include (depending on your database type) host name and port number.

Renditions

Renditions are different versions of an image component or element. Renditions can be thumbnails or smaller versions of an image formatted for mobile devices.

Documentation resource: Renditions

What's new with CF03

This Combined Cumulative Fix includes new features and improvements.

Some features are ready for immediate use when you apply the latest combined cumulative fix. Other features require extra configuration or a procedure to enable the feature.

Documentation resource: “Roadmap: Applying maintenance” on page 88

Theme analyzer for portlet modules

The Theme Optimization Analyzer now supports Resource Aggregation for Portlets. You can view modules, contributions, and capabilities by page. You can see what resources are coming from the theme and what resources are coming from the portlets on the page. Support for pages was also extended to the export theme data function, so your output includes page, theme, and profile information.

Resource Aggregation for portlets

The system resource aggregator automatically loads dependencies on capabilities for portlets, if the theme metadata **`resourceaggregation.autoLoadPortletCapabilities`** is set to `true`. These capabilities and modules load automatically regardless of the profile on the page, if the capabilities and modules are installed and active anywhere on the system. The resource aggregator for portlets:

- Reduces the profile size
- Reduces the number of profiles that are required
- Reduces the need to modify the theme (a profile) or page (which profile assigned) to use certain portlets on a page
- Makes the system overall simpler and easier to use.

Documentation resource: Resource Aggregator overview

Public ResourceCombinerService API

Use the ResourceCombinerService public API for portlets that must link multiple resources on a page. The ResourceCombinerService public API links these resources in a combined, optimized way to keep the number of requests to a minimum.

Syndication extension points

The Web Content Manager API has been updated with new extension points for syndication to give developers additional tools to control the syndication of items. See the Web Content Manager Javadoc for details.

Worklight 6.2 integration

Integration with IBM Worklight is upgraded to support version 6.2. Use the features in Apache Cordova and the Worklight Client APIs to use local device capabilities in your Portal solution. With this upgrade, you can use the improved operational analytics, client-side log capture, rolling server upgrades, and more.

SmartCloud for Social Business Search (SAML)

You can now establish single sign-on between your portal installation and IBM Connections in SmartCloud for Social Business which provides an integrated digital experience for users. Integration between WebSphere Portal Express and IBM Connections in SmartCloud for Social Business is completed by using Tivoli Federated Identity Manager, which supports SAML-based single sign-on. For more information on integrating IBM Connections in SmartCloud for Social Business with WebSphere Portal Express, review the documentation resource.

Documentation resource: "Configuring Portal to work with Connections in SmartCloud for Social Business" on page 762

Invalid friendly URLs

You can now validate friendly URLs for web content. Additionally, you can create customized error messages that display when a user tries to access an invalid URL.

Documentation resource: "How to validate friendly URLs for web content" on page 2045

SmartCloud for Social Business HTTP Outbound

You can now activate outbound HTTP connections to remote resources with IBM Connections in SmartCloud for Social Business by using SAML 2.0 tokens.

Documentation resource: "Establishing SSO connections through SAML 2.0 tokens" on page 3036

@mentions

Starting with IBM Connections 5.0 you can use the @mentions feature to mention other IBM Connections users in your content or to notify them of the post. You can insert the feature @username anywhere in the body of the post. The feature is supported in the body and comment sections of the Wiki page, Blog post, Forum topic, and file comments. A site visitor can get details about a user mentioned in IBM Connections content that is rendered on WebSphere Portal Express pages. @mention reference is displayed by using the portlet person card when you hover over the link. If WebSphere Portal Express is configured to use IBM Connections business card, then the business card is shown instead of portal person card.

SmartCloud for Social Business Connections integration

You can now use social rendering with content items from IBM Connections in SmartCloud for Social Business. The IBM Connections integration assets that are

used to integrate IBM WebSphere Portal Express with IBM Connections can also be used to integrate WebSphere Portal Express with IBM Connections in SmartCloud for Social Business as well.

Web Application Bridge Mobile support

Mobile support is provided for web applications that were developed and tested for rendering inside mobile device browsers.

Windows Mobile Support

Device detection has been added for Windows Mobile devices. Windows smart phones can render the mobile theme instead of the full desktop version of the theme.

Web Content Manager Rest API

The Web Content Manager Rest API has been extended to include projects and workflow item types.

Documentation resource: "How to manage web content items by using REST" on page 3324

Inplace editing for Web content

The default setting for inplace editing of Web content has been changed to "embed mode" for text and rich text fields. See the section **Default inplace editing mode** in the Web content authoring options topic.

Documentation resource: "Web content authoring options" on page 396

What's new in V8.5

Learn what's new in IBM WebSphere Portal Express Version 8.5 .

What's new for administrators in V8.5

Version 8.5 includes new features and improvements for administrators, such as syndication troubleshooting tools, staging-to-production tools and more.

If you are migrating from version 7.0, review the *What's new* content for version 8.0 too. A link is provided at that end of the page.

Roadmaps

Roadmaps provide high-level steps that help you set up your environment. For example, an environment might be a development environment or an authoring environment. The roadmaps are intended to help you simplify the complex tasks and interfaces that are required to help you achieve your environment.

Document resource: Chapter 3, “Roadmaps,” on page 69

The roadmaps include links to essential supporting documentation resources. The installation roadmaps include topology diagrams to help you visualize your environment.

Installation

The installation and deployment is improved. Start with the appropriate roadmap for your environment. Then, use the Installation Manager to install a working portal with a Derby database. After a successful installation, go to the Configuration Wizard to deploy your environment.

- Chapter 4, “Installing,” on page 101
- “Configuration Wizard” on page 232

These changes simplify the installation and configuration process.

DB2® is no longer preinstalled with the Installation Manager installation. You can upgrade your WebSphere Portal Express installation to Enable, Extend, Web Content Manager, or Web Content Manager Standard Edition. These changes simplify the installation and create a flexible deployment.

Configuration Wizard

For new deployments, the configuration wizard provides you with a guided path to apply a topology to your environment. The topologies guide you through the steps that are required for your environment. You can transfer your database, enable federated security, and create your cluster. For existing deployments, you can also use it to add on features, migrate, or upgrade your existing product offering.

Migration

Review the migration roadmaps to develop your migration plan. When you are ready to migrate, start with the roadmap to prepare your source and target environments. Then, use the Configuration Wizard to run the migration from your previous version to Version 8.5. The Configuration Wizard automatically migrates your data.

Security

Attribute based security for Web Content Manager content is a new access filter in the product filter chain. You can extend the access control permission checks for Web Content Manager content beyond the user or group-based decisions. You can define your own criteria. The criteria might involve categories, keywords, textComponents, htmlComponents, or shortTextComponents for an item. For more information, read “Enabling Attribute Based Security” on page 1572.

Search

The remote search service installation requires fewer manual steps. Install the remote search service with the Installation Manager.

The **Did you mean?** Search feature improves the search experience. It recommends suggestions or corrections for keywords in a search query. The **Did you mean?** Search feature is available for immediate use.

New search configuration parameters provide higher-quality search results for site visitors. The **boostingSettings** parameter enables the allocation of extra weight to search terms in a query that are found in specific metadata fields of a document, such as title or description. You can also change the default search operator from `Or` to `And`. This change ensures that all terms listed in a search query are found in all of the documents that are returned in the search results list.

Staging to production

Use a Portal Application Archive (PAA) file to package and deploy your initial server. Export your initial server into the PAA file. Then, you can deploy the single PAA file instead of importing multiple resources.

After you set up your initial server, you can create a PAA file for your differential release. Then, you can deploy the single PAA file instead of deploying multiple differential resources. You must create PAA files for all of your virtual portals.

Syndication

Additional tools have been added to the syndication and subscriber views to help troubleshoot failed items during syndication.

Each failed item for a selected syndicator is displayed in the **Failed Items** view. Information is displayed about each failed item, including information about what the appropriate action is to fix the issue.

Root and Impact columns have been added. These new views are used to find the root cause of a syndication failure, and what secondary items are impacted by the root cause. By finding and fixing the root cause of the syndication failure, you also potentially fix the syndication failures of the items that are impacted by the root cause.

Web application bridge

Use the new web application bridge interface to create pre-configured web dock applications for your content authors. Create content provider profiles that include at least one policy. The policy provides directives and tuning parameters for a specific context root or a regex to provision certain applications or resource paths. Then, create web dock applications that are pre-configured with the correct settings. The content author finds the appropriate web dock application and adds it to their page.

Digital Data Connector

The IBM Digital Data Connector (DDC) for WebSphere Portal Express is a new feature to integrate data from external data sources on portal pages by using IBM Web Content Manager presentation components. Use the Digital Data Connector

for WebSphere Portal Express to create list-rendering profiles that define the set of attributes available for your content authors to integrate external data sources.

Information mode and user assistance

Information mode displays more inline information, examples, and hovers help in the user interface, such as the site toolbar. Information mode gives you more assistance when you need it. After you are comfortable and understand the user interface, you can turn off information mode. Information mode is a global setting. Information mode is not implemented for the entire user interface. For example, it is not available for the administration portlets. From the site toolbar, you can turn it on and off to suit your needs. The user assistance is now divided into two help sections. One section is specific to the administrator and one is specific to the content author.

Accessing administration options

You can now access Administration from the toolbar. Click  and select a specific area of administration from the menu. You can access all the Administration options in the navigation section after you open an administration page from the menu.

IBM Knowledge Center

IBM Knowledge Center requires active scripting. If active scripting is disabled, IBM Knowledge Center displays a gray page, and the content is not available.

Related information:

 WebSphere Portal V8.0: What's new for administrators

 IBM Web Content Manager V8.0: IBM Web Content Manager new features and improvements

What's new for developers in V8.5

Version 8.5 includes new features, such as theme optimization analyzer and simple modules.

If you are migrating from version 7.0, review the *What's new content* for version 8.0. A link is provided at that end of the page.

What's new for front-end developers

Configuring outbound HTTP connections

IBM WebSphere Portal Express now provides an easier way to configure outbound HTTP connections. In WebSphere Portal Express Version 8.0 and earlier versions, outbound HTTP connections were accessible through the Ajax Proxy service. The Ajax Proxy service was configured by a configuration document named `proxy-config.xml`. You find this document in the `/WEB-INF` directory of the web module that uses the Ajax Proxy service. Starting with WebSphere Portal Express Version 8.5 and the new outbound connection service, the configuration of outbound HTTP connections is now part of the standard datastore-based portal configuration.

Theme optimization analyzer

The theme optimization analyzer creates a validation report that analyzes your theme and theme components for known issues and reports the

number of errors, warnings, and informational messages. It also includes a detailed explanation about how to fix the errors that occur.

Simple modules
Simple modules for the resource aggregator framework are provided in the WebDAV folder. You can define modules quickly with a limited set of features with these simple modules.

Collaborating with Worklight
You can expand the capabilities available to your application when you create a hybrid application that adds native device functions to your portal with Worklight. When your hybrid application runs with your WebSphere Portal Express pages rendered in a native application, WebSphere Portal Express loads the appropriate native resources for the device. These resources are loaded automatically through modules that are provided in WebSphere Portal Express.

What's new for portlet and application developers

Attribute Based Security for Web Content Manager content

Attribute based security for Web Content Manager content is a new access filter in the product filter chain. You can extend the access control permission checks for Web Content Manager content beyond the user or group-based decisions. You can define your own criteria. The criteria might involve categories, keywords, textComponents, htmlComponents, or shortTextComponents for an item. For more information, read "Enabling Attribute Based Security" on page 1572.

Dojo is no longer required for tagging and rating
The tag and rating widgets of earlier portal versions required Dojo to be interactive. The new inline tag and rating widgets do not require Dojo to be interactive.

Use the Configuration Wizard to deploy PAA files
You can now install and deploy Portal Application Archive (PAA) files with the Configuration Wizard. Start the wizard and then go to **Add On New Capability** > **Install Add-ons**.

Social Rendering List templates
WebSphere Portal Express page editors can use social rendering to feature social data that is hosted on a remote IBM Connections server in the context of portal pages.

IBM UX Screen Flow Manager
The new IBM UX Screen Flow Manager enables you to quickly build wizard-like applications that guide users through sequences of screens. In many cases such flows can be modeled declaratively, without any programming efforts by interconnecting multiple portlets. Thus, IBM UX Screen Flow Manager fosters reuse of portlets across multiple flows and eases the maintainability of your applications.

What's new for web content developers

Custom HTML editor integration
Custom HTML fields are used to integrate third-party editors into the web content authoring interface. You can use custom HTML editors in all HTML fields of the web content authoring interface, or in single HTML elements that are defined in an authoring template.

Default inplace editing mode

The default inplace editing mode can now be configured. Supported fields can be pre-configured to either use inplace editing mode, embedded editing mode, or dialog editing mode. The default inplace editing mode can be overridden in EditableElement tags using the mode parameter, or in the content template for content items.

Related information:

WebSphere Portal V8.0: What's new for user interface developers

Theme Enhancements in WebSphere Portal 8.5

Theme Analyzer Enhancements in WebSphere Portal 8.5

What's new for content authors in V8.5

Version 8.5 includes new capabilities for content authors to make content creation easier.

Enhanced authoring user interface

Use the new integrated site toolbar to quickly create and edit content. Within the new site toolbar, you can drag content to the page you are editing.

You can associate vanity URLs with portal pages and labels. Vanity URLs are short URLs that people can easily remember. They are shorter than full WebSphere Portal Express URLs. They are sometimes also called marketing URLs. You can publish vanity URLs for marketing campaigns through different channels, such as email or print. This way, you can use vanity URLs to direct customers to a specific portal page or content item. Interested site visitors who want to view your campaign can then remember or copy the short vanity URL and type it into the browser address field.

You can now add social content from external sources to your page.

You can integrate third-party content on your site with web dock application portlets.

Page editors can integrate social content in the context of portal pages.

Learn more: Site toolbar

Targeted content

Targeted content matches the content that displays in a spot to the site visitor that views the spot. Content authors do not need IT experience to configure a spot on a page to show targeted content. The administrator creates profiler rules for the content authoring and marketing team in the personalization area of the site. The profiles that are created in the profiler rules appear as segments when you configure your spot. Specifically, the segment name that is displayed in the UI matches the label that is specified for the profiler rule. Then, the content author uses the **Targeted Content** selection in the Configure Spot menu to map content to segments.

Learn more: Configure your content spot

Digital Data Connector

Use the new IBM Digital Data Connector (DDC) for WebSphere Portal Express to integrate data from external data sources on portal pages by using IBM Web Content Manager presentation components. With Digital Data Connector, content authors and designers can use Web Content Manager presentation components to generate the web page markup for external data.

Syndication status

A new information window in the authoring portlet user interface that displays the current syndication status for each item. Users can determine whether an item is synchronized between the syndicator and subscriber, pending syndication, failed, or configured to be syndicated.

Information mode and user assistance

Information mode displays more inline information, examples, and hovers help in the user interface, such as the site toolbar. Information mode gives you more assistance when you need it. After you are comfortable and understand the user interface, you can turn off information mode. Information mode is a global setting. From the site toolbar, you can turn it on and off to suit your needs. You can now view online help that is specific to content authors. Click **Learn More** links or the question mark icon to find help that is specific to that topic.

What's changed

WebSphere Portal Express includes changes to existing features.

The following areas are changed in WebSphere Portal Express:

Installation Manager
: The Installation Manager installs WebSphere Portal Express with an Apache Server database and a default file repository. Then, you must use the Configuration Wizard to set up a stand-alone or clustered environment.

Roadmaps
: Go to Chapter 3, “Roadmaps,” on page 69 to find information about installation and deployment options, migration options, and integration options.

Configuration Wizard
: You can now use the Configuration Wizard to set up a stand-alone server and set up a cluster. Use the wizard to transfer from the Apache Server database to another supported database, enable federated security, migrate your server, install add-ons, and more.

Site toolbar
: The system administrator can use the site toolbar to create the projects and templates for their websites. The content authors can use the site toolbar to create pages and to add content and applications to their websites.

  You can now access Administration from the toolbar. Click  and select a specific area of administration from the menu. You can access all the Administration options in the navigation section after you open an administration page from the menu.

Vanity URLs
Vanity URLs are a new feature within WebSphere Portal Express. You can use vanity URLs instead of URL mappings. Go to “Vanity URLs” on page 2094 for information.

Sun Java™ Directory Server
Sun Java Directory Server was rebranded to Oracle Directory Server.

Web application bridge
The system administrator can create and configure multiple web dock applications. Then, the content author adds the application to their page without having to configure the Web Dock portlet.

Remote search
You can install the remote search service with Installation Manager.

Online help
There is online help for system administrators and a separate online help for content authors.

IBM Web Content Manager
The Web Content Manager documentation is merged with the WebSphere Portal Express documentation.

Dojo Dojo is not required anymore in your custom theme even in edit mode. You now can write a Dojo free theme, and still use Edit mode. However, some components require Dojo. You must use Dojo to use `wcm_inplaceEdit`, `wp_federated_documents_picker`, `wp_content_mapping_picker`, and the Search and Tag Center Profile.

TopNav removal
The TopNav from earlier themes has been removed from desktop view. The TopNav itself still exists, but it is hidden on desktops. If you want to use the TopNav in the desktop view, you can update the dynamic content spot definition in your theme's `plugin.xml`.

Default theme profiles
The standard profiles are now Lightweight and Lightweight with Dojo, Deferred and Deferred with Dojo, Basic Content and Basic Content with Dojo. The Full profile has been removed. Profiles can now be hidden also.

Web Content Viewer (JSR 286) portlet
The display title of the JSR 286 Web Content Viewer portlet changed from “Web Content Viewer (JSR 286)” to “Web Content Viewer.” The portal shows the new display title in the toolbar and administration portlets.

The portlet application ID, `ilwwcm-localrenderingportlet-jsr.war`, and the portlet name, Web Content Viewer (JSR 286), that are used with the XML configuration interface and with the portal scripting interface did not change.

Related information:

WebSphere Portal V8.0: What's changed

Unsupported and deprecated features for V8.5

Review the features that were available in previous versions of IBM WebSphere Portal Express but are no longer available.

After a migration, features that are no longer supported or are deprecated can result in unpredictable behavior. Remove unsupported and deprecated features

before you start your migration. As they become available, links to more information are provided to help you move away from deprecated features.

If you are migrating from version 7.0, review the unsupported and deprecated page for version 8.0 too. A link is provided at that end of the page.

Unsupported features and themes in Version 8.5

Web Clipper

The **Web Clipper** portlet is no longer supported. Use the **Virtual Web Application Manager** portlet instead.

IBM themes from a previous version

The following themes are no longer supported: Portal, PortalWeb2, and Tab Menu - Page Builder. These themes are migrated as is to WebSphere Portal Express Version 8.5. However, they no longer work and are no longer supported. You must manually update those themes. Merge their function into a clean copy of a Portal 8.5 theme on the target server.

The PageBuilder2 and 7.0.0.2 themes are supported if migrated to Version 8.5.

Documentation resource: "Enabling new functionality in a migrated portal" on page 909

Composite applications

Composite applications are no longer supported. If you have a composite application in your system and you are migrating to Version 8.5, the migration fails. Ensure that all composite applications are deleted before you start the migration. When you delete a composite application, you must also run the resource cleaner, otherwise pages can still exist in the database.

Documentation resource: "Removing unsupported composite applications" on page 828

CAI/TAI portlets

When you are migrating from one version to another, your script can contain references to the CAI/TAI portlets. These portlets are no longer available and any reference to these portlets cause your script to fail. For more information, see "Virtual Portal tasks" on page 876.

IBM Portlet API

The IBM Portlet API is no longer supported. Go to "Converting IBM portlets (IBM i Linux Windows)" on page 3110 to learn how to convert your portlets that are based on IBM Portlet API to the Standard Portlet API.

Deprecated features

Shared pages

Shared pages are deprecated.

Enabler, Builder, and Mashups components and API

The Enabler and the Builder components are deprecated. The Mashups Enabler and the Builder API are deprecated.

DB2 pre-installation

The WebSphere Portal Express installation no longer installs DB2. You can now install DB2 locally or remotely from the WebSphere Portal Express media. You can also use an existing DB2. With this change, you must upgrade to an extended offering. Extended offerings include WebSphere

Portal Express Extend, WebSphere Portal Express Enable, Web Content Manager, and Web Content Manager Standard Edition.

Internet and intranet templates
The following items are deprecated and replaced with Site Builder and the Content Template Catalog:

- New Site Wizard
- Sample intranet template
- Sample internet template

Full and Base installation options
Before WebSphere Portal Express Version 8.5, a customer chose either a full deployment with all the same pages and artifacts or a base deployment to customize their portal. Starting with Version 8.5, the Configuration Wizard installs the full deployment. Customers can then remove pages to customize their portal. Then, they can package their customizations as a Portal Application Archive (PAA) file. Finally, customers can install their production server, run the **empty-portal** task, and install the customization PAA file.

LikeMinds and Feedback
The LikeMinds and Feedback database domains are deprecated.

Stand-alone LDAP user registry
The stand-alone LDAP user registry configuration is deprecated. Instead, configure the federated LDAP user registry. If you upgraded from WebSphere Portal Express Version 7.0 or 8.0 with a stand-alone LDAP user registry, you can continue to use your stand-alone LDAP user registry. However, run the **wp-modify-federated-security** to change to a federated LDAP user registry.

Documentation resource: "Changing from a stand-alone repository to a federated repository" on page 589

Active Credentials
Active credentials are deprecated from the Credential Vault portlet. Passive credentials are still available.

Parallel Portlet rendering
The **Parallel Portlet rendering** feature is deprecated.

Adding a category from an outside component.
You can no longer add a category from an outside component. You must use the site toolbar instead.

LTPA version 1 token support
The LTPA version 1 token is deprecated. WebSphere Application Server Version 8.5.5. disables the LTPA version 1 token by default. If you are integrating with third-party applications that rely on LTPA version 1, update the application to support LTPA version 2. If you cannot update the application, you must manually re-enable LTPA version 1 support after you complete the migration. For information on updating your application to support LTPA version 2, see the documentation for the application.

Tagging and rating dialog and inline widgets
In tagging and rating, the tag and rating widgets of previous portal versions are deprecated. This affects both pairs of the old widgets, the dialog widgets of the default user interface and the inline widgets of the

alternative user interface. They are replaced by a new pair of interactive inline widgets. The new widgets combine the functions of the separate widgets of earlier portal versions.

URL mappings
URL mappings are deprecated. If you upgrade from Version 8.0 to Version 8.5, you can continue to use your existing URL mappings, but creating new URL mappings is no longer supported. Use vanity or friendly URLs.

Vanity URL documentation resource: "Vanity URLs" on page 2094

Friendly URL documentation resource: "Using friendly URLs" on page 1280

IBM Portlet API Web Content Viewer portlet
The Web Content Viewer portlet that is based on the IBM Portlet API has been removed and is no longer supported. If you use the IBM Portlet API Web Content Viewer, and you migrate to Version 8.5, then you must replace the portlet and its clones with the JSR 286 Web Content Viewer portlet as a post-migration step.

Documentation resource: "Convert the IBM Portlet API Web Content Viewer to the JSR 286 Web Content Viewer" on page 870

Note: Note: In the version 8.5 user interface, the JSR 286 Web Content Viewer portlet has been renamed to Web Content Viewer.

IBM Portlet API Remote Web Content Viewer portlet
The Remote Web Content Viewer portlet that is based on the IBM Portlet API has been removed and is no longer supported. If you use the IBM Portlet API Remote Web Content Viewer, and you migrate to Version 8.5, then you must replace the portlet and its clones with the JSR 286 Web Content Viewer portlet as a post-migration step.

Documentation resource: "Convert the IBM Portlet API Remote Web Content Viewer to the JSR 286 Web Content Viewer" on page 871

Note: Note: In the version 8.5 user interface, the JSR 286 Web Content Viewer portlet has been renamed to Web Content Viewer.

Deprecated integration portlets

The following integration portlets were removed in WebSphere Portal Express Version 8.5:

IBM WebSphere Portal Integrator for SAP
The IBM WebSphere Portal Integrator for SAP portlet is now deprecated. For SAP integration of single iViews or iPages, use the web application bridge.

Documentation resource: "Integrating with web applications" on page 977

Deprecated Business portlets

The following Business portlets were removed in WebSphere Portal Express Version 8.5:

Remote Rendering Portlet
The remote rendering portlet is now deprecated. Use the **Web Content Viewer (JSR 286)** portlet and Web Services for Remote Portlets (WSRP) instead.

Web2Bookmarks portlet

The **Web2Bookmarks** portlet is no longer available for immediate use. Instead, download the portlet from the IBM WebSphere Portal Business Solutions Catalog.

Catalog: IBM Collaboration Solutions Catalog

Deprecated theme

The WebSphere Portal Express Page Builder 7.x theme was deprecated.

Related concepts:

"Configuring authentication filters" on page 265
The portal authentication filters are a set of plug-in points. You can use them to intercept or extend the portal login, logout, session timeout, and request processing by custom code, for example to redirect users to a specific URL.

Related tasks:

"Federating the LDAP user registry" on page 860
The stand-alone LDAP user registry configuration is deprecated. Instead, configure the federated LDAP user registry. Run the **wp-modify-federated-security** task to change to a federated LDAP user registry.

Solutions Catalog: WebSphere Portal

WebSphere Application Server Network Deployment 8.5.5: Deprecated features

Product capabilities

IBM WebSphere Portal Express capabilities let you quickly implement web experiences that are engaging, flexible, and high performing.

WebSphere platform

WebSphere is IBM's integration software platform. It includes the entire middleware infrastructure - such as servers, services, and tools - needed to write, run, and monitor 24x7 industrial-strength, on-demand Web applications and cross-platform, cross-product solutions. WebSphere provides reliable, flexible, and robust integration software.

WebSphere provides software for Service Oriented Architecture (SOA) environments that enables dynamic, interconnected business processes, and delivers highly effective application infrastructures for all business situations.

IBM WebSphere Application Server drives business agility by providing millions of developers and IT Architects with an innovative, performance-based foundation to build, reuse, run, integrate, and manage Service Oriented Architecture (SOA) applications and services. From business critical and key enterprise-wide applications to the smallest departmental level applications, WebSphere Application Server offers the highest levels of reliability, availability, security, and scalability.

Customization

You can customize WebSphere Portal Express to meet the needs of your organization, users, and user groups. You can adapt the look and feel of the portal to fit the standards of your organization and to customize page content for users and groups in accordance with business rules and user profiles. Users, such as business partners, customers, or employees, can further customize their own views of the portal. Users can add portlets to pages and arrange them as they want and control portlet color schemes. By aggregating portlets in one place and giving users the power to customize their own desktops, WebSphere Portal Express gives users a means for doing business efficiently and with high satisfaction.

Portlets

Portlets are central to WebSphere Portal Express. As special reusable Java servlet that appear as defined regions on portal pages, portlets provide access to many different applications, services, and web content. WebSphere Portal Express ships a rich set of standard portlets, including portlets for displaying syndicated content, transforming XML, and accessing search engines and web pages. More portlet solutions are available on the IBM Lotus and WebSphere Portal Business Solutions Catalog. These portlets are used to access Lotus Notes® iNotes, IBM Sametime®, IBM Connections, and Microsoft Exchange. Several third-party portlets are also available. Examples include Enterprise Resource Planning (ERP), Dashboards, Business Intelligence, Process Management, and Customer Relationship Management (CRM) portlets.

It is possible to develop custom portlets, too. WebSphere Portal Express supports the Java Standard API (JSR 286) that portlet developers can use to create custom portlets.

Widgets

WebSphere Portal Express now includes widgets inside the portal. You can even create mashups that consist of both portlets and widgets. Widgets are highly interactive user interface components that are written in JavaScript. These widgets are typically very narrow in scope and can easily be created using a script-based language. Widgets can also be a solution for creating a mashup between different backend technologies like a Java EE-based portal server and a PHP-based server.

For additional information about new features, main components, and what each component provides to the overall solution, explore the subtopics of this section.

"Streamlined site creation" on page 23
You can use the Site Builder to generate your own portal site.

"Web analytics" on page 23
WebSphere Portal Express includes a number of solutions to help you understand how visitors use your site, including server-side analytics and client-side analytics. Client-side analytics is also called active site analytics.

"Web content" on page 25
IBM WebSphere Portal Express and IBM Web Content Manager help you manage content, share information, and communicate your message.

"Social business" on page 31
WebSphere Portal offers wikis, blogs, and tagging and rating capabilities. In addition, you can integrate existing collaboration applications with your portal site, such as Lotus Connections.

"Integration" on page 36
WebSphere Portal integrates with many products.
"Mobile" on page 38
A portal is a website that provides users with a single point of access to Web-based resources by aggregating those resources in one place and by requiring that users log in only to the portal itself, and not to each portlet they use. WebSphere Portal Express can also deliver Web content to WAP-enabled devices, i-Mode phones, Smart phones, and to various Web browsers. In addition, the IBM Mobile Portal Accelerator multi-channel server and mobile device repository extends portal content dynamically to over 7000 mobile devices, with new updates and devices added as they reach the market.
"Versatile framework" on page 40
IBM WebSphere Portal Express provides users a consistent view of portal applications and allows users to define specific sets of applications that are presented in a single context. Depending on the requesting device, the rendering of this application set must vary to fulfill the requirements of the device.

Streamlined site creation

You can use the Site Builder to generate your own portal site.

Creating portal sites on demand

Use the Site Builder to generate your own site – without needing any portal development skills or assistance from an administrator. Select a template from the available samples, choose the look that you want, and then allow the Site Builder do the rest.

The Site Builder automatically creates sites as virtual portals; however, administrators and developers can extend the wizard to create any type of portal site. Portal developers can also enhance the Site Builder by creating custom templates, and then adding them to the Site Builder.

Download the Site Builder from the IBM WebSphere Portal Express Business Solutions Catalog. Package contents include the portlet `.war` (web application archive) file, supporting files and directories, and detailed instructions in a `.pdf` file. After you deploy the Site Builder, you must add the portlet to a page that users can access. For more information, read the `.pdf` file that comes with the Site Builder.

Web analytics

WebSphere Portal Express includes a number of solutions to help you understand how visitors use your site, including server-side analytics and client-side analytics. Client-side analytics is also called active site analytics.

With Portal analytics you can achieve the following goals:

- Measure the success of your portal site.
- Predict the demand to a portal in the future.
- Plan for changing site visitor needs.

Active site analytics

Through active site analytics (client-side) WebSphere Portal Express makes it easier to collect, process, and report on your site usage. Integration with leading web

analytics products is easy. For example, Coremetrics page view tags are immediately available on pages in your site. In addition to integration with Coremetrics, you can also integrate with other web analytics tools such as, Unica, Omniture, and Webtrends.

Active site analytics:

Captures visitor behavior data directly from the web browser to ensure that every action is recorded.

Dynamically accommodates all content changes to the site so adding a page, product, or category typically requires no tag maintenance.

Creates a comprehensive record of visitor interactions and clients also do not have to pre-define segments, visitor events, campaigns, or categories for analysis.

Active site analytics uses a flexible, backend business logic instead of hardcoding the logic into the site instrumentation. As a result, you enjoy reduced IT maintenance and maximum analytical flexibility.

You can analyze web analytics reports in context, without switching to an external tool. This capability is called overlay reports. Overlay reports provide a quick look at the success of a page, portlet, or web content. Overlay reports are immediately available for Coremetrics, but you can extend that capability to other analytics tools.

Server-side analytics

Using server-side analytics, you can gather information about page and site visitor management activities, site visitor page and portlet requests, and session activities. Page and visitor management activities include creating, reading, updating, and deleting. Session activities include login, logout, timeouts, and login failures.

Related concepts:

"Logging and analyzing server side site data" on page 1688
IBM WebSphere Portal Express implements a logging function for your usage data. The portal writes usage records to a dedicated log file if site analysis logging is enabled. Multiple types of site analyzer loggers allow portal administrators to collect statistical data in various areas. The portal server manages the collection of data on its own, but from a business point of view you can also log custom details of business events. You can configure the portal for site analysis logging for the web content viewer.

"Analyzing user behavior by Active Site Analytics" on page 1696
You can collect data about user behavior in your portal and send that data to a service for analysis. For this purpose the portal provides Active Site Analytics (ASA).

"Collecting analytics data" on page 1698
Before you can send data about user behavior in your portal to a service for analysis, you need to collect that data. See the following topics for information about how to do this.

"Displaying overlay analytics reports" on page 1714
You can use Active Site Analytics to show graphical statistics reports about individual portal resources, such as pages or portlets. These reports are called Active Site Analytics overlay reports.

"Analytics tags and site promotions" on page 1724
To obtain further analytics information from your portal, you can use analytics tags for your portal resources. You can also use analytics tags for site promotions.

Web content

IBM WebSphere Portal Express and IBM Web Content Manager help you manage content, share information, and communicate your message.

"IBM Web Content Manager"
IBM Web Content Manager accelerates the creation, maintenance, and delivery of content across intranet, extranet, Internet, and portal sites.

"Conceptual and functional divisions of a website" on page 26
When you build a website by using Web Content Manager, you break up your website into the following conceptual and functional divisions.

"Content Template Catalog" on page 28
The content template catalog is a set of templates that you can use to accelerate building a website. Using these templates you can build a basic site quickly with little or no customization.

"Targeted content and Portal Personalization" on page 28
Targeted content provides you with a way to deliver multiple pieces of content to different audiences. Targeted content matches the best content with the most appropriate group by using segments. Segments help you split your audience into meaningful groups with different interests or characteristics.

"Portlets" on page 29
Portlets are a central part of IBM WebSphere Portal Express. Portlets are small applications that are independently developed, deployed, managed, and displayed. Administrators and users compose personalized pages by choosing and arranging portlets, resulting in customized Web pages.

Related information:

IBM Web Content Manager Multilingual Solution

IBM Web Content Manager

IBM Web Content Manager accelerates the creation, maintenance, and delivery of content across intranet, extranet, Internet, and portal sites.

IBM Web Content Manager is a comprehensive solution for creating, managing, and delivering content on your website.

Use Web Content Manager to publish your information and pull in content from other sources, either RSS feeds or other content management systems. On a single page, you can publish your corporate news and highlight news from an external news source.

Authors can edit content inline on staging servers and editors can approve content inline.

Using Personalization, you can target content based on the website users authentication and preferences. Personalization rules let you control what information specific users or user groups can see.

Workflows let you control how content is reviewed, approved, and published. You can create custom workflows to reflect your existing business processes.

Use syndication to publish approved content to your live website.

Content

You can manage and store content in Web Content Manager, using an external content management system, or both.

Set up libraries to manage and store content in Web Content Manager.

Use IBM Web Content Integrator to import content in RSS feed format.

Integrate and link directly to external content management systems using CMIS support included with Web Content Manager.

Use WebDAV to import content from a file system.

Wikis and blogs are immediately available for you to add to pages in your site.

Management

Use projects to manage changes to a group of items. Projects can help you coordinate approvals and publication.

Workflow is immediately available and you can develop custom workflows if needed. Workflows help you control how content progresses from draft to publication. Projects can have associated workflows too.

Authoring

Multiple authoring home pages are immediately available. You can also develop a custom authoring environment if needed.

In addition to the authoring home pages, authors can edit content in context on the staging servers. Using the edit mode, authors can select to edit content on a page. Changes adhere to defined workflows and syndication publishes changes.

Multilingual websites

The IBM Web Content Manager Multilingual Solution download, available on the solution catalog, provides a reference implementation for a multilingual website. It includes a set of extension plugins that you can use to configure and deliver a multilingual site.

Conceptual and functional divisions of a website

When you build a website by using Web Content Manager, you break up your website into the following conceptual and functional divisions.

Table 1. Conceptual and functional divisions for layout

Content	Layout
• Content items • Site areas • Components	• Presentation templates • Component designs • Page layout and portlets • Themes

Table 2. Conceptual and functional divisions for style

Context	Style
• Site framework • Page hierarchy • Profiling • Current user • Personalization	• CSS • Themes

When you are developing a website by using Web Content Manager and WebSphere Portal, you are splitting the elements of your website between content, context, layout, and style.

Content:

There are two types of content:

Dynamic

Dynamic content is generated dynamically based on a set of preconfigured parameters, such as navigator or menu.

Static Static content is content where you store markup or files directly in a component, content item, or site area. Where you store your static content depends on how the content is used:

- Page-specific content is stored in content items.
- Content that is related to a section of your site can be stored in a site area.
- Content that is reused in multiple sections of your site is stored in components.

Layout:

The layout and structure of each page in your website are defined by using these features:

- The overall structure of each page is determined by the theme you are using, the page layout you choose, and the web content viewer portlets you add to the page layout.
- The layout of the content that is displayed within each web content viewer is determined by markup that is used by the current presentation template, and by the markup that is stored within the elements and components that are referenced within the presentation template.

Context:

The context of the content that is displayed is also important. The layout and design of the page where a content item is displayed is different depending on:

- The current portal page (Different pages can use different themes, layouts, web content viewer portlets, and even different presentation templates.)
- The current site area (Content that is linked to different site areas can use different template maps that map to different site areas.)
- The current user (Different users can have different access to various page elements, including individual pages, portlets, and web content items.)

Each of these contextual variables can be used to display content or components in different ways, depending on the current context. Additionally, the profile of the current portlet, content item, or current user can determine what is displayed on a page, as do any personalization features used by your website.

Style: While you can place stylistic elements directly within your HTML, it is becoming increasingly common to use CSS to store and manage all the stylistic elements of a website, including:

- Stored server-side and referenced within a WebSphere Portal theme
- Stored directly within a content item or component

One good practice is to store your CSS markup within an HTML field that is stored in a content item. This provides quick access to the CSS if you need to edit the CSS. In addition, you can use advanced features such as workflows and inline editing to help you maintain your CSS. By storing all

your stylistic elements in CSS, you can quickly make stylistic changes to your website by editing a CSS file instead of editing multiple items.

When a web page is rendered, Web Content Manager takes all these individual item types and combines them to build a complete web page.

Content Template Catalog

The content template catalog is a set of templates that you can use to accelerate building a website. Using these templates you can build a basic site quickly with little or no customization.

The content template catalog is a comprehensive set of templates, pre-configured portlets, content-oriented theme, and layouts. Use the palette of pre-configured portlets to drop components on your pages for navigation, teasers, slide shows, carousels, and more. The template pattern supports the creation of your own templates. A page created from a template can be modified and then turned into a new template. You could build up you own custom template library and provide a self-service site development offering to your users.

You can download the content template catalog form the IBM Lotus and WebSphere Portal Business Solution Catalog

Related information:

 IBM Web Content Manager Forum: Content Template Catalog Announcement

Targeted content and Portal Personalization

Targeted content provides you with a way to deliver multiple pieces of content to different audiences. Targeted content matches the best content with the most appropriate group by using segments. Segments help you split your audience into meaningful groups with different interests or characteristics.

A targeted spot displays different content to different segments. You can create a target spot by defining content that is targeted to specific segments:

- Add content items to your content spot in a web content viewer.
- Add segments to each content item to display your content to the correct audience. Segments help you define your target audience. For example, you can define the audience by users, device class, or other attributes.

Personalization of content

Targeted content applies Personalization concepts to a new user interface where you create Personalization rules as you work to target content to selected segments. Personalization allows a portal or website to choose which content must appear for a particular user. The WebSphere Portal Express Personalization component selects content for users based on information in their profiles and on business rules. Using Portal Personalization, business experts can classify site visitors into segments and target relevant content to each segment. For example, a site that is using Personalization might show different news articles to managers than to regular employees or different information to valued customers. Personalization offers analytic capabilities to record site usage patterns and includes the LikeMinds recommendation engine, which provides collaborative filtering capabilities. Collaborative filtering uses statistical techniques to identify groups of users with similar interests or behaviors. Inferences can be made about what a particular user might be interested in, based on the interests of the other members of the group.

You can define content through a number of applications, including IBM Web Content Manager. Personalization automatically detects the content definition from these applications. Definitions of database or LDAP content types can also be made through a Personalization wizard included with IBM Rational® Application Developer.

After you define the content type, attributes of the content are shown to the rule author. The rule author can use these attributes to make conditions that define if and when certain content is displayed, or even if certain actions like database updates and triggered emails occur. To create new Personalization rules, go to **Applications** > **Personalization** > **Business Rules**.

Benefits of Personalization

- The Personalization component selects content for users that are based on information in their profiles and on business logic. With Personalization facilities, subject matter experts can select content that is suited to the needs and interests of each site visitor. These web-based tools help companies quickly and easily use content that is created by business and subject matter experts.
- Personalization classifies site visitors into segments and then targets relevant content to each segment. Business experts create the rules for classifying users and selecting content, by using web-based tools.
- Personalization has built-in capabilities for the IBM Java Content Repository. This means that personalization rules can easily be used in your Web Content Manager solutions.
- Personalization also includes a recommendation engine that provides collaborative filtering capabilities. Collaborative filtering uses statistical techniques to identify groups of users with similar interests or behaviors. Inferences can be made about what a particular user might be interested in, based on the interests of the other members of the group.
- Campaign management tools are also included with Personalization. Campaigns are sets of business rules that work together to accomplish a business objective. For example, a Human Resources manager might want to run a campaign to encourage employees to enroll in a stock purchase plan or sign up for some other new benefit that is now available to employees. The Human Resources manager would define a set of rules that are shown to accomplish this business objective. Campaigns have start and stop dates and times and can be email and web-page based. Several campaigns can run simultaneously and can be prioritized.

Related concepts:

"Developing a personalized portlet" on page 2385
This exercise demonstrates how to use Personalization features of WebSphere Portal and Rational Application Developer to build your first personalized portlet. Your final result is a working portlet that uses Personalization rules and content spots to display personal news based on user attributes (or profiles).

Portlets

Portlets are a central part of IBM WebSphere Portal Express. Portlets are small applications that are independently developed, deployed, managed, and displayed. Administrators and users compose personalized pages by choosing and arranging portlets, resulting in customized Web pages.

WebSphere Portal Express ships a rich set of standard portlets. For the most up-to-date information about portlets, including the latest portlets that are

available for download, visit the IBM WebSphere Portal Business Solutions Catalog. Or, refer to Developing portlets for information on creating custom portlets.

Portlet applications

Portlets are more than simple views of existing Web content. A portlet is a complete application, following a standard model-view-controller design. Portlets have multiple states and view modes, plus event and messaging capabilities.

Portlets run inside the application server, similar to the way a servlet runs on an application server, but are aggregated to a complete Web page by the WebSphere Portal server. The portlet container provides a run-time environment where portlets are instantiated, used, and finally destroyed. Portlets rely on the WebSphere Portal Express infrastructure to access user profile information, participate in window and action events, communicate with other portlets, access remote content, look up credentials, and store persistent data.

Generally, portlets are administered more dynamically than servlets. For example, portlet applications that consist of several portlets can be installed or removed while the WebSphere Portal component is running. The settings and access rights of a portlet can be changed by an administrator while WebSphere Portal is running, even in a production environment.

Portlet modes allow a portlet to display a different user interface, depending on the task that is required of the portlet. A portlet has several modes of display that can be invoked by icons on the portlet title bar: View, Help, Edit, Configure, and Edit Shared Settings.

A portlet is initially displayed in View mode. As the user interacts with the portlet, the portlet can display a sequence of view states, such as forms and responses, error messages, and other application-specific states. Help mode provides user assistance. Edit mode lets the user change portlet settings. For example, a weather portlet might provide an Edit page for users to specify location. Users must be logged in to WebSphere Portal Express to access Edit mode. Configure mode changes the default look of the portlet for all portlet instances and Edit Shared Settings changes the look of the portlet on a specific page.

Each portlet mode can be displayed in normal, maximized, or minimized state. When a portlet is maximized, it is displayed in the entire body of a page, replacing the view of other portlets. When a portlet is minimized, by default, only the portlet title bar is displayed on the page.

Portlet API

The Java Portlet Specification addresses the requirements of aggregation, personalization, presentation, and security for portlets that run in a portal environment. WebSphere Portal Express supports both portlet standards JSR 168 and JSR 286. For more information about the standard portlet API, go to the topic *Standard portlet API*.

Portlet communications

WebSphere Portal Express allows portlets to communicate with each other. Portlet communication can be used to exchange data between portlets. This feature makes the portal easier to use.

The portal supports events as defined in the JSR 286 specification. It allows administrators to wire portlets by using the portal user interface.

For example, one portlet can display information about accounts, and a second portlet displays information about transactions that occurred for one of the accounts over the last 30 days. To display this information, the transactions portlet needs to obtain the appropriate account information when it displays the transaction details. This exchange of information is accomplished by communication between the two portlets, by using events as described in the JSR 286 specification. In this example, the account portlet defines a publishing event in its portlet descriptor. The transaction portlet defines this event as a processing event in its portlet descriptor. By using the portal user interface, you can now wire those two portlets together. After you did this wiring, when the account portlet throws an event, the transaction portlet receives this event and can show information about the transactions of this account.

Portlet services

Portlet services are used to provide common functionality to portlets. Each portlet service has its own service-specific interface for the functionality that it offers. WebSphere Portal Express supports portlet services for standard portlets. Standard portlets use a JNDI lookup to retrieve a `PortletServiceHome` object, which is used to retrieve a portlet service implementation. A portlet service can be started only by the code within a portlet. For more information about portlet services in the portal,go to the topic *Portlet services*.

Social business

WebSphere Portal offers wikis, blogs, and tagging and rating capabilities. In addition, you can integrate existing collaboration applications with your portal site, such as Lotus Connections.

"IBM Connections"
Integrate IBM Connections into your site by using community pages and Connections Portlets.

"IBM Sametime" on page 33
The IBM Sametime portlets are installed with WebSphere Portal Express and deployed automatically.

"Blogs and wikis" on page 33
A set of preinstalled web content libraries are supplied. With these libraries, you can add blog and wiki features to your websites. Use blogs, blog libraries, and wikis to tap into the power of the community and to change the way you work.

"Tagging and rating portal content" on page 34
Users can tag or rate portal content and view the tags and ratings. Tagging and rating allow users to better organize, categorize, and find portal content. This task includes Web Content Manager, Connections, and custom content. For example, users can tag or rate books in an online bookstore.

IBM Connections

Integrate IBM Connections into your site by using community pages and Connections Portlets.

Connections Portlets

Connection portlets are not installed with the portal but you can easily download them from IBM Lotus and WebSphere Portal Business Solutions Catalog.

The portlet includes activities, blogs, blog summary, bookmarks, bookmarks summary, profiles, profiles summary, wikis, forums, forums summary, community overview, and tags.

Community pages

Portlets on community pages are automatically scoped to the community membership and display content from the community in the portlets. For example, if your community contains a forum you can add the forum portlet to a community page. The portal site visitors can view and interact with the forum content from the portal site.

You can automatically create new communities for your pages during the page template instantiation.

Search integration

Integrating Connections content into your portal search makes it easier for site visitors to find community content. Visitors can search for a term and see results from your portal site and Connections. Each Connections component has a unique seedlist provider. To configure your portal search to include Connections content, you must configure a content source for each seedlist. Instructions are provided in the Connections product documentation.

Tag integration

You can configure you portal tag cloud to include tags from Connections. This configuration makes it easier for your site users to find content in the communities.

You can also add the Connections Tags Portlet to a page. Then, you can wire it to other Connections portlets. Then, site visitors can use tags to find community content faster in blogs, wikis, and more.

Profiles integration

You can configure your portal site to show Connections Business Card information. Names that are associated with Connections profiles display as active links. Your site visitors click the name to see the business card. From the business card visitors can link to communities, blogs, and more for the selected user.

Files integration

Content authors can easily create links to files stored on Connections. From the rich text editor, in IBM Web Content Manager, the author can browse Files. Authors can also use Web Content Manager markup generation to render the current contents of specific IBM Connections Folders.

Integration with Connections Files is based on the generic Content Management Interoperability Services (CMIS).

“What's new for administrators in V8.5” on page 10
Version 8.5 includes new features and improvements for administrators, such as syndication troubleshooting tools, staging-to-production tools and more.

“Roadmap: Integrating with IBM Connections” on page 97

Related information:

IBM WebSphere Portal Business Solutions Catalog

IBM Connections Portlets for WebSphere Portal

How the Tags portlet interacts with the other IBM Connections portlets

IBM Sametime

The IBM Sametime portlets are installed with WebSphere Portal Express and deployed automatically.

The Sametime Web 2.0 Contact List portlet is available from the **Applications** > **Collaboration** area of the portal site.

People awareness

Users can view contact and other typical business card information for a registered user by displaying the Person card. The Person card is available through a wide range of portal components including Domino® and Sametime integration, personalization, and Web content authoring. To view the Person card, move the cursor over an active (underlined) person's name and then select **Click** for **Person Card**.

When Sametime is enabled in your portal configuration, users can work with the complete set of people awareness functionality, which includes instant messaging and application sharing through e-meetings. Person names appear aware - with a dynamic online status indicator. Click **Profile** to display full information about the person. Additional actions can include:

- **Send Mail**
- **Chat**
- **Add as Sametime Contact**

If you choose not to enable Sametime in your portal configuration, people awareness functionality is more limited. People's names appear as hyperlinks, but with no people awareness icon next to each name, and available actions on the Person card are limited to those that are native to WebSphere Portal Express.

Related concepts:

"Integrate with collaboration software " on page 927
IBM WebSphere Portal Express integrates with collaboration software to provide you with more effective and cost-efficient ways of accessing information, sharing ideas, communicating and working together. Key software that WebSphere Portal Express integrates with includes IBM Domino, IBM Sametime, and IBM Connections.

Blogs and wikis

A set of preinstalled web content libraries are supplied. With these libraries, you can add blog and wiki features to your websites. Use blogs, blog libraries, and wikis to tap into the power of the community and to change the way you work.

Blogs are a great tool to use when you want to generate ideas around a single topic. You can use blogs for your own individual work or to gain feedback on a single concept from the larger team. Blog libraries take blogs to the next level. Rather than creating a blog per topic, you can use blog libraries to track multiple

topics in a centralized location. Wikis also provide you with another alternative for authoring content. Simple inline editing, including the insertion of images and links, makes authoring wikis quick and easy. You can also tag and rate blog and wiki content.

Blogs, blog libraries, and wikis use the template libraries that are provided by IBM Web Content Manager. Each blog, blog library, and wiki have its own library. The page hierarchy that is provided for these components is the common one defined by the Web Content Manager template libraries.

Tagging and rating portal content

Users can tag or rate portal content and view the tags and ratings. Tagging and rating allow users to better organize, categorize, and find portal content. This task includes Web Content Manager, Connections, and custom content. For example, users can tag or rate books in an online bookstore.

Portal users can tag or rate portal content. This task includes the following types of resources:

- Portal resources, such as pages and portlets
- Web Content Manager resources, such as articles or images
- Custom resources. For example, these resources can be items in an online store or pictures in a portlet. Administrators can add these custom resources to the portal so that users can tag or rate them.

In general, all content in a portal that can be uniquely identified can be tagged or rated.

Users can apply tags and ratings both publicly and privately for the following purposes:

- Public tagging and rating helps users categorize, evaluate, and find portal content that is based on tags and ratings by other users.
- Private tagging and rating can help users create their own personal way to categorize, evaluate, and find portal content.

In detail, portal users can do the following tasks:

- Work with tags:
  - Tag portal content. Users can add tags to portal content. For example, the user can apply the tag `websphere` to a page that provides information about IBM WebSphere products. Users can remove tags that they applied themselves.
  - View tags and related portal content: Users can view the tags that are applied to individual portal resources, for example by starting the default tag and rating widgets. Users can also work with aggregated sets of selected tags:
    - Users can view tags that are applied to a set of resources by using a **tag cloud**. The tag cloud lists the tags in alphabetical order. Different font sizes indicate how often the tags are applied. Depending on how the administrator configures the tag cloud, the list can be portal wide or limited to particular items. For example, portal pages, or books available on the page where the user clicked the tag.
    - The tag cloud supports different views: users can switch between these views. For example, they can view all tags, only tags that they themselves applied, their own private tags, or the tags that were added most recently.

- Users can switch between different display modes. For example, they can have the tags to be displayed in a cloud as described earlier, or in a simple list.
- Users can use the tags that are displayed in the tag cloud to search for content. When a user clicks a tag, the portal shows a list of resources that have that tag that is applied. Clicking such a resource redirects the user to that resource itself. Users can also click multiple tags; in this case the list shows only resources that have **all** selected tags applied.
- When users work with the list of resources, they can have the list that is sorted by different criteria, for example, title, date, rating. The result list portlet also supports two different view modes: a summary and a detail view.

- Work with ratings:
  - Rate portal content:
    - Users can apply ratings to individual resources to show how much they "like" them. For example, a user can give a good book a rating of 4.
    - Users can change or remove ratings that they applied themselves. For example, a user can update the previous rating 4 to a 5.
  - View the ratings that they or other users apply to portal content.

Administrators can do the following tasks:

- All tasks that portal users can do as previously listed.
- Add content that users can tag or rate, for example, books in a bookstore.
- Assign users the access rights for tagging or rating content.
- Configure the tag clouds. By default, a tag cloud shows all tags that are applied to portal-wide resources. Administrators can add tag clouds to portal pages or themes and configure them as required. For example, they can limit a tag cloud to display only tags that is assigned to resources of a certain category, such as portlets. When users click a tag from that tag cloud, the result list shows only resources, in this case portlets.
- Move tags to a different portal system, for example, for staging or during migration.
- Obtain basic statistics about tagging and rating. For example, you can obtain the tags and tag counts for a specific portal page, or all tags that a specific user applied. You can write queries for more detailed statistics, or create a user interface to visualize them.

Developers can do the following tasks:

- Extend the tagging and rating capabilities of the portal by writing a custom user interface that uses the Java Model API or the REST API.
- Write queries to obtain statistics about tagging and rating, and write a user interface to visualize these statistics.
- Enable or disable filters, for example to prevent users from using unwanted words as tags. By default the portal provides a blacklist and a whitelist filter.

Note: Depending on your portal and your user groups, administrators or developers might consider creating user documentation for tagging and rating for their portal users.

Integration

WebSphere Portal integrates with many products.

"Web application bridge integration"
Use the *Web Application Bridge* to integrate with web applications, such as Sharepoint.

"Process integration"
Use the Unified Task List portlet to integrate with business process solutions such as IBM Process Server, WebSphere Lombardi Edition, and other enterprise resource planning software.

"IBM Industry Toolboxes for WebSphere Portal" on page 37
Industry Toolboxes for WebSphere Portal provide a resource forum for customers and partners. They pair technology expertise with industry thought leadership to offer best-practice guidance optimized for the particular business you are in.

"Application integration" on page 38
A portal provides access to content, data, and services that are located throughout the enterprise. These services include predefined connectors and portlets, and tools for creating additional connectors and portlets.

Web application bridge integration

Use the *Web Application Bridge* to integrate with web applications, such as Sharepoint.

The web application bridge uses reverse proxy technology to integrate web-based content providers, such as the Microsoft SharePoint server, with IBM WebSphere Portal Express. Administrators must first define the virtual web applications or content providers. A lightweight iFrame portlet displays the content from the backend applications. Users can then access the iFrame on a page without requiring direct network access to the backend application. A special engine maps the Uniform Resource Identifiers (URIs) on the iFrame portlet to real URIs from the content providers.

Integrating the web application bridge with WebSphere Portal Express is a multistep process. First, create the content provider profile. Second, create at least one policy for each content provider profile. Then, create the web dock applications for the content providers. Finally, add the web dock application portlets to a new or existing page.

Related concepts:

IBM Industry Toolboxes for WebSphere Portal

Application integration

A portal provides access to content, data, and services that are located throughout the enterprise. These services include predefined connectors and portlets, and tools for creating additional connectors and portlets.

Enterprise resource planning (ERP) and customer relationship management (CRM) systems are excellent candidates for portlets because efficient, personalized access to these functions provides measurable return on your portal investment. IBM provides connectors to enterprise applications by using the Java Connector Architecture (JCA).

Standard Java connectors

JCA is a standard architecture for integrating Java 2 Enterprise Edition (J2EE) applications with enterprise information systems that are not relational databases. Each of these systems provides native APIs for identifying a function to call, specifying its input data, and processing its output data. The goal of the JCA is to provide an independent API for coding these functions.

JCA also defines a standard Service Provider Interface (SPI) for integrating the transaction, security, and connection management facilities of an application server with those of a transactional resource manager. Thus, JCA is a standards-based approach to managing connections, transactions, and secure access to enterprise application systems. IBM JCA connectors provide access to systems such as SAP, PeopleSoft, J.D. Edwards, Oracle Enterprise Edition, CICS, IMS, and Host-on-Demand. Leveraging its CrossWorlds acquisition, IBM plans to develop and integrate JCA connectors to many other systems.

Rational Application Developer provides a complete development and unit test environment for applications that use JCA connectors, Web services, and microflows. Rational Application Developer tools include support for Web Service Definition Language (WSDL), developer versions of the connectors, the Web Services Invocation Framework (WSIF), and the microflow engine.

Mobile

A portal is a website that provides users with a single point of access to Web-based resources by aggregating those resources in one place and by requiring that users log in only to the portal itself, and not to each portlet they use. WebSphere Portal Express can also deliver Web content to WAP-enabled devices, i-Mode phones, Smart phones, and to various Web browsers. In addition, the IBM Mobile Portal Accelerator multi-channel server and mobile device repository extends portal content dynamically to over 7000 mobile devices, with new updates and devices added as they reach the market.

"WebSphere Portal Mobile Experience" on page 39
Pages are optimized on smartphones, desktops, or almost any device. This optimization is made possible with the WebSphere Portal Mobile Experience, IBM Web Experience Factory smartphone builders, or the Mobile Portal Accelerator.

"Mobile Portal Accelerator" on page 39
If your site needs to support a broad range of mobile devices, the Mobile Portal Accelerator provides a mobile multi-channel server solution. Mobile Portal Accelerator offers a multi-channel server and mobile device repository capable

of automating web page presentation to over 8,400 mobile devices. Each of those devices can be optimized to the display and services capabilities that include smartphones, tablets, handheld phones, and kiosk devices. Site developers can write the content. Then, the multi-channel server solution automates the presentation for optimized display on thousands of mobile devices.

"Development tools"
Both IBM Web Experience Factory and IBM Rational Application Developer include functionality to help you develop exceptional web experiences for your mobile site visitors.

WebSphere Portal Mobile Experience

Pages are optimized on smartphones, desktops, or almost any device. This optimization is made possible with the WebSphere Portal Mobile Experience, IBM Web Experience Factory smartphone builders, or the Mobile Portal Accelerator.

The Mobile Experience demonstrated how to use a lightweight architecture that provides exceptional performance on mobile devices. You can start with the included sample code and then customize it to meet your specific business needs.

The Mobile Experience includes:

Sample mobile navigation widgets that follow common mobile application navigation patterns

Sample mobile page layouts that demonstrate common content interaction patterns

The Mobile Experience is available on the IBM Lotus and WebSphere Portal Business Solutions Catalog.

Development tools

Both IBM Web Experience Factory and IBM Rational Application Developer include functionality to help you develop exceptional web experiences for your mobile site visitors.

Web Experience Factory

Web Experience Factory includes new smartphone builders and samples to help developers generate mobile portlets and pages faster. Automation components include:

Native-looking navigation tabs, lists, buttons, and controls

Scrolling lists with display options, such as thumbnails and multiple line test with multiple styles

Access to smartphone features, such as HTML 5, orientation, and geographical location

Input UI patterns appropriate for smartphones, such as selectable lists and check box lists

Rational Application Developer

Rational Application Developer includes tools designed to help you develop portlet applications for WebSphere Portal Express. The portlet tools provide the following capabilities:

- Portlet project support for the standard portlet API.
- Web perspective views and editors for developing portlets.
- Portlet project wizard to create basic portlets, Faces portlets, and Struts portlets.
- Editing and validation of the portlet deployment descriptor (portlet.xml).
- Testing and debugging of portlets within the workbench using the WebSphere Portal Test Environment.
- Testing and debugging of portlets on a remote machine using the WebSphere Portal Server Attach.
- Visual tooling to insert portlet programming objects into JSP files, using Page Designer.
- Portlet sample applications, available in the Samples Gallery.
- Educational tutorials, available in the Tutorials Gallery.

Web Experience Factory 8 Documentation

Versatile framework

IBM WebSphere Portal Express provides users a consistent view of portal applications and allows users to define specific sets of applications that are presented in a single context. Depending on the requesting device, the rendering of this application set must vary to fulfill the requirements of the device.

The tasks of the aggregation, which are repeated with each request that comes from the device, are:

- Gather information about the user, the device, and the selected language.
- Select the active portlets from the set of applications to which the user has access.
- Aggregate the output of the active portlets into a coherent, usable display.

WebSphere Portal Express also provides the ability to create a custom navigation model, which includes such features as:

- Multilevel navigation
- Customized themes and skins

- Custom navigation - navigation tree can be contributed to by portlets themselves
- Custom arrangement of portlets (and thus content) on a page

Another aspect of the versatile framework is the ability to personalize a user's portal experience, using "content spots" that render subscribed content based on the user and user's role in the portal.

"User experience"
Customizing the user's experience is one of the main goals of IBM WebSphere Portal Express. User and administrative portlets are provided for customizing content and the look and layout of pages.

User experience

Customizing the user's experience is one of the main goals of IBM WebSphere Portal Express. User and administrative portlets are provided for customizing content and the look and layout of pages.

Customizing pages

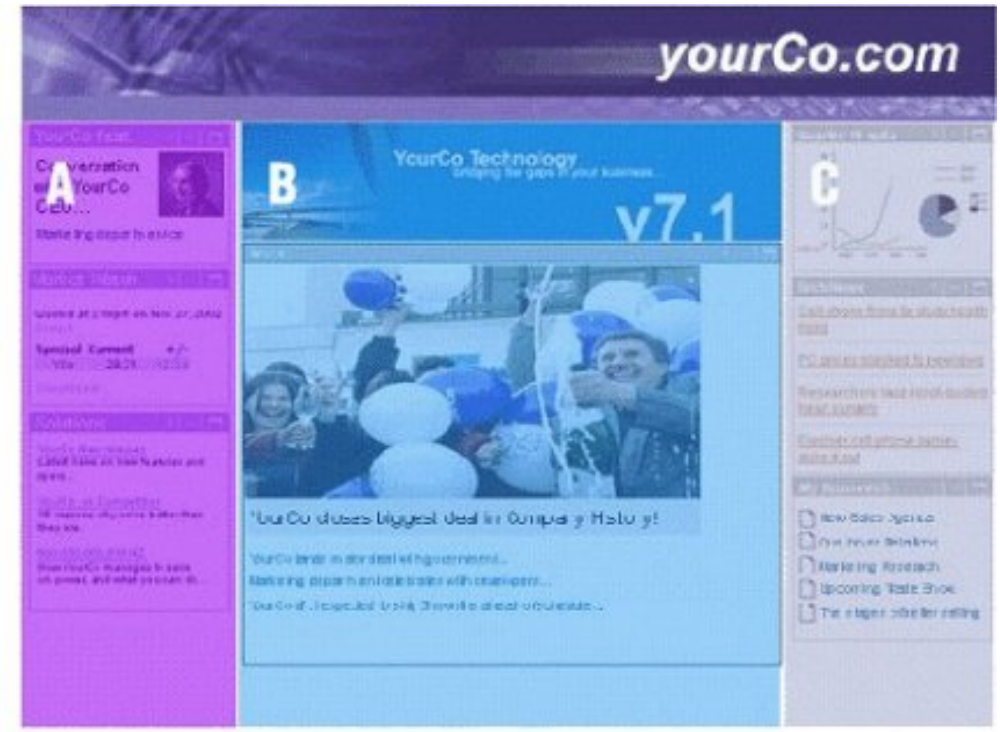
Users can have one or more custom pages and access each one through a different page. A page can contain a group of pages that is organized for a specific purpose. Each page can have a different set of portlets. Depending on authorizations, users can change the look and feel of their pages by using skins and page layouts. Also, page navigation hierarchy is tree-based, allowing any depth of nested pages.

The user or an administrator can set up the contents of each page. Administrators can specify that certain portlets be required, so that users are unable to move them or to remove them from the pages. Each page can have its own color scheme and column layout.

Cascading authorization

An administrator can grant or revoke access to customize a page or portion of a page to other administrators or users. The administrator can determine user's rights to modify a page. Administrators can control the edit authority that other administrators have on a page and its contents. This is designed to help organizations enforce policies and consistency, and create region-specific portals with some centrally managed content. This control is best explained through an example.

The first administrator can determine that a page will have three columns and not allow the column layout to be modified by any other administrators. A second administrator with lesser access cannot modify the column layout but can add portlets to these columns. The following figure shows a page split into three columns. Administrators can add portlets to these columns.



The second administrator adds a stock portlet to column one and a company news portlet to column two. This administrator wants these portlets to be available to everyone and does not want them to be removed. However, the administrator can add portlets to the columns. Therefore, the portlets are locked and cannot be removed by other administrators with lesser access. The following figure shows an example of how cascading authorization from one administrator to another would look.

Skins and themes

WebSphere Portal Express uses html, cascading style sheets, images, and other standard web design artifacts to define the look of pages. Java Server Pages (JSP) and other server-side dynamic techniques can also be used to help define the look of a site. You can add or modify elements to control visual aspects of WebSphere Portal Express, perhaps to add company-specific brand elements or to achieve a different color scheme and visual style. The system for defining color themes and skins supports multiple skins per theme, additional branding elements, navigation styles, and dynamic, browser-independent cascading style sheets.

You can apply skins and themes to a page, not only to the overall product. You can apply different skins individually to portlets as well, so that the appearance of a portal can be fine-tuned to meet any user need. By using a different theme for each page, a single installation can give the appearance of supporting many virtual portals.

Branding elements

You can change all visual elements of WebSphere Portal Express, including the masthead, the navigation areas, graphics, portlet title areas, and style sheets, to give WebSphere Portal Express a custom look. You can use standard file formats, such as JPEG, GIF, CSS, and JSP files, to define the look and layout.

The structure of the component installation folder contains folders named "skin" and "theme," with folders "html," "wml," and "chtml." These folders contain most of the files that are used for defining the basic structure of the home page, its color schemes, and portlet decorations. Portal designers can copy these folders and modify their contents to create a custom look and feel. The theme administration portlet registers the new files.

Changing portlet layout

You can change the placement of individual portlets on a page by using the drag-and-drop feature. To rearrange a portlet on a page, click the title bar of the portlet and then drag the portlet to a new location on the page. You can also add portlets to the page for quick and easy page customization by dragging portlets from the Portlet Palette to the page.

Universal access

The system of page templates, themes, skins, and portlet rendering is fully enabled for internationalization and accessibility by people with disabilities. For globally accessible portals, WebSphere Portal Express searches for and selects the proper JSP pages, based on the target browser and its settings for language and country.

Types of websites

Different types of websites require different solutions and use different applications and features. These examples describe details of different websites and the types of applications and features that are required to deliver them.

"Intranet portal"
An intranet portal site is designed to allow information to be quickly disseminated to employees, to make common internal business processes more efficient and to provide a sense of community within an organization.

"E-business site" on page 47
An e-business site is an externally facing site that is designed to market a company's products and services to consumers and allow them to purchase these items online. The focus of the site is on helping consumers match their needs to the appropriate product or service and maximizing their purchases.

"Brochure-ware site" on page 48
A brochure-ware site is an externally facing site that acts as an organization's presence on the World Wide Web. The overriding focus is on representing the organization's brand to its potential customers.

"E-library site" on page 49
An online library site is dedicated to providing access to a large amount of content. The prime example is a news site, where new content is created throughout the day, every day of the week and is published online and then archived as it becomes out of date. Other examples include journals, analyst reports, and software libraries.

"Partner site" on page 50
The audiences for a partner site are the partners of an organization. The site provides information and applications that are not applicable to the broader audience of consumers. A partner site would typically require a login but would not use an automated registration system. The business partners would be known to the company and given a login to access the partner site.

Intranet portal

An intranet portal site is designed to allow information to be quickly disseminated to employees, to make common internal business processes more efficient and to provide a sense of community within an organization.

The site provides access to:

- News about what is happening within the organization.
- Alerts that contain information that employees should be aware of and potentially action.
- Forms for working with various internal processes such as leave, purchases, and travel.
- A policies and procedures library with online versions of all policy and procedure documentation.
- Organizational communities with collaborative features like blogs and forums.
- A search system to enable employees to find content.

The intranet portal also has a personalized home page that is dynamically built by using a set of rules that retrieve content based on the current user's role, department, and location. By tagging the content, and then matching this content with the current user, only content that is appropriate for the current user is displayed.

A number of components are used together to make this intranet portal work:

- WebSphere Portal is used to provide a platform for the integration of content and applications that form the intranet portal.
- The overall theme and top-level navigation of the intranet is also managed by using WebSphere Portal.
- Web Content Manager provides the micro-level layout of the content within the portal, and is also used to directly build the news, alerts, and communities content.
- The forms are online applications that are built by using the Forms/Lists system, being pulled into the site by using Web Content Manager
- Policies and Procedures are document libraries managed using IBM FileNet Content Manager.
- A custom feed producer would be written to allow the Web Content Integrator to consume a feed from IBM FileNet Content Manager and Web Content Manager would be used to present the documents in a website.
- Personalization is used to associate content with users, dynamically generating the content that is displayed in the personalized home page
- A third-party discussion system is used to deliver collaborative forums in the communities section of the site using a custom portlet.
- WebSphere Portal search is used with the Web Content Manager categorization to provide both a simple text search and a more advanced category-based search.

The size of an intranet portal tends to scale with the size of the organization. A large organization has more information to disseminate, more business processes, more communities of employees. This means that the content and the user population tend to grow at the same rate.

Related concepts:

"Roadmap to building a web content system" on page 1781
To build a web content system you need to deploy hardware, configure servers, design an authoring system, configure a delivery environment and enable syndication. Get an overview of the steps required to build your web content system. Keep in mind the analysis and design documents developed during the planning phase of a project as you review the roadmap.

"IBM Web Content Integrator" on page 1936
The Web Content Integrator is a solution for integrating externally managed web content with WebSphere Portal Express. By using standard content syndication feed technologies based on RSS 2.0, the Web Content Integrator provides a loosely coupled mechanism for transferring published content and metadata to the portal after they are approved in the source system. When the content and metadata are transferred to the portal, it is possible to use the built-in content management features of Web Content Manager to secure, personalize, and display the content to users.

"Targeted content and Portal Personalization" on page 28
Targeted content provides you with a way to deliver multiple pieces of content to different audiences. Targeted content matches the best content with the most appropriate group by using segments. Segments help you split your audience into meaningful groups with different interests or characteristics.

Related information:

FileNet Content Manager

E-business site

An e-business site is an externally facing site that is designed to market a company's products and services to consumers and allow them to purchase these items online. The focus of the site is on helping consumers match their needs to the appropriate product or service and maximizing their purchases.

The site provides:

- Press releases about the latest news about the company's products and services.
- A promotions area with information about products and services that include sales, special package deals, and discounts.
- A products and services catalog area with the entire catalog displayed as a searchable taxonomy.
- A shopping area where users can see:
  - A searchable list of available products and services available for purchase online.
  - A summary of the items they are intending to purchase.
  - An area to calculate tax, shipping, and other costs.
  - An area to purchase these items online using mail order, or by using a follow-up call from a salesperson.
  - An area to track orders they initiated.
- Articles where the organization can help customers by using articles that discuss their products and services.
- A support area with technical documentation, contact numbers, support request forms, FAQs, and downloads.
- A service for subscribing to a newsletter where the user is sent a regular update that highlights new promotions, products, or articles.

The home page of the site is used to highlight the latest promotions, and to give a strong sense of the brand of the organization. Throughout the site, collaborative filtering is used to help suggest products and services to consumers based on their purchasing and navigational activity. A discussion system can also be used to allow users to build a community where they can comment on and rate various products and services.

A number of components are used together to build the e-business site:

- WebSphere Portal is used to provide a platform for the integration of content and applications that form the e-business site.
- The overall theme and top-level navigation of the intranet is also managed by using WebSphere Portal.
- Web Content Manager provides the micro-level layout of the content within the site, and is also used to directly build the press releases, FAQs, articles, and promotional content.
- The catalog and shopping areas are being run by using WebSphere Commerce.
- Personalization is used to suggest products to users based on collaborative filtering, and to email the newsletter.
- A third-party discussion system is used to deliver collaborative forums in the communities section of the site by using a custom portlet.

An e-business site can generate a large amount of traffic with a relatively small amount of content.

Designing and setting up a portal site
WebSphere Portal Express 7 provides improved page builder and improved client side rendering and has a new default portal theme, the Page Builder theme. Themes define how your portal site will look. After installation, a default theme is deployed and you can either customize that theme or create your own. The new themes approach introduced in 7 involves less editing of JSPs and allows you to mix iWidgets and portlets on the same portal page and take advantage of both client side and server side rendering mode. WebSphere Portal 7 continues to support other themes, including your custom themes. If you have an existing portal site you can continue to use your existing themes or you can migrate your themes to the new standard.

"Roadmap to building a web content system" on page 1781
To build a web content system you need to deploy hardware, configure servers, design an authoring system, configure a delivery environment and enable syndication. Get an overview of the steps required to build your web content system. Keep in mind the analysis and design documents developed during the planning phase of a project as you review the roadmap.

"Targeted content and Portal Personalization" on page 28
Targeted content provides you with a way to deliver multiple pieces of content to different audiences. Targeted content matches the best content with the most appropriate group by using segments. Segments help you split your audience into meaningful groups with different interests or characteristics.

Brochure-ware site

A brochure-ware site is an externally facing site that acts as an organization's presence on the World Wide Web. The overriding focus is on representing the organization's brand to its potential customers.

This type of site is relatively static and does not need the aggregation capabilities of WebSphere Portal and is instead delivered by using both the servlet delivery and pre-rendering features of Web Content Manager. The site is also designed to be easily indexed by search engines like Google.

This site would include:

- Information about the organization that includes its ethics, goals, mission, and history.
- A news area where the organization can talk about what they are doing now and into the future.
- A contact area with lists of locations, phone numbers, and online contact forms where users can submit queries, ask for follow-up calls.
- A job opportunities area where an organization can advertise positions
- A partners area where partners of the organization are listed with information about them and their relationship with the organization, and links to partner websites and partner contact details
- Information about the organization's products and services that includes case studies and testimonials

The components in this site are limited with Web Content Manager providing all the presentation, navigation, and content.

A brochureware site can generate a large amount of traffic with a relatively small amount of content.

E-library site

An online library site is dedicated to providing access to a large amount of content. The prime example is a news site, where new content is created throughout the day, every day of the week and is published online and then archived as it becomes out of date. Other examples include journals, analyst reports, and software libraries.

Users would typically register for these sites, and might then be sent emails regularly summarizing the latest content. On a news site, the latest news might be free, but users might pay for access to archived content. On other types of "library" sites, users might pay for access to any of the content.

A number of components are used together to deliver an e-library site:

- WebSphere Portal is used to provide a platform for the integration of content and applications that form the e-business site.
- The overall theme and top-level navigation of the intranet is also managed by using WebSphere Portal.
- Web Content Manager provides the micro-level layout of the content within the site, and is also used to directly build content.
- For e-libraries where the content is presented as documents, then IBM FileNet Content Manager would be used to store and manage the documents.
- A custom feed producer would be written to allow the Web Content Integrator to consume a feed from IBM FileNet Content Manager and Web Content Manager would be used to present the documents in a website.

An e-library site might have a large audience and a large amount of content.

"IBM Web Content Integrator" on page 1936

The Web Content Integrator is a solution for integrating externally managed web content with WebSphere Portal Express. By using standard content syndication feed technologies based on RSS 2.0, the Web Content Integrator provides a loosely coupled mechanism for transferring published content and metadata to the portal after they are approved in the source system. When the content and metadata are transferred to the portal, it is possible to use the built-in content management features of Web Content Manager to secure, personalize, and display the content to users.

Partner site

The audiences for a partner site are the partners of an organization. The site provides information and applications that are not applicable to the broader audience of consumers. A partner site would typically require a login but would not use an automated registration system. The business partners would be known to the company and given a login to access the partner site.

A partner site can include the following areas:

- A news area that is focused on partners. Larger organizations that work in multiple areas of business might personalize the news area to suit each partner.
- A promotions area that details special deals for partners.
- Online services, providing useful tools and resources for partners to use, such as calculators, forms, and catalogs.
- A billing area where partners can see the current bill status for services that are contracted from the organization.
- A community area where partners might post information about themselves, and also interact to help each other and receive help from the organization.

A number of components are used together to deliver a partner site:

- WebSphere Portal is used to provide a platform for the integration of content and applications that form the intranet portal.
- The overall theme and top-level navigation of the intranet is also managed by using WebSphere Portal.
- Web Content Manager provides the micro-level layout of the content within the portal, and is also used to directly build the news and promotions content.
- Various IBM products plus third-party applications are used to build and deploy the online services area.
- The catalog and billing services in the site is run by using WebSphere Commerce.
- A third-party discussion system is used to deliver collaborative forums in the communities section of the site by using a custom portlet.
- Personalization is being used to filter content throughout the site to ensure that the appropriate content and inline services are reaching the appropriate partners.

A partner site is likely to have a limited audience but a large amount of content.

Accessibility features

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use software products successfully.

Accessibility by people with disabilities A US Section 508 Voluntary Product Accessibility Template (VPAT) can be requested with the IBM accessibility website. IBM Digital Experience offerings use the newest W3C Standard, WAI-ARIA 1.0 to ensure compliance to US Section 508 and Web Content Accessibility Guidelines (WCAG) 2.0. The best accessibility experience is provided by using the newest release of the browser and the newest release of the screen reader. For more information, see the following URLs:

- Accessible Rich Internet Applications (WAI-ARIA) 1.0
- Section 508 Standards for Electronic and Information Technology
- Web Content Accessibility Guidelines (WCAG) 2.0

Updated IBM Digital Experience V8.5 offerings include the following products.

- IBM Customer Experience Suite V8.5
- IBM Customer Experience Suite Rich Media Edition V8.5
- IBM Employee Experience Suite V8.5
- IBM Portal Server V8.5
- IBM Portal Enable V8.5
- IBM Portal Express V8.5
- IBM Web Content Manager V8.5
- IBM Web Content Manager Rich Media Edition V8.5
- IBM Web Content Manager Standard Edition V8.5

- IBM Content Accelerator V8.5
- IBM Content Accelerator and WebSphere Portal V8.5

This version of IBM WebSphere Portal Express:

- Supports installation through a command-line interface known as *console mode*. It is the accessible equivalent of installing by using the graphical user interface.
- Supports interfaces commonly used by screen readers and screen magnifiers (Windows only)
- Supports use of screen-reader software and digital speech synthesizers to hear what is displayed on the screen.
- Can be operated with only the keyboard
- Allows the user to request more time to complete timed responses
- Supports customization of display attributes such as color, contrast, and font size
- Communicates all information independently of color
- Supports the attachment of alternative input and output devices
- Supports alternatives to audio information
- Supports adjustable volume control
- Does not flash the screen at rates that can induce epileptic seizures
- Provides documentation in an accessible format

Supported browser: Firefox 25.

Recommended screen reader: JAWS 15.

The documentation includes the following features to aid accessibility:

- All documentation is available in HTML formats to give the maximum opportunity for users to apply screen-reader software technology.
- All images in the documentation are provided with alternative text so that users with vision impairments can understand the contents of the images.

When appropriate, the documentation for specific product features contains more information about accessibility.

See the related links for information about IBM's commitment to accessibility.

Chapter 2. Tutorials

Explore the following tutorials to learn more about using the IBM WebSphere Portal Express features.

"Tutorial: Creating and publishing content "
This tutorial demonstrates how you can use pages, projects, and workflow to create and approve draft pages. After approval, changes are published to a delivery server with syndication.

Related information:

Getting Started with Your Digital Web Experience

Tutorial: Creating and publishing content

This tutorial demonstrates how you can use pages, projects, and workflow to create and approve draft pages. After approval, changes are published to a delivery server with syndication.

During the tutorial, you will use different parts of the portal user interface. Most actions originate for the site toolbar.

Figure 1. Screen capture of the site toolbar with annotations.

1 Menu options

There are three menu options: Site, Application, and Administration.

Use the **Site** menu to switch between the sites that are hosted on a single portal server.

Use the **Application** menu to access application such as Content, Collaboration, Messaging, Personalization, and Unified Task List.

Use the **Administration** menu to access the administration portlets.

2 Toolbar

The toolbar provides access to authoring tools such as **Projects**, **Create**, and **Page**.

From the Projects tab, the content authors can create new projects to manage multiple changes. The tab displays the content that has been created or changed in the website for that project. Each content item can be managed individually. The content author can also create project templates.

From the Create tab, content authors can create pages, add applications to a page, or add content to a page. The content shelf contains Web Content Viewer portlets that are preconfigured with content associations. When the content author drags content to the page, a copy of the associated content is added to the page. Then the content author can customize the content.

From the Page tab, content authors can view and modify page settings, such as layout, vanity URLs, and more.

3 Project indicator

The project indicator provides access to the project menu and displays the currently active project. If there is no active project, then the indicator shows "Published Site" and you are viewing the currently published website.

4 Edit Mode

Use the **Edit Mode** control to turn editing capability on and off.

5 Information Mode

Turns inline user assistance on and off. Inline assistance includes descriptions and examples that appear in the user interface and hover help.

Currently this mode is only implemented in the site toolbar.

6 Menu

Provides access to additional page and preview actions.

Page actions include: View Page Properties, Show Hidden Pages, Show Hidden Content, Move Page, and Delete Page.

Preview actions include: Preview as a specific user and preview as an unauthenticated user.

Contents

When the project is submitted, SiteAdmin publishes the project, and the changes are then available for all users on the authoring server.

"Step 7. Syndicate changes to delivery server" on page 66

After SiteAdmin publishes the project, the updates are ready for syndication to the delivery server. Although syndication runs at scheduled intervals, SiteAdmin accesses the delivery server and manually starts the syndication process.

Create users and groups

The tutorial uses multiple user roles to demonstrate how content is created and flows through the system. To complete the steps in the tutorial as they are documented, you must create the groups and user IDs.

About this task

This tutorial uses the following user roles, IDs, and group assignments.

Table 3. User roles in this tutorial and their related user IDs and group assignments

User Role	User ID	Group
Site administrator	SiteAdmin	wpsadmins This group already exists and you do not need to create it.
Content author	Author1	ContentEditors
Content reviewer	Reviewer1	ContentReviewers
Content approver	Approver1	ContentApprovers

The tutorial highlights four user roles, the site administrator, content author, content reviewer, and content approver. Each user role performs specific tasks in the tutorial.

Site administrator (SiteAdmin)

The site administrator has administrator privileges in the portal and in Web Content Manager. SiteAdmin is part of the user group wpsadmins, and does these tasks:

- Sets up workflow stages and creates a custom workflow.
- Creates a page template that uses the custom workflow.
- Specifies access control settings where needed.
- Sets up a syndication relationship between the authoring server and the delivery server.
- Publishes projects for syndication.

Content author (Author1)

The content author is responsible for a certain portion of the site and can create pages as needed. In addition the content author adds and edits content on those pages. Author1 is part of the user group ContentEditors.

Content reviewer (Reviewer1)

Reviewer1 reviews changes submitted by content authors and either approves or rejects the individual changes. Upon approval, Reviewer1 submits the complete project for approval. Reviewer1 is part of the group ContentReviewers.

Content approver (Approver1)

Approver1 oversees changes to the site and is responsible for approving projects for publishing. Approver1 is part of the group ContentApprovers.

Procedure

1. Click the **Administration menu** icon. Then, click **Access** > **Users and Groups**.
2. Click **All Portal User Groups**.
3. Click **New Group** and type `ContentEditor` as the **ID**. Repeat this step to create ContentReviewers and ContentApprovers.
4. Click **ContentApprovers** to open the group. Then click **New User** to create Approver1.
5. Click **All Portal User Groups** in the breadcrumb.
6. Click **ContentEditors** to open the group. Then click **New User** to create Author1.
7. Click **All Portal User Groups** in the breadcrumb.
8. Click **ContentReviewers** to open the group. Then click **New User** to create Reviewer1.
9. Click **All Portal User Groups** in the breadcrumb.
10. Click **wpsadmins** to open the group. Then click **New User** to create SiteAdmin.

Step 1. Set up library access

Before the content authors, editors, and approvers can get started, the SiteAdmin must grant library access to content authors and approvers.

About this task

In this step, access is defined for the following libraries:

Portal Site
: Page objects and content for pages are stored in the Portal Site library. Contributor access is required for the ContentEditors group.

Web Content
: The custom workflow and workflow stages are stored in the Web Content library. Contributor access is required for the ContentEditors, ContentReviewers, and ContentApprovers groups.

Procedure

1. Log in as SiteAdmin.
2. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.
3. Set **permissions** for the Portal Site library.
   a. Click the **Set permissions** icon for the Portal Site library.
   b. Click the **Edit Role** icon for the Editor role.
   c. Click **Add**. Then, click **Search** to show all groups.
   d. Select the **ContentEditors** group.
4. Click **Portal Content** > **Web Content Libraries**.
5. Set **permissions** for the Web Content library.
   a. Click the **Set permissions** icon for the Web Content library.
   b. Click the **Edit Role** icon for the Contributor role.
   c. Click **Add**. Click **Search** to show all groups.
   d. Select the **ContentEditors**, **ContentReviewers**, and **ContentApprovers** group.

What to do next

Remember: In addition to appropriate access to libraries, content authors require Editor access to any pages and portlets that are involved. This access enables authors to create pages and add portlets to pages. This tutorial relies on sample content with predefined access. However, if you use your own content, ensure that you specify sufficient access on these resources in the portal so authors can work with them.

Step 2. Set up syndication

Updates to pages and content are transferred from the authoring server to the delivery server with syndication. When you publish a project, you can use syndication to automatically publish new pages and content updates. To enable this behavior, SiteAdmin sets up syndication between the required web content libraries of the two servers.

About this task

In this syndication relationship, the delivery server is the subscriber, and the authoring server is the syndicator.

Procedure

1. Log in to the delivery server as an administrator.
2. Create a shared credential vault slot for accessing the syndicator.
   a. Click the **Administration menu** icon. Then, click **Access** > **Credential Vault**.
   b. Click **Add a vault slot**.
   c. Enter a name for the vault slot. For example, `syndication-slot`.
   d. Click **new**, and enter a vault resource to associate with the slot. For example, `syndication-resource`
   e. Click **Vault slot is shared**, and enter the user ID and password to access the slot from the authoring server. This user ID and password must be defined on the authoring server. This tutorial uses the credentials for SiteAdmin.
   f. Click **OK**.
3. Then, click **Portal Content** > **Subscribers**.
4. Click **Subscribe Now**.
5. Specify the details for the syndicator and subscriber.
   a. In the **Syndicator URL** field, enter the URL to access the authoring server.

      This URL takes the form `http://hostname:port_number/wcm_context_root`. The default context root for Web Content Manager is `wps/wcm`. For example:

      `http://www.example.com:10039/wps/wcm`
   b. In the **Syndicator Name** field, enter a name to identify the authoring server in the syndication relationship. This name is used for the syndicator item that is created on the authoring server.
   c. In the **Subscriber Name** field, enter a name to identify the delivery server in the syndication relationship. This name is used for the subscriber item that is created on the delivery server.
   d. In the **Credential Vault Slot** field, select the credential vault slot that you created previously. For example, `syndication-slot`
   e. Click **Next**, and select the libraries that you want to syndicate.

      The following libraries are needed for this tutorial:

      - Portal Site: Contains page artifacts and related content.

- Web Content: Contains workflow items.
- Web Content Templates 3.0: Required for sample web content items.
- Template Page Content 3.0: Required for sample web content items.

For each library, select **Live items** in the **Scope** field.

f. Click **Finish**.

g. To verify the syndication connection, click the **Test connection** icon.

Step 3. Create workflow

Pages that are created in this tutorial are subject to custom workflow that is attached to the page template. Before the SiteAdmin creates the page template on the authoring server, the SiteAdmin creates the custom workflow to be used with new pages.

About this task

The custom workflow is stored in the Web Content library and is a simple, three-stage workflow that contains the following stages: Draft, Review, Publish. A Draft and Publish stage is available for immediate use. Therefore you only need to create the Review stage.

Table 4. Workflow stage access

Workflow stage	Access	Group	Description
Draft (already exists)	**Grant Manager Access**	ContentEditors	Enables authors to edit content that is in the draft state.
	Grant Reviewer Access	ContentEditors	Enables authors to move items to the next stage in the workflow.
Publish (already exists)	**Grant Draft Creator Access**	ContentEditors	Enables authors to create drafts of published content.
Review	**Grant User Access**	ContentEditors	Enables authors to view the status of content in the review stage.
	Grant Reviewer Access	ContentReviewers	Ensures that only reviewers can submit draft content for approval.

Procedure

1. Log in to the authoring server as SiteAdmin.
2. Create the Review workflow stage.
   a. Click the **Applications menu** and then click **Content**.
   b. Click the **Web Content Authoring** tab.
   c. Click **Web Content** > **Workflow Items** > **Workflow Stages**.
   d. Click **New** > **Workflow Stage**.
   e. Enter **Review Stage** for the workflow stage name.
   f. Click **Save and Close**.
3. Edit the access for Draft workflow stage.
   a. Click the **Draft** workflow stage.
   b. Click **Edit**.
   c. Expand **Workflow Defined Access** section.
   d. Click **Grant Manager Access**.
   e. Type `Co` in the search field and click **Search**.
   f. Select ContentEditors and click **Add**. Then click **OK**.
   g. Click **Grant Reviewer Access**.
   h. Type `Co` in the search field and click **Search**.

i. Select ContentReviewers and click **Add**. Then click **OK**.
j. Click **Save and Close**.

4. Edit the access for Publish workflow stage.
   a. Click the **Publish** workflow stage.
   b. Click **Edit**.
   c. Expand **Workflow Defined Access** section.
   d. Click **Grant Draft Creator Access**.
   e. Type `Co` in the search field and click **Search**.
   f. Select ContentEditors and click **Add**. Then click **OK**.
   g. Click **Save and Close**.
5. Edit the access for Review workflow stage.
   a. Click the **Review** workflow stage.
   b. Click **Edit**.
   c. Expand **Workflow Defined Access** section.
   d. Click **Grant User Access**.
   e. Type `Co` in the search field and click **Search**.
   f. Select ContentEditors and click **Add**. Then click **OK**.
   g. Click **Grant Reviewer Access**.
   h. Type `Co` in the search field and click **Search**.
   i. Select ContentReviewers and click **Add**. Then click **OK**.
   j. Click **Save and Close**.

   In the following example screen capture shows the access settings for Review workflow stage. The ContentEditors group is listed with User access, and the ContentReviewers group is listed with Approver access.

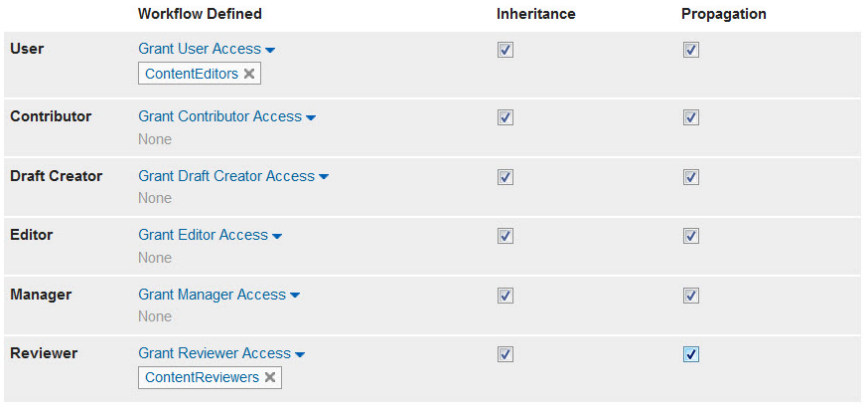

Figure 2. Screen capture of access settings for Review workflow stage.

6. Create the custom workflow named Workflow1.
   a. Click **Web Content** in the breadcrumb.
   b. Click **Workflow Items** > **Workflows**.
   c. Click **New** > **Workflow**.
   d. Enter **Workflow1** for the workflow name.
   e. In the **Workflow Properties** section, click **Add Workflow Stages**.
   f. Add the following stages: Draft Stage, Review Stage, Publish Stage.

g. Use the up and down arrows to order them accordingly: Draft Stage, Review Stage, Publish Stage. The following example screen capture shows the workflow of these stages.

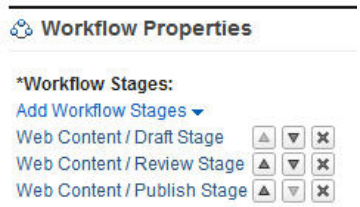

Figure 3. Screen capture of workflow stages in the Workflow1 workflow.

h. Save your changes.

Step 4. Create page template

SiteAdmin creates a page template that content authors can use to create pages.

About this task

Because page changes need to be approved before they are published in this tutorial, the SiteAdmin specifies a custom workflow (Workflow1) when they set page properties for the template. When a content author creates a page from the template, changes to the page are subject to the Workflow1 workflow.

Procedure

1. From the **Site** menu, click **Home** to go to the default site.
2. Click **Projects**.

   Tip: You can set a workflow only on items that are in a draft state. Because of this behavior, you must create the template as a draft in the context of a project. By working in a project, you can also verify the workflow to make sure that the stages behave as expected.
3. Type `New Template` and click **Create**.
   The new project is shown as the active project.

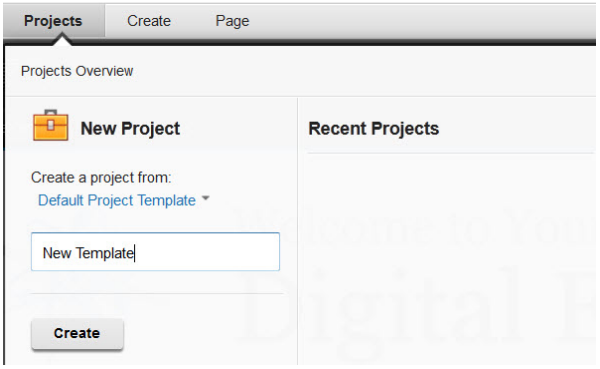

Figure 4. Screen capture of the open **Projects** *tab.*

Figure 5. Screen capture of the active project indicator.

4. Create the page template.
   a. Turn on **Edit Mode**.
   b. Click the **Administration menu** icon and then click **Portal User Interface**.

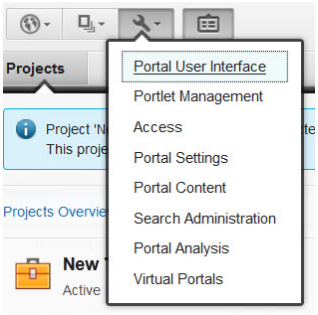

Figure 6. Screen capture of the **Administration menu**.

   c. Click **Page Templates**
   d. From the toolbar click **Create** > **Page**.
   e. Use the Basic template and type `Template1` as the page title of the new page template. You must be in Edit mode.
   f. Click **Create Page**. Parentheses around the page name indicate that the page is in a draft state. Close the toolbar in order to view the page.

Figure 7. Screen capture of the Template1 page.

5. Add the custom workflow to the page template.
   a. From the toolbar click **Page** > **General**.
   b. Click **Edit Page Properties**.

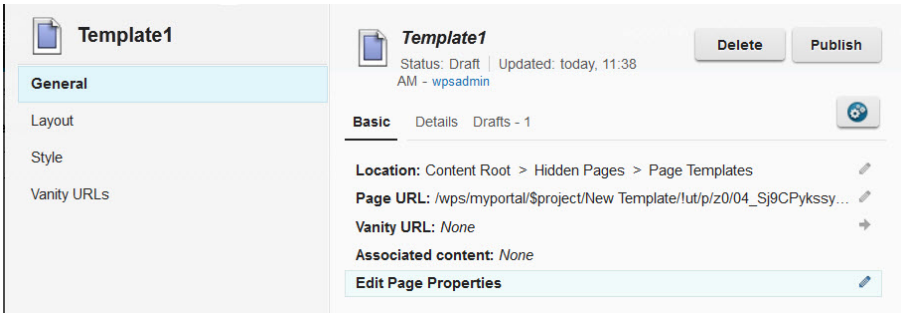

Figure 8. Screen capture of General section of the Page tab.

c. Click the **Security** tab.

d. For the Workflow, click **Select**. Click the Web Content library and select **Workflow1** and click **OK**.

   As soon as you select the workflow, the page draft enters the selected workflow. You can confirm the current workflow stage by examining the workflow properties. In this case, the Draft stage is the current stage and the Review stage is the next stage.

e. Close the Manage Page Properties dialog.

6. Complete the workflow for the draft template. Before you can publish the project and make the new page template available to users, you must move the template through the workflow.

   a. On the General page, click **Submit for Review**.

      Note: The **Submit for Review** button is only available to users that have Approver access on the current workflow stage.

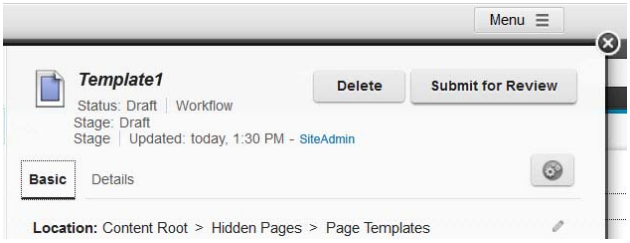

Figure 9. Screen capture of the Submit for Review button in the General view for the Page tab.

When you click **Submit for Review**, the draft item progresses to the next stage in the current workflow. In this scenario, the template moves to the Review Stage of the Workflow1 workflow. The General view displays the current workflow stage.

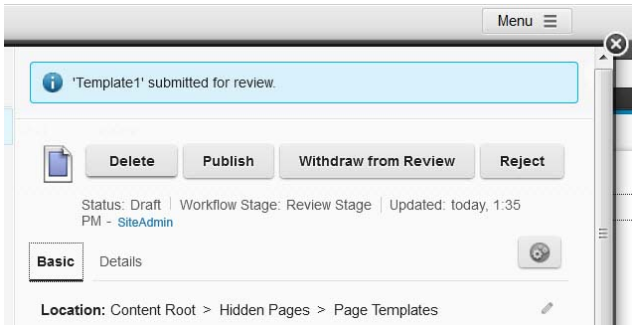

Figure 10. Screen capture of the General view of the Template1 page, showing the updated workflow stage.

b. Click **Publish** to move the template into the publish state.

7. Click **Projects**. With the **New Template** project as the current project, click **Publish**.

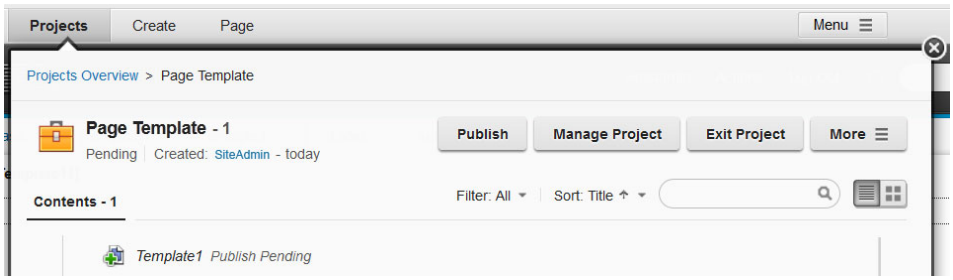

Figure 11. Screen capture of the General view of the Template1 page, showing the updated workflow stage.

8. After the project is published, you are taken out of the project context and restored to the published site. Template1 is listed with the other page templates on the Create Page tab.

What to do next

Important: Workflow changes are not dynamically applied to page templates that use the workflow. If you change the workflow or its stages after you publish the project that contains the template, repeat the steps to set the workflow:

1. Create a project.
2. Edit the page template, and specify the workflow again on the **Security** tab in the page properties.
3. Move the template through the workflow, and publish the project.

Step 5. Create page from template and submit changes for review

After SiteAdmin adds the Template1 page template, content authors can create pages from the template.

About this task

In this scenario, Author1 is responsible for the section of the website that is identified by a page called **News**. The **News** page itself was created by SiteAdmin and was based on the Template1 page template.

Procedure

1. Log in as Author1.
2. Create a project to manage updates.
   a. Open the toolbar and click **Projects**.
   b. Enter **News Section Update** as the project name.
   c. Click **Create**.
   d. Click **Manage Project**.
   e. Click **Edit**. Expand the **Approval** section and click **Add**.
   f. Search for Approver1 and add the user. When the project changes are reviewed and submitted, Approver1 can do the final approval of the complete project.

      Note on project approval: This review step is a separate review from the review of individual items in the project. Even if item workflow is complete for all items in the project, the updates cannot be published until the project is approved.
   g. On the **Properties** tab, expand the **Access** section.
   h. For the Editor access level, click **Grant Editor Access**.
   i. Search for the ContentReviewers group and add it. This access is needed to enable the reviewer to view the items in the project and do the approval steps.
   j. Click **Save and Close**.
3. Create the **News** page.
   a. Go to the **Home** page.
   b. From the toolbar, click **Create** > **Page**.
   c. Select the **Template1** page template, and type **News** for the name of the page.
   d. Click **Create Page**.

   Pages that you create in the portal are stored in the Portal Site library. For example, in this tutorial, when Author1 creates the **News** page, a corresponding site area is created in the Portal Site library. The path to the portal page site area includes the entire page hierarchy up to the content root:

   ```
   Content > Content Root > Home > News
   ```
4. Add the News page to the project. You can use access settings on the Publish stage of your workflow to enable authors to create drafts of published content by granting authors Approver access. This approach ensures that authors cannot directly edit published content. In this scenario, the ContentEditors group has Approver access on the Publish stage of the Workflow1 workflow. As Author1 is a member of the ContentEditors group, Author1 can create a draft of the **News** page.
   a. From the open project, News Section Update, click **More** > **Add to Project**.
   b. Click **Portal SiteContentContent RootHome**.
   c. Check **News** and click **Finish**.
   d. Close the Projects.
5. Create the **Business** page.
   a. Go to the **News** page.
   b. From the toolbar, click **Create** > **Page**.

Note: As Author1 has access only to the **News** page, the **Page** tab only lets you create a child page.

c. Select the **Template1** page template, and type **Business** for the name of the page.

d. Click **Create Page**.

Pages that you create in the portal are stored in the Portal Site library. For example, in this tutorial, when Author1 creates the **Business** page, a corresponding site area is created in the Portal Site library. The path to the portal page site area includes the entire page hierarchy up to the content root:

```
Content > Content Root > Home > News > Business
```

6. Add content to the **Business** page.
   a. Click **Content**.
   b. Click **Web Content** from the list of categories. The site toolbar shows a list of preconfigured Web Content Viewer portlets that you can add to the page.
   c. Add **Rich Text** and an **Image** to the page. Close the toolbar to see the new content on the page.
7. Click **Projects**. As you update the page and add content, the project information reflects the changes.

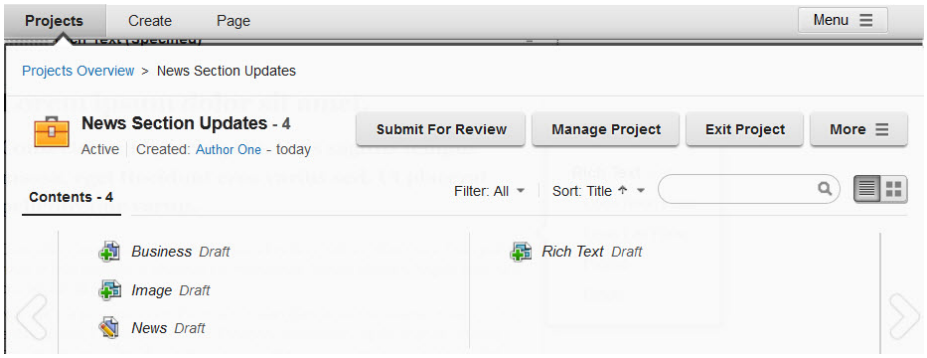

Figure 12. Screen capture of the project properties in the site toolbar, listing the recent items in the project that are updated.

8.

9. When content changes are complete, submit each item in the project for review.

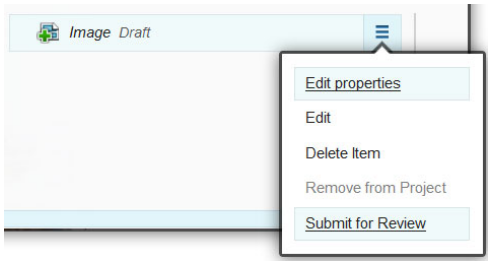

Figure 13. Screen capture of content item menu option listing the Submit for Review option highlighted.

Step 6. Approve and publish changes

After Author1 submits the changes in the **News Section Updates** project for review, Reviewer1 reviews the changes and submits the project for approval. Approver1 then accesses the project and approves the updates for publishing.

When the project is submitted, SiteAdmin publishes the project, and the changes are then available for all users on the authoring server.

Procedure

1. Reviewer1 opens the **News Section Updates** project in edit mode.
   a. Open the site toolbar and click **Projects**.
   b. Select **News Section Updates** from the list of projects.

      Note: The list of projects includes only those projects to which you have access.
   c. For each item, click **Publish**.

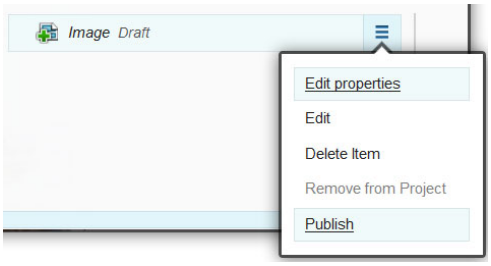

Figure 14. Screen capture of the content item menu with the Publish option highlighted.

2. Then Approver1, can open the **News Section Updates** project and approve the project.

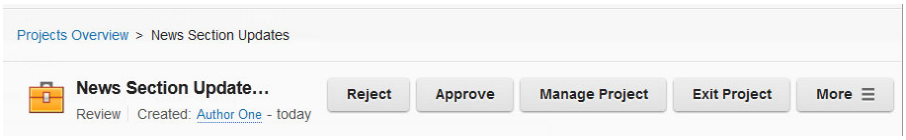

Figure 15. Screen capture of the buttons that are available in project overview to Approver1.

3. When the project changes are approved, SiteAdmin publishes the project by making the **News Update** project the current project and clicking **Publish** from the project menu.

Related tasks:

"Previewing as another user" on page 1922
You can preview changes to your website without logging out and logging on again as another user. This preview capability is used to quickly verify that users with different access levels see only content that they are authorized to see. You can preview changes as a specific user or as an unauthenticated user.

Step 7. Syndicate changes to delivery server

After SiteAdmin publishes the project, the updates are ready for syndication to the delivery server. Although syndication runs at scheduled intervals, SiteAdmin accesses the delivery server and manually starts the syndication process.

Procedure

1. Log in to the delivery server as an administrator.
2. Click the **Administration menu** icon. Then, click **Portal Content** > **Subscribers**.
3. For the syndication relationship to the authoring server, click the **Update subscriber** icon.

Results

After syndication completes, the delivery server is automatically updated with the **Business** page and its associated content.

Figure 16. Screen capture of the delivery server, with the new **Business** *page shown.*

Chapter 3. Roadmaps

Review the roadmaps to understand the common deployment patterns that are supported by the configuration wizard.

"Roadmaps for installation and deployment"
Installation and deployment roadmaps are designed for different environments, such as a development or authoring environment. The environment reflects how the server configuration is used. Under each environment is a topology. The topology describes how the server and other elements are arranged. Each roadmap includes a topology and high-level instructions for setting up the selected environment.

"Roadmap: Applying maintenance" on page 88
Portal maintenance is delivered through two mechanisms: individual fixes (iFixes) and combined cumulative fixes. iFixes are provided, when necessary, for severe or security-related bugs. Combined cumulative fixes are delivered on a regular schedule. They provide a mechanism to deliver fixes faster, improve existing features, deliver new features, update documentation, and provide new documentation on a frequent basis. To deliver continuous improvements for your digital experience software, it is recommended that you apply the latest combined cumulative fix to your environment.

"Roadmaps for migration" on page 92
Choose the appropriate migration roadmap for your environment.

"Roadmaps for integration" on page 97
Choose the appropriate integration roadmaps for your environment.

"Roadmaps for web content" on page 98
Some roadmaps to help you create and integrate web content into your site.

Roadmaps for installation and deployment

Installation and deployment roadmaps are designed for different environments, such as a development or authoring environment. The environment reflects how the server configuration is used. Under each environment is a topology. The topology describes how the server and other elements are arranged. Each roadmap includes a topology and high-level instructions for setting up the selected environment.

"Roadmaps for stand-alone servers"
A stand-alone server topology is useful for many environments. While the underlying topology is similar for many environments, the configuration steps to achieve a desired environment varies.

"Roadmap: Web content servers" on page 83
A web content server is ideal to create presentation templates, content components, and other presentation elements of your website. In this roadmap, the web server, database, and user registry software are distributed to different physical servers.

Roadmaps for stand-alone servers

A stand-alone server topology is useful for many environments. While the underlying topology is similar for many environments, the configuration steps to achieve a desired environment varies.

Roadmaps for WebSphere Portal Express are also available in IBM Knowledge Center. For WebSphere Portal Express roadmaps, see WebSphere Portal Express: Roadmaps for stand-alone servers.

"Roadmap: Demonstration environment"
This roadmap is ideal for running product, feature, and application demonstrations. After the installation, you have an Apache Derby database and a default file-based repository. You might not need to make any additional changes to your demonstration environment. If you need to demonstrate a specific database or user registry, use the Stand-alone server roadmap.

"Roadmap: Portlet and theme development environment" on page 72
A portlet and theme development server is ideal to develop and test portlets and themes.

"Roadmap: Test or small production environment" on page 75
A stand-alone server topology is ideal for a test or small production environment. In this roadmap, the web server, database, and user registry software are distributed to different physical servers.

"Roadmap: Failover environment" on page 79
Set up your IBM WebSphere Portal Express environment as an idle standby configuration for failover. Your idle standby cluster server is not operational to service user transactions or to query workloads. The idle standby cluster server becomes active only if the primary node fails.

Roadmap: Demonstration environment

This roadmap is ideal for running product, feature, and application demonstrations. After the installation, you have an Apache Derby database and a default file-based repository. You might not need to make any additional changes to your demonstration environment. If you need to demonstrate a specific database or user registry, use the Stand-alone server roadmap.

Who should use this roadmap

Use this roadmap if you are an organization with the following requirements:

- An organization that needs to explore new features or functions.
- An organization that needs to demonstrate Version 8.5 to customers, clients, or colleagues.
- An organization that needs an environment to demonstrate applications and designs.

Topology diagram

A demonstration environment is a portal server with a local database. Since Apache Derby is installed, configured, and ready for use, a database is not included in the topology diagram.

Preparing for the installation process

Gather information and software before you install WebSphere Portal Express.

Procedure

1. Check requirements.

   Documentation resource: Detailed system requirements

2. Get the software.

   Documentation resource: “Getting the software” on page 135

Installing the Exceptional Digital Experience

Installing WebSphere Portal Express involves preparing your operating system, installing or upgrading the installation manager, and running the installation program.

About this task

Documentation resource: “Installing the digital experience software” on page 167

Applying the latest cumulative fix

Portal maintenance is delivered through two mechanisms: individual fixes (iFixes) and combined cumulative fixes. iFixes are provided, when necessary, for severe or security-related bugs. Combined cumulative fixes are delivered on a regular schedule. They provide a mechanism to deliver fixes faster, improve existing features, deliver new features, update documentation, and provide new documentation on a frequent basis. To deliver continuous improvements for your digital experience software, it is recommended that you apply the latest combined cumulative fix to your environment.

About this task

Documentation resource: “Roadmap: Applying maintenance” on page 88

Tuning the servers in your environment

Tuning the servers is important to the performance of your portal environment. WebSphere Portal Express is not tuned for a production environment after installation and deployment. Your database needs tuning for improved performance. You can organize your database now or soon after you finish your configuration. You need to tune and maintain your database on a regular basis.

Procedure

Run the performance tuning tool to complete an initial tuning of your servers.

Documentation resource: "Portal server performance tuning tool" on page 240

Roadmap: Portlet and theme development environment

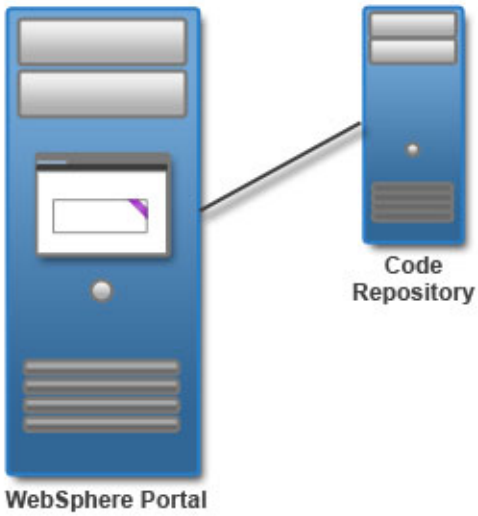
A portlet and theme development server is ideal to develop and test portlets and themes.

Who should use this roadmap

Use this roadmap if you are an organization that needs an environment to develop and test your portlets and themes before you go live to the server. Do not use this roadmap to develop web content. Go to "Roadmap: Web content servers" on page 83 to develop web content.

Topology diagram

The topology for a portlet and theme environment is the same as the demonstration environment. It includes a portal server with a local database. However, the software configuration is different. The topology diagram depicts a portal server that is connected to a code repository for group development. While the topology diagram depicts a server, the portlet and theme environment might be configured on a notebook.



Preparing for the installation process

Gather information and software before you install WebSphere Portal Express.

Procedure

1. Check requirements.

   Documentation resource: Detailed system requirements

2. Get the software.

   Documentation resource: “Getting the software” on page 135

Installing prerequisites

Before you install WebSphere Portal Express, install any prerequisites that are necessary for your environment. You can use existing prerequisite software installations. Verify that your existing version is supported. If it does not, upgrade to the appropriate version.

Procedure

1. Prepare a database server.

   Documentation resource: “Installing and preparing the database software” on page 149

2. Prepare a user registry.

   Documentation resource: “Preparing the user registry software” on page 158

Installing the Exceptional Digital Experience

Installing WebSphere Portal Express involves preparing your operating system, installing or upgrading the installation manager, and running the installation program.

About this task

Documentation resource: “Installing the digital experience software” on page 167

Applying the latest cumulative fix

Portal maintenance is delivered through two mechanisms: individual fixes (iFixes) and combined cumulative fixes. iFixes are provided, when necessary, for severe or security-related bugs. Combined cumulative fixes are delivered on a regular schedule. They provide a mechanism to deliver fixes faster, improve existing features, deliver new features, update documentation, and provide new documentation on a frequent basis. To deliver continuous improvements for your digital experience software, it is recommended that you apply the latest combined cumulative fix to your environment.

About this task

Documentation resource: “Roadmap: Applying maintenance” on page 88

Transferring your database

After you install your web experience, Apache Server is your available database. Depending on your requirements, you might need to transfer to a different database. The **Database Transfer** configuration option in the Configuration Wizard assigns users and permissions, creates databases, obtains support for database collation, and transfers your database.

Before you begin

Log in to WebSphere Portal Express to verify that you have a working portal:

`http://`*`hostname.example.com`*`:`*`10039`*`/wps/portal,`
`where` *`hostname.example.com`* `is the fully qualified`
`host name of the server where Portal is running and` *`10039`* `is`
`the default transport port that is created by WebSphere Application Server. The port number might be different for your environment.`

Procedure

1. To get the latest updates for the wizard, apply the most recent combined cumulative fix. For more information about applying the latest fix pack, see WebSphere Portal and Web Content Manager V8.5.0.0 combined cumulative fix overview.

   Note: Skip this step, if you have the most recent fix pack applied.
2. Access the Configuration Wizard. Go to `http://your_server:10200/ibm/wizard`.
3. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.

   Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For details on the supported languages for all of the WebSphere Portal Express user interfaces, see "Supported languages" on page 3622.
4. Select **Set Up a Stand-alone Server** > **Database Transfer**.
5. Provide information about your environment.
6. Save your configuration settings.
7. Choose one of the following options:
   - Click **Download Files** to run the steps remotely.
   - Click **Run All Steps** to run the steps locally.
8. Log in to WebSphere Portal Express to verify that you have a working portal server.

Enabling federated security

After you install your web experience, a default file-based repository is your available user registry. Depending on your requirements, you might need to enable a federated LDAP user registry.

About this task

Note: If you set **Use Administrator IDs stored in your LDAP user registry** to `yes`, the WebSphere Application Server and WebSphere Portal Express user IDs and passwords are changed to the LDAP user ID and password. If you do not want to change both user IDs and passwords to match the LDAP user ID and password, set this value to `no`. After you configure your LDAP user registry, you can manually change the user IDs and passwords.

Documentation resource: "Updating user ID and passwords" on page 1670

Procedure

1. To get the latest updates for the wizard, apply the most recent combined cumulative fix. For more information about applying the latest fix pack, see WebSphere Portal and Web Content Manager V8.5.0.0 combined cumulative fix overview.

   Note: Skip this step, if you have the most recent fix pack applied.
2. Access the Configuration Wizard. Go to `http://your_server:10200/ibm/wizard`.
3. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.

   Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For

details on the supported languages for all of the WebSphere Portal Express user interfaces, see “Supported languages” on page 3622.

4. Select **Set Up a Stand-alone Server** > **Enable Federated Security**.

   Note: If you set **Use Administrator IDs stored in your LDAP user registry** to `yes`, the WebSphere Application Server and WebSphere Portal Express user IDs and passwords are changed to the LDAP user ID and password. If you do not want to change both user IDs and passwords to match the LDAP user ID and password, set this value to `no`. After you configure your LDAP user registry, you can manually change the user IDs and passwords.

   Documentation resource: “Updating user ID and passwords” on page 1670
5. Provide information about your environment.
6. Save your configuration settings.
7. Choose one of the following options:
   - Click **Download Files** to run the steps remotely.
   - Click **Run All Steps** to run the steps locally.
8. Log in to WebSphere Portal Express to verify that you have a working portal server.

Tuning the servers in your environment

Tuning the servers is important to the performance of your portal environment. WebSphere Portal Express is not tuned for a production environment after installation and deployment. Your database needs tuning for improved performance. You can organize your database now or soon after you finish your configuration. You need to tune and maintain your database on a regular basis.

Procedure

Run the performance tuning tool to complete an initial tuning of your servers.

Documentation resource: “Portal server performance tuning tool” on page 240

Change to developer mode

Change your stand-alone server to developer mode to improve startup performance.

About this task

Documentation resources: “Changing to developer mode” on page 2511

Roadmap: Test or small production environment

A stand-alone server topology is ideal for a test or small production environment. In this roadmap, the web server, database, and user registry software are distributed to different physical servers.

Remember: Ensure that you configure the web server plug-in after you transfer your database.

Who should use this roadmap

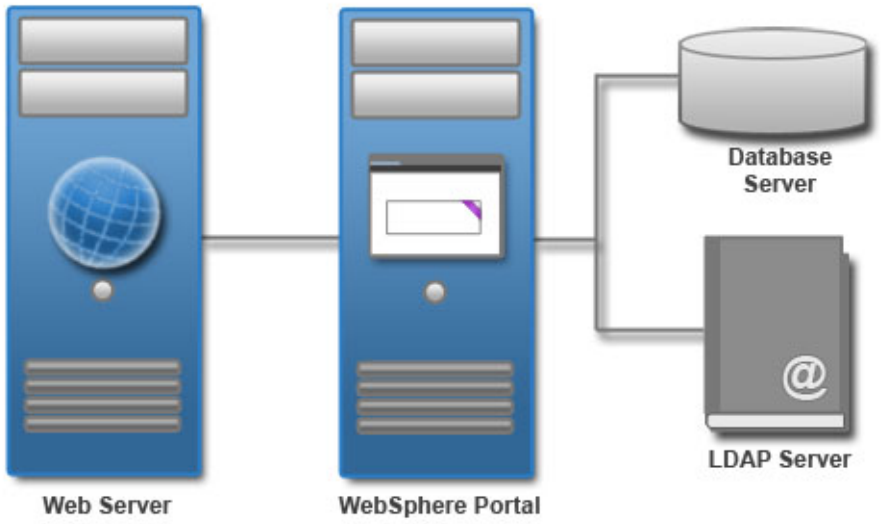
Use this roadmap if you are an organization with the following requirements:

- An organization that needs an environment to test their applications and designs before they go live to the server.
- An organization that does not need a clustered environment for failover or high availability.

- An organization with limited server resources that wants to set up a department server or small website.

Topology diagram

A stand-alone server topology is versatile. It is the foundation for a portal farm, authoring environment, test or rendering environment, small department-level deployments, and more. A typical stand-alone portal server topology includes a remote database and LDAP server. For many environments, it also includes a web server to direct incoming traffic.



Preparing for the installation process

Gather information and software before you install WebSphere Portal Express.

Procedure

1. Check requirements.

   Documentation resource: Detailed system requirements
2. Get the software.

   Documentation resource: “Getting the software” on page 135

Installing prerequisites

You can use existing prerequisite software installations. Verify that your existing version is supported. If it is not, upgrade to the appropriate version. Otherwise, install a web server, database server, and user registry server. Typically the database and user registry servers are already installed and configured. However, there might be specific configuration steps that are required to integrate them with the portal server.

Procedure

1. Install web server.

   Documentation resource: “Preparing a remote web server” on page 166
2. Prepare a database server.

   Documentation resource: “Installing and preparing the database software” on page 149
3. Prepare a user registry.

Documentation resource: “Preparing the user registry software” on page 158

Installing the Exceptional Digital Experience

Installing WebSphere Portal Express involves preparing your operating system, installing or upgrading the installation manager, and running the installation program.

About this task

Documentation resource: “Installing the digital experience software” on page 167

Applying the latest cumulative fix

Portal maintenance is delivered through two mechanisms: individual fixes (iFixes) and combined cumulative fixes. iFixes are provided, when necessary, for severe or security-related bugs. Combined cumulative fixes are delivered on a regular schedule. They provide a mechanism to deliver fixes faster, improve existing features, deliver new features, update documentation, and provide new documentation on a frequent basis. To deliver continuous improvements for your digital experience software, it is recommended that you apply the latest combined cumulative fix to your environment.

About this task

Documentation resource: “Roadmap: Applying maintenance” on page 88

Setting up a stand-alone server

Start the configuration wizard to set up your stand-alone server. First, transfer your database. The **Database Transfer** configuration option in the Configuration Wizard assigns users and permissions, creates databases, obtains support for database collation, and transfers your database. After you transfer your database, enable your federated LDAP user registry.

Before you begin

Log in to WebSphere Portal Express to verify that you have a working portal:
`http://hostname.example.com:10039/wps/portal`,
where *hostname.example.com* is the fully qualified
host name of the server where Portal is running and *10039* is
the default transport port that is created by WebSphere Application Server. The port number might be different for your environment.

Procedure

1. To get the latest updates for the wizard, apply the most recent combined cumulative fix. For more information about applying the latest fix pack, see WebSphere Portal and Web Content Manager V8.5.0.0 combined cumulative fix overview.

   Note: Skip this step, if you have the most recent fix pack applied.
2. Access the Configuration Wizard. Go to `http://your_server:10200/ibm/wizard`.
3. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.

   Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For

details on the supported languages for all of the WebSphere Portal Express user interfaces, see "Supported languages" on page 3622.

4. Select **Set Up a Stand-alone Server** > **Database Transfer**.
5. Provide information about your environment.
6. Save your configuration settings.
7. Choose one of the following options:
   - Click **Download Files** to run the steps remotely.
   - Click **Run All Steps** to run the steps locally.
8. Optional: If you changed the context root during the installation or configuration of IBM WebSphere Portal Express, then you must complete the optional next step from the Configuration Wizard to update parameters with the new context path after you complete the Create a Deployment Manager configuration option. For more information about this configuration option and completing the next steps, see Create a deployment manager.
9. Log in to WebSphere Portal Express to verify that you have a working portal server.
10. Select **Set Up a Stand-alone Server** > **Enable Federated Security**.

    Note: If you set **Use Administrator IDs stored in your LDAP user registry** to `yes`, the WebSphere Application Server and WebSphere Portal Express user IDs and passwords are changed to the LDAP user ID and password. If you do not want to change both user IDs and passwords to match the LDAP user ID and password, set this value to `no`. After you configure your LDAP user registry, you can manually change the user IDs and passwords.

    Documentation resource: "Updating user ID and passwords" on page 1670
11. Provide information about your environment.
12. Save your configuration settings.
13. Choose one of the following options:
    - Click **Download Files** to run the steps remotely.
    - Click **Run All Steps** to run the steps locally.
14. Log in to WebSphere Portal Express to verify that you have a working portal server.

Configuring the web server

Procedure

Move the web server plug-in from the WebSphere Application Server to the web server.

Documentation resource: "Web servers" on page 242

Tuning the servers in your environment

Tuning the servers is important to the performance of your portal environment. WebSphere Portal Express is not tuned for a production environment after installation and deployment. Your database needs tuning for improved performance. You can organize your database now or soon after you finish your configuration. You need to tune and maintain your database on a regular basis.

Procedure

1. Run the performance tuning tool to complete an initial tuning of your servers.

   Documentation resource: "Portal server performance tuning tool" on page 240

2. Check the tuning guide for more instructions. Use the tuning guide for the previous product version when the tuning guide for the current release is unavailable.

   Documentation resource: Performance tuning guide

Next steps

Depending on the choices that you made during the installation and set up, there are additional tasks to configure your environment.

The following options are available to continue configuring your environment:

Configure global settings
Documentation resource: "Configuring portal behavior" on page 248

Change the default portal Uniform Resource Identifier (URI)
If you changed the context root on the Configuration for IBM WebSphere Portal: Profile configuration details: Advanced panel during installation: "Completing the portal URI change started during installation" on page 362

If you want to change the context root after installation: "Changing the portal URI after an installation" on page 368

Adapt the attribute configuration to match the LDAP server
Documentation resource: "Adding more attributes to VMM" on page 568

Configure syndication
Documentation resource: "Syndication" on page 448

Update your user registry
Documentation resource: "User registry" on page 562

Configure your search
Documentation resource: "" on page 667

Roadmap: Failover environment

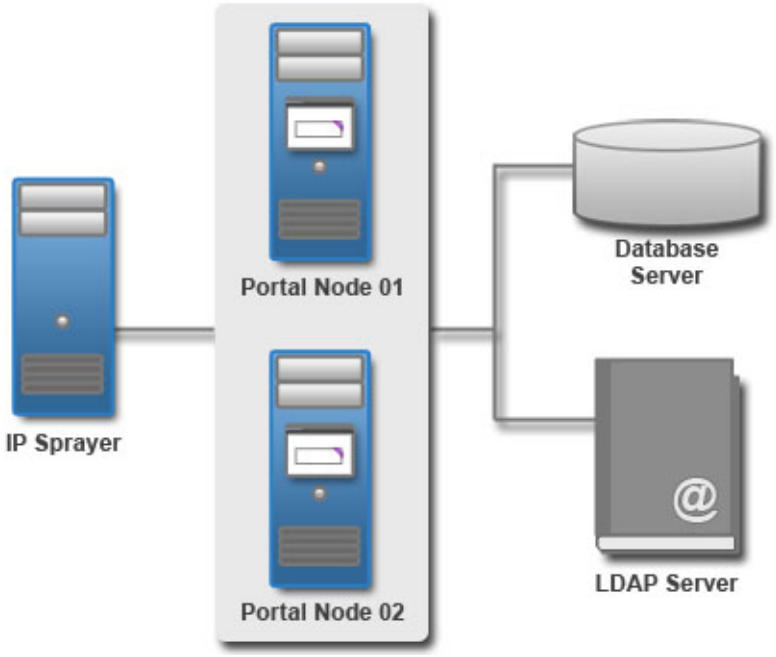
Set up your IBM WebSphere Portal Express environment as an idle standby configuration for failover. Your idle standby cluster server is not operational to service user transactions or to query workloads. The idle standby cluster server becomes active only if the primary node fails.

Who should use this roadmap

Use this roadmap if you installed WebSphere Portal Express and want a failover configuration.

Topology diagram

The idle-standby topology includes a portal cluster, database server, and user registry server. The cluster includes two nodes. The second node is only used when the primary node fails.



Preparing for the installation process

Gather information and software before you install WebSphere Portal Express.

Procedure

1. Check requirements.

   Documentation resource: Detailed system requirements
2. Get the software.

   Documentation resource: “Getting the software” on page 135

Installing prerequisites

You can use existing prerequisite software installations. Verify that your existing version is supported. If it is not, upgrade to the appropriate version. Otherwise, install a web server, database server, and user registry server. Typically the database and user registry servers are already installed and configured. However, there might be specific configuration steps that are required to integrate them with the portal server.

Procedure

1. Install web server.

   Documentation resource: “Preparing a remote web server” on page 166
2. Prepare a database server.

   Documentation resource: “Installing and preparing the database software” on page 149
3. Prepare a user registry.

   Documentation resource: “Preparing the user registry software” on page 158

Installing the Exceptional Digital Experience

Installing WebSphere Portal Express involves preparing your operating system, installing or upgrading the installation manager, and running the installation program.

About this task

Documentation resource: “Installing the digital experience software” on page 167

Setting up an idle standby

Start the configuration wizard to get a running portal and to configure the portal with your database and user registry.

Before you begin

Log in to WebSphere Portal Express to verify that you have a working portal:

`http://hostname.example.com:10039/wps/portal`,
where *hostname.example.com* is the fully qualified
host name of the server where Portal is running and *10039* is
the default transport port that is created by WebSphere Application Server. The port number might be different for your environment.

Procedure

1. Access the Configuration Wizard. Go to `http://your_server:10200/ibm/wizard`.
2. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.

   Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For details on the supported languages for all of the WebSphere Portal Express user interfaces, see “Supported languages” on page 3622.

Complete the following steps to transfer your database:

3. Select **Set Up a Cluster** > **Database Transfer**.
4. Provide information about your environment.
5. Save your configuration settings.
6. Choose one of the following options:
   - Click **Download Files** to run the steps remotely.
   - Click **Run All Steps** to run the steps locally.
7. Log in to WebSphere Portal Express to verify that you have a working portal server.

Complete the following steps to create your deployment manager:

8. Select **Set Up a Cluster** > **Create a Deployment Manager**.
9. Provide information about your environment.
10. Save your configuration settings.
11. Choose one of the following options:
    - Click **Download Files** to run the steps remotely.
    - Click **Run All Steps** to run the steps locally.
12. Log in to WebSphere Portal Express to verify that you have a working portal server.

Complete the following steps to create a cluster node:

13. Select **Set Up a Cluster** > **Create a Cluster**.
14. Provide information about your environment.
15. Save your configuration settings.
16. Choose one of the following options:
    - Click **Download Files** to run the steps remotely.

- Click **Run All Steps** to run the steps locally.

17. Log in to WebSphere Portal Express to verify that you have a working portal server.

Complete the following steps to enable federated security:

18. **Set Up a Cluster** > **Enable Federated Security**.

    Note: If you set **Use Administrator IDs stored in your LDAP user registry** to `yes`, the WebSphere Application Server and WebSphere Portal Express user IDs and passwords are changed to the LDAP user ID and password. If you do not want to change both user IDs and passwords to match the LDAP user ID and password, set this value to `no`. After you configure your LDAP user registry, you can manually change the user IDs and passwords.

    Documentation resource: "Updating user ID and passwords" on page 1670

19. Provide information about your environment.
20. Save your configuration settings.
21. Choose one of the following options:
    - Click **Download Files** to run the steps remotely.
    - Click **Run All Steps** to run the steps locally.
22. Log in to WebSphere Portal Express to verify that you have a working portal server.

Complete the following steps to create an idle standby:

23. Install WebSphere Portal Express on the idle standby.

    Documentation resource: "Installing the digital experience software" on page 167.

    Tip: For additional nodes, you only need to install the WebSphere Portal Express product binary files. Therefore, on the Features screen of the IBM Installation Manager, ensure that **Portal Server Profile** is not selected.

24. **Set Up a Cluster** > **Create an Additional Cluster Node**.
25. Provide information about your environment.
26. Save your configuration settings.
27. Choose one of the following options:
    - Click **Download Files** to run the steps remotely.
    - Click **Run All Steps** to run the steps locally.
28. Log in to WebSphere Portal Express to verify that you have a working portal server.
29. Complete the following steps to configure the Idle Standby node as a backup server:
    a. Log on to the deployment manager WebSphere Integrated Solutions Console.
    b. Select **Servers** > **Server Types** > **WebSphere application servers** > *server_name* > **Web server plug-in properties**.
    c. From the **Server Role** menu, select **Backup**.
    d. Apply and save the changes.
    e. Log out of the deployment manager WebSphere Integrated Solutions Console.

Configuring the web server
Procedure

Move the web server plug-in from the WebSphere Application Server to the web server.

Documentation resource: "Web servers" on page 242

Tuning the servers in your environment

Tuning the servers is important to the performance of your portal environment. WebSphere Portal Express is not tuned for a production environment after installation and deployment. Your database needs tuning for improved performance. You can organize your database now or soon after you finish your configuration. You need to tune and maintain your database on a regular basis.

Procedure

1. Run the performance tuning tool to complete an initial tuning of your servers.

   Documentation resource: "Portal server performance tuning tool" on page 240
2. Check the tuning guide for more instructions. Use the tuning guide for the previous product version when the tuning guide for the current release is unavailable.

   Documentation resource: Performance tuning guide

Next steps

Depending on the choices that you made during the installation and set up, there are additional tasks to configure your environment.

The following options are available to continue configuring your environment:

Configure global settings
Documentation resource: "Configuring portal behavior" on page 248

Adapt the attribute configuration to match the LDAP server
Documentation resource: "Adding more attributes to VMM" on page 568

Configure syndication
Documentation resource: "Syndication" on page 448

Configure search
Documentation resource: "Configuring search in a cluster" on page 662

Update your user registry
Documentation resource: "User registry" on page 562

Roadmap: Web content servers

A web content server is ideal to create presentation templates, content components, and other presentation elements of your website. In this roadmap, the web server, database, and user registry software are distributed to different physical servers.

Who should use this roadmap

Use this roadmap if you are an organization with the following requirements:

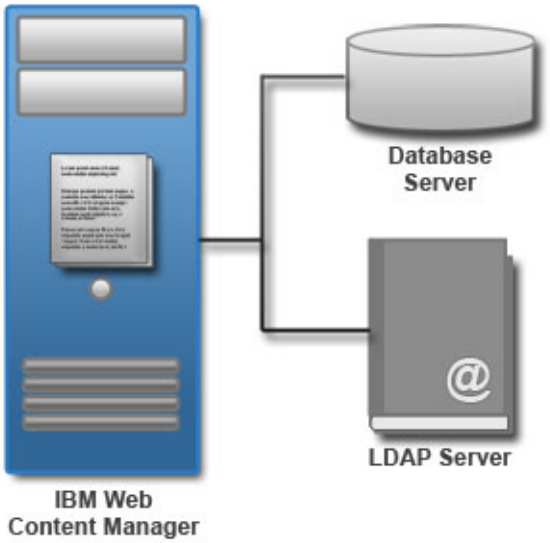
- An organization that needs an environment to create and test your web content before they publish to other staging or production servers
- An organization that needs to create presentation templates (Authoring or Presentation) for content authors and content rendering

- An organization that needs to create the site structure and entitlements
- An organization that needs to develop content with HTML, CSS, JavaScript, JSP, or Java.
- An organization needs a staging server to perform final quality tests before publishing.
- An organization needs a server to publish content to end users.

Important: Developing or publishing web content requires a supported database other than Apache Server. An Apache Server database is available after installation. Therefore, you must transfer to a supported database; for example DB2 or Oracle.

Topology diagram

The topology for a web content server includes a remote database and LDAP server. The topology depicts an IBM Web Content Manager server, instead of a portal server. When you install IBM WebSphere Portal, it includes Web Content Manager. The configuration steps for the web content development server are different from a basic stand-alone server. The web content server configuration includes syndication with the rendering or test server.



Preparing for the installation process

Gather information and software before you install WebSphere Portal Express.

Procedure

1. Check requirements.

   Documentation resource: Detailed system requirements
2. Get the software.

   Documentation resource: “Getting the software” on page 135

Installing prerequisites

Before you install WebSphere Portal Express, install any prerequisites that are necessary for your environment. You can use existing prerequisite software installations. Verify that your existing version is supported. If it does not, upgrade to the appropriate version.

Procedure

1. Prepare a database server.

   Documentation resource: “Installing and preparing the database software” on page 149
2. Prepare a user registry.

   Documentation resource: “Preparing the user registry software” on page 158

Installing the Exceptional Digital Experience

Installing WebSphere Portal Express involves preparing your operating system, installing or upgrading the installation manager, and running the installation program.

About this task

Documentation resource: “Installing the digital experience software” on page 167

Applying the latest cumulative fix

Portal maintenance is delivered through two mechanisms: individual fixes (iFixes) and combined cumulative fixes. iFixes are provided, when necessary, for severe or security-related bugs. Combined cumulative fixes are delivered on a regular schedule. They provide a mechanism to deliver fixes faster, improve existing features, deliver new features, update documentation, and provide new documentation on a frequent basis. To deliver continuous improvements for your digital experience software, it is recommended that you apply the latest combined cumulative fix to your environment.

About this task

Documentation resource: “Roadmap: Applying maintenance” on page 88

Transferring your database

After you install your web experience, Apache Server is your available database. Depending on your requirements, you might need to transfer to a different database. The **Database Transfer** configuration option in the Configuration Wizard assigns users and permissions, creates databases, obtains support for database collation, and transfers your database.

Before you begin

Log in to WebSphere Portal Express to verify that you have a working portal:

`http://hostname.example.com:10039/wps/portal,`
`where hostname.example.com is the fully qualified`
`host name of the server where Portal is running and 10039 is`
`the default transport port that is created by WebSphere Application Server. The port number might be different for your environment.`

Procedure

1. To get the latest updates for the wizard, apply the most recent combined cumulative fix. For more information about applying the latest fix pack, see WebSphere Portal and Web Content Manager V8.5.0.0 combined cumulative fix overview.

   Note: Skip this step, if you have the most recent fix pack applied.

2. Access the Configuration Wizard. Go to `http://your_server:10200/ibm/wizard`.
3. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.

   Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For details on the supported languages for all of the WebSphere Portal Express user interfaces, see "Supported languages" on page 3622.
4. Select **Set Up a Stand-alone Server** > **Database Transfer**.
5. Provide information about your environment.
6. Save your configuration settings.
7. Choose one of the following options:
   - Click **Download Files** to run the steps remotely.
   - Click **Run All Steps** to run the steps locally.
8. Log in to WebSphere Portal Express to verify that you have a working portal server.

Enabling federated security

After you install your web experience, a default file-based repository is your available user registry. Depending on your requirements, you might need to enable a federated LDAP user registry.

About this task

Note: If you set **Use Administrator IDs stored in your LDAP user registry** to `yes`, the WebSphere Application Server and WebSphere Portal Express user IDs and passwords are changed to the LDAP user ID and password. If you do not want to change both user IDs and passwords to match the LDAP user ID and password, set this value to `no`. After you configure your LDAP user registry, you can manually change the user IDs and passwords.

Documentation resource: "Updating user ID and passwords" on page 1670

Procedure

1. To get the latest updates for the wizard, apply the most recent combined cumulative fix. For more information about applying the latest fix pack, see WebSphere Portal and Web Content Manager V8.5.0.0 combined cumulative fix overview.

   Note: Skip this step, if you have the most recent fix pack applied.
2. Access the Configuration Wizard. Go to `http://your_server:10200/ibm/wizard`.
3. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.

   Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For details on the supported languages for all of the WebSphere Portal Express user interfaces, see "Supported languages" on page 3622.
4. Select **Set Up a Stand-alone Server** > **Enable Federated Security**.

   Note: If you set **Use Administrator IDs stored in your LDAP user registry** to `yes`, the WebSphere Application Server and WebSphere Portal Express user IDs and passwords are changed to the LDAP user ID and password. If you do not

want to change both user IDs and passwords to match the LDAP user ID and password, set this value to `no`. After you configure your LDAP user registry, you can manually change the user IDs and passwords.

Documentation resource: "Updating user ID and passwords" on page 1670

5. Provide information about your environment.
6. Save your configuration settings.
7. Choose one of the following options:
   - Click **Download Files** to run the steps remotely.
   - Click **Run All Steps** to run the steps locally.
8. Log in to WebSphere Portal Express to verify that you have a working portal server.

Tuning the servers in your environment

Tuning the servers is important to the performance of your portal environment. WebSphere Portal Express is not tuned for a production environment after installation and deployment. Your database needs tuning for improved performance. You can organize your database now or soon after you finish your configuration. You need to tune and maintain your database on a regular basis.

Procedure

Run the performance tuning tool to complete an initial tuning of your servers.

Documentation resource: "Portal server performance tuning tool" on page 240

Configuring the Authoring portlet

Configure your Authoring portlet on your WebSphere Portal Express server.

Procedure

1. Configure extra Authoring portlet parameters.

   Documentation resource: "Further authoring portlet configuration options" on page 395
2. Configure the workflow, profiling, and version control settings.

   Documentation resource: "Web content authoring options" on page 396
3. Configure the Authoring portlet search.

   Documentation resource: "How to configure authoring portlet search" on page 402
4. Configure your server to import large files and images.

   Documentation resource: Importing large files and images
5. Configure your server to avoid time-out issues.

   Documentation resource: "Increase timeouts to prevent save errors" on page 403
6. Configure remote server access so you can link to files and documents on remote content management systems.

   Documentation resource: "Configuring remote server access for links" on page 404
7. Set up support for federated documents.

   Documentation resource: "Setting up support for federated documents" on page 405

Syndication

Use syndication to synchronize content between authoring, staging, and publishing environments.

Procedure

1. Plan your syndication strategies.

   Documentation resource: “Syndication relationships” on page 449
2. Define syndication properties.

   Documentation resource: “Syndication properties” on page 454
3. Tune your syndication strategy to improve performance.

   Documentation resource: “Syndication tuning” on page 456
4. Create your syndication relationships.

   Documentation resource: Creating a syndication relationship by using the Administration Portlet

Roadmap: Applying maintenance

Portal maintenance is delivered through two mechanisms: individual fixes (iFixes) and combined cumulative fixes. iFixes are provided, when necessary, for severe or security-related bugs. Combined cumulative fixes are delivered on a regular schedule. They provide a mechanism to deliver fixes faster, improve existing features, deliver new features, update documentation, and provide new documentation on a frequent basis. To deliver continuous improvements for your digital experience software, it is recommended that you apply the latest combined cumulative fix to your environment.

Use this roadmap to learn more about the following information:

- What the latest combined cumulative fix contains
- How to apply the latest combined cumulative fix
- How to configure and enable new combined cumulative fix features

Who should use this roadmap

Use this roadmap if you:

- Installed WebSphere Portal V8.5 for the first time and want to apply an iFix or the latest combined cumulative fix.
- Need a high-level view of which features or improvements are ready to use by default after you apply the latest combined cumulative fix and which features need additional configuration.

What is continuous delivery

Continuous delivery is short development cycles with continuous integration and automated tests. The result is a releasable product at any time. Continuous delivery has the following benefits:

- Accelerated time to market
- Building the right product
- Improved productivity and efficiency
- Reliable releases
- Improved product quality

- Improved customer satisfaction

The continuous delivery features are delivered with the combined cumulative fixes.

Learning about this combined cumulative fix

Some combined cumulative fixes focus on fixing known issues that are identified by APARs. Other cumulative fixes are focused on new features.

Procedure

1. View a list of APAR fixes delivered a combined cumulative fix.

   Documentation resource: Fixes integrated in WebSphere Portal 8.5.0.0 Combined Cumulative Fixes
2. Get an overview of the features and improvements delivered in the latest combined cumulative fix.

   Documentation resource: “What's new with CF07” on page 2

Applying a combined cumulative fix

To apply a combined cumulative fix, you must update the product files with IBM Installation Manager. You must also update properties files, download the cumulative fix, and run ConfigEngine tasks to apply the changes to each profile in your system. The IBM WebSphere Portal Express V8.5.0.0 combined cumulative fix readme file provides detailed instructions on how to apply a fix and planning information.

Before you begin

CF03 Use the Health Checker tool to identify issues with your installation. You should use the Health Checker tool on your target system before you apply a combined cumulative fix. You can learn more about how to apply the Health Checker tool in the readme instructions.

Individual fixes: Individual fixes (iFixes) are included in the combined cumulative fix. However, if you need a fix before the combined cumulative fix is available, you can install the iFix. iFixes are found on IBM Fix Central (http://www.ibm.com/support/fixcentral/). To install an iFix, download it from Fix Central and use the IBM Installation Manager to update the portal server. An iFix can be installed with the Installation Manager GUI or command line interface. It can also be automated with a response file. Most iFixes also require a command to update your profile. This requirement differs with each fix. Refer to the readme file that comes with the iFix for details.

Procedure

To apply this cumulative fix, follow the readme instructions that apply to your environment. You can find separate instructions for stand-alone, cluster, farm, and remote search environments from the overview topic.

Documentation resource: IBM WebSphere Portal V.8.5.0 combined cumulative fix instructions: stand-alone

Documentation resource: IBM WebSphere Portal V.8.5.0 combined cumulative fix instructions: cluster

Documentation resource: IBM WebSphere Portal V.8.5.0 combined cumulative fix instructions: farm

Documentation resource: IBM WebSphere Portal V.8.5.0 combined cumulative fix instructions: remote search

Configuring features in CF06

Some features are configured by default after you apply your cumulative fix. Other features require additional configuration tasks or enablement steps before you can use them. This section provides documentation resources for features and improvements that require additional configuration.

Updates to custom search box in the portal theme
This feature requires additional configuration to redirect search requests issued by a custom search form to the Search Center.

Documentation resource: "Redirecting search requests from a custom search form to the Search Center" on page 645

Using remote session invalidation with WSRP
This feature requires additional configuration to enable remote session invalidation.

Documentation resource: "Configuring remote session invalidation" on page 1493

Configuring features from previous cumulative fixes

After you install the current combined cumulative fix, you might decide that you want to use a feature from a previous fix. This section provides documentation resources for those features and improvements that require additional configuration.

CF05

Features from CF05

The following features, included with the fifth combined cumulative fix, requires additional configuration:

SmartCloud for Social Business Search (SAML)
This feature requires configuration to integrate WebSphere Portal Express and IBM Connections in SmartCloud for Social Business. As of CF05, you can integrate by using either Active Directory Federation Services (ADFS) or Tivoli Federated Identity Manager (TFIM).

Documentation resource: "Establishing single sign-on (SSO) between the portal installation and IBM Connections in SmartCloud for Social Business" on page 763.

Searching in a multilingual environment
This feature requires configuration. By default, the Search Center uses the preferred language of the user to analyze search terms and refine search results. To enable searching in other languages, configure the Search Center portlet.

Documentation resource: "Configuring search for multilingual sites" on page 684.

Content as a Service pages
This feature requires configuration. Content as a Service pages require the new functions of WebSphere Portal Express and IBM Web Content Manager version 8.5 CF05 to be enabled. Run the configuration task `install-caas` to enable the Content as a Service pages.

Documentation resource: “Setting up Content as a Service” on page 1884.

CF04
Features from CF04

The following feature, included with the fourth combined cumulative fix, requires additional configurations:

Renditions
This feature requires configuration. Renditions are disabled by default. You must run a ConfigEngine task to enable them.

Documentation resource: “Enabling renditions” on page 2015

CF03
Features from CF03

The following feature, included with the third combined cumulative fix, requires additional configurations:

Resource aggregation for portlets
This feature requires configuration if your custom theme was created from the Portal 8.5 theme on a system before CF03. Connect to your WebDAV and edit the local copy of your `metadata.properties` file. Set the theme `metadata resourceaggregation.autoLoadPortletCapabilities` to `true`.

Documentation resource: “Change the auto-loading of portlet capabilities” on page 2538

Blogs and wikis
This feature requires enablement. You must run a configuration task to update the content that is used by Blogs and Wikis to apply the newest updates.

If you customized your Blogs and Wikis, you lose your customizations and you must reapply those customizations after you run the task. Enablement is manual and optional.

Documentation resource: “Blogs and wikis” on page 887

SmartCloud for Social Business HTTP Outbound
This feature requires configuration to use social rendering with a Connections server that runs in the Smart Cloud for Social Business.

To configure the Connections server type, set the custom property **`server.type`** in the WP Connections Integration Service resource environment provider to **`SC4SB`** in the WebSphere Integrated Solutions Console.

Documentation resource: “Configuring the Connections server type” on page 2122.

Invalid friendly URLs
This feature requires enablement and configuration. Set the **`friendly.pathinfo.validation.enabled`** property to `true` in the WebSphere Portal Express Configuration Service Resource Environment Provider.

Documentation resource: “How to enable the validation of friendly URLs for web content” on page 2046.

Documentation resource: “Configuring the validation of friendly URLs for web content” on page 2046.

Roadmaps for migration

Choose the appropriate migration roadmap for your environment.

"Roadmap: Migrating a stand-alone server environment"
Roadmaps provide a high-level overview of complex tasks such as migrating a stand-alone server environment to a new version of IBM WebSphere Portal Express.

"Roadmap: Migrating a clustered environment" on page 94
Roadmaps provide a high-level overview of complex tasks such as migrating a clustered environment to a new version of IBM WebSphere Portal Express.

Roadmap: Migrating a stand-alone server environment

Roadmaps provide a high-level overview of complex tasks such as migrating a stand-alone server environment to a new version of IBM WebSphere Portal Express.

Who should use this roadmap?

Use this roadmap if you are:

- Migrating a stand-alone server environment from Version 7.0.0.x to Version 8.5.
- Migrating a stand-alone server environment from Version 8.0.0.x to Version 8.5.

Note: If you are migrating from IBM WebSphere Portal Express Version 8.0.0.1 on WebSphere Application Server Version 8.5.5.2 to WebSphere Portal Express Version 8.5, you must follow a different migration process. For more information, see "Migrating from Portal 8.0.0.1 on WebSphere Application Server 8.5.5.2" on page 800.

You must apply the latest cumulative fix and one of the two most recent fix packs to your source environment, and the latest cumulative fix and the most recent fix pack to your target environment before you can migrate to WebSphere Portal Version 8.5. For more information, see Supported migration paths.

Planning for migration

Gather information and create a plan for migration.

Check the requirements and considerations for migration:

- Documentation resources: Planning for migration
  - Backup and recovery of data files and databases is an essential operation for any business system, particularly for data and applications that are running in production environments. Create and follow a plan for backing up and recovering data on all tiers of your WebSphere Portal Express deployment. For more information, see Backup and recovery.
  - Remove unsupported or deprecated features before you start migration. For more information, see Deprecated features.
  - If you need to migrate multiple environments, such as a production environment or development environment, you can use staging to production techniques. For more information, see Migrate multiple tier environments.

Plan a local migration if your source and target environments are on the same system, and plan for a remote migration if your source and target environments

are on separate systems. For more information about local and remote migrations, see Local versus remote.

Preparing your source environment

Prepare the source portal that you want to use for migration.

- Documentation resources: Preparing your source environment
  - To keep the earlier portal environment in production and reduce the amount of downtime during migration copy the earlier portal server JCR and Release domains. For more information, see "Using copies of source database domains to minimize downtime" on page 835.

Setting up your target environment

Set up your target environment for migrating to Version 8.5.

- Documentation resource: Setting up your target environment
  - The portal migration attempts to install custom applications in the target environment, but it does not automatically copy the files that are required for those applications. If the files are not copied over, it is possible that the applications will fail to install or not work properly. For more information about copying these files, see "Copying files for third party and custom applications" on page 835.
  - To effectively set up your target environment, install the Portal and WebSphere binary files on all target systems. For more information, see "Installing Portal and WebSphere binary files" on page 833.

Migrating to WebSphere Portal Express Version 8.5

Start the Configuration Wizard to migrate data, applications, databases, property files, security settings, and more.

1. To get the latest updates for the wizard, apply the most recent cumulative fix. For more information about applying the latest fix pack, see WebSphere Portal and Web Content Manager V8.5.0.0 combined cumulative fix overview.

   Note: Skip this step, if you have the most recent fix pack applied.
2. Access the Configuration Wizard using your target environment and system host name. Go to: `http://your_server:10200/ibm/wizard`.
3. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, cw_profile.
4. Select **Migrate to a New Version** > **Migrate a Stand-alone Server**.
5. Provide information about your environment.
6. Save your wizard selections.
7. Choose one of the following options:
   - Click **Download Configuration Scripts** to run the steps remotely.
   - Click **Start Configuration** to run the steps locally. This option starts to run the automated steps until a manual step is encountered.

Migration is partially complete after you do the tasks in the configuration wizard. You must return to the product documentation to complete the final steps of the migration process.

Next steps

Migration is not complete until you review the Next steps section in the product documentation. Complete the post-migration activities and enabling new functionality tasks that are applicable to your environment. Do not complete any of the enabling new functionality tasks until all post-migration activities tasks are finished.

- Documentation resources: Next steps
  - Then, you must run the **PRE-APPLY-FIX** and **APPLY-FIX** tasks to ensure that your migrated system is up-to-date. This step is required. For more information, see "Applying the latest combined cumulative fix updates" on page 857.
  - More tasks must be completed depending on how you customized the source portal environment and which components you used. For example, if you use a virtual portal, then complete the virtual portal post-migration activities. For more information, see Post-migration activities.
  - New functionality that was not available in the earlier portal version requires extra attention after migration is complete. For more information, see Enabling new functionality.

After you complete the tasks in the Next steps section of the product documentation, migration is complete.

Roadmap: Migrating a clustered environment

Roadmaps provide a high-level overview of complex tasks such as migrating a clustered environment to a new version of IBM WebSphere Portal Express.

Who should use this roadmap?

Use this roadmap if you are:

- Migrating a clustered environment from Version 7.0.0.x to Version 8.5.
- Migrating a clustered environment from Version 8.0.0.x to Version 8.5.

Note: If you are migrating from IBM WebSphere Portal Express Version 8.0.0.1 on WebSphere Application Server Version 8.5.5.2 to WebSphere Portal Express Version 8.5, you must follow a different migration process. For more information, see "Migrating from Portal 8.0.0.1 on WebSphere Application Server 8.5.5.2" on page 800.

You must apply the latest cumulative fix and one of the two most recent fix packs to your source environment, and the latest cumulative fix and the most recent fix pack to your target environment before you can migrate to WebSphere Portal Version 8.5. For more information, see Supported migration paths.

Planning for migration

Gather information and create a plan for migration.

Check the requirements and considerations for migration:

- Documentation resources: Planning for migration
  - Backup and recovery of data files and databases is an essential operation for any business system, particularly for data and applications that are running in production environments. Create and follow a plan for backing up and

recovering data on all tiers of your WebSphere Portal Express deployment. For more information, see Backup and recovery.
  - Remove unsupported or deprecated features before you start migration. For more information, see Deprecated features.
  - If you need to migrate multiple environments, such as a production environment or development environment, you can use staging to production techniques. For more information, see Migrate multiple tier environments.

Plan a local migration if your source and target environments are on the same system, and plan for a remote migration if your source and target environments are on separate systems. For more information about local and remote migrations, see Local versus remote.

Preparing your source environment

Prepare the source portal that you want to use for migration.

- Documentation resources: Preparing your source environment
  - Review the considerations for a multiple cluster environment for information on supporting multiple clusters that use different database credentials. For more information, see "Multiple cluster environments" on page 799.
  - To keep the earlier portal environment in production and reduce the amount of downtime during migration copy the earlier portal server JCR and Release domains. For more information, see "Using copies of source database domains to minimize downtime" on page 835.
  - The target environment initially uses the same ports as the source environment. There are three important steps you must complete to ensure that the source and target environments do not become corrupted. For more information, see "Disabling automatic synchronization to protect your clustered source environment" on page 817.

Setting up your target environment

Set up your target environment for migrating to Version 8.5.

- Documentation resource: Setting up your target environment
  - The portal migration attempts to install custom applications in the target environment, but it does not automatically copy the files that are required for those applications. If the files are not copied over, it is possible that the applications will fail to install or not work properly. For more information about copying these files, see "Copying files for third party and custom applications" on page 835.
  - To effectively set up your target environment, install the Portal and WebSphere binary files on all target systems. For more information, see "Installing Portal and WebSphere binary files" on page 833.

Migrating to WebSphere Portal Express Version 8.5

Start the Configuration Wizard to migrate data, applications, databases, property files, security settings, and more.

1. During a cluster migration, you might need to enter information into the Configuration Wizard more than once. Use the following worksheet to identify the information that is entered multiple times, and use these values during the migration process.

Table 5. Worksheet: Migration information for the Configuration Wizard

Field description:	Value:
Deployment manager host name	
Deployment manager cell name	
Deployment manager node name	
Administrator user name	
Administrator password	
Soap port	

2. To get the latest updates for the wizard, apply the most recent cumulative fix. For more information about applying the latest fix pack, see WebSphere Portal and Web Content Manager V8.5.0.0 combined cumulative fix overview.

   Note: Skip this step, if you have the most recent fix pack applied.
3. Access the Configuration Wizard using your target environment and system host name. Go to: `http://your_server:10200/ibm/wizard`.
4. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, cw_profile.
5. Select **Migrate to a New Version** > **Migrate a Cluster Step 1: Migrate the Deployment Manager Profile**.
6. Provide information about your environment.
7. Save your wizard settings.
8. Click **Download Configuration Scripts** to run the steps on the deployment manager.
9. After you complete the steps from Step 1, select **Migrate to a New Version** > **Migrate a Cluster Step 2: Migrate Node Profiles**.
10. Provide information about your environment.
11. Save your wizard settings.
12. Choose one of the following options:
    - Click **Download Configuration Scripts** to run the steps remotely.
    - Click **Start Configuration** to run the steps locally. This option starts to run the automated steps until a manual step is encountered.
13. Complete these steps on all nodes.
14. After you complete the steps for Step 2, select **Migrate to a New Version** > **Migrate a Cluster Step 3: Upgrade Node Profiles**.
15. Provide information about your environment.
16. Save your wizard settings.
17. Choose one of the following options:
    - Click **Download Configuration Scripts** to run the steps remotely.
    - Click **Start Configuration** to run the steps locally. This option starts to run the automated steps until a manual step is encountered.
18. Complete these steps on all nodes

Next steps

Migration is not complete until you review the Next steps section in the product documentation. Complete the post-migration activities and enabling new

functionality tasks that are applicable to your environment. Do not complete any of the enabling new functionality tasks until all post-migration activities tasks are finished.

- Documentation resources: Next steps
  - Then, you must run the **PRE-APPLY-FIX** and **APPLY-FIX** tasks to ensure that your migrated system is up-to-date. This step is required. For more information, see "Applying the latest combined cumulative fix updates" on page 857.
  - More tasks must be completed depending on how you customized the source portal environment and which components you used. For example, if you use a virtual portal, then complete the virtual portal post-migration activities. For more information, see Post-migration activities.
  - New functionality that was not available in the earlier portal version requires extra attention after migration is complete. For more information, see Enabling new functionality.

After you complete the tasks in the Next steps section of the product documentation, migration is complete.

Roadmaps for integration

Choose the appropriate integration roadmaps for your environment.

"Roadmap: Integrating with IBM Connections"

Roadmap: Integrating with IBM Connections

Integrating your portal site with IBM Connections is a multiple step process. Some steps are required and others are optional. Optional steps depend on the level of integration that you need. This roadmap is intended to provide an overview of the process. Links to detailed instructions are provided from the roadmap.

Installing Connections and WebSphere Portal

Before you begin, the following programs must be installed and configured.

Install Connections

Documentation resource: Installing IBM Connections

Install IBM WebSphere Portal Express.

Documentation resource: Installing WebSphere Portal

Configure portal to use a federated LDAP server.

Documentation resource depends on your WebSphere Portal Express installation scenario, stand-alone server, or cluster.

Note: Do not remove the file system user repository after you federate your LDAP server.

Configuring your portal to work with IBM Connections

Procedure

1. Import the SSL certificate from Connections to your portal server.

   Documentation resource: Importing a certificate to support SSL
2. Configure the portal Ajax proxy. The Ajax proxy is updated for the base Connections URLS during the IBM Connections Portlets installation. If FileNet

is used, you must still configure the Ajax proxy manually to update for FileNet. Configure the Ajax proxy so that direct requests that the CCM portlet makes to the FileNet server are allowed to pass through the proxy Server.

Documentation resource: Configuring the Ajax proxy to allow FileNet requests

3. Configure single sign-on.

   Documentation resource: "Set up single sign-on" on page 748

   Documentation resource for portlets: Configuring authentication for the portlets

4. Install and Deploy the Portlets

   Note: Before you install the portlets, steps 1 - 3 must be completed.

   a. Download the Connections portlets for WebSphere Portal Express.

      IBM Connections Portlets for WebSphere Portal

   b. Install the portlets.

      Documentation resource: Installing the IBM Connections Portlets for WebSphere Portal

   c. Add modules that are needed by the Connections portlets to the portal theme default profile.

      Documentation resource: Updating the portlet theme

5. Configure a common directory service for the portlets.

   Documentation resource: Configuring common Directory Services for your security configuration

6. Integrate community membership to allow access control administration that is based on community membership.

   a. Documentation resource: Integrating community membership with Portal security

   b. Documentation resource: Automatically grant page access to community members

7. Enhance the deployment of Connections portlets for WebSphere Portal Express with optional configuration steps.

   Documentation resource:Optional and Recommended Configurations

   Documentation resource: Social rendering

   Documentation resource: Social Media Publisher

   Documentation resource: IBM Social Rendering Templates for Digital Data Connector

8. Configure search with the Remote Content Server Search Service Type (RCSS), for a portal cluster setup that is integrated with Connections.

   Documentation resource:Configuring search using Remote Content Server Search Service Type (RCSS)

Roadmaps for web content

Some roadmaps to help you create and integrate web content into your site.

"Roadmap: Importing web content" on page 99
When you set up a new site, you might have content in an existing system that you need to migrate or import into your site.

Roadmap: Importing web content

When you set up a new site, you might have content in an existing system that you need to migrate or import into your site.

Using REST to import web content into Web Content Manager

Application developers can use Representational State Transfer (REST) services to work with Web Content Manager. The REST service for Web Content Manager provides authoring access to content items and elements. The service follows the Atom Publication Protocol, and atom feeds, and entries are accessible in XML (application/atom+xml) and JSON (application/json) format.

This is useful when you need to perform a once-off migration of Web content from an external system into an Web Content Manager authoring environment.

See "REST service for Web Content Manager" on page 3306 for further information.

Using WCI to import web content managed in an external system

The Web Content Integrator is a solution for integrating externally managed Web content with WebSphere Portal Express. Through the use of standard content syndication feed technologies based on RSS 2.0, the Web Content Integrator provides a loosely-coupled mechanism for transferring published content and metadata to the portal after they have been approved in the source system. When the content and metadata have been transferred to the portal, it is possible to use the built-in content management features of WebSphere Portal Express to secure, personalize, and display the content to users.

This is useful when you need to continue to use externally managed Web content in a site delivered using Web Content Manager.

See "IBM Web Content Integrator" on page 1936 for further information.

Chapter 4. Installing

IBM WebSphere Portal Express provides flexible deployment options that range from proof-of-concept where you can examine and test functionality to a highly available and scalable production environment. Review the planning information to learn more about hardware and software requirements, high availability, scalability, supported topologies, and much more. Select your operating system and then select the installation pattern that most reflects your business needs.

1. "Planning to install WebSphere Portal Express"
   Before you install IBM WebSphere Portal Express in a production environment, you need to assess your hardware and software needs, possible database configurations, security options, and LDAP server options. Skipping this important step can lead to unexpected results and costly delays.
2. "Getting the software" on page 135
   There are different ways for you to get WebSphere Portal Express and Web Content Manager Version 8.5 software.
3. "Installing and preparing the prerequisite software" on page 148
   Before you install the digital experience software, make sure that the prerequisite software is installed and configured. Depending on your environment, you might already have the prerequisites, such as a database server and user registry. Verify that the prerequisite software is the correct version, has the required fix packs applied, and is configured to work with the digital experience software.
4. "Installing the digital experience software" on page 167
   IBM's Exceptional Digital Experience is designed to help create, manage, simplify, and integrate your processes into an engaging online experience. IBM WebSphere Portal and IBM Web Content Manager are a part of the Exceptional Digital Experience. The product documentation uses digital experience software as a shorthand for IBM WebSphere Portal and IBM Web Content Manager.
5. "Installing add-ons" on page 210
   You can use the Solution Installer through the Configuration Wizard to install and uninstall add-ons to an IBM WebSphere Portal Express server instance. The Solution Installer uses the Portal Application Archive (PAA) format as the standard format for application distribution. Portal Application Archive (PAA) updates are not supported in the configuration wizard currently. For more information about updating add-ons using a command prompt, see the Managing your existing PAA file section.
6. "Uninstalling the digital experience software" on page 218
   Uninstalling the digital experience software is a multiple step process. Manual uninstallation instructions are provided for a single-server configuration in case of an error situation.

Planning to install WebSphere Portal Express

Before you install IBM WebSphere Portal Express in a production environment, you need to assess your hardware and software needs, possible database configurations, security options, and LDAP server options. Skipping this important step can lead to unexpected results and costly delays.

About this task

Restriction: The serverName is hardcoded to WebSphere Portal Express. The serverName cannot be changed in a stand-alone environment. If you do change it, the ConfigEngine scripts do not work. For a clustered environment, see Technote 1370392 for options on replacing the WebSphere Portal Express JVM.

"System requirements" on page 103
Before you install IBM WebSphere Portal Express, review the hardware and software requirements to ensure that you have the supported versions of prerequisite and corequisite software and the required hardware.

"Release notes" on page 103
Known issues and problems are centrally available on the support page. Links into the support knowledge base are integrated throughout the documentation to make sure that you have the most current information. Before you start the installation process, check the IBM Support site for the most current information about known limitations or issues. Use the following dynamic queries to find late breaking information about this release.

"WebSphere Portal Express Support Statement" on page 103
This support statement proposes a revision to the definition of "supported" and "unsupported" about the various products of which IBM WebSphere Portal Express depends on for proper operation.

"User IDs and passwords" on page 107
Understanding character limitations for user IDs and passwords is important because they are used throughout the system to provide access and secure content. The character limitations provided here apply to the IBM WebSphere Portal Express administrator, IBM WebSphere Application Server administrator, database administrator, LDAP server administrator, and user IDs. Database and LDAP servers can have more restrictive limitations than provided here. Therefore, check the database and LDAP server product documentation for restrictions. Failure to correctly define user IDs and passwords during the installation process can result in installation failure. In addition, your company might have more restrictive user ID and password requirements that you must also follow.

"Web Content Manager environments" on page 109
To use a Web Content Manager system, you need to deploy a set of Web Content Manager environments within your overall WebSphere Portal system. Reviewing the Web Content Manager environments help you understand what happens in each environment and how you might want to set up your physical severs. Web Content Manager is installed by using the WebSphere Portal installation user interface.

"Evaluation license" on page 119
IBM WebSphere Portal Express comes with a special license that you can use to install and deploy the product for a 60-day evaluation at no charge. If you then purchase WebSphere Portal Express, with a simple utility you can convert the evaluation license to a full production license. Users who prefer to purchase and install WebSphere Portal Express directly, without the evaluation license, can do so without having to install or convert the evaluation license.

"Database" on page 119
IBM WebSphere Portal Express includes an Apache Derby database that is configured and ready for immediate use. As a result, you have a running portal that is ready for exploration or portlet and theme development. But for a production environment or any environment for Web Content Manager, you must use one of the other supported database management systems.

"User registry considerations" on page 128
A user registry or repository authenticates a user and retrieves information about users and groups to do security-related functions, including authentication and authorization.

"WebSphere Portal Express high availability" on page 135
IBM WebSphere Portal Express is licensed for use in a single-server configuration and might not be used in either a cloned configuration or a clustered configuration except when implementing idle standby for the purpose of failover.

System requirements

Before you install IBM WebSphere Portal Express, review the hardware and software requirements to ensure that you have the supported versions of prerequisite and corequisite software and the required hardware.

See the detailed system requirements document at the following URL: WebSphere Portal detailed system requirements

Release notes

Known issues and problems are centrally available on the support page. Links into the support knowledge base are integrated throughout the documentation to make sure that you have the most current information. Before you start the installation process, check the IBM Support site for the most current information about known limitations or issues. WebSphere Portal Express Support Statement

This support statement proposes a revision to the definition of "supported" and "unsupported" about the various products of which IBM WebSphere Portal Express depends on for proper operation.

Introduction

WebSphere Portal Express requires the use of several collateral products for its normal operations. In particular, it requires WebSphere Application Server, a database, a repository for user information (typically an LDAP), and other products depending on specific customer requirements.

During the testing of a new release, Development generally tests WebSphere Portal Express with a prescribed list of these collateral products. These products are designated as "Supported Products" in the documented hardware and software requirements for that release.

Because the list of "Supported Products" cannot reasonably describe all possible configurations that a customer might need to use, some customers voiced concerns

about the level of support that is provided for configurations that are not designated as “Supported”. This document is intended to provide clarification of the level of support that can be expected for the current release with various combinations of dependent products.

Note: Although the statements in this document reflect the general level of support that can be expected for WebSphere Portal Express, the terms and conditions of any specific support offering, license or other Agreement you might have with IBM will determine the actual delivered support for the product. Nothing herein shall be construed as supplementing, modifying or superseding the terms of your IBM license agreement for WebSphere Portal Express or any other agreement you might have with IBM, nor shall it create any obligation for IBM to deliver a level of support other than might be set forth in such Agreements.

Categories of Support

There are three categories of support for collateral products to WebSphere Portal Express. They are “Supported Products”, “Newer Versions, and Releases of Supported Products” and “Unsupported Products”. The definition and support statement for each category follows:

Supported Product

A “Supported Product” is a product (at a specified version, release and fix level) that was tested by Development and is known to work with WebSphere Portal Express.

Products in this category are supported according to the terms of your WebSphere Portal Express License Agreement. PMRs (Problem Management Records) are accepted by IBM Support in accordance with the conditions of the WebSphere Portal Express License Agreement.

Newer Versions and Releases of Supported Products

Many products outside the specific version(s), release(s), or fix pack(s) of the “Supported” version (referenced in the documented hardware and software requirements) might not be explicitly tested by IBM WebSphere Development, yet can reasonably be expected to perform within the accepted bounds of reliability, function, and performance by a customer.

Products that fall into this category are typically newer releases or fix levels of a product already in the “Supported Product” category or a product that adheres to a standard API that WebSphere Portal Express supports (such as an LDAP server). Some specific examples might include a newer operating system fix level, a WebSphere Application Server (WAS) fix pack newer than the original “Supported” fix pack level, an IBM Java (JVM) fix pack, a new fix pack, or release of DB2 or an updated LDAP server.

For products that fall into this category, support is as follows:

For IBM products, such as IBM Directory Server or Domino LDAP, IBM DB2, IBM JDKs (JVMs) and WebSphere Application Server, WebSphere Portal Express will fully support fix-pack, release and version updates that do not significantly change interfaces or other underlying support that WebSphere Portal Express depends on for its functionality. If and when a newer release of one of these products is shipped that WebSphere Portal Express cannot accommodate, that fact will be noted as described in the next section entitled “Unsupported Products”. Note that in order for WebSphere Portal Express to support an update to a database or LDAP product, WebSphere Application Server must support that update as well.

For non-IBM products, the Support team makes a commercially reasonable effort to support products in this category. Support accepts problem reports (PMRs) for the appropriate releases that use these untested products. If Support is able to re-create the reported problem with a "Supported" version of the product, we will attempt to fix the problem.

If Support is not able to re-create the problem with a "Supported" version of the product in question and is not able to resolve the problem on the untested version of the product in question, Support will look to the support organization for the product in question to provide resolution. Please note that varying degrees of customer involvement may be necessary to handle this process for non-IBM products.

If the support organization for the untested product in question is unable to resolve the problem, Support will deem that version, release or fix pack level of the untested product in question to now be an "Unsupported Product".

Unsupported Products

An "Unsupported Product" is a product (at a specified version, release and fix level) that is known to not work with WebSphere Portal Express and is therefore not supported. A product can be included in this category as a result of an explicit test effort by Development or as a result of discovery from a prior customer problem. The WebSphere Portal Express Support team maintains a list, by release, of all known "Unsupported Products". The list is published as a techdoc and is available to all customers.

WebSphere Application Server has a similar support statement, which can be found on the web.

Note: WebSphere Application Server uses specially customized builds of the IBM Java SDKs on certain platforms. Updates to these builds must be obtained from WebSphere Application Server support.

WebSphere Portal Express can be sensitive to changes in the underlying WebSphere Application Server. Upgrading to a new fix pack level of the application server is well tolerated and encouraged (such as from WebSphere Application Server version 8.0 to 8.0.x) as long as all required fixes for WebSphere Application Server are available as integrated into that fix pack or by applying an interim fix specifically for that maintenance level. However, upgrading from one version of WebSphere Application Server to the next (such as from 7.0 to 8.0) is problematic if not done within the context of a migration of versions and must never be attempted with an "in-place" system.

For example, an existing instance of WebSphere Portal Express version 8.0 that is installed and functioning on WebSphere Application Server version 8.0 cannot be successfully migrated to WebSphere Application Server version 8.x by using the WebSphere Application Server Migration Tools. Such attempts might result in a non-functional system. For more information on such scenarios, consult IBM WebSphere Portal Express support.

Support for LDAP Servers

LDAP support spans two categories:

Fully tested and supported LDAP servers:

The list of fully tested LDAP servers for each release of WebSphere Portal

Express is documented in the detailed system requirements for each release. WebSphere Portal Express support accepts problem reports for the appropriate WebSphere Portal Express releases using the tested directory servers. These problem reports receive high-priority attention. Features that are tested with these directories include relatively simple search and retrieval functions for user and group objects. Functions outside this scope, such as the Active Directory Global Catalog feature, are considered advanced features and have not been tested with WebSphere Portal Express. WebSphere Portal Express support encourages customers to work with their LDAP provider for additional support on these advanced features.

Untested and partially supported LDAP servers:
In general, WebSphere Portal Express support makes a best effort to support directory servers that have not been tested with WebSphere Portal Express. WebSphere Portal Express support accepts problem reports for the appropriate WebSphere Portal Express releases using untested directory servers. If WebSphere Portal Express support can re-create the reported problem using a tested LDAP server, staff will attempt to fix the problem. If the support team is not able to re-create the problem on a tested LDAP server, customers are referred to the LDAP provider for further assistance.

Support for External Security Managers (ESM)

ESM support spans two (2) categories:

Fully tested and supported ESM software:
The list of fully tested ESM software versions for each release of WebSphere Portal Express is documented in the detailed system requirements for each release. WebSphere Portal Express support accepts problem reports for the appropriate WebSphere Portal Express releases using the tested ESM servers. These problem reports receive high-priority attention. Features that are tested with these software products include authentication and authorization. Functions outside this scope, such as login customizations, referrals, impersonation, and step up authentication are considered advanced features and have not been tested with WebSphere Portal Express. WebSphere Portal Express support encourages customers to work with their ESM provider for additional support on these advanced features.

Untested and partially supported ESM servers:
In general, WebSphere Portal Express support makes a best effort to support ESM servers that have not been tested with WebSphere Portal Express when relying on the ESM for authentication only. WebSphere Portal Express support accepts problem reports for the appropriate WebSphere Portal Express releases using untested ESM Trust Association Interceptor (TAI) implementations. If WebSphere Portal Express support can re-create the reported problem using a tested ESM, staff will attempt to fix the problem. If the support team is not able to re-create the problem on a tested ESM, customers are referred to the ESM provider for further assistance.

Related information:

System requirements

User IDs and passwords

Understanding character limitations for user IDs and passwords is important because they are used throughout the system to provide access and secure content. The character limitations provided here apply to the IBM WebSphere Portal Express administrator, IBM WebSphere Application Server administrator, database administrator, LDAP server administrator, and user IDs. Database and LDAP servers can have more restrictive limitations than provided here. Therefore, check the database and LDAP server product documentation for restrictions. Failure to correctly define user IDs and passwords during the installation process can result in installation failure. In addition, your company might have more restrictive user ID and password requirements that you must also follow.

When a person signs up as a user or when an administrator enrolls a user, they must complete the user information form. On this form, do not enter characters that might not be supported. Regardless of what characters you are able to enter on the user information form, user ID and passwords are limited to the valid characters described here. You can specify other characters in the given name and surname fields. If your company policy is more restrictive, you can provide that information to your users in the enrollment form help or as inline help directly on the form.

Important: WebSphere Portal Express cannot create user IDs or passwords that contain spaces, although it fully supports any existing user IDs and passwords or those IDs created in the user repository that contain spaces.

Under normal circumstances a valid user ID and password can contain the following characters:

Note: The only supported characters in IBM i are lowercase characters, uppercase characters, numbers, and the underscore.

Lowercase characters {a-z}

Uppercase characters {A-Z}

Numbers {0-9}

Exclamation point {!}

Open parenthesis {(}

Close parenthesis {)}

Dash {-}; this character is not supported as the first character in the user ID or password

Period {.}; this character is not supported as the first character in the user ID or password

Underscore {_}; this character is the only supported special character in IBM i

Grave accent {`}

Tilde {~}

Commercial at {@}, this character is not supported when you create the WebSphere Portal Express and WebSphere Application Server administrator during installation.

Important: These characters are all ASCII characters. Non-ASCII characters are not allowed for user name or password.

Note: If you plan on using a non-ASCII-based encoding, ensure your Java virtual machine has the correct generic arguments specific for the non-ASCII-based

encoding. For example, for UTF-8 encoding, add the following two parameters to the Java virtual machine generic arguments for WebSphere Portal: **-Dfile.encoding=UTF-8** and **-Dclient.encoding.override=UTF-8**

Note: (Linux only) Some tasks might require you to enter the fully qualified user ID. If your fully qualified user ID contains a space; for example: `cn=wpsadmin,cn=users,l=SharedLDAP,c=US,ou=Lotus,o=Software Group,dc=ibm,dc=com`, you must place the fully qualified user ID in the properties file or into a parent properties file instead of as a flag on the command line. For example, create a parent properties file called `mysecurity.properties`, enter the fully qualified user ID, and then run the task: `./ConfigEngine.sh` *`task_name`* `-DparentProperties=/opt/mysecurity.properties`.

Note: (Windows only) Some tasks might require you to enter the fully qualified user ID. If your fully qualified user ID contains a space; for example: `cn=wpsadmin,cn=users,l=SharedLDAP,c=US,ou=Lotus,o=Software Group,dc=ibm,dc=com`, you must place quotations around the fully qualified user ID before you run the task; for example, `"cn=wpsadmin,cn=users,l=SharedLDAP,c=US,ou=Lotus,o=Software Group,dc=ibm,dc=com"`.

The following table contains a list of the required fields on the user information form and the supported characters.

Table 6. Valid characters and unsupported characters for user information

User information	Valid characters	Unsupported characters
User ID	**Note:** The only supported characters in IBM i are lowercase characters, uppercase characters, numbers, and the underscore. Lowercase characters {a-z} Uppercase characters {A-Z} Numbers {0-9} Exclamation point {!} Open parenthesis {(} Close parenthesis {)} Dash {-}; this character is not supported as the first character in the user ID or password Period {.}; this character is not supported as the first character in the user ID or password Underscore {_}; this character is the only supported special character in IBM i Grave accent {`} Tilde {~} Commercial at {@}, this character is not supported when you create the WebSphere Portal Express and WebSphere Application Server administrator during installation.	Only ASCII characters are allowed. **Other restrictions:** The user ID cannot contain spaces; for example, *`user name`*. **Note:** User IDs cannot be longer than 200 characters. If you enter any unsupported characters during the installation, you receive an error message that states which character is invalid. For example, "The special character [@] was found in the **administrative user ID** field. Enter the administrative user ID again." **Important:** You receive a different error message if you enter any unsupported characters when you create users through the **Manage users and groups** portlet.

Table 6. Valid characters and unsupported characters for user information (continued)

User information	Valid characters	Unsupported characters
Password / Confirm password	**Note:** The only supported characters in IBM i are lowercase characters, uppercase characters, numbers, and the underscore. Lowercase characters {a-z} Uppercase characters {A-Z} Numbers {0-9} Exclamation point {!} Open parenthesis {(} Close parenthesis {)} Dash {-}; this character is not supported as the first character in the user ID or password Period {.}; this character is not supported as the first character in the user ID or password Underscore {_}; this character is the only supported special character in IBM i Grave accent {`} Tilde {~} Commercial at {@}, this character is not supported when you create the WebSphere Portal Express and WebSphere Application Server administrator during installation.	Diacritics, such as the umlaut, and DBCS characters are not allowed. **Other restrictions:** The password cannot contain spaces; for example, *pass word*. **Note:** Passwords cannot be longer than 128 characters. **Attention:** Login or **ConfigEngine** tasks might fail if the password contains any unsupported characters, including DBCS characters. This action happens even if a user is successfully enrolled with a password that contains DBCS characters. If you enter any unsupported characters during the installation, you receive an error message that states which character is invalid. For example, "The special character [@] was found in the password field. Enter the password again."
Given name	All characters	n/a
Surname	All characters	n/a

Note: The previous characters are true if the **user.UNIQUEID.charset** parameter is set to `ascii`. If set to `unicode`, the standard Java Letter definition is used and all characters that are recognized as letter or digit by Java are allowed by default. See the **Puma Validation Service** section in the "Portal configuration services" link for information about further parameters that can be modified to affect the behavior of Portal's validation of users, groups, and passwords.

Web Content Manager environments

To use a Web Content Manager system, you need to deploy a set of Web Content Manager environments within your overall WebSphere Portal system. Reviewing the Web Content Manager environments help you understand what happens in each environment and how you might want to set up your physical severs. Web Content Manager is installed by using the WebSphere Portal installation user interface.

Each server or cluster in your web content system requires a separate data repository, but they would usually share LDAP. A Web Content Manager system can be deployed in isolation or in parallel with a WebSphere Portal system.

"Web content system overview"
The type of web content system you deploy is determined by the size of your web content system, the type of website, and the number of users that create content, or view your web content.

"Web content authoring environments" on page 111
An authoring environment is used to create and manage web content and is used by your content authors and website designers.

"Web content testing environments" on page 114
Testing environments can be simple or complex. A simple example is a stand-alone server where content and non-content items are tested before they are sent to the live site. A complex environment is a complete replica of your delivery environment. A more complex environment is used to test content, theme, and application changes and the performance of your delivery environment.

"Web content delivery environments" on page 116
A production delivery environment is the environment that hosts your website. If you have a IBM Web Content Manager only license, you can deliver your website without using WebSphere Portal features.

Web content system overview

The type of web content system you deploy is determined by the size of your web content system, the type of website, and the number of users that create content, or view your web content.

Web content system types

There are three main types of web content systems:

Single environment systems
This environment is where authoring and delivery occur within a single environment. This type of environment would be deployed by a small organization with a small website, such as an intranet. Authoring and delivering content within the same environment can be resource-intensive, so the type of environment you deploy needs to be robust enough to allow authoring and delivery to occur at the same time. For example, running clustered servers is a common solution for a single instance system.

Dual environment systems
This environment is where authoring and delivery are split into different environments. This model reduces the load on both authoring and delivery servers and also allows the authoring environment to be located behind a firewall. This type of system would be used with externally facing websites, or where you have many users authoring content or many users viewing a website.

Staged systems
This environment is where a staging environment is added between the authoring and delivery environments. The staging environment can be used for user acceptance testing (UAT) or to accumulate changes from your authoring environment before changes are syndicated to your delivery environment in a single batch. This system would be deployed to deliver large, complex sites with many content creators and you need to ensure that the website content is accurate, error-free and can run under load.

Environment types

Authoring environment

An authoring environment is used to create and manage web content. This environment is used by your content creators and website designers. An authoring system can consist of:

- An authoring server or cluster.
- Individual UAT servers where site and content updates can be tested before the content is syndicated to the delivery environment.

Staging environment

A staging environment can consist of:

- Individual holding servers where changes from your authoring environment can be accumulated before your changes are syndicated to your delivery environment in a single batch. Pairs of holding servers can be used to provide you with built-in redundancy.
- A complete replica of your delivery environment where UAT can occur to both review site and content updates, and to test the performance of your delivery environment.

Delivery environment

This environment is used by your website viewers. A delivery environment can consist of:

- Pre-rendered sites where a web content site is pre-rendered as a set of HTML files that are then used to deliver a static website.
- a WebSphere Portal server or cluster where content is delivered by a servlet. Servlet delivery is used to deliver websites that contain dynamic content, but do not include any WebSphere Portal content or applications.
- a WebSphere Portal server or cluster where content is delivered by either a local or remote web content viewer portlet. Web content viewer portlets are used to deliver websites that contain dynamic web content alongside other portlets or applications.
- A combination of the previous three.

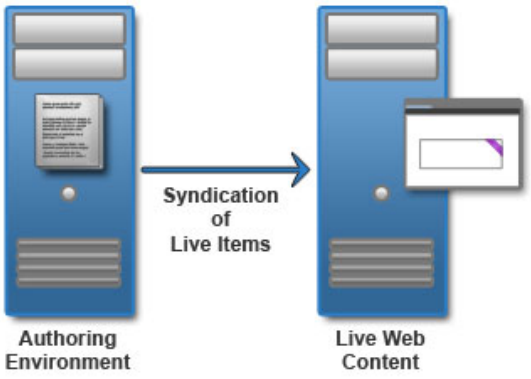
Web content authoring environments

An authoring environment is used to create and manage web content and is used by your content authors and website designers.

Most Web Content Manager sites need to support many content authors. A clustered server solution is the best solution for this scenario.

Standard authoring environment

A standard authoring environment consists of a single authoring cluster that syndicates directly to either a staging or delivery environment. The following topology depicts an authoring environment that is configured to syndicate live items to the live production environment. The production server hosts the live site that visitors browse. Live items include published and expired items. The authoring environment is depicted as a stand-alone server, however it might be clustered.



The following activities occur in the authoring environment:

- Create drafts
- Approve drafts
- Test changes
- Publish changes

Authoring environment with testing

Add a test environment to run user acceptance testing on your content management system and website. The test environment provides an extra layer of validation before content and design changes are pushed to the live website.

In the following topology, all items are syndicated from the authoring environment to the testing environment. After the content is tested, only live items are syndicated back to the authoring environment. Then, live items are syndicated to the production server.

In the diagram, the following activities happen on each server.

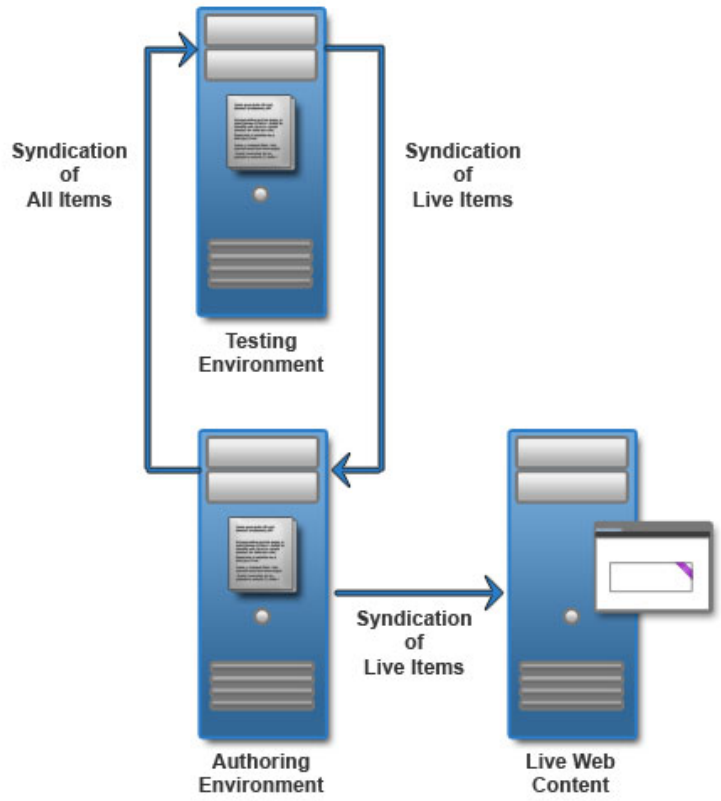
Authoring environment

- Create drafts
- Approve drafts
- Test changes
- Syndicate all items to test environment
- Syndicate live items to live site

Testing environment

- Publish changes
- Test changes
- Syndicate live items to authoring environment

In addition, theme changes might be pushed to testing environment to validate that the content elements and design elements integrate as expected. Design integration elements are not included in the topology diagram.



Decentralized authoring environments

If your content authors are at different locations, or you have different groups of content authors, consider deploying a set of decentralized authoring clusters. This scenario works best if the decentralized content authors work with separate content stored in different content libraries.

For example, if you have users that are in different locations, it might be more efficient to set up a local authoring environment at each location. Two-way syndication is used between all authoring environments with a centralized authoring environment. The centralized authoring environment provides an integrated view of all changes from the different authoring environments.

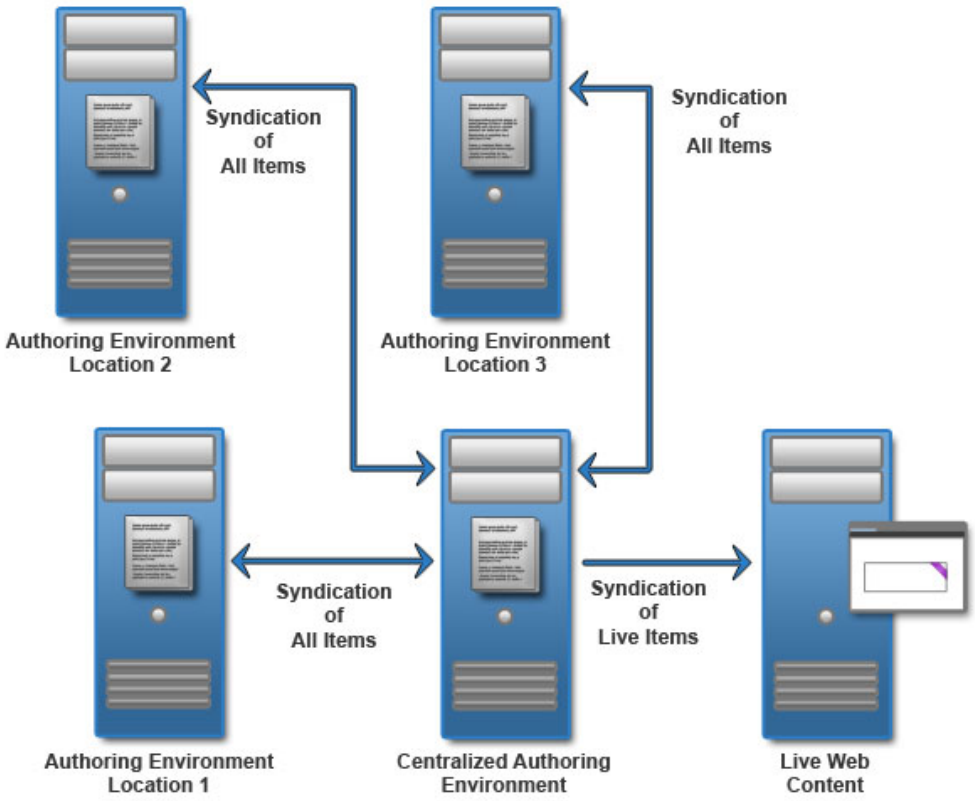
In the diagram, the following activities happen on each server.

Authoring environments 1, 2, and 3

- Create drafts
- Approve drafts
- Test changes
- Syndicate all items to central authoring environment

Centralized authoring environment

- Receive all items from authoring environments
- Syndicate all items to authoring environment
- Syndicate live items to testing environment (not shown)
- Syndicate live items to the live website



Decentralized authoring creates the risk of conflicting updates between authoring environments. To reduce the risk of conflicts, you can allocate different sites, or different sections of a site, to each authoring environment. You can also use different authoring environments for different user roles. For example, content authors might use a different authoring environment than presentation template designers.

Access to each decentralized authoring environment is controlled with a combination of authoring portlet access controls and item security settings. For example, only users that require access to the local authoring environment would be granted access to the local authoring portlet. Users would be given "Read" access to all items, but only "Edit" access to items they are required to update.

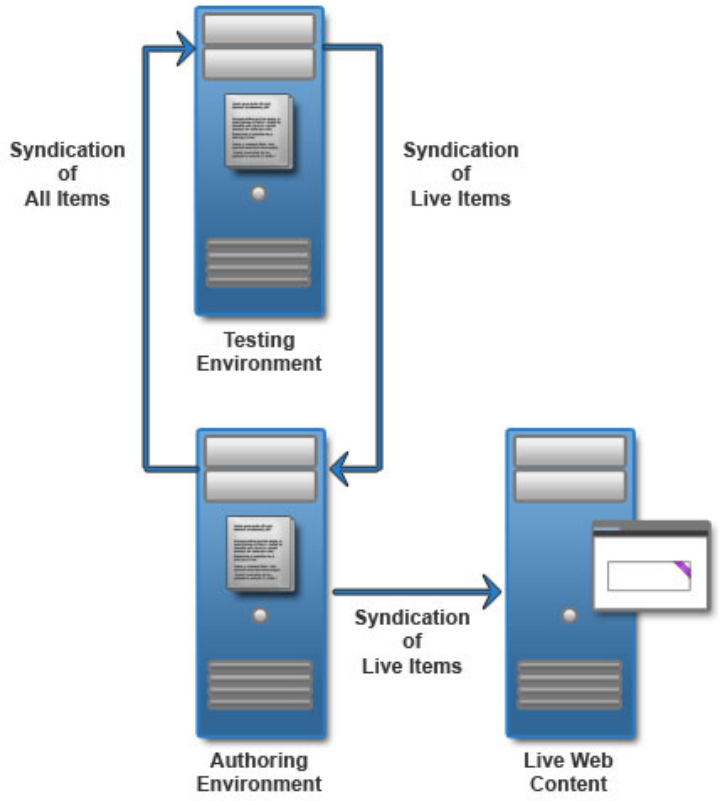
Web content testing environments

Testing environments can be simple or complex. A simple example is a stand-alone server where content and non-content items are tested before they are sent to the live site. A complex environment is a complete replica of your delivery environment. A more complex environment is used to test content, theme, and application changes and the performance of your delivery environment.

A single website might have multiple testing environments. Some testing environments focus on content and design integration, application and data integration, performance, and more. A web content test environment is a layer of validation before changes are sent to the live website. The test environment might be used to accumulate changes from your authoring environments before the changes are syndicated to the production delivery environment.

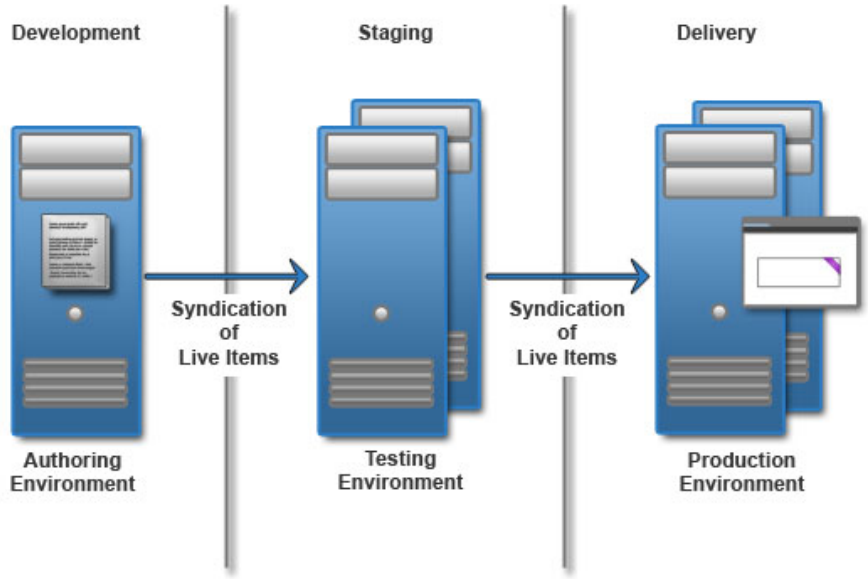
Site testing within an authoring environment

When testing within an authoring environment a testing server is paired with an authoring server. The testing server simulates the delivery environment and is used to test major changes to a website.



System testing within a staging environment

When testing within a staging environment, data from the authoring environment is syndicated to a staging environment. User acceptance testing happens in the staging environment. If all tests are passed, data is syndicated from staging to the delivery production environment.



Specific activities take place in each environment.

Authoring environment

- Create drafts
- Approve drafts
- Test changes
- Publish changes
- Syndicate live items to the staging environment

Testing environment

Test changes.

Syndicate live items to production environment.

Production environment

Deliver live website.

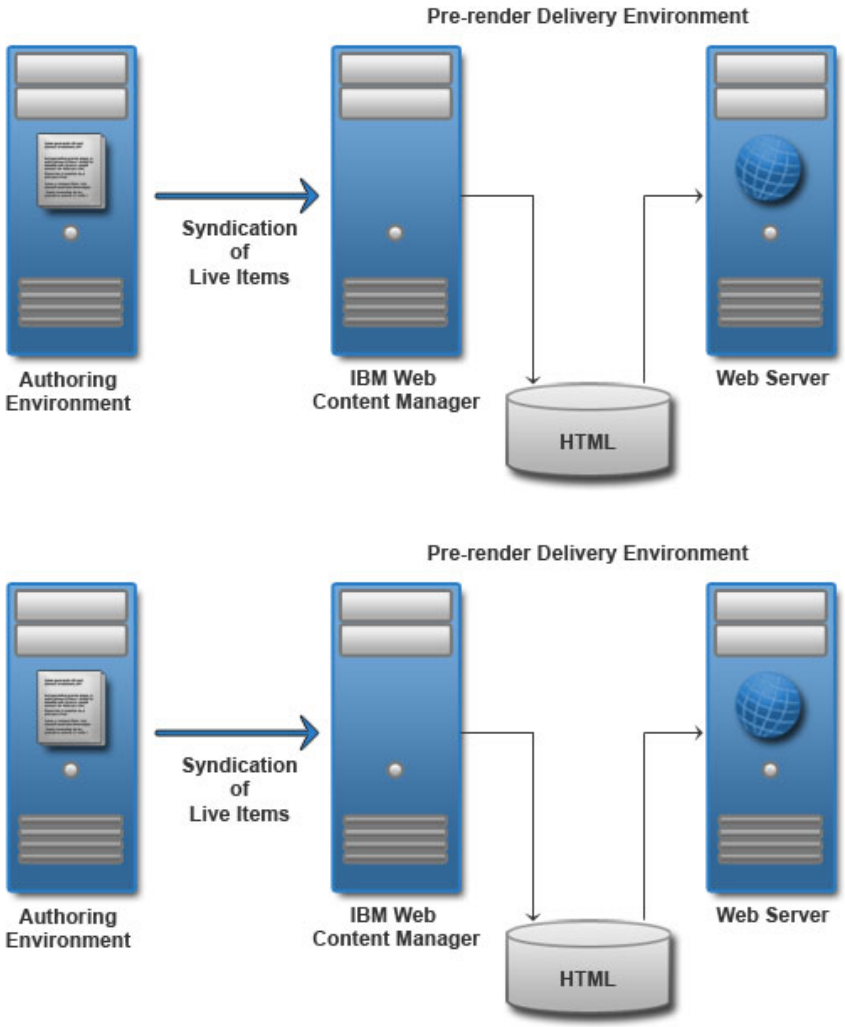
Web content delivery environments

A production delivery environment is the environment that hosts your website. If you have a IBM Web Content Manager only license, you can deliver your website without using WebSphere Portal features.

Pre-rendered delivery

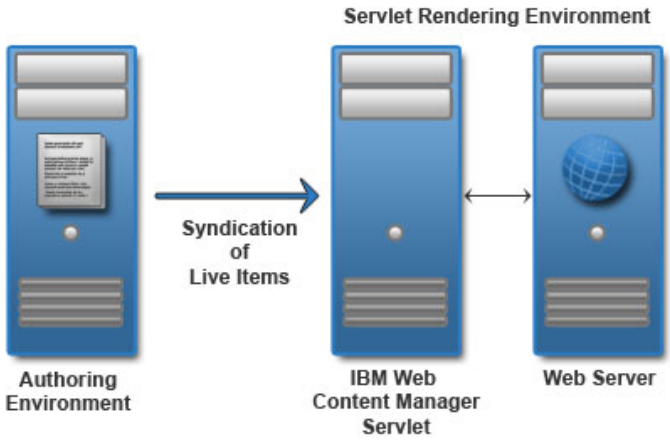
Deploy a pre-rendered site when you are not using any WebSphere Portal features, such as portlets, and your content is static and is only updated periodically. When you set up a pre-render delivery environment, your complete website is converted to static HTML files.

In a pre-rendered delivery environment, live items are syndicated from the authoring environment to the delivery environment. The content is converted into a set of static HTML files, which are then displayed to users through a web server.



Servlet delivery

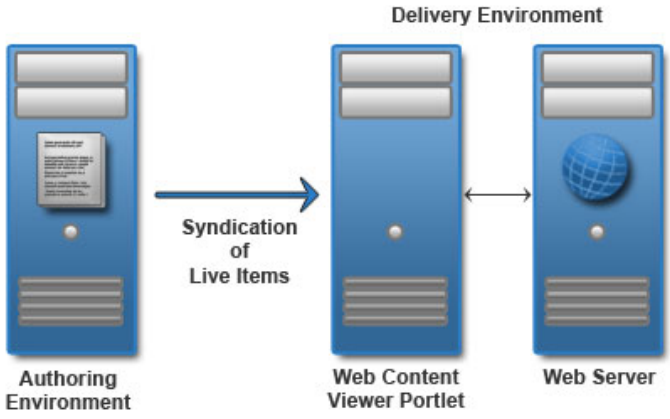
A servlet delivered website is used when you do not need to use any portlet-based features such as authoring tools. In a servlet delivery environment, content is syndicated from the authoring server to the delivery server. The Web Content Manager servlet displays the content. Site visitors access the site through a web server.



Portlet delivery

Web content viewers are portlets that display content from a web content library as part of a portal page. If your presentation is simple, a single web content viewer can be sufficient. However, you can also use multiple web content viewers to aggregate content from different libraries and provide a richer experience for site visitors. A local web content view portlet is used to display content within your web content delivery environment.

In a portlet delivery environment, content is syndicated from the authoring server to the delivery server. It is displayed to users through a web content viewer portlet that is deployed on a portal server. When a local web content viewer is used, the web content viewer portlet is deployed on the same server as Web Content Manager.

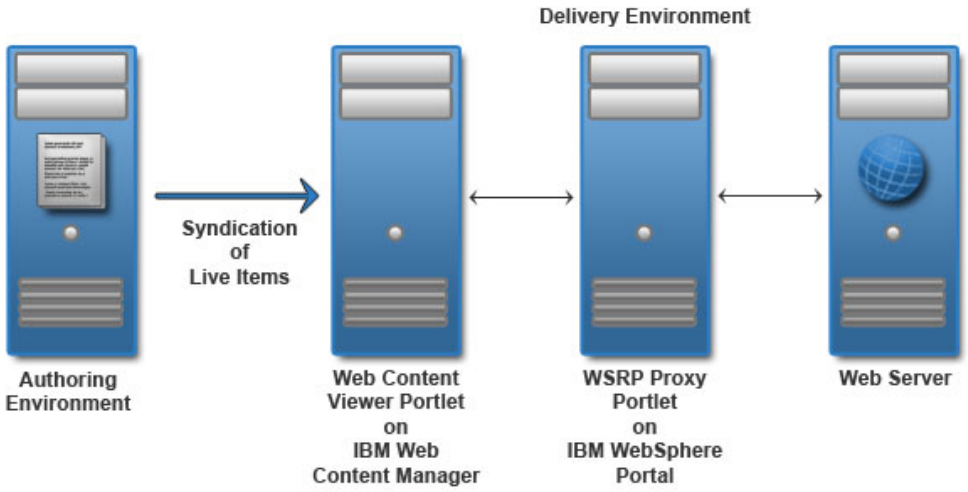


Remote portlet delivery

WSRP support in the web content viewer is used to display content on a remote WebSphere Portal server or cluster.

In a remote portlet delivery environment, content is syndicated from the authoring server to a Web Content Manager server in the delivery environment. The web content viewer portlet is deployed on the Web Content Manager server. It is configured to communicate with the WSRP proxy portlet that is installed on a portal server in the delivery environment. Users view web content by accessing the

proxy portlet on the remote portal server, typically through a web server.



Evaluation license

IBM WebSphere Portal Express comes with a special license that you can use to install and deploy the product for a 60-day evaluation at no charge. If you then purchase WebSphere Portal Express, with a simple utility you can convert the evaluation license to a full production license. Users who prefer to purchase and install WebSphere Portal Express directly, without the evaluation license, can do so without having to install or convert the evaluation license.

Note: This version is intended for new users who did not previously install WebSphere Portal Express. You cannot use the WebSphere Portal Express media or downloaded installation image to upgrade an existing installation.

Using the evaluation license

When you install WebSphere Portal Express under the terms of the 60-day evaluation license, individuals and teams can explore and use the site immediately.

Each time that you launch the site, the SystemOut log file records the number of days that remain in the evaluation license. The log file is in *wp_profile_root*`/logs/WebSphere_Portal`.

To continue use after the evaluation license expires, you need to purchase WebSphere Portal Express. The purchased production software includes the files that are needed to convert the previously installed evaluation license to a full production license. Custom templates and data files that users created during the evaluation period are fully compatible with the production license, so no additional migration is required.

For purchasing information, contact your local IBM representative or authorized IBM Business Partner.

Database

IBM WebSphere Portal Express includes an Apache Derby database that is configured and ready for immediate use. As a result, you have a running portal that is ready for exploration or portlet and theme development. But for a

production environment or any environment for Web Content Manager, you must use one of the other supported database management systems.

Apache Derby

Derby does not support clustered environments, enabling security in a database-only mode, or vertical cloned environments in which multiple application servers are configured on a single server.

The Derby database that is installed by default is not supported for use in a production environment.

Apache Derby and Web Content Manager

Use one of the other supported databases in a production environment or when you are developing presentation templates or authoring web content. The Derby database can be sufficient for non-production installations of WebSphere Portal Express, the performance of Derby with Web Content Manager is poor. A typical cause of performance issues is transaction timeouts. Although you can increase these timeouts, the resulting performance is prohibitively slow. You must use one of the other supported database management systems. They are better able to handle large amounts of data and can be tuned for performance.

CF07
Apache Derby and Site Builder

The use of Apache Derby with Site Builder is not supported on development or production environments.

Database transfer

Transfer data to another supported database before you use the portal extensively. Large amounts of data in the databases can cause the database transfer to fail if your Java heap size is not large enough. Do not postpone transferring data to another database management system. Waiting to transfer the database can cause errors to occur during the transfer process, such as not having adequate Java heap size.

Configuration Wizard

Use the wizard to either create scripts that you or your database administrator can use to create databases, create database user IDs, and configure database user ID privileges. The wizard collects information about your database management system, the database topology you want, the user IDs you require, and more. Then, it generated custom scripts and instructions.

"Database users" on page 121
There are two types of database users: database configuration users and database runtime users. Become familiar with the privileges required for each user type to work with the database domains of IBM WebSphere Portal Express and the commands for creating database configuration users and granting privileges.

"Database topologies" on page 123
Consider the database configuration options in relation to your IBM WebSphere Portal Express deployment scenario. The complexity of the network topology

increases as you scale from a proof-of-concept environment using IBM DB2 Universal Database™ Workgroup Server Edition to systems using vertical and horizontal cloning techniques.

"Portal database domains" on page 126
Sets of databases tables and schemas for portal resources are called *database domains*. Database domains classify and help you determine how to distribute portal data. There are six database domains: release, customization, community, JCR, feedback, and likeminds.

"JDBC type 2 and type 4 drivers" on page 128
The Configuration Wizard uses JDBC type 4 drivers by default. You can change the default selection in the Configuration Wizard.

Database users

There are two types of database users: database configuration users and database runtime users. Become familiar with the privileges required for each user type to work with the database domains of IBM WebSphere Portal Express and the commands for creating database configuration users and granting privileges.

Database configuration user

The database administration user that is typically created when a database management system (DBMS) is installed is the *database installation user* or the *database configuration user*. The database configuration user is not necessarily the user that is created by default when the database management system is installed. The default user might be used as the database configuration user. The database configuration user is used by WebSphere Portal Express for configuration tasks and creates the database structure that is needed by WebSphere Portal Express. For example, the database configuration user can create database tables and indexes, do database transfer, and often times has operating system privileges, depending on the database management system.

Database runtime user

The *database runtime user* has fewer privileges than the database configuration user. The runtime user has runtime access to the data source of a database and can do basic read and write operations on the data. Consider creating a dedicated runtime user for each database domain of WebSphere Portal Express. If you do not create runtime users, then WebSphere Portal Express uses the configuration user to connect to the databases at run time.

Privileges of database users

The following table identifies the minimum privileges that are needed to correct function by the two types of database users: configuration users and runtime users. The privileges that are listed pertain to all WebSphere Portal Express database domains.

Table 7. List of minimum privileges held by database runtime users for all database domains.

Permission within the database domain	Release	Community	Customization	JCR	Feedback	Likeminds
Access to the database	Yes	Yes	Yes	Yes	Yes	Yes
Read on all tables	Yes	Yes	Yes	Yes	Yes	Yes
Write on all tables	Yes	Yes	Yes	Yes	Yes	Yes
Update on all tables	Yes	Yes	Yes	Yes	Yes	Yes
Delete on all tables	Yes	Yes	Yes	Yes	Yes	Yes
Create tables	No	No	No	No	No	No
Create indexes	No	No	No	No	No	No
Use of sequences	No	No	No	No	Yes	No

Table 8. List of privileges held by database configuration users for all database domains.

Permission within the database domain	Release	Community	Customization	JCR	Feedback	Likeminds
Access to the database	Yes	Yes	Yes	Yes	Yes	Yes
Read on all tables	Yes	Yes	Yes	Yes	Yes	Yes
Write on all tables	Yes	Yes	Yes	Yes	Yes	Yes
Update on all tables	Yes	Yes	Yes	Yes	Yes	Yes
Delete on all tables	Yes	Yes	Yes	Yes	Yes	Yes
Quota on disk to create new objects	Yes	Yes	Yes	Yes	Yes	Yes
Create table spaces	Yes	Yes	Yes	Yes	Yes	Yes
Drop table spaces	Yes	Yes	Yes	Yes	Yes	Yes
Create tables	Yes	Yes	Yes	Yes	Yes	Yes

Table 8. List of privileges held by database configuration users for all database domains. (continued)

Permission within the database domain	Release	Community	Customization	JCR	Feedback	Likeminds
Alter tables	Yes	Yes	Yes	Yes	Yes	Yes
Drop tables	Yes	Yes	Yes	Yes	Yes	Yes
Create indexes	Yes	Yes	Yes	Yes	Yes	Yes
Drop indexes	Yes	Yes	Yes	Yes	Yes	Yes

Related information:

"Database Transfer: Granting privileges to database users for DB2 for i" on page 514

Configuration and runtime database users are granted a different set of privileges, depending on whether these users are schema owners or not. You can create a copy of the SQL scripts and edit this copy to manually grant permissions to configuration and runtime database users.

Database topologies

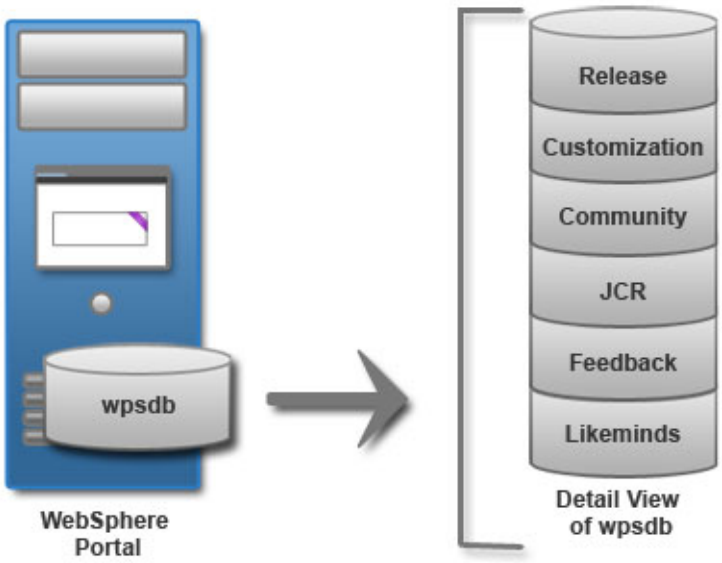
Consider the database configuration options in relation to your IBM WebSphere Portal Express deployment scenario. The complexity of the network topology increases as you scale from a proof-of-concept environment using IBM DB2 Universal Database Workgroup Server Edition to systems using vertical and horizontal cloning techniques.

WebSphere Portal Express data is separated into six portal database domains: release, customization, community, JCR, feedback, and likeminds. The portal database domains facilitate the flexibility that is required to meet different availability requirements. The database topology varies depending on the deployment scenario. A proof-of-concept or development environment has different database topology requirements than a production environment. Review the topologies to determine your portal deployment requirement.

Local database

For proof-of-concept, demonstrations, and development environments, you can use a local database. You can install the database management software on the same server as WebSphere Portal Express. When the database is on the same server as the portal, it is referred to as a *local* database. Using a local database can make administering your environment easier. However, this setup is best used for proof-of-concept deployments only. A local database competes for server resources with your portal.

In the topology diagram, all of the portal database domains are stored in one database, **wpsdb**.

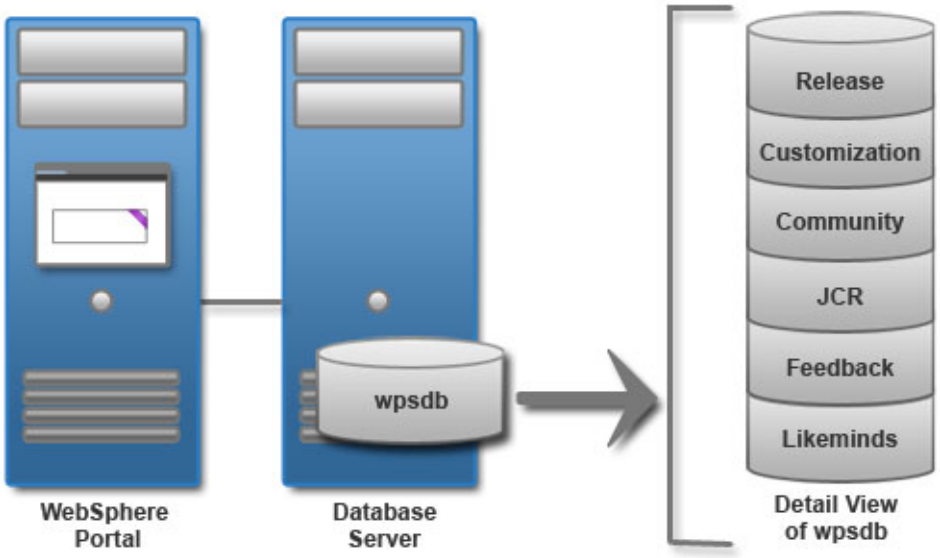


Remote database

For normal load balancing, you can use one or more remote databases. You can install the database management software on a different server from WebSphere Portal Express. When the database is on a different physical server than the portal, it is referred to as a *remote* database. Using a remote database can provide performance benefits, depending on the speed of the network.

When multiple lines of production are involved and each line of production is implemented as a cluster of servers, share portal database domains. Each database domain can be placed on a separate database for efficient maintenance. The release and JCR portal database domains cannot be shared.

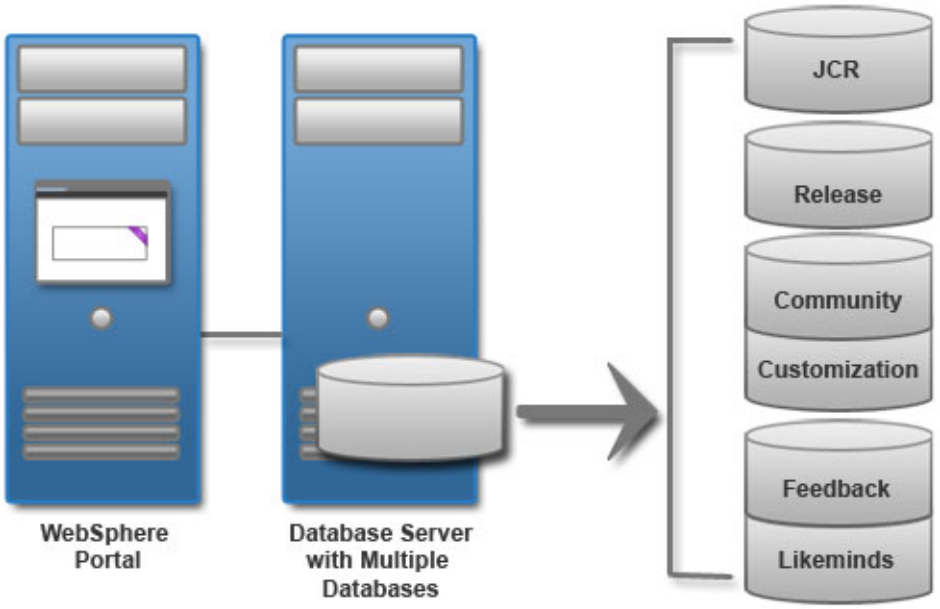
The topology diagram is similar to the local database topology. The main difference is that the database is on a different server than the portal.



High capacity and availability

For high capacity load balancing, use one or multiple remote databases. When you deploy the portal in a large-scale, high-demand environment, you can dedicate a server specifically for database transactions. As more users access the portal, the portal application becomes database intensive. Database activity can take up processor resources and disk I/O time. Separating the database from the server that the portal is running on increases its capacity.

In the topology diagram, there is a remote database server with four databases. The JCR and release portal database domains have unique databases. They cannot be shared. Also, the release portal database domain cannot be taken offline. Another database contains the customization and community portal database domains. Finally, there is another database to contain the feedback and likeminds portal database domains.



Portal database domains

Sets of databases tables and schemas for portal resources are called *database domains*. Database domains classify and help you determine how to distribute portal data. There are six database domains: release, customization, community, JCR, feedback, and likeminds.

The database domains categorize portal data into the following categories and subcategories to help you decide how to distribute portal data into different databases:

Release data (release and JCR)
Includes all portal content definitions, rules, and rights that are designed externally then brought into the portal by a staging process, such as page hierarchy, available portlets and themes, templates, credential slots, Personalization rules, and policies. These resources are typically not modified during production and need administrative rights to do so. Administrators typically create release data on an integration server and stage it to the production system. Release data is protected by access control and contains only data, not code. Release data includes two separate portal database domains: release and JCR.

The release portal database domain contains portal static site configuration, including access control, pages, and portlets.

The JCR portal database domain contains authored content, Personalization rules, and theme policy definitions.

Customization data (customization)
This data is associated with a particular user only and cannot be shared across users or user groups. Typical examples are portlet data or customized pages (implicitly derived pages). Because this data is scoped to a single user only, access control protection is simplified.

Community data (community)
This data includes all resources that are modified during production. Typically, users and groups are allowed to modify or delete shared resources. Community resources are protected by access control.

Configuration data
Configuration data is not store in a portal database domain. It is typically kept in property files. The property files are either protected by file system security or application server administration rights. This data defines the portal server setup, such as database connection, object factories, and deployment descriptors. This type of data typically is constant during the time a server node is running.

Feedback and likeminds portal database domains store data exclusively for the Feedback and LikeMinds applications.

Database schema names

The table includes the default names that are used in the Configuration Wizard. Replace these values with the values in your environment; schema names must be different when the database is shared.

All table spaces are approximately 2.8 GB by default. The size increases with the use of the Java Content Repository function.

For some database software, such as DB2, the database name cannot exceed 8 characters and can contain letters and numbers only.

Table 9. Space required for various databases

Application	Database name	Space required
WebSphere Portal Express Used for the portal (at a minimum) or to hold all data. Stores information about user customization, such as pages, and user profile and login information.	*reldb* *commdb* *custdb*	Depends on the number of users and portal objects, such as pages and portlets.
Personalization,Web Content Manager Contains documents, personalization rules, personalization campaigns, and document library configuration information.	*jcrdb*	Depends on the number and size of Personalization rules and campaigns, and the number and size of items and elements that are created in.Web Content Manager
Feedback Contains the information that is logged by your website for analysis of site activity and generating reports.	*fdbkdb*	Depends on the amount of traffic to the site. The amount of data that is logged per login-enabled page can vary.
LikeMinds Contains the recommendations that are displayed to users. The LikeMinds application analyzes the visitor's interactions with your website are and generates predictions.	*lmdb*	Depends on the amount of traffic to the site.

Database users

The table indicates types of objects that are owned by each user. The architecture allows each of the following users to exist in the same database. All table spaces are approximately 2.8 GB by default. The size increases with the use of Java Content Repository.

Application	Database user	Function
WebSphere Portal Express	*releaseusr* *communityusr* *customizationusr*	Core user who owns approximately 230 tables, which are used for WebSphere Portal Express core objects, which include tables that store the user customizations that are made to pages.
Java Content Repository	*jcr*	Java Content Repository user who owns approximately 100 tables. The number might be higher depending on usage.
Feedback	*feedback*	Feedback user who owns approximately 50 tables that are used for logging site and personalization usage.

Application	Database user	Function
LikeMinds	*likeminds*	LikeMinds user who owns approximately 15 tables that are used to hold the website usage analysis routines and recommendation text.

JDBC type 2 and type 4 drivers

The Configuration Wizard uses JDBC type 4 drivers by default. You can change the default selection in the Configuration Wizard.

During step 2, Customize Values, click **Advanced** to change the driver type.

When you use a JDBC type 2 connection, WebSphere Portal Express and DB2 Connect are installed on one system (the local system). The DB2 server is installed on a different system (the remote system).

When you use a JDBC type 4 connection, you do not need DB2 Connect. Instead, the DB2 Universal JDBC driver that is supplied with DB2 is copied to portal server. It is used within the Java virtual machine (JVM) of WebSphere Portal Express and connects directly to the remote DB2 server.

Depending on your database software, there might be more required configuration steps for using type 2 drivers. Review the installing database software topics.

User registry considerations

A user registry or repository authenticates a user and retrieves information about users and groups to do security-related functions, including authentication and authorization.

User registries store user account information, such as user ID and password, that can be accessed during authentication. User repositories store user profiles and preference information. A user registry or repository is used to:

- Authenticate a user by using basic authentication, identity assertion, or client certificates
- Retrieve user and group information to do security-related administrative functions such as mapping users and groups to security roles

By default, IBM WebSphere Portal Express is installed with a federated repository with a built-in file repository. The federated repository allows you to add various user registries, realm support for Virtual Portals, and/or property extensions to create a single, working unit. The available user registries that you can add to the federated repository are LDAP user registries, database user registries, and custom user registries.

Remember: Using the built-in file repository is not recommended in a production environment. After you add another repository and choose the administrative users from that repository, you must remove the file repository.

Based on the federated repository, WebSphere Portal Express allows you to create a user base that can be federated over multiple repositories: LDAP, DB, and/or custom user registry. It also allows you to define additional attributes in a separate store if your corporate LDAP directory is read-only.

If you are using a federated repository, you must plan on where you want to store new users and groups. By default, new users and groups are stored in the default file repository. If you use use multiple LDAP user registries and database user registries, you must figure out which user registry you want to define as your default user registry where new users and groups are stored. After you add all user registries to your federated repository, you can run the `wp-set-entitytypes` task to set a specific user registry as the default location.

Remember: Before you combine multiple user registries, review the registries for the following limitations and correct any issues:

- Distinguished names must be unique for a realm over all registries. For example, if `uid=wpsadmin,o=yourco` exists in LDAP1, it must not exist in LDAP2, LDAP3, or DB1.
- The short name, for example wpsadmin, should be unique for a realm over all registries.
- The base distinguished names for all registries that are used within a realm must not overlap; for example, if LDAP1 is `c=us,o=yourco`, LDAP2 must not be `o=yourco`.
- Do not leave the base entry blank for any of the registries used within a realm.
- If IBM Domino is one of your user registries in a multiple registry configuration and shares a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=`*`groupName`* and the hierarchical format is `cn=`*`groupName`*`,o=`*`root`*.
- The user must exist in a user registry and not within the property extension configuration; otherwise, the user cannot be a member of the realm.

"User registry options" on page 130
IBM WebSphere Portal Express provides various security configuration tasks. In the past, there was one task and you might not recover from errors. Also, you might not expand your user registry to meet your growing business needs. Now there are multiple tasks and you can fine-tune your system to meet your business needs.

"Virtual Member Manager integration" on page 132
IBM WebSphere Application Server includes the Virtual Member Manager (VMM), which IBM WebSphere Portal Express uses to access user and group information. VMM provides an interface that enables communication between WebSphere Portal Express and any repository, whether federated repositories or your own custom user registry.

"Realm support" on page 134
A realm is a collection of users or groups from one or more branches of your repository tree. Those branches can be part of a single repository, for example an LDAP user registry, or it can be a combination of multiple user registries. A realm is then mapped to a Virtual Portal to allow the realm's user population to log in to the Virtual Portal. This functionality allows you to define areas within WebSphere Portal Express that only a limited set of users can access.

"Property extension" on page 134
Use the property extension, formerly known as the lookaside database, to store extra user attributes into a database store without touching your backend user registry. You can use the property extension if your LDAP is read-only but you want users to specify an extra attribute such as Timezone. You can store this extra attribute in the database store. You can also add extra attributes for an application if you cannot change your repository schema. Property extension can be used with a federated repository or a custom user registry.

User registry options

IBM WebSphere Portal Express provides various security configuration tasks. In the past, there was one task and you might not recover from errors. Also, you might not expand your user registry to meet your growing business needs. Now there are multiple tasks and you can fine-tune your system to meet your business needs.

You have the following general security options to choose from:

Table 10. Security options with explanation

Security option	Explanation
Federated security	With this option, you can create Virtual Portals with multiple realms. You can also use multiple repositories (LDAP, database, custom), and you can add Application Groups to your system. This option is good if you must merge multiple LDAP servers into one cohesive structure. **Attention:** If you plan to enable the transient user feature, you must choose the federated user registry configuration. **Important:** You must take special care that there are no duplicate names between the various repositories. For example, if you installed the product with a Portal Administrator of `admin1`, then `admin1` must not exist in the corporate LDAP server.
Custom security	This option provides you with the ability to write a fully controlled WebSphere Security environment. There is a custom user registry and a custom member adapter for Virtual Member Manager (VMM). The abilities of this option depend on your implementation.

Federated security

WebSphere Portal Express is configured with a default federated repository with a built-in file repository. The federated repository offers you the richest number of options to meet your business needs. You can easily expand your business as your needs grow. For example, your company acquires a new business that has an existing LDAP user registry. You can add that LDAP server to your federated repository. Choose one of the following tasks to enable a production repository:

Table 11. Tasks to enable a production repository

Task	Description
Add a federated LDAP repository to the VMM configuration	Select this option to add an LDAP server to the federated repository. This task does not change the current security assignment. Therefore, the administrative user that is defined during installation is still active.
Add a federated database repository to the VMM configuration	Select this option to add a database to the federated repository. This task does not change the current security assignment. Therefore, the administrative user that is defined during installation is still active.
Add a federated custom user registry	Select this option to add a custom user registry that your company created to the federated repository. This task does not change the current security assignment. Therefore, the administrative user that is defined during installation is still active.

After you add your initial user registry, you can add more user registries to the repository to create a multiple user registry configuration. After you configure your repository, you must remove the default file-based repository. You do not have to remove the file-based repository in a development environment or if you are using IBM Connections. The following tasks are required to remove the default file-based repository:

Table 12. Tasks required to remove the default file-based repository

Task	Description
Change the user registry where users and groups are stored	This task changes the default repository where new users and groups are stored.
Change WebSphere Application Server administrator	This task changes the WebSphere Application Server administrator user ID and password.
Change WebSphere Portal Server administrator	This task changes the WebSphere Portal Express administrator user ID and password.
Delete a federated repository from the VMM configuration	This task deleted the default file-based repository from your configuration.

After you use your federated repository, you might need to manage your user registry. You can run any of the following optional tasks to fine-tune your federated repository:

Table 13. Optional tasks to manage the federated repository

Task	Description
Updating the federated LDAP user registry	Choose this option to update certain parameters such as your bind ID and password to fix issues with your LDAP user registry.
Updating the federated database user registry	Choose this option to update certain parameters such as the data source name, database URL, and database type to fix issues with your database user registry.

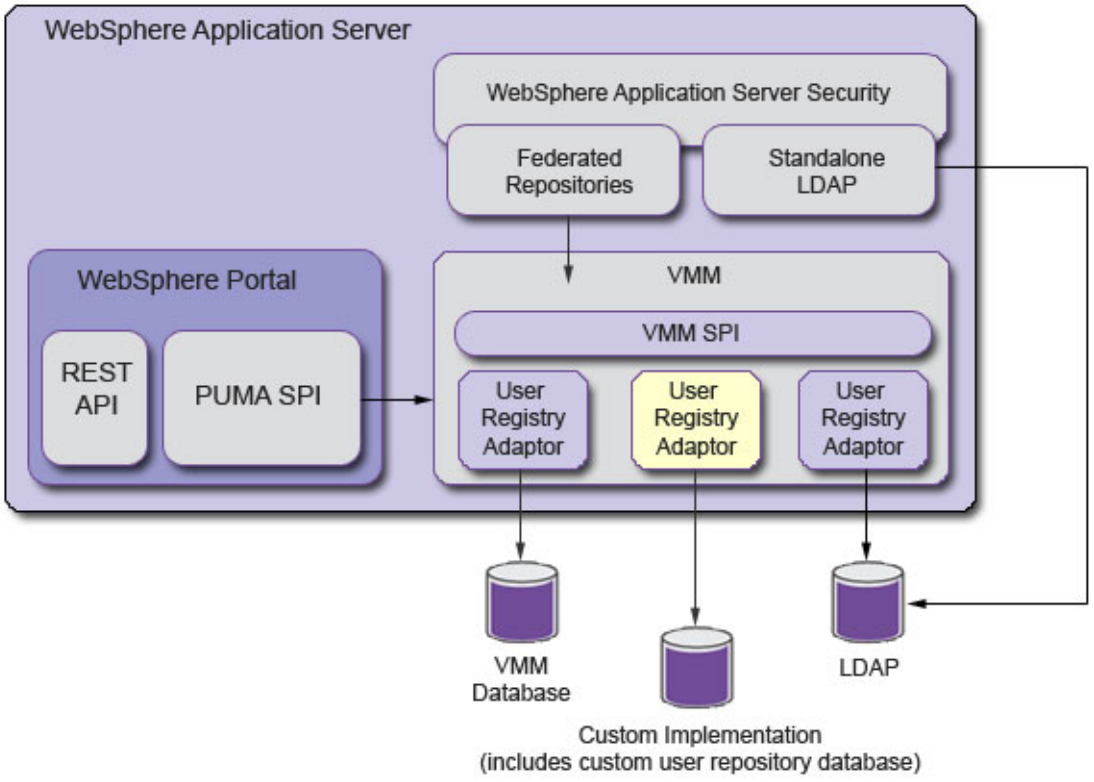
Table 13. Optional tasks to manage the federated repository (continued)

Task	Description
Create a realm	Choose this option to create a realm, which is a group of users from one or more user registries that form a coherent group within WebSphere Portal Express. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. In a federated repository, you can create multiple realms.

Virtual Member Manager integration

IBM WebSphere Application Server includes the Virtual Member Manager (VMM), which IBM WebSphere Portal Express uses to access user and group information. VMM provides an interface that enables communication between WebSphere Portal Express and any repository, whether federated repositories or your own custom user registry.

The Virtual Member Manager (VMM) is an abstract component within the WebSphere Application Server infrastructure. As the following diagram illustrates, WebSphere Portal Express uses the Portal User Management Architecture (PUMA) System Programming Interface (SPI) to retrieve and set attributes on user objects. PUMA passes these requests to VMM, which then passes the requests on to a corresponding registry adapter that connects VMM to the repository.



The preceding diagram includes the following components:

Federated repositories

An out-of-box implementation of the `UserRegistry` interface that supports multiple repositories. To communicate with the federated repositories, both WebSphere Application Server and WebSphere Portal Express dispatch all operations to VMM.

VMM SPI

VMM offers a Service Provider Interface (SPI), `wim.Repository`, that enables communication with repositories. WebSphere Application Server uses this SPI to connect to federated repositories. WebSphere Portal Express uses this SPI to connect to all repositories.

User registry adapter

An implementation of the VMM SPI that enables VMM to connect to a specific repository, whether an LDAP directory, database, files, or other repository. Registry adapters enable communication between WebSphere Portal Express and any repository.

Important: You must create a user registry adapter if you plan to use a custom user registry or repository that WebSphere Portal Express does not support out-of-box. To create a user registry adapter, implement the `wim.Repository` interface. Refer to the following topics in the WebSphere Application Server Information Center for information and instructions:

Repository SPI (System programming interfaces for virtual member manager adapters)

Sample custom adapters for federated repositories examples

Related tasks:

"Setting up custom user repositories" on page 1615
A custom user repository is any repository that WebSphere Portal Express does not support out-of-box. However, you can configure WebSphere Portal Express to support any type of repository in a federated or stand-alone user registry, whether an LDAP directory, database, file system, and so on. Setting up custom user repositories involves tasks such as defining additional repositories to the default federated user registry, creating a custom stand-alone user repository, and updating your user repository to reflect changes in your environment. Learn what steps are required to create and update custom user repositories and what specific interfaces you must implement to enable communication between WebSphere Portal Express and a repository.

 Repository SPI

Realm support

A realm is a collection of users or groups from one or more branches of your repository tree. Those branches can be part of a single repository, for example an LDAP user registry, or it can be a combination of multiple user registries. A realm is then mapped to a Virtual Portal to allow the realm's user population to log in to the Virtual Portal. This functionality allows you to define areas within WebSphere Portal Express that only a limited set of users can access.

For example, if you are an international company with employees in Asia, Europe, USA, and Canada, you might have an application or information that applies only to a subset of these employees. You can create a subset of employees and create a Virtual Portal that contains the application or information for that realm. Users from one realm cannot access another realm unless they are also members of that realm. For example, the wpsadmin user cannot log in to a Virtual Portal unless the wpsadmin user is a member of the corresponding realm.

You can create a realm that combines users from your various user registries; for example, your realm can span three LDAP user registries and a database user registry: LDAP1, LDAP2, LDAP3, and DB1.

Remember: Before you combine multiple user registries, review the registries for the following limitations and correct any issues:

- Distinguished names must be unique for a realm over all registries. For example, if `uid=wpsadmin,o=yourco` exists in LDAP1, it must not exist in LDAP2, LDAP3, or DB1.
- The short name, for example wpsadmin, should be unique for a realm over all registries.
- The base distinguished names for all registries that are used within a realm must not overlap; for example, if LDAP1 is `c=us,o=yourco`, LDAP2 must not be `o=yourco`.
- Do not leave the base entry blank for any of the registries used within a realm.
- If IBM Domino is one of your user registries in a multiple registry configuration and shares a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=`*`groupName`* and the hierarchical format is `cn=`*`groupName`*`,o=`*`root`*.
- The user must exist in a user registry and not within the property extension configuration; otherwise, the user cannot be a member of the realm.

Property extension

Use the property extension, formerly known as the lookaside database, to store extra user attributes into a database store without touching your backend user registry. You can use the property extension if your LDAP is read-only but you want users to specify an extra attribute such as Timezone. You can store this extra attribute in the database store. You can also add extra attributes for an application if you cannot change your repository schema. Property extension can be used with a federated repository or a custom user registry.

IBM Web Content Manager stores extra information for the following features:

- Web content user profiling
- Category selection trees

If this information cannot be stored in the main repository, for example the main repository is read-only, a property extension configuration is required.

WebSphere Portal Express high availability

IBM WebSphere Portal Express is licensed for use in a single-server configuration and might not be used in either a cloned configuration or a clustered configuration except when implementing idle standby for the purpose of failover.

In an idle standby configuration, a server is considered idle if it is used exclusively for administrative needs and to help a failover situation. WebSphere Portal Express is installed on the idle standby server, but it is not operational to service user transactions or to query workloads.

Implementing idle standby requires the purchase of a separate WebSphere Portal Express Idle Standby Part Number, in addition to licensing the primary server, regardless of whether your primary servers are currently licensed under the per User License Option or the per Processor Value Unit License Option.

Once you have an Idle Standby License Option, you can use WebSphere Portal Express in an idle standby configuration. To achieve failover, implement a primary node and a secondary node. The primary node can be configured to be active always; the secondary node becomes active only if the primary node fails.

Remember: For the deployment manager and each WebSphere Portal Express node to be in the cluster, verify that each system clock is set to within 5 minutes of the others or the `addNode` command fails.

The deployment scenario, Deploying WebSphere Portal Express for high availability using idle standby, in the WebSphere Portal Express wiki provides information about setting up an idle standby configuration.

Getting the software

There are different ways for you to get WebSphere Portal Express and Web Content Manager Version 8.5 software.

"Physical media"
WebSphere Portal Express is available on DVD. Installing from physical media is practical when installing on a limited number of servers.

"Live repository" on page 136
You can download and install WebSphere Portal Express directly from a live repository. All that you need is IBM Installation Manager and you can select the portal repository from the list.

"Electronic images" on page 138
Use Passport Advantage for downloading the electronic images of WebSphere Portal Express. Installing is simpler than ever before. IBM Installation Manager makes it easy. The following sections, formerly referred to as download documents, provide download information for the different WebSphere Portal Express and Web Content Manager offerings.

Physical media

WebSphere Portal Express is available on DVD. Installing from physical media is practical when installing on a limited number of servers.

Benefits:

This option has the following benefits and is best if performing a limited number of installations:

- No prerequisite steps required before installation
- Provides a seamless way to install IBM Installation Manager if it is not currently installed
- Provides an installation path if a file server is not available or is slower than the DVD

Limitations:

- Installing from the DVD on IBM i is not supported
- Silently installing from the DVD is not supported

Linux note: For security reasons, some Linux versions, such as Red Hat Enterprise Linux, prevent programs from running from automounted DVDs. Thus, not allowing to run the installer from the DVD. To fix this issue, add the `/dev/hdc /media/ auto pamconsole,fscontext=system_u:object_r:removable_t,exec,noauto,managed 0 0` line to the end of the `/etc/fstab` file to update file system table.

Live repository

You can download and install WebSphere Portal Express directly from a live repository. All that you need is IBM Installation Manager and you can select the portal repository from the list.

About this task

After you enter your credentials in IBM Installation Manager, you can see the software repositories that you are entitled to download and install. This option is ideal when you perform installations at a large scale.

Depending on your operating system, choose one of the following paths to install directly from a live repository:

- From the IBM Installation Manager graphical user interface, complete the following steps:
  1. Click **File** > **Preferences** > **Passport Advantage**.
  2. Select the **Connect to Passport Advantage** check box.
  3. Click **Apply**.
  4. Click **OK**.
  5. On the main Installation Manager panel, select **Install**.
  6. In the Password Required dialog box, enter your credentials.
  7. Click **OK**.
  8. Select the package that you want to download and install.
     - If you are installing Portal to an existing copy of WebSphere Application Server, then select only **IBM WebSphere Portal Server.** To complete this installation option, your existing copy of WebSphere Application Server must meet the following requirements:
       - WebSphere Application Server Version 8.5.5.2 or later
       - Java Version 7
       - No existing Portal profile

– If you are not installing Portal to an existing copy of WebSphere Application Server, then select the following packages:
  - **IBM WebSphere Application Server Network Deployment**
  - **IBM WebSphere Portal Server**
  - **IBM WebSphere SDK Java Technology Edition**

    Note: The **IBM WebSphere SDK Java Technology Edition** option is required for a WebSphere Portal Express installation even though it might be marked as "Optional."

  If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.

Tip: If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.

- From the IBM Installation Manager console user interface, complete the following steps:
  1. Enter `P` to go to the **Preferences** menu.
  2. Enter `6` to go to the **Passport Advantage** menu.
  3. Enter `1` to connect to Passport Advantage.
  4. Enter `P` to enter your user name and password.
  5. Enter `0` for OK.
  6. Enter `A` to apply your changes and return to the **Preferences** menu.
  7. Enter `R` to return to the **Main** menu.
  8. Enter `1` to see all of the repositories that you are entitled to download and install.
  9. Enter the number of the package that you want to download and install.
     – If you are installing Portal to an existing copy of WebSphere Application Server, then select only **IBM WebSphere Portal Server.** To complete this installation option, your existing copy of WebSphere Application Server must meet the following requirements:
       - WebSphere Application Server Version 8.5.5.2 or later
       - Java Version 7
       - No existing Portal profile
     – If you are not installing Portal to an existing copy of WebSphere Application Server, then select the following packages:
       - **IBM WebSphere Application Server Network Deployment**
       - **IBM WebSphere Portal Server**
       - **IBM WebSphere SDK Java Technology Edition**

         Note: The **IBM WebSphere SDK Java Technology Edition** option is required for a WebSphere Portal Express installation even though it might be marked as "Optional."

     If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.
  10. Enter `1` to install the package that you selected.

Related tasks:

Running the installation program
Use the IBM Installation Manager program to install the software. IBM Installation Manager provides multiple user interfaces. Select the one that you are more comfortable with. You can use the graphical user interface or the console to create a response file for automated installations.

Electronic images

Use Passport Advantage for downloading the electronic images of WebSphere Portal Express. Installing is simpler than ever before. IBM Installation Manager makes it easy. The following sections, formerly referred to as download documents, provide download information for the different WebSphere Portal Express and Web Content Manager offerings.

"Getting WebSphere Portal Express software"
This section describes how to download and assemble IBM WebSphere Portal Express Version 8.5 components by using the Passport Advantage Online website.

Getting WebSphere Portal Express software

This section describes how to download and assemble IBM WebSphere Portal Express Version 8.5 components by using the Passport Advantage Online website.

Downloadable eAssembly images

The IBM WebSphere Portal Express Version 8.5 product consists of multiple offerings and each offering includes multiple downloadable electronic images that are packaged by platform. Each platform package is called an eAssembly and each eAssembly contains all of the electronic images that are required for that offering to run on that platform. The following table shows the eAssembly numbers for each of the IBM WebSphere Portal Express Version 8.5 offerings.

Important: When you expand the eAssembly files, ensure that you expand the files into the same parent directory to create a complete installable image. For example, if you expand into a parent directory that is called *download_directory*, the following directory structure results:

download_directory/Setup
download_directory/IBMJAVA7
download_directory/WAS8552
download_directory/WP85_Express

Failure to expand all files in the same parent directory results in an installation failure.

The following directories might also exist but are not required to be expanded in the same parent directory:

download_directory/qsg_850_portal_wcm
download_directory/WP85_RemoteSearch

Related information:

WebSphere Portal detailed system requirements

IBM Passport Advantage

Installing and preparing the prerequisite software

Before you install the digital experience software, make sure that the prerequisite software is installed and configured. Depending on your environment, you might already have the prerequisites, such as a database server and user registry. Verify that the prerequisite software is the correct version, has the required fix packs applied, and is configured to work with the digital experience software.

"Installing and preparing the database software" on page 149
You might already have a database software installed. You still need to make sure that the installed database software is a supported version and has the required fix packs applied. In addition, you might need to configure the supported database software to work with the digital experience software.

"Preparing the user registry software" on page 158
You probably already have a user registry that is deployed and configured for your network. Before you install and deploy the digital experience software, make sure that your user registry software is a support version. In addition, you might need to configure the user registry to work with the digital experience software.

"Preparing a remote web server" on page 166
Install and configure the web server plug-in. The IBM WebSphere Application Server provides the plug-in. Configure the web server to communicate with IBM WebSphere Portal Express.

Related tasks:

"Planning to install WebSphere Portal Express" on page 101
Before you install IBM WebSphere Portal Express in a production environment, you need to assess your hardware and software needs, possible database configurations, security options, and LDAP server options. Skipping this important step can lead to unexpected results and costly delays.

Installing and preparing the database software

You might already have a database software installed. You still need to make sure that the installed database software is a supported version and has the required fix packs applied. In addition, you might need to configure the supported database software to work with the digital experience software.

"Installing and preparing DB2"
Use this information to install DB2 or DB2 pureScale for use with IBM WebSphere Portal Express.

"Installing and preparing Oracle or Oracle RAC" on page 151
You can use Oracle or Oracle RAC as the database software.

"Installing and preparing SQL Server" on page 152
Use this information to install and configure SQL Server for use with WebSphere Portal Express.

"Installing and preparing DB2 for z/OS" on page 154
Use this information to install DB2 for z/OS for use with IBM WebSphere Portal Express.

"Preparing IBM DB2 for i" on page 157
DB2 is integrated with IBM i. However, the databases and users that are required for WebSphere Portal Express must be created.

Installing and preparing DB2

Use this information to install DB2 or DB2 pureScale for use with IBM WebSphere Portal Express.

Before you begin

- Review the database considerations.
- Ensure the database that you plan to use is supported by this version of WebSphere Portal Express. Refer to the list of supported databases in the WebSphere Portal Express detailed system requirements.
- Set up the operating system with updated kernel parameters according to the DB2 Quick Beginnings guide at DB2 Technical Support.
- When you install DB2 with the DB2 installation program, it automatically creates a DB2 administrative user with the correct operating system rights.
- Ensure that you have enough disk space for the DB2 instance home directory to be able to create the required databases.
- A DB2 instance supports a limited number (NUMDB) of concurrently active databases. Increase this value if the DB2 instance maintains databases for WebSphere Portal Express and other applications. The NUMDB value depends on how many databases are concurrently used on the DB2 instance. Examples of concurrent usage include two portals that access the same DB2 instance or transferring data from multiple portals that use the same DB2 instance. To change the default to 30, enter the following command at the database prompt: `UPDATE DATABASE MANAGER CONFIGURATION USING NUMDB 30`. A message displays that confirms a successful completion of the update.
- WebSphere Portal Express supports DB2 JDBC Type 2 (CLI-based) and Type 4 (JCC) drivers.

About this task

All DB2 instructions apply to DB2 pureScale except where specifically noted.

Procedure

1. To install DB2 or the DB2 client and the required fix pack, follow the instructions that are provided with the DB2 documentation.
2. If DB2 is installed on another system than WebSphere Portal Express, copy the driver JAR files from the DB2 server to the Portal server. The typical location for these files on the DB2 server is in the `db2_home/java` directory. Place these driver files within the *wp_profile_root* directory, for example:

   wp_profile_root`/PortalServer/dbdrivers/db2jcc4.jar`

   wp_profile_root`/PortalServer/dbdrivers/db2jcc_license_cu.jar`
3. Ensure that the DB2 instance port was added to the services file during the DB2 installation.

   Linux :

   a. Get the value for the TCP/IP service name (SVCENAME). Open a shell and log in as the instance owner. Enter the following command:

      ```
      db2 "get dbm cfg"|grep (SVCENAME)
      ```

      A typical value for the SVCENAME is `(SVCENAME) = db2c_db2inst1`

   b. Get the DB2 port number by using the SVCENAME value. Enter the following command:

      ```
      echo /etc/services | grep your_SVCENAME_value
      ```

      A typical output for the port number:

      your_SVCENAME_value 50000`/tcp`

      In this example, 50000 is the port number.

   Windows:

   a. Get the value for the TCP/IP service name (SVCENAME). Open a DB2 Command Window and enter the following command:

      ```
      db2 get dbm cfg | findstr (SVCENAME)
      ```

      A typical value for the SVCENAME is `(SVCENAME) = db2c_DB2`

   b. Get the DB2 port number by using the SVCENAME value. Enter the following command:

      ```
      type %SystemRoot%\system32\drivers\etc\services | findstr db2c_DB2
      ```

      A typical output for the port number:

      your_SVCENAME_value 50000`/tcp`

      In this example, 50000 is the port number.

What to do next

Use the Configuration Wizard to set up and configure the database to work with WebSphere Portal Express. You can use the wizard to create custom scripts that you or your database administrator can use to configure the database. You can also use the wizard to automatically set up and configure the database. The wizard creates instructions and scripts that are based on your selections and provided data.

When you use the wizard and provide information about the database for your environment, be aware of the following considerations:

- The value for the database name, database server node, or schema name must be unique.
- When the DB2 Universal JDBC driver (type 4 mode) is used, connect to the database directly. Do not connect to an alias database (gateway), instead specify the real database name in the JDBC connection URL (*dbdomain*.DbUrl) and in the database name property (*dbdomain*.DbName).
- The Configuration Wizard's default configuration uses the instance (*db2inst1*) that is created by the installation program. Using separate databases can improve scalability and performance. The wizard allows you to change the default behavior. You can select whether each of the portal database domains exist in one or many instances.
- Your database name (*dbdomain*.DbName) cannot exceed eight characters.
- You cannot use the **Database Transfer** option in the configuration wizard to assign custom table spaces on your database server. You can perform manual steps to assign custom table spaces. Go to "Assigning custom table spaces" on page 555 for more information.

(Optional) After you transfer your data to DB2, run a configuration task to enable support for high availability recovery (HADR) and rollforward recovery.

Related tasks:

"DB2: Enabling support for high availability recovery and rollforward recovery " on page 560
Optional: To prevent data loss on DB2, modify the JCR schema to support High Availability Disaster Recovery and rollforward recovery.

Installing and preparing Oracle or Oracle RAC

You can use Oracle or Oracle RAC as the database software.

Before you begin

- Review the database considerations.
- Ensure the database that you plan to use is supported by this version of WebSphere Portal Express. Refer to the list of supported databases in the WebSphere Portal Express detailed system requirements.
- For Linux and Oracle OCI Type-2 JDBC driver: The Oracle OCI Type-2 JDBC driver with the full oracle client works with WebSphere Portal Express. However, to successfully complete the database transfer task, the Oracle Thin Type-4 JDBC is required for Linux. After successfully completing the database transfer task using the thin driver, if needed, you can specify and then return to using the Oracle OCI Type-2 full client.

Procedure

1. Install the Oracle client and any required fix packs. Follow the instructions that are provided with the Oracle documentation.
2. Install Oracle JDBC Type 4 drivers or Oracle JDBC OCI Type 2 drivers as appropriate.

   Refer to the Oracle or Oracle RAC product documentation for installation instructions.

Oracle RAC

3. Ensure the Oracle CRS (Cluster Ready Service) and Oracle RAC databases are installed and configured on the primary and secondary nodes.
4. Start global services daemon (GSD), oracle listeners, and agents in both RAC nodes. Run the following commands:

```
$ gsdctl start
$ lsnrctl start
$ agentctl start
```

5. The default tablespace size for Oracle RAC may need to be set to 1024MB with `autoextend` turned on for database transfer to be successful.

Update environment variables

6. `LIBPATH=/u01/app/oracle/product/11.2.0/client_1;export LIBPATH`
7. JDBC OCI (Linux and Solaris): Set the environment variable on the IBM WebSphere Portal Express server to point to the directory where you downloaded and extracted the compressed Oracle client files.

   `LD_LIBRARY_PATH=/u01/app/oracle/product/11.2.0/client_1;export LD_LIBRARY_PATH`
8. Restart server1 to ensure that the Configuration Wizard uses the updated environment variables. Go to *AppServer_home*`/profiles/cw_profile/bin` and stop the server:
   - Linux : `./stopServer.sh server1 -username` *username* `-password` *password*
   - IBM i: `stopServer server1 -username` *username* `-password` *password*
   - Windows: `stopServer.bat server1 -username` *username* `-password` *password*

   Then, start the server:
   - Linux : `./startServer.sh server1`
   - IBM i: `startServer server1`
   - Windows: `startServer.bat server1`

What to do next

Use the Configuration Wizard to set up and configure the database to work with WebSphere Portal Express. You can use the wizard to create custom scripts that you or your database administrator can use to configure the database. You can also use the wizard to automatically set up and configure the database. The wizard creates instructions and scripts that are based on your selections and provided data.

Important: To successfully complete the database transfer task, the Oracle Thin Type-4 JDBC is required for Linux.

When you use the wizard, you provide information about the database for your environment.

Note: Before you enter your database name (*dbdomain*`.DbName`) in the Configuration Wizard, check your database documentation for restrictions on character length.

You cannot use the **Database Transfer** option in the configuration wizard to assign custom table spaces on your database server. You can perform manual steps to assign custom table spaces. Go to "Assigning custom table spaces" on page 555 for more information.

Installing and preparing SQL Server

Use this information to install and configure SQL Server for use with WebSphere Portal Express.

Before you begin

- Review the database considerations.

- Ensure the database that you plan to use is supported by this version of WebSphere Portal Express. Refer to the list of supported databases in the WebSphere Portal Express detailed system requirements.
- Download a JDBC 4.0 compliant driver from Microsoft

Procedure

1. Install SQL Server and all required patches.
2. In the SQL Server Setup, choose the following:
   a. In the Setup Role panel, choose **SQL Server Feature Installation**.
   b. In the Features Selection panel, choose at least **Database Engine Services**.
   c. In the Database Engine Configuration, select **Mixed Mode (SQL Server Authentication and Windows authentication)**.

      Important:
      Mixed Mode authentication allows either a Windows user or an SQL Server user to log in to the SQL Server. However, WebSphere Portal Express requires the user to be an SQL Server user.
3. Complete the installation. Use the SQL Server documentation as a guide.
4. Install the JDBC driver. Use Microsoft SQL Server JDBC drivers and enable XA connections:
   a. Download and install the Microsoft SQL Server JDBC driver; see Microsoft Download Center for information.
   b. Copy the `sqljdbc_xa.dll` file from the `xa` subdirectory to the following directory of the SQL Server installation:
      - Microsoft SQL Server 2012: `C:\Program Files\Microsoft SQL Server\MSSQL11.MSSQLSERVER\MSSQL\Binn`
      - CF05 Microsoft SQL Server 2014: `C:\Program Files\Microsoft SQL Server\MSSQL12.MSSQLSERVER\MSSQL\Binn`
   c. Start the database server.
   d. Ensure that the Distributed Transaction Coordinator is started. Verify this status in the list of services in the Computer Management console.
   e. Start the Microsoft SQL Server Management Studio and connect to the local database engine as the system administrator, `sa`.
   f. Select **File** > **Open** > **File** and select `xa_install.sql` from the subdirectory of the downloaded and extracted JDBC driver.
   g. Run the script by Select **Query** > **Execute** to run the script.

      Note: Ignore any warnings that say that stored procedures cannot be found.
   h. To grant permission to a specific user to participate in distributed transactions with the JDBC driver, add the user to the SqlJDBCXAUser role.
5. Complete the following steps to enable XA Transactions in Windows Component Services:
   a. Choose **Component Services** of the **Administrative Tools**.
   b. Expand the tree view to locate the computer where you want to turn on support for XA transactions. For example, My Computer.
   c. Display the menu for the computer name and click **Properties**.
   d. Click **Options** and tune the Transaction Timeout. The minimum requirement is 180 seconds.
   e. Click **OK** to save your changes.

f. Expand **Component Services,** > **Computers,** > **My Computer,** > **Distributed Transaction Coordinator.**

g. Right-click **Local DTC** and then select **Properties**.

h. Click the **Security tab** on the Local DTC Properties dialog box.

i. Select the **Enable XA Transactions** check box, and then click **OK**. This action causes a MS DTC service restart.

6. Start SQL Server.
7. Connect at least one user to the SQL Server instance. A user can be granted permission to use several schema names, so a single user for each instance is sufficient.

What to do next

Use the Configuration Wizard to set up and configure the database to work with WebSphere Portal Express. You can use the wizard to create custom scripts that you or your database administrator can use to configure the database. You can also use the wizard to automatically set up and configure the database. The wizard creates instructions and scripts that are based on your selections and provided data.

When you use the wizard, you provide information about the database for your environment.

Note: Before you enter your database name (*dbdomain*.DbName) in the Configuration Wizard, check your database documentation for restrictions on character length.

You cannot use the **Database Transfer** option in the configuration wizard to assign custom table spaces on your database server. You can perform manual steps to assign custom table spaces. Go to "Assigning custom table spaces" on page 555 for more information.

Installing and preparing DB2 for z/OS

Use this information to install DB2 for z/OS for use with IBM WebSphere Portal Express.

Before you begin

- Review the database considerations.
- Ensure the database that you plan to use is supported by this version of WebSphere Portal Express. Refer to the list of supported databases in the WebSphere Portal Express detailed system requirements.
- The DB2 subsystem must be on a supported z/OS operating system.
- Ensure that Java Database Connectivity requirements are met. Consult the following references:
  - *DB2 Universal Database for OS/390 and z/OS: Application Programming Guide and Reference for Java*
  - The IBM Redbooks publication, DB2 for z/OS and OS/390: Ready for Java SG24-6435-00.
- If the current version of WebSphere Portal Express and an earlier version coexist with the same DB2 for z/OS subsystem, the database user IDs for the current version must be different from the earlier version to avoid conflicts during

installation. If the two versions of WebSphere Portal Express connect to two different DB2 for z/OS subsystems, using the same user ID does not cause conflict.

Procedure

1. To use DB2 for z/OS as the database software for WebSphere Portal Express, you must have DB2 for z/OS installed on your z/OS system. Refer to the DB2 for z/OS product documentation for instructions.
2. Read the Planning for DB2 for z/OS topic before you configure DB2 for z/OS as the WebSphere Portal Express database.
3. Check the buffer pool allocations for your system and define the buffer pools as appropriate for your installation and define a large enough size.

   ```
   -db2 display bufferpool(bp2)
   -db2 alter bufferpool(bp2) vpsize(15000)
   ```

   a. Repeat for extra buffer pools as needed. For example:

      bp3

      bp4

      bp5

      bp32k1

      bp32k2
4. Update the BP8K0 catalog buffer pool to 35,000 buffers before you transfer the database. Change this value according to your environment. The SYSIBM.SYSDATABASE table is in this buffer pool and is used extensively by DB2 for z/OS for the database transfer.
5. Change the Common Service Area (CSA) setting to `3500,350000`. Read the appropriate DB2 for z/OS topic for complete information about calculating and setting CSA:
   - DB2 for z/OS Version 10.1, Common service area
   - DB2 for z/OS Version 11.1, Common service area storage requirements
6. During database transfer from Derby to DB2 for z/OS, a supporting low-order byte table space is created for the database tables that store documents. The PRIQTY and SECQTY for the table space are assigned with the default values. If you plan to store many documents, use an automatic class selection (ACS) routine to allocate the DB2 for z/OS data sets with a primary and secondary space allocation of at least 10 cylinders. Or, specify a large enough value for **PRIQTY** and **SEQTY** in the DB2 DSNTIJUZ member. The table spaces can be identified by their name, having a structure like JCRDB.S*xxxxxxx*, where *xxxxxxx* is a system-assigned combination of seven numbers and characters.

   a. Also, in member DSNTIJUZ, update the following parameters and then verify DSNTIJUZ runs successfully.

      edmdbdc = *204800*

      edmpool=*409600*

      edmstmtc=*204800*

      rrulock=*no*

      cachedyn=*yes* (prepared, dynamic SQL statements are cached)

      dbacrvw=*yes* (to allow database administrators to create Views)

      +++tbsbpxml=BP16K1 (to explicitly create an XML table space. This value can be changed to any valid 16 K buffer pool where the Administrative User has the USE privilege.)

7. Ensure that the job DSNTIJSG ran to create the objects that are needed for the DB2 JDBC and ODBC metadata methods. See the DB2 Installation Guide Enabling stored procedures and tables for JDBC and ODBC support.
8. Ensure that job DSNTIJMS runs successfully (re-execute binds).
9. Ensure that job DSNTIJEX runs successfully.
10. Because large objects are stored in columns that can become large, logging changes to these columns requires a huge amount of log space. For this reason, large object (LOB) logging is disabled by default for table spaces that contain such data. With LOB logging disabled, you can recover full backups, but not incremental backups that can be used for point in time recovery. To recover point in time backups, you must enable LOB logging. For detailed instructions, see technote 1306637, *Managing LOB logging in DB2 for z/OS*.

LikeMinds

11. If you intend to run the LikeMinds sample, increase the **NUMLKTS** and **NUMLKUS** parameters: Ten times the default is sufficient, more depending on your usage of the sample. For example, if **NUMLKTS**=*1000* and **NUMLKUS**=*10000* are the installation default values, then update these values to **NUMLKTS**=*10000* and **NUMLKUS**=*100000*.
12.

Type 2 driver configuration

13. If you are planning to use Type 2 driver with DB2 for z/OS Version 9.1.2, ensure that DB2 for z/OS APAR PK58105 is installed.
14. If you are using the older DB2 Type 2 JDBC driver, enable extended shared memory usage with the following commands:

    ```
    export EXTSHM=ON
    db2set DB2ENVLIST=EXTSHM
    db2start
    ```

    For permanent changes, add the environment variable to the `profile.env` file:

    ```
    DB2ENVLIST='EXTSHM'
    ```

    in `/home/db2inst/sqllib/userprofile` add:

    ```
    export EXTSHM=ON
    ```

    Note: The shell must be reopened before you restart DB2 for z/OS.
15. If you are using the older DB2 Type 2 JDBC driver, configure your DB2 Connect client with the following commands:

    ```
    db2 update dbm cfg using tp_mon_name WAS
    db2 update dbm cfg using spm_name hostname
    ```

    where *hostname* is the host name for the server where the DB2 Connect client is installed (same as portal server).\
16. If you are using the older DB2 Type 2 JDBC driver, install the DB2 Connect client on the WebSphere Portal Express server to connect to the remote database.

What to do next

Use the Configuration Wizard to set up and configure the database to work with WebSphere Portal Express. You can use the wizard to create custom scripts that you or your database administrator can use to configure the database. You can also use the wizard to automatically set up and configure the database. The wizard creates instructions and scripts that are based on your selections and provided data.

When you use the Configuration wizard and provide information about your database, consider the following points:

•
•
•

- Before you enter your database name (*dbdomain*.DbName) in the Configuration Wizard, check your database documentation for restrictions on character length.
- You cannot use the **Database Transfer** option in the configuration wizard to assign custom table spaces on your database server. You can perform manual steps to assign custom table spaces. Go to "Assigning custom table spaces" on page 555 for more information.

Preparing IBM DB2 for i

DB2 is integrated with IBM i. However, the databases and users that are required for WebSphere Portal Express must be created.

Before you begin

- Ensure the database that you plan to use is supported by this version of WebSphere Portal Express. Refer to the list of supported databases in the WebSphere Portal Express detailed system requirements.

What to do next

Use the Configuration Wizard to set up and configure the database to work with WebSphere Portal Express. You can use the wizard to create custom scripts that you or your database administrator can use to configure the database. You can also use the wizard to automatically set up and configure the database. The wizard creates instructions and scripts that are based on your selections and provided data.

When you use the wizard and provide information about the database for your environment, be aware of the following considerations:

- If you choose to use one database to store all WebSphere Portal Express, Member Manager, and content publishing information, only one user profile is required. Additional user profiles are necessary only if using multiple IBM i systems or separate databases are required.
- Before you enter your database name (*dbdomain*.DbName) in the Configuration Wizard, check your database documentation for restrictions on character length.
- The Configuration Wizard uses JDBC type 4 drivers by default. The examples in the Configuration Wizard apply only to JDBC type 4 drivers. You can change the default selection in the Configuration Wizard to JDBC type 2 during step 2, Customize Values. If you select JDBC type 2, apply these examples to your configuration:

Table 26. Example values for JDBC type 2 driver

Field label in Configuration Wizard	Example value
Database name	*LOCAL/wpsdb
Database URL	jdbc:db2:*LOCAL/wpsdb
DB2 for IBM i library	/QIBM/ProdData/OS400/Java400/ext/db2_classes16.jar
DB2 for IBM i driver class name	com.ibm.db2.jdbc.app.DB2Driver

Preparing the user registry software

You probably already have a user registry that is deployed and configured for your network. Before you install and deploy the digital experience software, make sure that your user registry software is a support version. In addition, you might need to configure the user registry to work with the digital experience software.

"Preparing an Active Directory-Lightweight-Directory-Services on Windows"
If you plan to use an Active Directory-Lightweight-Directory-Services as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

"Preparing a Domino Directory server" on page 159
If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

"Preparing a IBM Directory Server" on page 161
If you plan to use a IBM Directory Server as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

"Preparing an Active Directory server" on page 162
If you plan to use Active Directory as an LDAP user registry, you must install and set up the server so that it can communicate with IBM WebSphere Portal Express.

"Preparing a Novell eDirectory" on page 163
If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

"Preparing a SecureWay Security Server" on page 164
If you plan to use a SecureWay Security Server as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

"Preparing an Oracle Directory Server" on page 165
If you plan to use an Oracle Directory Server as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express. Oracle Directory Server was formerly known as Sun Java System Directory Server.

Preparing an Active Directory-Lightweight-Directory-Services on Windows

If you plan to use an Active Directory-Lightweight-Directory-Services as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

Procedure

1. Download and install Active Directory Application Mode.
2. Complete the following steps as a guide to create the WebSphere Portal Express administrative user:
   a. Create a user with the Windows administrative tools.

      Note: There is a 20 character limitation for the user account name.
   b. Set the password for the new user.
   c. Activate the new user with the Windows administrative tools. Set the **msDS-UserAccountDisabled** attribute to `false`.

Preparing a Domino Directory server

If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

Procedure

1. Complete the following steps to install the Domino Directory:
   a. Go to Domino documentation.
   b. Select the appropriate version tab for your product.
   c. Click the **Download/View online** link for the Lotus Domino Information Center.
   d. Click **Domino Administrator Help** > **Installation** > **Installing and setting up Domino servers** > **Server installation** > **Installing Domino** and complete this task.
   e. Click **Domino Administrator Help** > **Installation** > **Installing and setting up Domino servers** > **The Domino server setup program** and complete this task.
2. Complete the following steps to install the Domino Directory:
   a. Go to Domino documentation.
   b. Select the appropriate version tab for your product.
   c. Click the **Download/View online** link for Installing and Managing Domino for System i.
   d. Complete the tasks under **Chapter 3 Installing Domino on your system**.
   e. Complete the tasks under **Chapter 6 Setting up a First Domino server**.
   f. Complete the tasks under **Chapter 8 Setting up an Additional Domino server**.
3. Complete the following steps as a guide to create the WebSphere Portal Express administrative user:
   a. Go to the **People** view of the Domino Directory and then click **Add Person**.
   b. Enter the following values in the **New Person** form to create the LDAP bind user. The following example uses `wpsbind` to represent the LDAP bind user:

      Last Name
      `wpsbind`

      User name
      `wpsbind/`*`DominoDomain`*, where *DominoDomain* is your Domino Internet domain.

      `wpsbind`

      Note: Make sure that you enter two values in the **User Name** field, where the first value includes the Domino domain.

      Short name/UserID
      `wpsbind`

      Internet password
      `wpsbind`
   c. Click **Save and Close** to save the new person record for `wpsbind` and return to the **People** view.
   d. Click **Add Person** and enter the following values in the **New Person** form to create the Portal administration user. The following example uses `wpsadmin` to represent the Portal administration user:

Last Name
wpsadmin, where wpsadmin is the user ID for the WebSphere Portal Express Administrator.

User name
wpsadmin/*DominoDomain*, where *DominoDomain* is your Domino Internet domain.

```
wpsadmin
```

Note: Make sure that you enter two values in the **User Name** field, where the first value includes the Domino domain.

Short name/UserID
wpsadmin

Internet password
wpsadmin

e. Click **Save and Close** to save the new person record for wpsadmin and return to the **People** view.

f. Go to the **Groups** view and click **Add Group**.

g. Enter the following values in the **New Group** form on the Basic tab:

Group name
wpsadmins

Note: If your Domino LDAP shares a realm with another user registry, you must use the hierarchical naming convention for the group names. Enter wpsadmins/DominoDomain to avoid unexpected results during WebSphere Portal Express run time.

Group type
Multi-purpose

Members
wpsbind/DominoDomain

wpsadmin/DominoDomain

Note: You can add more administrator users.

h. Click **Save and Close** to save the wpsadmins group with the wpsbind and wpsadmin users as members.

4. Complete the following steps to update the access control list for the Domino Directory:

a. Open the names.nsf file in the Domino Administrator or Lotus Notes client.

b. Click **File** > **Application** > **Access Control** from the main menu to open the access control list for the file.

c. In the **Access Control List** > **Basics** panel, ensure that the wpsadmins group has either Author or Editor access.

d. Add the following **Role Types** to the wpsadmins group:

GroupCreator

GroupModifier

UserCreator

UserModifier

e. Click **OK**.

Preparing a IBM Directory Server

If you plan to use a IBM Directory Server as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

Procedure

1. Install IBM Directory Server. Refer to the IBM Directory Server Installation and Configuration Guide for instructions.

   Restriction: Users or groups must not contain a Turkish uppercase dotted I or lowercase dotted i in the distinguished name. It prevents correct retrieval of that user or group.
2. Complete the following steps with the IBM Directory Server web administration tool to create the WebSphere Portal Express administrative user:
   a. Optional: Complete the following steps to create a directory suffix:
      1) Click the **Server Administration** folder in the directory server console navigation.
      2) Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
      3) Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
      4) Click **Add**.
      5) Click **OK** to save your changes.
   b. Open the appropriate LDIF file in the *PortalServer_root*`/installer/wp.iim/ldif` directory, with a text editor:

      Use the `PortalUsers.ldif` file as a working example and adapt appropriately to work with your LDAP server.

      Use the `ContentUsers.ldif` file for the IBM Content Manager group and user ID if you configured IBM Content Manager.
   c. Replace every `dc=yourco,dc=com` with your suffix.
   d. Replace any prefixes and suffixes that are unique to your LDAP server.
   e. You can specify user names other than `wpsadmin` and `wpsbind`. For security reasons, specify nontrivial passwords for these administrator accounts.
   f. Save your changes.
   g. Complete the instructions that are provided with your directory server to import the LDIF file.
3. Complete the following steps to create the WebSphere Portal Express administrative user:
   a. Open the appropriate LDIF file in the *PortalServer_root*`/installer/wp.iim/ldif` directory, with a text editor:

      Use the `PortalUsers.ldif` file as a working example and adapt appropriately to work with your LDAP server.

      Use the `ContentUsers.ldif` file for the IBM Content Manager group and user ID if you configured IBM Content Manager.
   b. Replace every `dc=yourco,dc=com` with your suffix.
   c. Replace any prefixes and suffixes that are unique to your LDAP server.
   d. You can specify user names other than `wpsadmin` and `wpsbind`. For security reasons, specify nontrivial passwords for these administrator accounts.

e. Optional: If you use IBM Security Access Manager Version 5.1, set the **objectclasses** to accessGroup. If you use Security Access Manager Version 6, set the **objectclasses** to groupOfNames.

f. Save your changes.

g. Complete the instructions that are provided with your directory server to import the LDIF file.

Preparing an Active Directory server

If you plan to use Active Directory as an LDAP user registry, you must install and set up the server so that it can communicate with IBM WebSphere Portal Express.

Procedure

1. Complete the following steps to install and configure Active Directory:
   a. Install Windows Server version 2008 or 2012, which includes Active Directory. Refer to http://www.microsoft.com/windows2000/technologies/directory/ad/default.asp for information.
   b. Install the necessary Service Packs.
   c. Use the Windows Server documentation to install Internet Information Services (IIS). Use IIS to export server certificates. It must be installed before you install Certificate Services.
   d. Use the Windows Server documentation to install Certificate Services if you plan on using Active Directory over SSL.
2. Complete the following steps as a guide to create the WebSphere Portal Express administrative user:
   a. Create a user with the Windows administrative tools.

      Note: There is a 20 character limitation for the user account name.
   b. Set the password for the new user.
   c. Activate the new user with the Windows administrative tools. Set the **msDS-UserAccountDisabled** attribute to false.
3. Complete the following steps to enable SSL for Active Directory; this step sets passwords during sign-up and user creation:
   a. Install an Enterprise certificate authority on a Windows Domain Controller. It installs a certificate on a server or a third-party certificate on the Domain Controller.
   b. Click **Start** > **All Programs** > **Administrative Tools** > **Active Directory Users and Computer**.
   c. In the Active Directory Users and Computers window, right-click on your domain name and select **Properties**.
   d. In the Domain Properties dialog box, select the **Group Policy** tab.
   e. Select the **Default Domain Policy** group policy and then click **Edit**.
   f. Select **Windows Settings** under Computer Configuration.
   g. Select **Security Settings** and then select **Public Key Policies**.
   h. Select **Automatic Certificate Request Settings**.
   i. Use the wizard to add a policy for Domain Controllers.

      Note: When these requirements are complete, all domain controllers request a certificate and support LDAP over SSL with port 636.

Preparing a Novell eDirectory

If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

Procedure

1. Install Novell eDirectory. Refer to eDirectory for information.
2. Complete the following steps with the web administration tool to create the WebSphere Portal Express administrative user:
   a. Optional: Complete the following steps to create a directory suffix:
      1) Click the **Server Administration** folder in the directory server console navigation.
      2) Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
      3) Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
      4) Click **Add**.
      5) Click **OK** to save your changes.
   b. Open the appropriate LDIF file in the *PortalServer_root*`/installer/wp.iim/ldif` directory, with a text editor:

      Use the `PortalUsers.ldif` file as a working example and adapt appropriately to work with your LDAP server.

      Use the `ContentUsers.ldif` file for the IBM Content Manager group and user ID if you configured IBM Content Manager.
   c. Replace every `dc=yourco,dc=com` with your suffix.
   d. Replace any prefixes and suffixes that are unique to your LDAP server.
   e. You can specify user names other than `wpsadmin` and `wpsbind`. For security reasons, specify nontrivial passwords for these administrator accounts.
   f. Save your changes.
   g. Complete the instructions that are provided with your directory server to import the LDIF file.
3. Complete the following steps to create the WebSphere Portal Express administrative user:
   a. Open the appropriate LDIF file in the *PortalServer_root*`/installer/wp.iim/ldif` directory, with a text editor:

      Use the `PortalUsers.ldif` file as a working example and adapt appropriately to work with your LDAP server.

      Use the `ContentUsers.ldif` file for the IBM Content Manager group and user ID if you configured IBM Content Manager.
   b. Replace every `dc=yourco,dc=com` with your suffix.
   c. Replace any prefixes and suffixes that are unique to your LDAP server.
   d. You can specify user names other than `wpsadmin` and `wpsbind`. For security reasons, specify nontrivial passwords for these administrator accounts.
   e. Optional: If you use IBM Security Access Manager Version 5.1, set the **`objectclasses`** to `accessGroup`. If you use Security Access Manager Version 6, set the **`objectclasses`** to `groupOfNames`.
   f. Save your changes.
   g. Complete the instructions that are provided with your directory server to import the LDIF file.

Preparing a SecureWay Security Server

If you plan to use a SecureWay Security Server as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

Procedure

1. Install SecureWay Security Server. Refer to IBM SecureWay Security Server for z/OS and OS/390® for information.
2. Complete the following steps with the web administration tool to create the WebSphere Portal Express administrative user:
   a. Optional: Complete the following steps to create a directory suffix:
      1) Click the **Server Administration** folder in the directory server console navigation.
      2) Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
      3) Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
      4) Click **Add**.
      5) Click **OK** to save your changes.
   b. Open the appropriate LDIF file in the *PortalServer_root*`/installer/wp.iim/ldif` directory, with a text editor:

      Use the `PortalUsers.ldif` file as a working example and adapted appropriately to work with your LDAP server.

      Use the `ContentUsers.ldif` file for the IBM Content Manager group and user ID if you configured IBM Content Manager.
   c. Replace every `dc=yourco,dc=com` with your suffix.
   d. Replace any prefixes and suffixes that are unique to your LDAP server.
   e. You can specify user names other than `wpsadmin` and `wpsbind`. For security reasons, specify nontrivial passwords for these administrator accounts.
   f. Save your changes.
   g. Complete the instructions that are provided with your directory server to import the LDIF file.
3. Complete the following steps to create the WebSphere Portal Express administrative user:
   a. Optional: Complete the following steps to create a directory suffix:
      1) Go to IBM System i and IBM i Information Center, select the appropriate documentation version and go to **Networking** > **TCP/IP applications, protocols, and services** > **IBM Directory Server for iSeries (LDAP)** > **Administering Directory Server** > **General administration tasks** > **Adding and Removing Directory Server suffixes** for information.
      2) Stop and restart the LDAP server.
   b. Open the appropriate LDIF file in the *PortalServer_root*`/installer/wp.iim/ldif` directory, with a text editor:

      Use the `PortalUsers.ldif` file as a working example and adapted appropriately to work with your LDAP server.

      Use the `ContentUsers.ldif` file for the IBM Content Manager group and user ID if you configured IBM Content Manager.
   c. Replace every `dc=yourco,dc=com` with your suffix.
   d. Replace any prefixes and suffixes that are unique to your LDAP server.

e. You can specify user names other than `wpsadmin` and `wpsbind`. For security reasons, specify nontrivial passwords for these administrator accounts.

f. Optional: If you use IBM Security Access Manager Version 5.1, set the **`objectclasses`** to `accessGroup`. If you use Security Access Manager Version 6, set the **`objectclasses`** to par.

g. Save your changes.

h. Complete the instructions that are provided with your directory server to import the LDIF file.

Preparing an Oracle Directory Server

If you plan to use an Oracle Directory Server as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express. Oracle Directory Server was formerly known as Sun Java System Directory Server.

Procedure

1. Install Oracle Directory Server. Refer to Oracle software for information.
2. Complete the following steps with the web administration tool to create the WebSphere Portal Express administrative user:
   a. Optional: Complete the following steps to create a directory suffix:
      1) Click the **Server Administration** folder in the directory server console navigation.
      2) Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
      3) Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
      4) Click **Add**.
      5) Click **OK** to save your changes.
   b. Open the appropriate LDIF file in the *PortalServer_root*`/installer/wp.iim/ldif` directory, with a text editor:

      Use the `PortalUsers.ldif` file as a working example and adapt appropriately to work with your LDAP server.

      Use the `ContentUsers.ldif` file for the IBM Content Manager group and user ID if you configured IBM Content Manager.
   c. Replace every `dc=yourco,dc=com` with your suffix.
   d. Replace any prefixes and suffixes that are unique to your LDAP server.
   e. You can specify user names other than `wpsadmin` and `wpsbind`. For security reasons, specify nontrivial passwords for these administrator accounts.
   f. Save your changes.
   g. Complete the instructions that are provided with your directory server to import the LDIF file.
3. Complete the following steps to create the WebSphere Portal Express administrative user:
   a. Open the appropriate LDIF file in the *PortalServer_root*`/installer/wp.iim/ldif` directory, with a text editor:

      Use the `PortalUsers.ldif` file as a working example and adapt appropriately to work with your LDAP server.

      Use the `ContentUsers.ldif` file for the IBM Content Manager group and user ID if you configured IBM Content Manager.
   b. Replace every `dc=yourco,dc=com` with your suffix.

c. Replace any prefixes and suffixes that are unique to your LDAP server.
d. You can specify user names other than `wpsadmin` and `wpsbind`. For security reasons, specify nontrivial passwords for these administrator accounts.
e. Optional: If you use IBM Security Access Manager Version 5.1, set the **`objectclasses`** to `accessGroup`. If you use Security Access Manager Version 6, set the **`objectclasses`** to `groupOfNames`.
f. Save your changes.
g. Complete the instructions that are provided with your directory server to import the LDIF file.

Preparing a remote web server

Install and configure the web server plug-in. The IBM WebSphere Application Server provides the plug-in. Configure the web server to communicate with IBM WebSphere Portal Express.

Procedure

1. Install and configure the web server. Refer to the web server documentation for information.

   Dynamic cluster: If you are creating a dynamic cluster environment, install and configure an OnDemand Router (ODR). Go to Creating and configuring ODRs for information.
2. If you are using Microsoft Internet Information Server, update the **UrlSegmentMaxLength** Registry key. Change it to a value of `0` to eliminate potential problems in a WebSphere Portal Express environment with the default IIS limitation on the length of URL path segments. Update the **AllowRestrictedChars** Registry key to a value of 1 to accept hex-escaped characters in request URLs that decode to the `U+0000 - U+001F` and `U+007F - U+009F` ranges.

   Refer to Configuring Microsoft Internet Information Services (IIS) for information.

   Note: Refer to Http.sys registry settings for IIS for information.
3. If you are using IBM Domino, edit the `NOTES.INI` file on the web server. Set the **`HTTPEnableConnectorHeaders`** and **`HTTPAllowDecodedUrlPercent`** parameters to 1. Also, if you are using WebDAV, enable it in the Domino web server administrative console.
4. If you are using IBM HTTP Server or Apache Server, edit the `httpd.conf` file on the web server. Set the **`AllowEncodedSlashes`** directive to `On`. Add the directive to the root level as a global directive.

Table 27. Links to HTTP and Apache server documentation

HTTP server type	Documentation link
Read the appropriate HTTP Server documentation	IBM HTTP Server
Read the appropriate Apache Server documentation	**`AllowEncodedSlashes`** directives

5. Stop the web server.
6. Install and configure the web server plug-in on the system where the web server is located. Use the plug-ins installation wizard that is provided with WebSphere Application Server. Refer to the following topic for information:

- IBM i: LinuxWindows: Selecting a Web server topology diagram and road map

Important: Depending on how you use the web server, you must adjust the **ServerIOTimeout** parameter. It defines how long the plug-in must wait for a response from the application. The minimum value is `60` but you must increase this value if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set **ServerIOTimeout** to an appropriate value.

7. If you are using an Oracle iPlanet web server, some portlets require that you disable the **unix-uri-clean** or **nt-uri-clean** directives. Edit the `obj.conf` file to enable or disable these directives. Refer to the Oracle iPlanet web server documentation to determine the appropriate setting for your environment.

   Note: If you are using Oracle iPlanet web server Version 7, you must disable **uri-clean**.
8. Web 2.0 REST features in portal might require an enabled PUT and DELETE method. If your web server has these methods disabled, complete one of the following options:
   - Enable HTTP tunneling to simulate PUT and DELETE requests, which means that POST requests are used instead. See the "Switch for tunneling of HTTP methods" link for information.
   - Follow the instructions for your web server to enable PUT and DELETE requests.
9. Start the web server.
10. Optional: Complete the following steps if you plan to use the web application bridge feature:
    a. Log on to the WebSphere Integrated Solutions Console.
    b. Go to **Applications** > **Application Types** > **WebSphere enterprise applications**.
    c. Find and click the **wp.vwat.servlet.ear** application link.
    d. Under the **Web Module Properties** heading, click **Context Root For Web Modules**.
    e. Change the context root to /. This step can create name conflicts. Add a rewrite rule to avoid these conflicts. For more information read *Apache Module mod_rewrite* and *Providing short vanity URLs*.
    f. Click **OK**.
    g. Click **Save** to save your changes to the master configuration.
    h. Stop and restart the **wp.vwat.servlet.ear** application.
11. Optional: If you want to use the short version of vanity URLs, add a rewrite rule to your web server. For more information, read *Providing short vanity URLs*.

Installing the digital experience software

IBM's Exceptional Digital Experience is designed to help create, manage, simplify, and integrate your processes into an engaging online experience. IBM WebSphere Portal and IBM Web Content Manager are a part of the Exceptional Digital Experience. The product documentation uses digital experience software as a shorthand for IBM WebSphere Portal and IBM Web Content Manager.

About this task

Select a roadmap to guide you through the installation and deployment process. The installation process uses IBM Installation Manager to install the digital experience. Select your operating system to get started. After you complete the installation, you have a functional portal, unless you selected to install only the binaries for a migration path. Then, use the Configuration Wizard to complete the deployment.

"IBM i: Installing WebSphere Portal Express and Web Content Manager"
Installing the digital experience software includes preparing your operating system and using IBM Installation Manager to install IBM WebSphere Portal Express and Web Content Manager. Then, use the Configuration Wizard to complete the deployment configuration.

"Linux: Installing WebSphere Portal Express and Web Content Manager" on page 181
Installing the digital experience software includes preparing your operating system and using IBM Installation Manager to install IBM WebSphere Portal Express and Web Content Manager. Then, use the Configuration Wizard to complete the deployment configuration.

"Windows: Installing WebSphere Portal Express and Web Content Manager" on page 196
Installing the digital experience software includes preparing your operating system and using IBM Installation Manager to install IBM WebSphere Portal Express and Web Content Manager. Then, use the Configuration Wizard to complete the deployment configuration.

Related concepts:

Chapter 3, "Roadmaps," on page 69
Review the roadmaps to understand the common deployment patterns that are supported by the configuration wizard.

Related tasks:

"Planning to install WebSphere Portal Express" on page 101
Before you install IBM WebSphere Portal Express in a production environment, you need to assess your hardware and software needs, possible database configurations, security options, and LDAP server options. Skipping this important step can lead to unexpected results and costly delays.

Related reference:

"Getting the software" on page 135
There are different ways for you to get WebSphere Portal Express and Web Content Manager Version 8.5 software.

IBM i: Installing WebSphere Portal Express and Web Content Manager

Installing the digital experience software includes preparing your operating system and using IBM Installation Manager to install IBM WebSphere Portal Express and Web Content Manager. Then, use the Configuration Wizard to complete the deployment configuration.

Before you begin

Roadmaps for installation and deployment are included in this product documentation to guide you through the process. Roadmaps provide a high-level overview of the process from beginning to end. Select the configuration that is closest to the configuration that you need.

1. “IBM i: Preparing your operating system”
   Prepare the operating system to ensure a successful installation.
2. “IBM i: Preparing the Installation Manager”
   The IBM Installation Manager is used to install installation packages such as IBM WebSphere Portal Express and IBM WebSphere Application Server.
3. “IBM i: Running the installation program” on page 170
   Use the IBM Installation Manager program to install the software. IBM Installation Manager provides multiple user interfaces. Select the one that you are more comfortable with. You can use the graphical user interface or the console to create a response file for automated installations.
4. “IBM i: Converting the evaluation license” on page 175
   If you initially installed IBM WebSphere Portal Express using the evaluation license and then purchased the product, you can convert the installed evaluation license to a production license. You can do this at any time, before or after the evaluation license expires.
5. “IBM i: Next steps” on page 176
   The configuration process has changed. Use the Configuration Wizard to set up your integration with prerequisites, clusters, and more.
6. “IBM i: Upgrading the SDK” on page 178
   Starting with IBM WebSphere Portal Express Combined Cumulative Fix 05, you can change your SDK Java Technology Edition from version 7.0 to version 7.1.
7. “IBM i: Rendering documents on IBM i” on page 179
   To enable document preview function for IBM Web Content Manager and the Common Mail portlet, you must set up an HTML rendering server to work with WebSphere Portal Express. Because IBM i does not contain native graphics support, you must install extra fonts to run the document conversion that is required by these functions. Document conversion enables WebSphere Portal Express to convert documents that are produced by commonly used office programs into web pages so that they can be viewed and searched by users online. The additional fonts include an HTML rendering server that is known as X virtual frame buffer for the X server.

IBM i: Preparing your operating system

Prepare the operating system to ensure a successful installation.

Procedure

1. Make sure that you have a CD drive
2. Make sure that the server is in an unrestricted state
3. If you do not have one, create a valid IBM i user ID and password
4. Create a user profile with a user type (user class) of `*SECOFR` (other than QSECOFR) to install and configure WebSphere Portal Express

IBM i: Preparing the Installation Manager

The IBM Installation Manager is used to install installation packages such as IBM WebSphere Portal Express and IBM WebSphere Application Server.

Procedure

If you have an existing Installation Manager, start it and go to **File** > **Preferences**. Then, click **Updates**. Click the **Search for Installation Manager updates** check box. This box enables the Installation Manager to search for updates the next time you run an installation or update.
If you do not have an existing Installation Manager, then complete the following procedure:

1. Start all servers and applications that require a port number to avoid port conflicts when installing WebSphere Portal Express.
2. Type **ping** `yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
3. Type **ping** `localhost` on a command line to verify that your network is properly configured.
4. If you are installing on a server with a firewall, antivirus, screen saver, or desktop search engine that is enabled, disable them before you install. If you do not disable them and the installation program detects them, a warning message displays during the installation.
5. Run the following task from the `IIM` directory: `installc -acceptLicense`

   Note: If you have an existing Installation Manager, search for updates to the latest supported version.

IBM i: Running the installation program

Use the IBM Installation Manager program to install the software. IBM Installation Manager provides multiple user interfaces. Select the one that you are more comfortable with. You can use the graphical user interface or the console to create a response file for automated installations.

"IBM i: Installing with the console"
Use the IBM Installation Manager to install IBM WebSphere Portal Express with an existing IBM WebSphere Application Server.

"IBM i: Creating a response file" on page 172
After IBM Installation Manager is installed, you can use it to record a response file that is based on your environment. Record a response file on the same operating system you plan for the installation. If you have multiple operating systems, you must record a response file for each operating system. Use a response file to automate your installation on multiple servers.

"IBM i: Installing with the response file" on page 174
Use either a sample response file or a response file that you created to install WebSphere Application Server and WebSphere Portal Express. You can create a response file with the graphical or console mode interface.

Related tasks:

"IBM i: Preparing your operating system" on page 169
Prepare the operating system to ensure a successful installation.

IBM i: Installing with the console:

Use the IBM Installation Manager to install IBM WebSphere Portal Express with an existing IBM WebSphere Application Server.

Before you begin

A working installation of IBM WebSphere Application Server is required. Ensure that it is not used by another copy of WebSphere Portal Express.

About this task

The installation program verifies the operating system and its prerequisites, available disk space, and any required software prerequisites before installation. You cannot install two instances of the server at the same time, even if you are installing to different directories. You must install each server completely before you install the next one.

Procedure

1. Start all servers and applications that require a port number to avoid port conflicts when you install WebSphere Portal Express. If you are installing multiple copies of IBM WebSphere Portal Express on your server, start the existing Configuration Wizard servers.
2. Open a command prompt and change to the `InstallationManager_root/eclipse/tools` directory.
3. Run the command to start the IBM Installation Manager in console mode: `imcl -c`
4. Complete the following steps to add the repositories:
   a. Enter `P` to go to the **Preferences** menu.
   b. Enter `1` to go to the **Repositories** menu.
   c. Enter `D` to add repositories.
   d. Type the path for your WebSphere Portal Express repository file.
   e. Enter `A` to apply your repositories and return to the **Preferences** menu.
   f. Enter `R` to return to the **Main** menu.
5. Enter `1` to install the software packages.
6. Select the software packages that you want to install.
   - If you are installing Portal to an existing copy of WebSphere Application Server, then select only **IBM WebSphere Portal Server.** To complete this installation option, your existing copy of WebSphere Application Server must meet the following requirements:
     – WebSphere Application Server Version 8.5.5.2 or later
     – Java Version 7
     – No existing Portal profile
   - If you are not installing Portal to an existing copy of WebSphere Application Server, then select the following packages:
     – **IBM WebSphere Application Server Network Deployment**
     – **IBM WebSphere Portal Server**
     – **IBM WebSphere SDK Java Technology Edition**

     Note: The **IBM WebSphere SDK Java Technology Edition** option is required for a WebSphere Portal Express installation even though it might be marked as "Optional."

   Tip: If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.
7. Choose one of the following options:
   - Enter `1` to choose version 8.5.0.0 for installation.
   - Enter `2` to show all available versions of the package.
8. Enter `N`.
9. Enter `A` to accept the license agreement.
10. Enter `N`.
11. Choose one of the following options for translation packages:
    - Enter `N` to select the default English package only.
    - Enter the number for the translation package you want to install.

12. On the **Incompatible package group** menu, choose one of the following options:
    - Enter `M` to change the installation directory. Then, enter the new installation directory.
    - Enter `N` to keep the existing directory.
13. Enter the number for the WebSphere Application Server root directory to use as the existing WebSphere Application Server.
14. On the **IBM Installation Manager** > **Install** > **Licenses** > **Location** > **Features** menu, enter `1` to select the **Portal Server Profile** feature. Then, enter `N` to continue.

    Note: Ensure that **Portal Server Profile** is selected to create a profile that contains the Portal application server and the product binary files. Clear this option if you need a binary only installation for migration.
15. Enter the configuration wizard administrator user ID and password.
16. If you selected the **Portal Server Profile** feature, enter the information for the following prompts:
    - **Enter the host name**
    - **Enter the node name**
    - **Enter the cell name**
    - **Enter an administrator user ID for the portal server**
    - **Enter an administrator user password for the portal server**
    - **Confirm administrator user password for the portal server**
17. Enter `N`.
18. Review the summary information.
19. Choose one of the following options:
    - Enter `G` to generate a response file.
    - Enter `I` to install WebSphere Portal Express.
20. When the installation is complete, enter `F` to return to the main installation menu.
21. Access the Configuration Wizard. Go to `http://`*`your_server`*`:`*`10200`*`/ibm/wizard`.
22. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.

    Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For details on the supported languages for all of the WebSphere Portal Express user interfaces, see “Supported languages” on page 3622.

What to do next

Before you access WebSphere Application Server, configure the software license agreement to set the usage limit from the Proof of Entitlement (POE) or invoice. Go to Configuring software license information for information.

IBM i: Creating a response file:

After IBM Installation Manager is installed, you can use it to record a response file that is based on your environment. Record a response file on the same operating system you plan for the installation. If you have multiple operating systems, you

must record a response file for each operating system. Use a response file to automate your installation on multiple servers.

About this task

Procedure

1. Start all servers and applications that require a port number to avoid port conflicts when you install WebSphere Portal Express. If you are installing multiple copies of IBM WebSphere Portal Express on your server, start the existing Configuration Wizard servers.
2. Go to the `InstallationManager_root/eclipse/tools` directory.
3. Run the following task to start the recording: `imcl -c`
4. Complete the following steps to add the repositories:
   a. Enter `P` to go to the **Preferences** menu.
   b. Enter `1` to go to the **Repositories** menu.
   c. Enter `D` to add repositories.
   d. Type the path for your WebSphere Portal Express repository file.
   e. Enter `A` to apply your repositories and return to the **Preferences** menu.
   f. Enter `R` to return to the **Main** menu.
5. Enter `1` to install the software packages.
6. Select the software packages that you want to install.
   - If you are installing Portal to an existing copy of WebSphere Application Server, then select only **IBM WebSphere Portal Server.** To complete this installation option, your existing copy of WebSphere Application Server must meet the following requirements:
     – WebSphere Application Server Version 8.5.5.2 or later
     – Java Version 7
     – No existing Portal profile
   - If you are not installing Portal to an existing copy of WebSphere Application Server, then select the following packages:
     – **IBM WebSphere Application Server Network Deployment**
     – **IBM WebSphere Portal Server**
     – **IBM WebSphere SDK Java Technology Edition**

     Note: The **IBM WebSphere SDK Java Technology Edition** option is required for a WebSphere Portal Express installation even though it might be marked as "Optional."

   Tip: If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.
7. Choose one of the following options:
   - Enter `1` to choose version 8.5.0.0 for installation.
   - Enter `2` to show all available versions of the package.
8. Enter `N`.
9. Enter `A` to accept the license agreement.
10. Enter `N`.
11. Choose one of the following options for translation packages:
    - Enter `N` to select the default English package only.

- Enter the number for the translation package you want to install.

12. On the **Incompatible package group** menu, choose one of the following options:
    - Enter `M` to change the installation directory. Then, enter the new installation directory.
    - Enter `N` to keep the existing directory.
13. Enter the number for the WebSphere Application Server root directory to use as the existing WebSphere Application Server.
14. Enter the configuration wizard administrator user ID and password.
15. If you selected the **Portal Server Profile** feature, enter the information for the following prompts:
    - **Enter the host name**
    - **Enter the node name**
    - **Enter the cell name**
    - **Enter an administrator user ID for the portal server**
    - **Enter an administrator user password for the portal server**
    - **Confirm administrator user password for the portal server**
16. Enter `N`.
17. Review the summary information.
18. Enter `G` to generate a response file.
19. If you plan to install on a different computer, copy the response file to the response file directory on that computer.

IBM i: Installing with the response file:

Use either a sample response file or a response file that you created to install WebSphere Application Server and WebSphere Portal Express. You can create a response file with the graphical or console mode interface.

About this task

Locate the sample response file in the *setup_root*`/responsefiles` directory. Modify the file with your environment values.

The installation program verifies the operating system and its prerequisites, available disk space, and any required software prerequisites before installation. You cannot install two instances of the server at the same time, even if you are installing to different directories. You must install each server completely before you install the next one.

Procedure

1. If the repository URL requires authentication, use the IBM Installation Manager command-line tool to create a secure **Storage File**.

   The secure **Storage File** stores the credentials that are required for the repositories. The IBM Installation Manager command-line tool **imutilsc** is available from the installation tools directory. The following information is an example of the **imutilsc** key ring file command:

   ```
   imutilsc saveCredential -url repository_URL -userName credential_userName
    -userPassword password -secureStorageFile storage_file [ -masterPasswordFile master_password_file ]
   [ -preferences com.ibm.cic.common.core.preferences.ssl.nonsecureMode=true|false ]
   ```

```
 [ -proxyHost proxy_host -proxyPort proxy_port
  [ -proxyUsername proxy_username -proxyUserPassword proxyuser_password ]
  [ -useSocks ] ]
 [ -verbose ]
```

Tip: If you install on a different computer, copy the secure **Storage File** to that computer.

2. Go to the `InstallationManager_root/eclipse/tools` directory.
3. Run the following task to install WebSphere Portal Express and IBM WebSphere Application Server:

   Tip: Add the **-secureStorageFile** *pathtosecureStorageFile* **-masterPasswordFile** *pathtomasterPasswordFile* parameters to the **imcl** command if you are using a secure **Storage File** to store credentials.
   `imcl -acceptLicense input pathtoresponse.xml -log dirpath/logfilename`

What to do next

Before you access WebSphere Application Server, configure the software license agreement to set the usage limit from the Proof of Entitlement (POE) or invoice. Go to Configuring software license information for information.

Attention: When you install WebSphere Application Server and WebSphere Portal Express together, you might find the following message in the `SystemErr.log` file:
AppServer_root`/properties/version/installed.xml (No such file or directory)`

This message is part of the installation process and is not repeated after the installation is complete. Therefore, the message can be ignored.

IBM i: Converting the evaluation license

If you initially installed IBM WebSphere Portal Express using the evaluation license and then purchased the product, you can convert the installed evaluation license to a production license. You can do this at any time, before or after the evaluation license expires.

Before you begin

Review the evaluation license.

About this task

You do not need to reinstall the program files to convert the evaluation license. However, the license conversion utility must have access to the purchased production software. You cannot use the evaluation software to convert the evaluation license.

Complete the following steps to convert the evaluation license:

Procedure

1. Run the `stopServer` *WebSphere_Portal* `-username` *admin_userid* `-password` *admin_password* task from the *wp_profile_root*`/bin` directory.
2. Run the `ConfigEngine.sh install-license -Dlicense=`*media_filepath* task from the *wp_profile_root*`/ConfigEngine` directory.

   Tip: *media_filepath* is the location of the `PortalExpress` subdirectory on either the WebSphere Portal Express CD or the downloaded installation image, for

example */QOPT/disk_volume_label/*PortalExpress where *QOPT* is the disk mount point or /wpdownload/PortalExpress for the installation image.

When the task completes, a message confirms that the product is now licensed for use.

3. Run the startServer *WebSphere_Portal* task.

Related tasks:

"IBM i: Preparing your operating system" on page 169
Prepare the operating system to ensure a successful installation.

"IBM i: Preparing the Installation Manager" on page 169
The IBM Installation Manager is used to install installation packages such as IBM WebSphere Portal Express and IBM WebSphere Application Server.

IBM i: Next steps

The configuration process has changed. Use the Configuration Wizard to set up your integration with prerequisites, clusters, and more.

Verify that the installation was successful

Unless you selected to install only the binary files, you can log in to the portal and verify that your installation was successful. Access WebSphere Portal Express with the http://*yourserver*:*yourport*/wps/portal format.

If you are not sure what your port number is, use the **list-server-ports** command to determine the port number. Change to the . Run the **list-server-ports** task to generate the WebSphere_Portal_PortMatrix.txt file. For example: ConfigEngine.sh list-server-ports -DWasPassword=*password*.

Change to the . Run the **list-server-ports** task to generate the server1_PortMatrix.txt file. For example: ConfigEngine.sh list-server-ports -DWasPassword=*password*.

Modify the uri.home.substitution custom property in the Resource Environment Provider

In the **WP ConfigService**, set the **uri.home.substitution** custom property to true to avoid functional errors that might occur in certain unusual use cases. For more information on **uri.home.substitution**, see *Configuration Service* in the related links.

Select a roadmap

If you have not already selected a roadmap to guide you through the installation and deployment process, look at the available roadmaps. The roadmaps are based on typical environments, such as development environment, test environment, and more. They provide a high-level overview of the installation and deployment process. Each roadmap includes a topology diagram, usage recommendations, and instructions. Roadmaps are available for both new deployments and migrations scenarios.

"Roadmaps for installation and deployment" on page 69

"Roadmaps for migration" on page 92

Run the Configuration Wizard to finish the deployment

Then, start the Configuration Wizard and select the option that is defined in your selected roadmap. Use the wizard to run the configuration steps in real time or to generate scripts. The wizard generates instructions and scripts specific to your environment and the data that you entered. You can save the selection and data that you entered as an XML file. Then, you can load the XML file during a subsequent wizard session to set up a similar configuration on a different server.

If you select to run the configuration in real time, you still have the opportunity to download scripts for selected steps. For example, if only the database administrator can databases, then you can download the database creation script and give it to your database administrator to run.

Default URLs

During the configuration process, you might need to following URLs to access different administration user interfaces.

Use the following default URLs to access IBM WebSphere Portal Express, the WebSphere Integrated Solutions Console, and the Configuration Wizard:

IBM WebSphere Portal Express

`http://localhost:10039/wps/portal`

`https://localhost:10042/wps/portal`

WebSphere Integrated Solutions Console

`http://localhost:10038/ibm/console`

`https://localhost:10041/ibm/console`

Configuration Wizard

`http://localhost:10200/ibm/wizard`

`https://localhost:10202/ibm/wizard`

If you had any processes from other software in the default port range when the installation started, you might have different port numbers than the defaults.

"Configuration Service" on page 297
The portal Configuration Service is responsible for collecting the most essential configuration data of the IBM WebSphere Portal Express engine.

IBM i: Upgrading the SDK

Starting with IBM WebSphere Portal Express Combined Cumulative Fix 05, you can change your SDK Java Technology Edition from version 7.0 to version 7.1.

About this task

IBM i note: SDK version 7.1 is an optional prerequisite for WebSphere Application Server on IBM i and has a separate, non-Installation Manager based installation.

Procedure

1. Install one of the following PTF Groups or higher:
   - V7R1: **PTF Group SF99572 level 15** or higher
   - V7R2: **PTF Group SF99716 level 4** or higher
2. Read the following information before you run the **managesdk** task:
   - For stand-alone environments: Stop the profile server (node) before you run the **managesdk** command.
   - For clustered environments:
     - If the profile is a federated node of a deployment manager, ensure that the deployment manager is running before you run the **managesdk** command to update the profile.
     - Stop all the nodes.
     - Ensure that the node agent for each node is started.
     - When you enable the SDK for a node, run the **managesdk** command from the `/bin` directory to which the node belongs. You can also run the command from the `/bin` directory of the profile that contains the node that you want to update.
     - A connection to the deployment manager must exist with a supported connector protocol in the following order of preference:
       - SOAP
       - Inter-Process Communications (IPC)
       - Remote Method Invocation (RMI)

       If the SOAP protocol is enabled, the **managesdk** command uses the SOAP protocol. If the SOAP protocol is not enabled but the IPC protocol is enabled, the command uses the IPC protocol. If the SOAP and IPC protocol are not enabled, then the command uses the RMI protocol.
     - You must provide the administrative user name and password with the **managesdk** command for each profile that contains a federated node or deployment manager node in a cell with security enabled. If you do not specify the **-user** and **-password** parameters, the **managesdk** command might fail or stop processing.

– When you enable the SDK for a deployment manager, only the deployment manager server is enabled. None of the managed nodes of the deployment manager are enabled to use the specific SDK.

3. Open a command prompt and change to the *AppServer_root*/bin directory.
4. Run the following command to enable all existing profiles to use the new SDK version:

   Go to managesdk command for information about the **managesdk** commands.

   - IBM i: `managesdk -enableProfileAll -sdkname 1.7.1_64 -enableServers`
5. Run the following commands to make the new SDK version the new default:
   - IBM i: `managesdk -setCommandDefault -sdkname 1.7.1_64`

     `managesdk -setNewProfileDefault -sdkname 1.7.1_64`
6. Repeat these steps on each node in your environment.

The IBM Installation Manager is used to install installation packages such as IBM WebSphere Portal Express and IBM WebSphere Application Server.

"IBM i: Running the installation program" on page 170
Use the IBM Installation Manager program to install the software. IBM Installation Manager provides multiple user interfaces. Select the one that you are more comfortable with. You can use the graphical user interface or the console to create a response file for automated installations.

"IBM i: Converting the evaluation license" on page 175
If you initially installed IBM WebSphere Portal Express using the evaluation license and then purchased the product, you can convert the installed evaluation license to a production license. You can do this at any time, before or after the evaluation license expires.

IBM i: Rendering documents on IBM i

To enable document preview function for IBM Web Content Manager and the Common Mail portlet, you must set up an HTML rendering server to work with WebSphere Portal Express. Because IBM i does not contain native graphics support, you must install extra fonts to run the document conversion that is required by these functions. Document conversion enables WebSphere Portal Express to convert documents that are produced by commonly used office programs into web pages so that they can be viewed and searched by users online. The additional fonts include an HTML rendering server that is known as X virtual frame buffer for the X server.

About this task

Before you begin, you must have:

A WebSphere Portal Express profile that runs on your IBM i system; record the name of your WebSphere Portal Express profile for future reference.

OS/400 - Additional Fonts (5770SS1, Option 43).

After you set up your HTML rendering server, you must also enable the Document Conversion Services.

Complete the following tasks on each WebSphere Portal Express node to render documents on IBM i:

Note: Use the HTML rendering server that you associate with your WebSphere Portal Express profile only for WebSphere Portal Express. Using the HTML rendering server with other applications might cause problems.

"IBM i: Configuring an HTML rendering server on IBM i"
After you have installed OS/400 - Additional Fonts (5770SS1, Option 43), on your IBM i system, an HTML rendering server (X virtual frame buffer for X server) is present. You must select a display number for the HTML rendering server.

"IBM i: Associating an HTML rendering server with WebSphere Portal Express on IBM i" on page 181
After you select a display number for the HTML rendering server (X virtual frame buffer for X server), you must associate this server with the installed IBM WebSphere Portal Express profile.

IBM i: Configuring an HTML rendering server on IBM i:

After you have installed OS/400 - Additional Fonts (5770SS1, Option 43), on your IBM i system, an HTML rendering server (X virtual frame buffer for X server) is present. You must select a display number for the HTML rendering server.

Procedure

1. If the QShell Interpreter is running, perform the following commands on the IBM i command line to stop it:

   ```
   QSH
   ```

   Press **F3**
2. Type `CALL QP2TERM` on the command line to start the OS/400 Portable Application Solutions Environment (OS/400 PASE) console.
3. Type `ps gaxuw | grep Xvnc ; ps gaxuw | grep vfb` on the command line to list all active HTML rendering servers:

   Note: If other rendering servers are already active, you might see output such as this (the number after the colon is the display number already in use):

```
v2kea554 40571 0.0  0.0 12484 0 - A Jul 13 4:08
/QOpenSys/QIBM/ProdData/DeveloperTools/vnc/Xvnc:6 -desktop X -httpd
```

4. Select any number from 1 to 99 that is not in use.
5. Press **F3** to return to the command line interface.
6. Type `SBMJOB CMD(CALL PGM(QP2SHELL) PARM('/usr/bin/X11/X' '-vfb' ':N')) JOB(XVFB) JOBQ(QSYSNOMAX) ALWMLTTHD(*YES)` on the command line to start the HTML rendering server, where *N* is the display number.
7. Verify that the HTML rendering server is started by repeating the prior steps to start PASE and list the active servers, confirming that an HTML rendering server with your display number is in the list.

What to do next

After you render your documents, you must enable the document conversion services. Go to Chapter 6, "Document Conversion Services," on page 727 for information.

IBM i: Associating an HTML rendering server with WebSphere Portal Express on IBM i:

After you select a display number for the HTML rendering server (X virtual frame buffer for X server), you must associate this server with the installed IBM WebSphere Portal Express profile.

Procedure

1. Log on to the WebSphere Integrated Solutions Console.
2. Go to **Servers** > **Server Types** > **WebSphere application servers** > **WebSphere_Portal** > **Server Infrastructure** > **Java and Process Management** > **Process definition** > **Environment Entries**.
3. Click **New**.
4. In the **Name** field type `DISPLAY`.
5. In the **Value** field type *host_name*`:n`, where *host_name* is the TCP/IP host name of your system and *n* is the display number of the HTML rendering server. (Example: `mysystem.xland.company.com:1`).
6. Click **OK**.
7. Save your changes to the master WebSphere Application Server configuration file.
8. Restart the server.

What to do next

After you render your documents, you must enable the document conversion services. Go to Chapter 6, "Document Conversion Services," on page 727 for information.

Linux: Installing WebSphere Portal Express and Web Content Manager

Installing the digital experience software includes preparing your operating system and using IBM Installation Manager to install IBM WebSphere Portal Express and Web Content Manager. Then, use the Configuration Wizard to complete the deployment configuration.

Before you begin

Roadmaps for installation and deployment are included in this product documentation to guide you through the process. Roadmaps provide a high-level overview of the process from beginning to end. Select the configuration that is closest to the configuration that you need.

1. "Linux: Preparing your operating system"
   Prepare the operating system to ensure a successful installation.
2. "Linux: Preparing the Installation Manager" on page 183
   The IBM Installation Manager is used to install installation packages such as IBM WebSphere Portal Express and IBM WebSphere Application Server.
3. "Linux: Running the installation program" on page 184
   Use the IBM Installation Manager program to install the software. IBM Installation Manager provides multiple user interfaces. Select the one that you are more comfortable with. You can use the graphical user interface or the console to create a response file for automated installations.
4. "Linux: Converting the evaluation license" on page 192
   If you initially installed IBM WebSphere Portal Express using the evaluation license and then purchased the product, you can convert the installed evaluation license to a production license. You can do this at any time, before or after the evaluation license expires.
5. "Linux: Next steps" on page 193
   The configuration process has changed. Use the Configuration Wizard to set up your integration with prerequisites, clusters, and more.
6. "Linux: Upgrading the SDK" on page 195
   Starting with IBM WebSphere Portal Express Combined Cumulative Fix 05, you can change your SDK Java Technology Edition from version 7.0 to version 7.1.

Linux: Preparing your operating system

Prepare the operating system to ensure a successful installation.

Procedure

1. If you are using IBM GPFS file sharing, set the file system inodes limit to 25000 or higher. For example, run the **mmchfs /dev/gpfs1nsd -F 250000** command. */dev/gpfs1nsd* is the IBM WebSphere Portal Express installation file system.
2. Set the file descriptor limit to `10240`.

   ```
   ulimit -n 10240
   ```

3. **Web Content Manager only:** Complete the following steps to remove any file size limits: Use the **ulimit -f** command to set the maximum size of files that can be created. Set this value to at least the size of the largest file you would upload to the content server. The **ulimit -f unlimited** command removes any limit on file size.
   a. Open a command prompt.
   b. Run the `ulimit -a` command to get a list of all the **ulimit** settings.
   c. Find the **-f** parameter. If the value is `unlimited`, no further action is required.
   d. If the **-f** parameter is not `unlimited`, choose one of the following options:
      - Remove the file size limit permanently. For information about how to remove the file size limit see your system documentation.
      - Run the `ulimit -f unlimited` command for each session.

4. Install and configure X server on Linux (such as X Window System or GNOME) to use the graphical user interface the installation program provides. For information about adding packages, read your system documentation.

   Note: If you plan to install with a response file, X server is not required.

Linux: Preparing the Installation Manager

The IBM Installation Manager is used to install installation packages such as IBM WebSphere Portal Express and IBM WebSphere Application Server.

Procedure

If you have an existing Installation Manager, start it and go to **File** > **Preferences**. Then, click **Updates**. Click the **Search for Installation Manager updates** check box. This box enables the Installation Manager to search for updates the next time you run an installation or update.
If you do not have an existing Installation Manager, then complete the following procedure:

1. Start all servers and applications that require a port number to avoid port conflicts when installing WebSphere Portal Express.
2. Type **ping** `yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
3. Type **ping** `localhost` on a command line to verify that your network is properly configured.
4. If you are installing on a server with a firewall, antivirus, screen saver, or desktop search engine that is enabled, disable them before you install. If you do not disable them and the installation program detects them, a warning message displays during the installation.
5. Optional: Complete the following steps to install as a non-root user:
   a. Log in to the operating system as the root user.
   b. Open a command line.
   c. Use the appropriate system commands to create the following items:

      Non-root user, including password

      Group

      Directory, used when you install IBM Installation Manager and WebSphere Portal Express
   d. Set the user profile for the number of open files. Set the value to **ulimit -n 10240**.
   e. Add the non-root user to the new group.
   f. Run the following task to change the owner of the directory to the non-root user:

      `chown user:group /directory`
   g. Run the following task to change permissions for the directory:

      `chmod 755 /directory`
   h. Log in as the non-root user.
   i. Use the following command to install IBM Installation Manager:

      `./userinst`

      Set the IBM Installation Manager installation location to `/directory/IBM/InstallationManager`.
6. Run the following task from the `IIM` directory: `./install`

7. Run the following task from the Portal Setup disk if you want to start the launchpad to complete all necessary installation steps: `./setup.sh`

   Launchpad tip: On the Launchpad: Install Portal panel, you have the following options:

   Install IBM WebSphere Portal from media
   Choose this option if you are installing directly from the DVD.

   Install IBM WebSphere Portal from network
   Choose this option if you downloaded the electronic images.

   Install IBM Installation Manager only
   Choose this option if you want to install multiple IBM products, or if you want to install WebSphere Portal Express directly from IBM Passport Advantage, and a previous version of Installation Manager is not already installed on your system.

   Restriction: If you have a previously installed 32-bit version of Installation Manager, then you cannot proceed with this option. You must manually install the 64-bit version of Installation Manager that is specific to your operating system using the Setup disc before you proceed with the WebSphere Portal Express installation.

   Tip: Add the `LaunchPadLocale` *`language_code`* to the **`setup`** task to change the display to your user locale or to another language.

   Note: If the language is not currently supported for the user interface, you might see the English version. For details on supported languages and the language codes for all of the WebSphere Portal Express user interfaces, see "Supported languages" on page 3622.

   After you complete all necessary steps from the launchpad, verify that your installation was successful.

Linux: Running the installation program

Use the IBM Installation Manager program to install the software. IBM Installation Manager provides multiple user interfaces. Select the one that you are more comfortable with. You can use the graphical user interface or the console to create a response file for automated installations.

"Linux: Installing with the graphical user interface" on page 185
Use the IBM Installation Manager to install IBM WebSphere Portal Express, IBM WebSphere Application Server, and the Apache Derby database.

"Linux: Installing with the console" on page 187
Use the IBM Installation Manager to install IBM WebSphere Portal Express with an existing IBM WebSphere Application Server.

"Linux: Creating a response file" on page 189
After IBM Installation Manager is installed, you can use it to record a response file that is based on your environment. Record a response file on the same operating system you plan for the installation. If you have multiple operating systems, you must record a response file for each operating system. Use a response file to automate your installation on multiple servers.

"Linux: Installing with the response file" on page 191
Use either a sample response file or a response file that you created to install WebSphere Application Server and WebSphere Portal Express. You can create a response file with the graphical or console mode interface.

Related tasks:

"Linux: Preparing your operating system" on page 182
Prepare the operating system to ensure a successful installation.

Linux: Installing with the graphical user interface:

Use the IBM Installation Manager to install IBM WebSphere Portal Express, IBM WebSphere Application Server, and the Apache Derby database.

About this task

The installation program verifies the operating system and its prerequisites, available disk space, and any required software prerequisites before installation. You cannot install two instances of the server at the same time, even if you are installing to different directories. You must install each server completely before you install the next one.

Procedure

1. Start all servers and applications that require a port number to avoid port conflicts when you install WebSphere Portal Express. If you are installing multiple copies of IBM WebSphere Portal Express on your server, start the existing Configuration Wizard servers.
2. If necessary, start the Installation Manager.
3. After you install or upgrade the Installation Manager, complete the following steps to add the repositories where the installation media exists:
   a. Open the IBM Installation Manager and go to **File** > **Preferences** > **Repositories**.
   b. Select **Add Repositories**.
   c. Select **Browse** and go to the *Portal-install-eimage*/Setup/repository.config file and then click **OK**.
   d. Ensure that all required repositories are checked. Then, click **Test Connections** to ensure that the IBM Installation Manager can successfully access the directory where the service repositories are stored.
   e. Select **Apply**.
   f. Select **OK**.
4. On the main IBM Installation Manager panel, select **Install**.
5. Optional: If you are installing Portal to an existing copy of WebSphere Application Server, then select only **IBM WebSphere Portal Server** on the Install Packages screen. To complete this installation option, your existing copy of WebSphere Application Server must meet the following requirements:
   - WebSphere Application Server Version 8.5.5.2 or later
   - Java Version 7
   - No existing Portal profile

   Skip the following step, if you choose to install to an existing copy of WebSphere Application Server.
6. On Install Packages: Select packages to install, select the following packages, and then click **Next**:
   - **IBM WebSphere Application Server Network Deployment**
   - **IBM WebSphere Portal Server**
   - **IBM WebSphere SDK Java Technology Edition**

Note: The **IBM WebSphere SDK Java Technology Edition** option is required for a WebSphere Portal Express installation even though it might be marked as "Optional" on the Select packages to install screen.

Tip: If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.

7. On Install Packages: Select the fixes to install screen, select any required fixes. Then, click **Next**.
8. Accept the license agreement and then click **Next**.
9. Enter the directory where you want to store shared resources and then click **Next**.
10. Complete the following steps on the Install Packages: Installation Directory panel:

    Remember: The installation directory that you specify must NOT contain any files or the following characters: `~ ! @ # $ % ^ & * ( ) + { } | < > ? ` = [ ] ; ' , . "` and spaces.

    a. Select the WebSphere Application Server Package Group Name and then enter the installation directory path.
    b. Select the WebSphere Portal Express Package Group Name and then enter the installation directory path.
    c. Click **Next**.
11. Select the translations to install and then click **Next**.
12. Optional: If you chose to install Portal to an existing copy of WebSphere Application Server, select the available copy of WebSphere Application Server, and click **Next**.

    Note: Skip this step, if you are not installing Portal to an existing copy of WebSphere Application Server.
13. On Install Packages: Select the features to install, expand the WebSphere Application Server and WebSphere Portal Express packages to modify the features you want to install and then click **Next**.

    Note: Ensure that **Portal Server Profile** is selected to create a profile that contains the Portal application server and the product binary files. Clear this option if you need a binary only installation for migration.

    Note: As you select the items, read the **Details** section for information.
14. On Profile configuration details, enter the user ID and password for the configuration wizard administrator. Then, click **Next**.
15. If you selected the **Portal Server Profile** package, click **Enter the Administrator user ID and password for the Portal Server**.
16. Confirm the Summary information and then click **Install**.

What to do next

After a successful installation, the summary displays. Choose the **Portal First Steps** radio button and then click **Finish** to start the servers and begin configuring WebSphere Portal Express with the Configuration Wizard.

Tip: To access First Steps later, you can either select **First Steps** from the **Start** menu or you can run the **./firststeps.sh** task from the *wp_profile_root*/

PortalServer/installer/wp.firststeps directory. Add the LaunchPadLocale *language_code* to the **firststeps** task to change the display to your user locale or to another language.

Attention: When you install WebSphere Application Server and WebSphere Portal Express together, you might find the following message in the SystemErr.log file:
AppServer_root/properties/version/installed.xml (No such file or directory)

This message is part of the installation process and is not repeated after the installation is complete. Therefore, the message can be ignored.

Linux: Installing with the console:

Use the IBM Installation Manager to install IBM WebSphere Portal Express with an existing IBM WebSphere Application Server.

Before you begin

A working installation of IBM WebSphere Application Server is required. Ensure that it is not used by another copy of WebSphere Portal Express. Before you install the WebSphere Portal Express package, install **IBM WebSphere SDK Java Technology Edition** into the same directory where IBM WebSphere Application Server is installed.

About this task

The installation program verifies the operating system and its prerequisites, available disk space, and any required software prerequisites before installation. You cannot install two instances of the server at the same time, even if you are installing to different directories. You must install each server completely before you install the next one.

Procedure

1. Start all servers and applications that require a port number to avoid port conflicts when you install WebSphere Portal Express. If you are installing multiple copies of IBM WebSphere Portal Express on your server, start the existing Configuration Wizard servers.
2. Open a command prompt and change to the InstallationManager_root/eclipse/tools directory.
3. Run the command to start the IBM Installation Manager in console mode: ./imcl -c
4. Complete the following steps to add the repositories:
   a. Enter P to go to the **Preferences** menu.
   b. Enter 1 to go to the **Repositories** menu.
   c. Enter D to add repositories.
   d. Type the path for your WebSphere Portal Express repository file.
   e. Enter A to apply your repositories and return to the **Preferences** menu.
   f. Enter R to return to the **Main** menu.
5. Enter 1 to install the software packages.
6. Select the software packages that you want to install.
   - If you are installing Portal to an existing copy of WebSphere Application Server, then select only **IBM WebSphere Portal Server.** To complete this

installation option, your existing copy of WebSphere Application Server must meet the following requirements:
  - WebSphere Application Server Version 8.5.5.2 or later
  - Java Version 7
  - No existing Portal profile
- If you are not installing Portal to an existing copy of WebSphere Application Server, then select the following packages:
  - **IBM WebSphere Application Server Network Deployment**
  - **IBM WebSphere Portal Server**
  - **IBM WebSphere SDK Java Technology Edition**

    Note: The **IBM WebSphere SDK Java Technology Edition** option is required for a WebSphere Portal Express installation even though it might be marked as "Optional."

Tip: If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.

7. Choose one of the following options:
   - Enter `1` to choose version 8.5.0.0 for installation.
   - Enter `2` to show all available versions of the package.
8. Enter `N`.
9. Enter `A` to accept the license agreement.
10. Enter `N`.
11. Choose one of the following options for translation packages:
    - Enter `N` to select the default English package only.
    - Enter the number for the translation package you want to install.
12. On the **Incompatible package group** menu, choose one of the following options:
    - Enter `M` to change the installation directory. Then, enter the new installation directory.
    - Enter `N` to keep the existing directory.
13. Enter the number for the WebSphere Application Server root directory to use as the existing WebSphere Application Server.
14. On the **IBM Installation Manager** > **Install** > **Licenses** > **Location** > **Features** menu, enter `1` to select the **Portal Server Profile** feature. Then, enter `N` to continue.

    Note: Ensure that **Portal Server Profile** is selected to create a profile that contains the Portal application server and the product binary files. Clear this option if you need a binary only installation for migration.
15. Enter the configuration wizard administrator user ID and password.
16. If you selected the **Portal Server Profile** feature, enter the information for the following prompts:
    - **Enter the host name**
    - **Enter the node name**
    - **Enter the cell name**
    - **Enter an administrator user ID for the portal server**
    - **Enter an administrator user password for the portal server**

- **Confirm administrator user password for the portal server**

17. Enter `N`.
18. Review the summary information.
19. Choose one of the following options:
    - Enter `G` to generate a response file.
    - Enter `I` to install WebSphere Portal Express.
20. When the installation is complete, enter `F` to return to the main installation menu.
21. Access the Configuration Wizard. Go to `http://your_server:10200/ibm/wizard`.
22. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.

    Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For details on the supported languages for all of the WebSphere Portal Express user interfaces, see "Supported languages" on page 3622.

Linux: Creating a response file:

After IBM Installation Manager is installed, you can use it to record a response file that is based on your environment. Record a response file on the same operating system you plan for the installation. If you have multiple operating systems, you must record a response file for each operating system. Use a response file to automate your installation on multiple servers.

About this task

You can also use the console mode to generate a response file. After you review the summary information, enter `G` to generate a response file instead of `I` to install.

Procedure

1. Start all servers and applications that require a port number to avoid port conflicts when you install WebSphere Portal Express. If you are installing multiple copies of IBM WebSphere Portal Express on your server, start the existing Configuration Wizard servers.
2. Go to the `InstallationManager_root/eclipse` directory.
3. Run the following task to start the recording: `./IBMIM -record pathtoresponsexmlfile -skipInstall tempinstalldirectory`

   `-record`
   This parameter indicates recording the actions and parameters into the response file. The *pathtoresponsexmlfile* text is the name of the response file, for example `Wp8SampleResp.xml`. The *tempinstalldirectory* text is the directory where the response file is recorded.

   `-skipInstall`
   This parameter indicates that no actual installation is completed even though it leads to the final pane.

   tempinstalldirectory
   This value is a directory where the installation saves the history and data when you record the response files.
4. Complete the following steps to add the repositories where the installation media exists:

a. Open the IBM Installation Manager and go to **File** > **Preferences** > **Repositories**.
b. Select **Add Repositories**.
c. Select **Browse** and go to the *Portal-install-eimage*/Setup/repository.config file and then click **OK**.
d. Ensure that all required repositories are checked. Then, click **Test Connections** to ensure that the IBM Installation Manager can successfully access the directory where the service repositories are stored.
e. Select **Apply**.
f. Select **OK**.

5. On the main IBM Installation Manager panel, select **Install**.
6. Optional: If you are installing Portal to an existing copy of WebSphere Application Server, then select only **IBM WebSphere Portal Server** on the Install Packages screen. To complete this installation option, your existing copy of WebSphere Application Server must meet the following requirements:
   - WebSphere Application Server Version 8.5.5.2 or later
   - Java Version 7
   - No existing Portal profile

   Skip the following step, if you choose to install to an existing copy of WebSphere Application Server.
7. On Install Packages: Select packages to install, select the following packages, and then click **Next**:
   - **IBM WebSphere Application Server Network Deployment**
   - **IBM WebSphere Portal Server**
   - **IBM WebSphere SDK Java Technology Edition**

     Note: The **IBM WebSphere SDK Java Technology Edition** option is required for a WebSphere Portal Express installation even though it might be marked as "Optional" on the Select packages to install screen.

   Tip: If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.
8. On Install Packages: Select the fixes to install screen, select any required fixes. Then, click **Next**.
9. Accept the license agreement and then click **Next**.
10. Enter the directory where you want to store shared resources and then click **Next**.
11. Complete the following steps on the Install Packages: Installation Directory panel:

    Remember: The installation directory that you specify must NOT contain any files or the following characters: `~ ! @ # $ % ^ & * ( ) + { } | < > ? ` = [ ] ; ' , . "` and spaces.
    a. Select the WebSphere Application Server Package Group Name and then enter the installation directory path.
    b. Select the WebSphere Portal Express Package Group Name and then enter the installation directory path.
    c. Click **Next**.
12. Select the translations to install and then click **Next**.

13. Optional: If you chose to install Portal to an existing copy of WebSphere Application Server, select the available copy of WebSphere Application Server, and click **Next**.

    Note: Skip this step, if you are not installing Portal to an existing copy of WebSphere Application Server.
14. On Install Packages: Select the features to install, expand the WebSphere Application Server and WebSphere Portal Express packages to modify the features you want to install and then click **Next**.

    Note: Ensure that **Portal Server Profile** is selected to create a profile that contains the Portal application server and the product binary files. Clear this option if you need a binary only installation for migration.

    Note: As you select the items, read the **Details** section for information.
15. On Profile configuration details, enter the user ID and password for the configuration wizard administrator. Then, click **Next**.
16. If you selected the **Portal Server Profile** package, click **Enter the Administrator user ID and password for the Portal Server**.
17. Confirm the Summary information and then click **Install**.
18. After the Installation Manager finishes creating the response file, click **Finish** and then close the Installation Manager to complete the response file recording.
19. If you plan to install on a different computer, copy the response file to the response file directory on that computer.

Linux: Installing with the response file:

Use either a sample response file or a response file that you created to install WebSphere Application Server and WebSphere Portal Express. You can create a response file with the graphical or console mode interface.

About this task

Locate the sample response file in the *setup_root*/responsefiles directory. Modify the file with your environment values.

The installation program verifies the operating system and its prerequisites, available disk space, and any required software prerequisites before installation. You cannot install two instances of the server at the same time, even if you are installing to different directories. You must install each server completely before you install the next one.

Procedure

1. If the repository URL requires authentication, use the IBM Installation Manager command-line tool to create a secure **Storage File**.

   The secure **Storage File** stores the credentials that are required for the repositories. The IBM Installation Manager command-line tool **imutilsc** is available from the installation tools directory. The following information is an example of the **imutilsc** key ring file command:

```
./imutilsc saveCredential -url repository_URL -userName credential_userName
 -userPassword password -secureStorageFile storage_file
[ -masterPasswordFile master_password_file ]
[ -preferences com.ibm.cic.common.core.preferences.ssl.nonsecureMode=true|false ]
```

```
[ -proxyHost proxy_host -proxyPort proxy_port
 [ -proxyUsername proxy_username -proxyUserPassword proxyuser_password ]
 [ -useSocks ] ]
[ -verbose ]
```

Tip: If you install on a different computer, copy the secure **Storage File** to that computer.

2. Go to the `InstallationManager_root/eclipse/tools` directory.
3. Run the following task to install WebSphere Portal Express and IBM WebSphere Application Server:

   Tip: Add the **-secureStorageFile** *pathtosecureStorageFile* **-masterPasswordFile** *pathtomasterPasswordFile* parameters to the **imcl** command if you are using a secure **Storage File** to store credentials.
   `./imcl -acceptLicense input` *pathtoresponse.xml* `-log` *dirpath/logfilename*

What to do next

Attention: When you install WebSphere Application Server and WebSphere Portal Express together, you might find the following message in the `SystemErr.log` file:
AppServer_root`/properties/version/installed.xml (No such file or directory)`

This message is part of the installation process and is not repeated after the installation is complete. Therefore, the message can be ignored.

Linux: Converting the evaluation license

If you initially installed IBM WebSphere Portal Express using the evaluation license and then purchased the product, you can convert the installed evaluation license to a production license. You can do this at any time, before or after the evaluation license expires.

Before you begin

Review the evaluation license.

About this task

You do not need to reinstall the program files to convert the evaluation license. However, the license conversion utility must have access to the purchased production software. You cannot use the evaluation software to convert the evaluation license.

Complete the following steps to convert the evaluation license:

Procedure

1. Run the `./stopServer.sh` *WebSphere_Portal* `-username` *admin_userid* `-password` *admin_password* task from the *wp_profile_root*`/bin` directory.
2. If you are using physical media on Linux mount the drive and then insert the CD.
3. Run the `./ConfigEngine.sh install-license -Dlicense=`*media_filepath* task from the *wp_profile_root*`/ConfigEngine` directory. .

   Tip: *media_filepath* is the location of the `PortalExpress` subdirectory on either the WebSphere Portal Express CD or the downloaded installation image, for example `/mnt/cdrom/PortalExpress` if the CD is in `/mnt/cdrom` or `/wpdownload/PortalExpress` for the installation image.

When the task completes, a message confirms that the product is now licensed for use.

4. Run the `./startServer.sh` *`WebSphere_Portal`* task.

Related tasks:

"Linux: Preparing your operating system" on page 182
Prepare the operating system to ensure a successful installation.

"Linux: Preparing the Installation Manager" on page 183
The IBM Installation Manager is used to install installation packages such as IBM WebSphere Portal Express and IBM WebSphere Application Server.

Linux: Next steps

The configuration process has changed. Use the Configuration Wizard to set up your integration with prerequisites, clusters, and more.

Verify that the installation was successful

Unless you selected to install only the binary files, you can log in to the portal and verify that your installation was successful. Access WebSphere Portal Express with the `http://`*`yourserver`*`:`*`yourport`*`/wps/portal` format.

If you are not sure what your port number is, use the **`list-server-ports`** command to determine the port number. Change to the *wp_profile_root*`/ConfigEngine/log`. Run the **`list-server-ports`** task to generate the `WebSphere_Portal_PortMatrix.txt` file. For example: `./ConfigEngine.sh list-server-ports -DWasPassword=`*`password`*.

Change to the `/opt/IBM/WebSphere/AppServer/profiles/cw_profile/ConfigEngine`. Run the **`list-server-ports`** task to generate the `server1_PortMatrix.txt` file. For example: `./ConfigEngine.sh list-server-ports -DWasPassword=`*`password`*.

Modify the `uri.home.substitution` custom property in the Resource Environment Provider

In the **WP ConfigService**, set the **`uri.home.substitution`** custom property to `true` to avoid functional errors that might occur in certain unusual use cases. For more information on **`uri.home.substitution`**, see *Configuration Service* in the related links.

Select a roadmap

If you have not already selected a roadmap to guide you through the installation and deployment process, look at the available roadmaps. The roadmaps are based on typical environments, such as development environment, test environment, and more. They provide a high-level overview of the installation and deployment process. Each roadmap includes a topology diagram, usage recommendations, and instructions. Roadmaps are available for both new deployments and migrations scenarios.

"Roadmaps for installation and deployment" on page 69

"Roadmaps for migration" on page 92

Run the Configuration Wizard to finish the deployment

Then, start the Configuration Wizard and select the option that is defined in your selected roadmap. Use the wizard to run the configuration steps in real time or to generate scripts. The wizard generates instructions and scripts specific to your

environment and the data that you entered. You can save the selection and data that you entered as an XML file. Then, you can load the XML file during a subsequent wizard session to set up a similar configuration on a different server.

If you select to run the configuration in real time, you still have the opportunity to download scripts for selected steps. For example, if only the database administrator can databases, then you can download the database creation script and give it to your database administrator to run.

Default URLs

During the configuration process, you might need to following URLs to access different administration user interfaces.

Use the following default URLs to access IBM WebSphere Portal Express, the WebSphere Integrated Solutions Console, and the Configuration Wizard:

IBM WebSphere Portal Express

```
http://localhost:10039/wps/portal
```

```
https://localhost:10042/wps/portal
```

WebSphere Integrated Solutions Console

```
http://localhost:10038/ibm/console
```

```
https://localhost:10041/ibm/console
```

Configuration Wizard

```
http://localhost:10200/ibm/wizard
```

```
https://localhost:10202/ibm/wizard
```

If you had any processes from other software in the default port range when the installation started, you might have different port numbers than the defaults.

Linux: Upgrading the SDK

Starting with IBM WebSphere Portal Express Combined Cumulative Fix 05, you can change your SDK Java Technology Edition from version 7.0 to version 7.1.

Before you begin

Ensure that IBM WebSphere Application Server and WebSphere Portal Express are installed with SDK version 7.0.

Procedure

1. Start the IBM Installation Manager.
2. Install IBM WebSphere SDK Java Technology Edition version 7.1.
3. Read the following information before you run the **managesdk** task:
   - For stand-alone environments: Stop the profile server (node) before you run the **managesdk** command.
   - For clustered environments:
     – If the profile is a federated node of a deployment manager, ensure that the deployment manager is running before you run the **managesdk** command to update the profile.
     – Stop all the nodes.
     – Ensure that the node agent for each node is started.
     – When you enable the SDK for a node, run the **managesdk** command from the `/bin` directory to which the node belongs. You can also run the command from the `/bin` directory of the profile that contains the node that you want to update.
     – A connection to the deployment manager must exist with a supported connector protocol in the following order of preference:
       - SOAP
       - Inter-Process Communications (IPC)
       - Remote Method Invocation (RMI)

       If the SOAP protocol is enabled, the **managesdk** command uses the SOAP protocol. If the SOAP protocol is not enabled but the IPC protocol is enabled, the command uses the IPC protocol. If the SOAP and IPC protocol are not enabled, then the command uses the RMI protocol.
     – You must provide the administrative user name and password with the **managesdk** command for each profile that contains a federated node or deployment manager node in a cell with security enabled. If you do not specify the **-user** and **-password** parameters, the **managesdk** command might fail or stop processing.
     – When you enable the SDK for a deployment manager, only the deployment manager server is enabled. None of the managed nodes of the deployment manager are enabled to use the specific SDK.
4. Open a command prompt and change to the *AppServer_root*`/bin` directory.
5. Run the following command to enable all existing profiles to use the new SDK version:

   Go to managesdk command for information about the **managesdk** commands.

- Linux: `./managesdk.sh -enableProfileAll -sdkname 1.7.1_64 -enableServers`

6. Run the following commands to make the new SDK version the new default:
   - Linux: `./managesdk.sh -setCommandDefault -sdkname 1.7.1_64`

     `./managesdk.sh -setNewProfileDefault -sdkname 1.7.1_64`
7. Repeat these steps on each node in your environment.

   Starting with IBM WebSphere Portal Express Combined Cumulative Fix 05, you can change your SDK Java Technology Edition from version 7.0 to version 7.1.

Windows: Preparing your operating system

Prepare the operating system to ensure a successful installation.

Procedure

1. Check that the system logon user ID you plan to use during installation has the following permissions and rights:
   - The user ID must exist before the installation.
   - The user ID must belong to the Windows local Administrators group.
2. Determine whether a user account is a member of the Administrators group:
   a. Click **Start** > **Programs** > **Administrative Tools** > **Computer Management**.
   b. Expand **Local Users and Groups** and select **Groups**.
   c. Open the **Administrators** group to see what members belong to it.
   d. Add the user to the Administrators group if necessary.
3. Consider the following recommendations when you install to avoid excessively long path names:

   Note: If you exceed the 259 maximum character length, you might receive one of the following error messages during configuration or in the IBM Installation Manager log files:
   - `The input line is too long.`
   - `The syntax of the command is incorrect.`
   - `The file name is too long.`

   a. Use a short installation path. For example, use `C:\WebSphere` instead of `C:\Program Files\IBM\WebSphere`
   b. Specify node names; do not use names longer than 5 characters. For example, you might use `node1` instead of `longnodename01`.
   c. Name WAR files with less than 21 characters. If necessary, modify the file name before you install.

Windows: Preparing the Installation Manager

The IBM Installation Manager is used to install installation packages such as IBM WebSphere Portal Express and IBM WebSphere Application Server.

Procedure

If you have an existing Installation Manager, start it and go to **File** > **Preferences**. Then, click **Updates**. Click the **Search for Installation Manager updates** check box. This box enables the Installation Manager to search for updates the next time you run an installation or update.
If you do not have an existing Installation Manager, then complete the following procedure:

1. Start all servers and applications that require a port number to avoid port conflicts when installing WebSphere Portal Express.
2. Type **`ping`** `yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.

3. Type **ping** `localhost` on a command line to verify that your network is properly configured.
4. If you are installing on a server with a firewall, antivirus, screen saver, or desktop search engine that is enabled, disable them before you install. If you do not disable them and the installation program detects them, a warning message displays during the installation.
5. Run the following task from the `IIM` directory: `install.bat`
6. Run the following task from the Portal Setup disk if you want to start the launchpad to complete all necessary installation steps: `setup64.exe` Right-click on **setup64.exe**. Then, select **Run as administrator** to start.

   Launchpad tip: On the Launchpad: Install Portal panel, you have the following options:

   Install IBM WebSphere Portal from media
   Choose this option if you are installing directly from the DVD.

   Install IBM WebSphere Portal from network
   Choose this option if you downloaded the electronic images.

   Install IBM Installation Manager only
   Choose this option if you want to install multiple IBM products, or if you want to install WebSphere Portal Express directly from IBM Passport Advantage, and a previous version of Installation Manager is not already installed on your system.

   Restriction: If you have a previously installed 32-bit version of Installation Manager, then you cannot proceed with this option. You must manually install the 64-bit version of Installation Manager that is specific to your operating system using the Setup disc before you proceed with the WebSphere Portal Express installation.

   Tip: Add the `LaunchPadLocale` *language_code* to the **setup** task to change the display to your user locale or to another language.

   Note: If the language is not currently supported for the user interface, you might see the English version. For details on supported languages and the language codes for all of the WebSphere Portal Express user interfaces, see "Supported languages" on page 3622.

   After you complete all necessary steps from the launchpad, verify that your installation was successful.

Windows: Running the installation program

Use the IBM Installation Manager program to install the software. IBM Installation Manager provides multiple user interfaces. Select the one that you are more comfortable with. You can use the graphical user interface or the console to create a response file for automated installations.

"Windows: Installing with the graphical user interface" on page 199
Use the IBM Installation Manager to install IBM WebSphere Portal Express, IBM WebSphere Application Server, and the Apache Derby database.

"Windows: Installing with the console" on page 201
Use the IBM Installation Manager to install IBM WebSphere Portal Express with an existing IBM WebSphere Application Server.

"Windows: Creating a response file" on page 203
After IBM Installation Manager is installed, you can use it to record a response file that is based on your environment. Record a response file on the same

operating system you plan for the installation. If you have multiple operating systems, you must record a response file for each operating system. Use a response file to automate your installation on multiple servers.

"Windows: Installing with the response file" on page 205
Use either a sample response file or a response file that you created to install WebSphere Application Server and WebSphere Portal Express. You can create a response file with the graphical or console mode interface.

Related tasks:

"Windows: Preparing your operating system" on page 197
Prepare the operating system to ensure a successful installation.

Windows: Installing with the graphical user interface:

Use the IBM Installation Manager to install IBM WebSphere Portal Express, IBM WebSphere Application Server, and the Apache Derby database.

About this task

The installation program verifies the operating system and its prerequisites, available disk space, and any required software prerequisites before installation. You cannot install two instances of the server at the same time, even if you are installing to different directories. You must install each server completely before you install the next one.

Procedure

1. Start all servers and applications that require a port number to avoid port conflicts when you install WebSphere Portal Express. If you are installing multiple copies of IBM WebSphere Portal Express on your server, start the existing Configuration Wizard servers.
2. If necessary, start the Installation Manager.
3. After you install or upgrade the Installation Manager, complete the following steps to add the repositories where the installation media exists:
   a. Open the IBM Installation Manager and go to **File** > **Preferences** > **Repositories**.
   b. Select **Add Repositories**.
   c. Select **Browse** and go to the *Portal-install-eimage*/Setup/repository.config file and then click **OK**.
   d. Ensure that all required repositories are checked. Then, click **Test Connections** to ensure that the IBM Installation Manager can successfully access the directory where the service repositories are stored.
   e. Select **Apply**.
   f. Select **OK**.
4. On the main IBM Installation Manager panel, select **Install**.
5. Optional: If you are installing Portal to an existing copy of WebSphere Application Server, then select only **IBM WebSphere Portal Server** on the Install Packages screen. To complete this installation option, your existing copy of WebSphere Application Server must meet the following requirements:
   - WebSphere Application Server Version 8.5.5.2 or later
   - Java Version 7
   - No existing Portal profile

   Skip the following step, if you choose to install to an existing copy of WebSphere Application Server.

6. On Install Packages: Select packages to install, select the following packages, and then click **Next**:
   - **IBM WebSphere Application Server Network Deployment**
   - **IBM WebSphere Portal Server**
   - **IBM WebSphere SDK Java Technology Edition**

     Note: The **IBM WebSphere SDK Java Technology Edition** option is required for a WebSphere Portal Express installation even though it might be marked as "Optional" on the Select packages to install screen.

   Tip: If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.
7. On Install Packages: Select the fixes to install screen, select any required fixes. Then, click **Next**.
8. Accept the license agreement and then click **Next**.
9. Enter the directory where you want to store shared resources and then click **Next**.
10. Complete the following steps on the Install Packages: Installation Directory panel:

    Remember: The installation directory that you specify must NOT contain any files or the following characters: `~ ! @ # $ % ^ & * ( ) + { } | < > ? ` = [ ] ; ' , . "` and spaces.
    a. Select the WebSphere Application Server Package Group Name and then enter the installation directory path.
    b. Select the WebSphere Portal Express Package Group Name and then enter the installation directory path.
    c. Click **Next**.
11. Select the translations to install and then click **Next**.
12. Optional: If you chose to install Portal to an existing copy of WebSphere Application Server, select the available copy of WebSphere Application Server, and click **Next**.

    Note: Skip this step, if you are not installing Portal to an existing copy of WebSphere Application Server.
13. On Install Packages: Select the features to install, expand the WebSphere Application Server and WebSphere Portal Express packages to modify the features you want to install and then click **Next**.

    Note: Ensure that **Portal Server Profile** is selected to create a profile that contains the Portal application server and the product binary files. Clear this option if you need a binary only installation for migration.

    Note: As you select the items, read the **Details** section for information.
14. On Profile configuration details, enter the user ID and password for the configuration wizard administrator. Then, click **Next**.
15. If you selected the **Portal Server Profile** package, click **Enter the Administrator user ID and password for the Portal Server**.
16. Confirm the Summary information and then click **Install**.

What to do next

After a successful installation, the summary displays. Choose the **Portal First Steps** radio button and then click **Finish** to start the servers and begin configuring WebSphere Portal Express with the Configuration Wizard.

Tip: To access First Steps later, you can either select **First Steps** from the **Start** menu or you can run the **firststeps.exe** task from the *wp_profile_root*/PortalServer/installer/wp.firststeps directory. Add the LaunchPadLocale *language_code* to the **firststeps** task to change the display to your user locale or to another language.

Attention: When you install WebSphere Application Server and WebSphere Portal Express together, you might find the following message in the SystemErr.log file:
AppServer_root/properties/version/installed.xml (No such file or directory)

This message is part of the installation process and is not repeated after the installation is complete. Therefore, the message can be ignored.

Windows: Installing with the console:

Use the IBM Installation Manager to install IBM WebSphere Portal Express with an existing IBM WebSphere Application Server.

Before you begin

A working installation of IBM WebSphere Application Server is required. Ensure that it is not used by another copy of WebSphere Portal Express. Before you install the WebSphere Portal Express package, install **IBM WebSphere SDK Java Technology Edition** into the same directory where IBM WebSphere Application Server is installed.

About this task

The installation program verifies the operating system and its prerequisites, available disk space, and any required software prerequisites before installation. You cannot install two instances of the server at the same time, even if you are installing to different directories. You must install each server completely before you install the next one.

Procedure

1. Start all servers and applications that require a port number to avoid port conflicts when you install WebSphere Portal Express. If you are installing multiple copies of IBM WebSphere Portal Express on your server, start the existing Configuration Wizard servers.
2. Complete the following steps to run the program as an administrator:
   a. Go to the InstallationManager_root/eclipse/tools directory.
   b. Right-click on the **imcl** command.
   c. Select **Properties**.
   d. Go to the **Compatibility** tab.
   e. Select **Run this program as an administrator**.
   f. Click **OK**.
3. Open a command prompt and change to the InstallationManager_root/eclipse/tools directory.

4. Run the command to start the IBM Installation Manager in console mode: `imcl -c`
5. Complete the following steps to add the repositories:
   a. Enter `P` to go to the **Preferences** menu.
   b. Enter `1` to go to the **Repositories** menu.
   c. Enter `D` to add repositories.
   d. Type the path for your WebSphere Portal Express repository file.
   e. Enter `A` to apply your repositories and return to the **Preferences** menu.
   f. Enter `R` to return to the **Main** menu.
6. Enter `1` to install the software packages.
7. Select the software packages that you want to install.
   - If you are installing Portal to an existing copy of WebSphere Application Server, then select only **IBM WebSphere Portal Server.** To complete this installation option, your existing copy of WebSphere Application Server must meet the following requirements:
     – WebSphere Application Server Version 8.5.5.2 or later
     – Java Version 7
     – No existing Portal profile
   - If you are not installing Portal to an existing copy of WebSphere Application Server, then select the following packages:
     – **IBM WebSphere Application Server Network Deployment**
     – **IBM WebSphere Portal Server**
     – **IBM WebSphere SDK Java Technology Edition**

     Note: The **IBM WebSphere SDK Java Technology Edition** option is required for a WebSphere Portal Express installation even though it might be marked as "Optional."

   Tip: If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.
8. Choose one of the following options:
   - Enter `1` to choose version 8.5.0.0 for installation.
   - Enter `2` to show all available versions of the package.
9. Enter `N`.
10. Enter `A` to accept the license agreement.
11. Enter `N`.
12. Choose one of the following options for translation packages:
    - Enter `N` to select the default English package only.
    - Enter the number for the translation package you want to install.
13. On the **Incompatible package group** menu, choose one of the following options:
    - Enter `M` to change the installation directory. Then, enter the new installation directory.
    - Enter `N` to keep the existing directory.
14. Enter the number for the WebSphere Application Server root directory to use as the existing WebSphere Application Server.

15. On the **IBM Installation Manager** > **Install** > **Licenses** > **Location** > **Features** menu, enter `1` to select the **Portal Server Profile** feature. Then, enter `N` to continue.

    Note: Ensure that **Portal Server Profile** is selected to create a profile that contains the Portal application server and the product binary files. Clear this option if you need a binary only installation for migration.
16. Enter the configuration wizard administrator user ID and password.
17. If you selected the **Portal Server Profile** feature, enter the information for the following prompts:
    - **Enter the host name**
    - **Enter the node name**
    - **Enter the cell name**
    - **Enter an administrator user ID for the portal server**
    - **Enter an administrator user password for the portal server**
    - **Confirm administrator user password for the portal server**
18. Enter `N`.
19. Review the summary information.
20. Choose one of the following options:
    - Enter `G` to generate a response file.
    - Enter `I` to install WebSphere Portal Express.
21. When the installation is complete, enter `F` to return to the main installation menu.
22. Access the Configuration Wizard. Go to `http://`*`your_server`*`:`*`10200`*`/ibm/wizard`.
23. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.

    Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For details on the supported languages for all of the WebSphere Portal Express user interfaces, see "Supported languages" on page 3622.

Windows: Creating a response file:

After IBM Installation Manager is installed, you can use it to record a response file that is based on your environment. Record a response file on the same operating system you plan for the installation. If you have multiple operating systems, you must record a response file for each operating system. Use a response file to automate your installation on multiple servers.

About this task

You can also use the console mode to generate a response file. After you review the summary information, enter `G` to generate a response file instead of `I` to install.

Procedure

1. Start all servers and applications that require a port number to avoid port conflicts when you install WebSphere Portal Express. If you are installing multiple copies of IBM WebSphere Portal Express on your server, start the existing Configuration Wizard servers.
2. Go to the `InstallationManager_root/eclipse` directory.

3. Run the following task to start the recording: `IBMIM.exe -record` *`pathtoresponsexmlfile`* `-skipInstall` *`tempinstalldirectory`*

   `-record`
   This parameter indicates recording the actions and parameters into the response file. The *pathtoresponsexmlfile* text is the name of the response file, for example `Wp8SampleResp.xml`. The *tempinstalldirectory* text is the directory where the response file is recorded.

   `-skipInstall`
   This parameter indicates that no actual installation is completed even though it leads to the final pane.

   tempinstalldirectory
   This value is a directory where the installation saves the history and data when you record the response files.

4. Complete the following steps to add the repositories where the installation media exists:
   a. Open the IBM Installation Manager and go to **File** > **Preferences** > **Repositories**.
   b. Select **Add Repositories**.
   c. Select **Browse** and go to the *`Portal-install-eimage`*`/Setup/repository.config` file and then click **OK**.
   d. Ensure that all required repositories are checked. Then, click **Test Connections** to ensure that the IBM Installation Manager can successfully access the directory where the service repositories are stored.
   e. Select **Apply**.
   f. Select **OK**.
5. On the main IBM Installation Manager panel, select **Install**.
6. Optional: If you are installing Portal to an existing copy of WebSphere Application Server, then select only **IBM WebSphere Portal Server** on the Install Packages screen. To complete this installation option, your existing copy of WebSphere Application Server must meet the following requirements:
   - WebSphere Application Server Version 8.5.5.2 or later
   - Java Version 7
   - No existing Portal profile

   Skip the following step, if you choose to install to an existing copy of WebSphere Application Server.
7. On Install Packages: Select packages to install, select the following packages, and then click **Next**:
   - **IBM WebSphere Application Server Network Deployment**
   - **IBM WebSphere Portal Server**
   - **IBM WebSphere SDK Java Technology Edition**

     Note: The **IBM WebSphere SDK Java Technology Edition** option is required for a WebSphere Portal Express installation even though it might be marked as "Optional" on the Select packages to install screen.

   Tip: If you have a WebSphere Portal Express Enable license, you must select both the **IBM WebSphere Portal Express** and **IBM WebSphere Portal Enable** packages.
8. On Install Packages: Select the fixes to install screen, select any required fixes. Then, click **Next**.

9. Accept the license agreement and then click **Next**.
10. Enter the directory where you want to store shared resources and then click **Next**.
11. Complete the following steps on the Install Packages: Installation Directory panel:

    Remember: The installation directory that you specify must NOT contain any files or the following characters: `~ ! @ # $ % ^ & * ( ) + { } | < > ? ` = [ ] ; ' , . "` and spaces.

    a. Select the WebSphere Application Server Package Group Name and then enter the installation directory path.
    b. Select the WebSphere Portal Express Package Group Name and then enter the installation directory path.
    c. Click **Next**.
12. Select the translations to install and then click **Next**.
13. Optional: If you chose to install Portal to an existing copy of WebSphere Application Server, select the available copy of WebSphere Application Server, and click **Next**.

    Note: Skip this step, if you are not installing Portal to an existing copy of WebSphere Application Server.
14. On Install Packages: Select the features to install, expand the WebSphere Application Server and WebSphere Portal Express packages to modify the features you want to install and then click **Next**.

    Note: Ensure that **Portal Server Profile** is selected to create a profile that contains the Portal application server and the product binary files. Clear this option if you need a binary only installation for migration.

    Note: As you select the items, read the **Details** section for information.
15. On Profile configuration details, enter the user ID and password for the configuration wizard administrator. Then, click **Next**.
16. If you selected the **Portal Server Profile** package, click **Enter the Administrator user ID and password for the Portal Server**.
17. Confirm the Summary information and then click **Install**.
18. After the Installation Manager finishes creating the response file, click **Finish** and then close the Installation Manager to complete the response file recording.
19. If you plan to install on a different computer, copy the response file to the response file directory on that computer.

Windows: Installing with the response file:

Use either a sample response file or a response file that you created to install WebSphere Application Server and WebSphere Portal Express. You can create a response file with the graphical or console mode interface.

About this task

Locate the sample response file in the *setup_root*`/responsefiles` directory. Modify the file with your environment values.

The installation program verifies the operating system and its prerequisites, available disk space, and any required software prerequisites before installation. You cannot install two instances of the server at the same time, even if you are installing to different directories. You must install each server completely before you install the next one.

Procedure

1. If the repository URL requires authentication, use the IBM Installation Manager command-line tool to create a secure **Storage File**.

   The secure **Storage File** stores the credentials that are required for the repositories. The IBM Installation Manager command-line tool **imutilsc** is available from the installation tools directory. The following information is an example of the **imutilsc** key ring file command:

   ```
   imutilsc saveCredential -url repository_URL -userName credential_userName
    -userPassword password -secureStorageFile storage_file
   [ -masterPasswordFile master_password_file ]
   [ -preferences com.ibm.cic.common.core.preferences.ssl.nonsecureMode=true|false ]
    [ -proxyHost proxy_host -proxyPort proxy_port
     [ -proxyUsername proxy_username -proxyUserPassword proxyuser_password ]
     [ -useSocks ] ]
    [ -verbose ]
   ```

   Tip: If you install on a different computer, copy the secure **Storage File** to that computer.
2. Go to the `InstallationManager_root/eclipse/tools` directory.
3. Run the following task to install WebSphere Portal Express and IBM WebSphere Application Server:

   Tip: Add the **-secureStorageFile** *pathtosecureStorageFile* **-masterPasswordFile** *pathtomasterPasswordFile* parameters to the **imcl** command if you are using a secure **Storage File** to store credentials.
   `imcl -acceptLicense input` *pathtoresponse.xml* `-log` *dirpath/logfilename*

What to do next

Attention: When you install WebSphere Application Server and WebSphere Portal Express together, you might find the following message in the `SystemErr.log` file:
AppServer_root`/properties/version/installed.xml (No such file or directory)`

This message is part of the installation process and is not repeated after the installation is complete. Therefore, the message can be ignored.

Windows: Converting the evaluation license

If you initially installed IBM WebSphere Portal Express using the evaluation license and then purchased the product, you can convert the installed evaluation license to a production license. You can do this at any time, before or after the evaluation license expires.

Before you begin

Review the evaluation license.

About this task

You do not need to reinstall the program files to convert the evaluation license. However, the license conversion utility must have access to the purchased production software. You cannot use the evaluation software to convert the evaluation license.

Complete the following steps to convert the evaluation license:

Procedure

1. Run the `stopServer.bat` *`WebSphere_Portal`* `-username` *`admin_userid`* `-password` *`admin_password`* task from the *wp_profile_root*`\bin` directory.
2. Run the `ConfigEngine.bat install-license -Dlicense=`*`media_filepath`* task from the *wp_profile_root*`\ConfigEngine` directory.

   Tip: *media_filepath* is the location of the `PortalExpress` subdirectory on either the WebSphere Portal Express CD or the downloaded installation image, for example `d:\PortalExpress` if the CD is in drive D or `c:\wpdownload\PortalExpress` for the installation image.

   When the task completes, a message confirms that the product is now licensed for use.
3. Run the `startServer.bat` *`WebSphere_Portal`* task.

Related tasks:

"Windows: Preparing your operating system" on page 197
Prepare the operating system to ensure a successful installation.

"Windows: Preparing the Installation Manager" on page 197
The IBM Installation Manager is used to install installation packages such as IBM WebSphere Portal Express and IBM WebSphere Application Server.

Windows: Next steps

The configuration process has changed. Use the Configuration Wizard to set up your integration with prerequisites, clusters, and more.

Verify that the installation was successful

Unless you selected to install only the binary files, you can log in to the portal and verify that your installation was successful. Access WebSphere Portal Express with the `http://`*`yourserver`*`:`*`yourport`*`/wps/portal` format.

If you are not sure what your port number is, use the **`list-server-ports`** command to determine the port number. Change to the *wp_profile_root*`\ConfigEngine\log\`. Run the **`list-server-ports`** task to generate the `WebSphere_Portal_PortMatrix.txt` file. For example: `ConfigEngine.bat list-server-ports -DWasPassword=`*`password`*.

Change to the `C:\IBM\WebSphere\AppServer\profiles\cw_profile\ConfigEngine`. Run the **`list-server-ports`** task to generate the `server1_PortMatrix.txt` file. For example: `ConfigEngine.bat list-server-ports -DWasPassword=`*`password`*.

Modify the `uri.home.substitution` custom property in the Resource Environment Provider

In the **WP ConfigService**, set the **`uri.home.substitution`** custom property to `true` to avoid functional errors that might occur in certain unusual use cases. For more

information on **uri.home.substitution**, see *Configuration Service* in the related links.

Select a roadmap

If you have not already selected a roadmap to guide you through the installation and deployment process, look at the available roadmaps. The roadmaps are based on typical environments, such as development environment, test environment, and more. They provide a high-level overview of the installation and deployment process. Each roadmap includes a topology diagram, usage recommendations, and instructions. Roadmaps are available for both new deployments and migrations scenarios.

"Roadmaps for installation and deployment" on page 69

"Roadmaps for migration" on page 92

Run the Configuration Wizard to finish the deployment

Then, start the Configuration Wizard and select the option that is defined in your selected roadmap. Use the wizard to run the configuration steps in real time or to generate scripts. The wizard generates instructions and scripts specific to your environment and the data that you entered. You can save the selection and data that you entered as an XML file. Then, you can load the XML file during a subsequent wizard session to set up a similar configuration on a different server.

If you select to run the configuration in real time, you still have the opportunity to download scripts for selected steps. For example, if only the database administrator can databases, then you can download the database creation script and give it to your database administrator to run.

Default URLs

During the configuration process, you might need to following URLs to access different administration user interfaces.

Use the following default URLs to access IBM WebSphere Portal Express, the WebSphere Integrated Solutions Console, and the Configuration Wizard:

IBM WebSphere Portal Express

```
http://localhost:10039/wps/portal
```

```
https://localhost:10042/wps/portal
```

WebSphere Integrated Solutions Console

```
http://localhost:10038/ibm/console
```

```
https://localhost:10041/ibm/console
```

Configuration Wizard

```
http://localhost:10200/ibm/wizard
```

```
https://localhost:10202/ibm/wizard
```

If you had any processes from other software in the default port range when the installation started, you might have different port numbers than the defaults.

Windows: Upgrading the SDK

Starting with IBM WebSphere Portal Express Combined Cumulative Fix 05, you can change your SDK Java Technology Edition from version 7.0 to version 7.1.

Before you begin

Ensure that IBM WebSphere Application Server and WebSphere Portal Express are installed with SDK version 7.0.

Procedure

1. Start the IBM Installation Manager.
2. Install IBM WebSphere SDK Java Technology Edition version 7.1.
3. Read the following information before you run the **managesdk** task:
   - For stand-alone environments: Stop the profile server (node) before you run the **managesdk** command.
   - For clustered environments:
     - If the profile is a federated node of a deployment manager, ensure that the deployment manager is running before you run the **managesdk** command to update the profile.
     - Stop all the nodes.
     - Ensure that the node agent for each node is started.
     - When you enable the SDK for a node, run the **managesdk** command from the `/bin` directory to which the node belongs. You can also run the command from the `/bin` directory of the profile that contains the node that you want to update.
     - A connection to the deployment manager must exist with a supported connector protocol in the following order of preference:
       - SOAP

- Inter-Process Communications (IPC)
- Remote Method Invocation (RMI)

If the SOAP protocol is enabled, the **managesdk** command uses the SOAP protocol. If the SOAP protocol is not enabled but the IPC protocol is enabled, the command uses the IPC protocol. If the SOAP and IPC protocol are not enabled, then the command uses the RMI protocol.

– You must provide the administrative user name and password with the **managesdk** command for each profile that contains a federated node or deployment manager node in a cell with security enabled. If you do not specify the **-user** and **-password** parameters, the **managesdk** command might fail or stop processing.
– When you enable the SDK for a deployment manager, only the deployment manager server is enabled. None of the managed nodes of the deployment manager are enabled to use the specific SDK.

4. Open a command prompt and change to the *AppServer_root*/bin directory.
5. Run the following command to enable all existing profiles to use the new SDK version:

   Go to managesdk command for information about the **managesdk** commands.

   • Windows: `managesdk.bat -enableProfileAll -sdkname 1.7.1_64 -enableServers`
6. Run the following commands to make the new SDK version the new default:

   • Windows: `managesdk.bat -setCommandDefault -sdkname 1.7.1_64`

   `managesdk.bat -setNewProfileDefault -sdkname 1.7.1_64`
7. Repeat these steps on each node in your environment.

Installing add-ons

You can use the Solution Installer through the Configuration Wizard to install and uninstall add-ons to an IBM WebSphere Portal Express server instance. The Solution Installer uses the Portal Application Archive (PAA) format as the standard format for application distribution. Portal Application Archive (PAA) updates are not supported in the configuration wizard currently. For more information about updating add-ons using a command prompt, see the Managing your existing PAA file section.

About this task

Portal Administrators can use the Solution Installer through the Configuration Wizard to install existing PAA-formatted applications to the WebSphere Portal Express server instance. Portal Solution Developers can use the Solution Installer through the Configuration Wizard to install PAA-formatted applications that they develop for their company.

Complete the following tasks to install, uninstall, and update add-ons.

"Install and uninstall add-ons using the Configuration Wizard" on page 212
You can install add-on functionality to your WebSphere Portal Express with the solution installer through the Configuration Wizard. The add-ons that are accepted by the configuration options are `.paa` files. For more information, see the solution installer documentation.

"Migrating PAA content" on page 213
If you installed a Portal Application Archive (PAA) file on a previous version of IBM WebSphere Portal Express, you can migrate the content to the current version of WebSphere Portal Express.

"Managing your existing Portal Application Archive (PAA) file" on page 214
When you update an existing Portal Application Archive (PAA) file, it is not as simple as overwriting the file with the new content. There might be large differences between the content in both files. Therefore, to manage your PAA file, you can upgrade to the latest version and rollback to the previous version.

"Solution Installer run time configuration" on page 217
The Solution Installer run time configuration properties allows you to control how the Solution Installer installs a Portal Application Archive (PAA) formatting application to IBM WebSphere Portal Express.

Related tasks:

"Planning to install WebSphere Portal Express" on page 101
Before you install IBM WebSphere Portal Express in a production environment, you need to assess your hardware and software needs, possible database configurations, security options, and LDAP server options. Skipping this important step can lead to unexpected results and costly delays.

"Installing and preparing the prerequisite software" on page 148
Before you install the digital experience software, make sure that the prerequisite software is installed and configured. Depending on your environment, you might already have the prerequisites, such as a database server and user registry. Verify that the prerequisite software is the correct version, has the required fix packs applied, and is configured to work with the digital experience software.

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Related reference:

"Getting the software" on page 135
There are different ways for you to get WebSphere Portal Express and Web Content Manager Version 8.5 software.

Install and uninstall add-ons using the Configuration Wizard

You can install add-on functionality to your WebSphere Portal Express with the solution installer through the Configuration Wizard. The add-ons that are accepted by the configuration options are `.paa` files. For more information, see the solution installer documentation.

Complete the following steps to use the Configuration Wizard to install or uninstall the add-ons:

1. Access the Configuration Wizard. Go to `http://your_server:10200/ibm/wizard`.
2. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.
3. Click **Add On New Capability**
4. To interact with the solution installer through the configuration wizard, select **Install Add-ons** or **Uninstall Add-ons**.
5. Provide information about your environment.
6. Save your wizard selections to use the same values that you entered later.
7. Choose one of the following options:
   - Click **Download Files** to run the steps remotely.
   - Click **Run All Steps** to run the steps locally.

Typical versus advanced installation scenarios

Two different installation scenarios are supported through the **Add On New Capability** options in the Configuration Wizard. These scenarios are the typical and advanced installation scenarios.

Typical

The typical scenario is for simple `paa` files that often contain only one component, but is not limited to it, and can be installed directly without any additional configuration. The typical scenario installs/registers the `paa` file with the configEngine and then automatically deploys the content to WebSphere Portal Express.

Advanced

The advanced scenario provides you with much greater flexibility in how to install the `paa` file. If you select **Advanced Install** on the Install type screen, when the workflow completes, the `paa` file is installed to the ConfigEngine, but it is not deployed to portal. Instead, a new configuration option specific to that `paa` file is generated. Use the generated instructions to configure the deployment settings. Finally, a **Launch configuration** button displays so that you can continue with the deployment. After you click **Launch configuration**, follow the steps to ensure that the `paa` file is deployed.

You can select the components that you want to install, if there is more than one component from the information that is presented in this additional configuration option. This step is useful where demonstration content is included in the `paa` file. Or, if one of the components is designated as virtual portal content only.

In addition, if there are IBM Web Content Manager libraries that are found in the `paa` file that exist on the server, you can select to replace them from the libraries in the `paa` file. A list of virtual portals that are available at the time of the creation of the configuration option are also presented so that you can choose where the selected content is deployed.

In the advanced scenario, the additional configuration that is called **Deploy-Remove-PAA-*assemblyName*** is also the mechanism in which content is removed from the portal. Depending on what is required, you can select the type of function from the configuration option.

The **Deploy-Remove_PAA-*.*** option is added to the **Add-on new capability** section of the configuration wizard. After the configuration option is added to the configuration wizard, you can add modifications to thepaa file. When you uninstall by using the **Uninstall Add-ons** with the **Advanced** setting the **Deploy-Remove-PAA-*.*** option is removed from the configuration wizard repository. However, the option still displays in the list of active configuration options under the **Add On New Capability section** of the wizard. To remove these items, you need to restart server1 in the `cw_profile`. Restarting refreshes the repository and ensures that the items no longer show up.

Note: If you install and deploy a `paa` file by using the advanced scenario, you must also remove the content that uses the `paa`-specific option before you uninstall. You can remove this content by using the advanced selection during the **Uninstall add-ons** option.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Migrating PAA content

If you installed a Portal Application Archive (PAA) file on a previous version of IBM WebSphere Portal Express, you can migrate the content to the current version of WebSphere Portal Express.

About this task

Migration is supported from WebSphere Portal Express Version 7.0 to 8.5 and from Version 8.0 to 8.5.

Procedure

1. If you are migrating from Version 7.0 to Version 8.5, copy the PAA content from the directory of the previous release to the directory in the current release.

   Note: If you are migrating from Version 8.0.0.1 to Version 8.5, you can skip this step.

   Tip: Starting with version 8.0, the PAA directory is in the *wp_profile_root*`/paa` directory.

   Remember: Select only the expanded PAA file directories that you want to migrate to the new release.
2. Open a command prompt and change to the following directory:
   - IBM i: *wp_profile_root*`/ConfigEngine`
   - Windows: *wp_profile_root*`\ConfigEngine`
3. Run the following task to migrate the PAA content:

This task deletes the auto-generated code and then re-creates it in the `config/includes` directory for each component. The task then registers the assembly and components with the current version ConfigEngine.

- IBM i: `ConfigEngine.sh migrate-paa -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
- Windows: `ConfigEngine.bat migrate-paa -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*

Managing your existing Portal Application Archive (PAA) file

When you update an existing Portal Application Archive (PAA) file, it is not as simple as overwriting the file with the new content. There might be large differences between the content in both files. Therefore, to manage your PAA file, you can upgrade to the latest version and rollback to the previous version.

About this task

The Solution Installer provides the following tasks to manage your existing PAA files:

- **`install-paa-update`**
- **`remove-paa-update`**

"Updating an existing Portal Application Archive (PAA) file"
You can update an existing Portal Application Archive (PAA) file when a new version is available. The process is not as simple as overwriting the file with the new content. There might be large differences between the content in both versions of the file.

"Uninstalling a Portal Application Archive (PAA) file update" on page 216
If there are issues with the Portal Application Archive (PAA) file update, you can uninstall the update and return to the previous version of the file.

Updating an existing Portal Application Archive (PAA) file

You can update an existing Portal Application Archive (PAA) file when a new version is available. The process is not as simple as overwriting the file with the new content. There might be large differences between the content in both versions of the file.

About this task

The **`install-paa-update`** command creates a backup of your current PAA file. It is stored in the *wp_profile_root*`/paa/backup` directory. The command then completes the following actions:

- Uninstalls the PAA file from IBM WebSphere Portal Express
- Deletes the content from the expanded PAA file
- Installs the new version of the PAA file

After you run the **`install-paa-update`** command, you must deploy the changes to your system.

PAA file developer note: Make all updates in the custom code. No code generation is available for an upgrade through the regular **`install-paa`** process. Read the guide about creating updated PAA files for information.

Cluster note: Complete these steps on the primary node and then on all additional nodes.

Procedure

1. Open a command line.
2. Change to the *wp_profile_root*/ConfigEngine directory.
3. Run the following task to update the PAA file:
   - Linux : `./ConfigEngine.sh install-paa-update -DPAALocation=paaLocation/yourPaa.paa -DappName=assemblyName -DWasPassword=password -DPortalAdminPwd=password`
   - IBM i: `ConfigEngine.sh install-paa-update -DPAALocation=paaLocation/yourPaa.paa -DappName=assemblyName -DWasPassword=password -DPortalAdminPwd=password`
   - Windows: `ConfigEngine.bat install-paa-update -DPAALocation=paaLocation/yourPaa.paa -DappName=assemblyName -DWasPassword=password -DPortalAdminPwd=password`

   Optional parameter: You can add the following parameter to your **install-paa-update** command: **-Dwcmdetect=true**. This parameter controls the behavior of the installed IBM Web Content Manager libraries. If you include this parameter, a properties file is created in the paa/*ComponentName* directory. The name of the properties file matches the PAA file name.
4. After the task successfully completes, verify that the following subdirectory exists:
   - IBM i: *wp_profile_root*/paa/*paa_filename*
   - Windows: *wp_profile_root*\paa*paa_filename*
5. From the PAA file subdirectory, open the components.properties file. Complete the following steps to check for and resolve conflicts with previously installed components:
   a. Search for the component parameters. Parameters that are set to true are not already installed. Parameters that are set to false are already installed.
   b. To update existing components, change their value in the components.properties file to true.
   c. Save your changes to the components.properties file.
6. Optional: Complete the following steps if you included the **-Dwcmdetect=true** parameter:
   a. Open the properties file in the paa/*ComponentName* directory.
   b. Set the value of all the Web Content Manager libraries that you want to update to true.
   c. Set the value of all the Web Content Manager libraries that you want to keep the old version to false.
   d. Save your changes.
7. Optional: Run the following task if you changed values in the components.properties file:

   This task updates the registration of the existing components with the new assembly.
   - IBM i: `ConfigEngine.sh update-paa-components -DappName=assemblyName -DWasPassword=password -DPortalAdminPwd=password`
   - Windows: `ConfigEngine.bat update-paa-components -DappName=assemblyName -DWasPassword=password -DPortalAdminPwd=password`

8. Optional: If you use the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) for single sign-on, complete the following steps to disable SPNEGO:
   a. Log on to WebSphere Integrated Solutions Console.
   b. Go to **Security** > **Global security** > **Web and SIP security** > **SPNEGO Web authentication**.
   c. Clear the **Enable SPNEGO** check box.
   d. Save your changes.
9. Run the following task to deploy the updated PAA content to WebSphere Portal Express:
   - IBM i: `ConfigEngine.sh deploy-paa -DappName=`*`assemblyName`* `-DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
   - Windows: `ConfigEngine.bat deploy-paa -DappName=`*`assemblyName`* `-DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*

   Clustered environment parameters: If you are deploying to a clustered environment and your PAA file contains XMLAccess script files, add the following two parameters to the **deploy-paa** task:
   - **-DmaxTimeToWait**
   - **-DmaxAppTimeToWait**

   These values define the time that the **wplc-wait-for-sync-to-complete** task waits to synchronize your nodes. The default values are `-DmaxTimeToWait=30` and `-DmaxAppTimeToWait=5`. The values are in minutes. Add these parameters to your **deploy-paa** task with values that meet your requirements.

   Virtual portal parameters: If you are deploying to a virtual portal, you must include the context root and host name parameters for the virtual portal. Add the **-DVirtualPortalHostName** and **-DVirtualPortalContext** parameters to the **deploy-paa** task. Read "Virtual portals" on page 1361 for information.

   Note: By default, only components that are set to `true` in the `components.properties` file are deployed. To deploy all components, add the **-DforceDeploy=true** parameter to the **deploy-paa** task.
10. Optional: Complete the following steps to enable SPNEGO:
    a. Log on to WebSphere Integrated Solutions Console.
    b. Go to **Security** > **Global security** > **Web and SIP security** > **SPNEGO Web authentication**.
    c. Check the **Enable SPNEGO** check box.
    d. Save your changes.

Uninstalling a Portal Application Archive (PAA) file update

If there are issues with the Portal Application Archive (PAA) file update, you can uninstall the update and return to the previous version of the file.

About this task

The **remove-paa-update** command uninstalls the updates to your IBM WebSphere Portal Express server. It then installs and deploys the original PAA file in the *wp_profile_root*`/paa/backup` directory.

PAA file developer note: Custom code is used to remove updates and restore the previous version of the PAA file. The Solution Installer does not generate code for

this task. However, the previously generated code is called from the custom tasks. Previously generated tasks are not run automatically.

Cluster note: Complete these steps on the primary node and then on all additional nodes.

Procedure

1. Optional: If you use the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) for single sign-on, complete the following steps to disable SPNEGO:
   a. Log on to WebSphere Integrated Solutions Console.
   b. Go to **Security** > **Global security** > **Web and SIP security** > **SPNEGO Web authentication**.
   c. Clear the **Enable SPNEGO** check box.
   d. Save your changes.
2. Open a command prompt.
3. Change to the *wp_profile_root*/ConfigEngine directory.
4. Run the following task to update the PAA file:
   - Linux : `./ConfigEngine.sh remove-paa-update -DappName=`*`assemblyName`* `-DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
   - IBM i: `ConfigEngine.sh remove-paa-update -DappName=`*`assemblyName`* `-DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
   - Windows: `ConfigEngine.bat remove-paa-update -DappName=`*`assemblyName`* `-DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
5. Optional: Complete the following steps to enable SPNEGO:
   a. Log on to WebSphere Integrated Solutions Console.
   b. Go to **Security** > **Global security** > **Web and SIP security** > **SPNEGO Web authentication**.
   c. Check the **Enable SPNEGO** check box.
   d. Save your changes.

Solution Installer run time configuration

The Solution Installer run time configuration properties allows you to control how the Solution Installer installs a Portal Application Archive (PAA) formatting application to IBM WebSphere Portal Express.

The Solution Installer run time configuration properties are located in the `wkplc_comp.properties` file. This file is located in the *wp_profile_root*`\ConfigEngine\properties` directory. Generally the Solution Installer run time configuration properties require no edits; the following exception applies:

To include custom code extension points with suffixes other than **`-applySIFeaturePack`** and **`-removeSIFeaturePack`**. If you want to include additional extension points to **`-applySIFeaturePack`** and **`-removeSIFeaturePack`**, add them to the existing items using a comma separated list.

The properties for adding different extension suffixes are the **`wp.si.configInstallExtensionList`** and **`wp.si.configRemoveExtensionList`**. For example:

- **`wp.si.configInstallExtensionList=`**`-applySIFeaturePack`
- **`wp.si.configRemoveExtensionList=`**`-removeSIFeaturePack`

"Running the Solution Installer without an internet connection"
You can run the Solution Installer from a server that does not have an internet connection.

Running the Solution Installer without an internet connection

You can run the Solution Installer from a server that does not have an internet connection.

Procedure

1. Open the `wkplc_comp.properties` file, which is in the *wp_profile_root*\`ConfigEngine\properties` directory.
2. Locate the **`wp.si.offlineMode`** parameter.
3. Change the value of the **`wp.si.offlineMode`** parameter to `true`.

   Setting this value to `true` means that no attempts are made to retrieve external DTD by the XML parser when reading XML content.
4. Save your changes.

Uninstalling the digital experience software

Uninstalling the digital experience software is a multiple step process. Manual uninstallation instructions are provided for a single-server configuration in case of an error situation.

1. "IBM i: Uninstalling WebSphere Portal Express"
   Use the IBM Installation Manager to uninstall IBM WebSphere Portal Express binary files.
2. "Linux: Uninstalling WebSphere Portal Express" on page 222
   Use the IBM Installation Manager to uninstall IBM WebSphere Portal Express binary files.
3. "Windows: Uninstalling WebSphere Portal Express" on page 226
   Use the IBM Installation Manager to uninstall IBM WebSphere Portal Express binary files.

Related tasks:

"Planning to install WebSphere Portal Express" on page 101
Before you install IBM WebSphere Portal Express in a production environment, you need to assess your hardware and software needs, possible database configurations, security options, and LDAP server options. Skipping this important step can lead to unexpected results and costly delays.

"Installing and preparing the prerequisite software" on page 148
Before you install the digital experience software, make sure that the prerequisite software is installed and configured. Depending on your environment, you might already have the prerequisites, such as a database server and user registry. Verify that the prerequisite software is the correct version, has the required fix packs applied, and is configured to work with the digital experience software.

There are different ways for you to get WebSphere Portal Express and Web Content Manager Version 8.5 software.

IBM i: Uninstalling WebSphere Portal Express

Use the IBM Installation Manager to uninstall IBM WebSphere Portal Express binary files.

"IBM i: Restrictions on moving a node to a stand-alone configuration"
In a working cluster, all nodes share a common database. If you want to remove a node from a cell to use the node in a stand-alone configuration, some restrictions apply.

"IBM i: Preparing to uninstall"
You must prepare your system before you uninstall your IBM WebSphere Portal Express environment. For example, add passwords to the properties files. You must also decide to keep or discard the database information.

"IBM i: Uninstalling WebSphere Portal Express" on page 221
If you have a complete and functional uninstallation program, you can uninstall IBM WebSphere Portal Express only or both WebSphere Portal Express and IBM WebSphere Application Server.

IBM i: Restrictions on moving a node to a stand-alone configuration

In a working cluster, all nodes share a common database. If you want to remove a node from a cell to use the node in a stand-alone configuration, some restrictions apply.

The configuration of all portlets deployed in a cell are stored in a common database. When you remove a node from a cell to use the node in a stand-alone configuration, the portlets that had been available to the node in the cell are no longer available to it as a stand-alone server. Other changes in configuration that were made after the node was federated to the cell, such as enabling LDAP security or applying fix pack maintenance, can prevent the node from operating normally after it is removed from the cell. Starting or modifying the configuration of the stand-alone node before taking steps to back up the database can introduce conflicts between the node and the remaining nodes in the cell.

Before you start or modify the configuration of the stand-alone node, restore the WebSphere Application Server file system and the WebSphere Portal Express databases using backups taken prior to federation. Reconnect to a database that represents the portlet and page configuration of the node before it was added to the cell. Do not reconnect to the default database.

IBM i: Preparing to uninstall

You must prepare your system before you uninstall your IBM WebSphere Portal Express environment. For example, add passwords to the properties files. You must also decide to keep or discard the database information.

About this task

Important cluster note: You must issue the **removeNode** command to unfederate a node before uninstalling because WebSphere Portal Express cannot uninstall a federated node.

Procedure

1. Optional: Make a backup of the WebSphere Portal Express configuration. Use the XML Configuration Interface.

   Important: If you delete the database, the following information is not backed up and is deleted:
   - User attributes that are stored in the database and not in the user registry
   - Credential data that is stored in the default vault implementation

2. Complete the following steps to remove a node from the cell in a clustered environment:

   Note: Removing a WebSphere Portal Express node from the cell does not affect the cluster definition that you originally created for your cluster. The cluster definition remains intact even after you remove all WebSphere Portal Express nodes from the cell. In addition, removing a WebSphere Portal Express node from the cell does not remove the product's enterprise applications from the deployment manager. The enterprise applications remain and continue to be associated with the cluster definition.

   a. Log on to the Deployment Manager WebSphere Integrated Solutions Console.
   b. Go to **Servers** > **WebSphere application server clusters** > ***cluster_name*** > **Cluster members**, where *cluster_name* is the name of your cluster, click the server that you want to stop, and then click **Stop**.
   c. Go to **System Administration** > **Nodes**. Select the node that contains the server that you want to remove from the cell, and then click **Remove Node** to remove the node from the cell.

      Important: Make sure that you choose the **Remove Node** option to remove the node from cell and not the **Delete** option on the **Cluster members** view. The **Delete** option completely deletes the node, which removes the existence of the server from the deployment manager. It does not leave a means for restoring the WebSphere Portal Express node to a stand-alone system. Using the **Delete** option can prevent the WebSphere Portal Express server from working after it is deleted from the cluster. If **Remove Node** does not successfully remove the node, click **Force Delete** to remove the node.
   d. Click **Save** to save the changes to the cell's configuration.
   e. Repeat the previous steps for each node in the cluster and cell that you want to uninstall.
   f. Optional: Complete the following steps if you plan to convert the stand-alone server to a working portal:
      1) Use a text editor to open the `wkplc.properties` file.
      2) Change the value of the **`CellName`** property so that it matches the cell name of the node itself.
         - The cell name for the node reverts to the cell name that was used before you federated the node.
         - The cell name can be identified by the *wp_profile_root*`/config/cells/`*`cell_name`* directory on the node, where *cell_name* indicates the cell to which the node belongs.
      3) Change the value of the **`ServerName`** property to the original WebSphere Portal Express server name.
      4) Ensure that the value of the **`PrimaryNode`** property is set to `true`.
      5) Save your changes.
3. Add passwords to the `wkplc.properties`, `wkplc_dbdomain.properties`, and `wkplc_dbtype.properties` files in the *wp_profile_root*`/ConfigEngine/properties` directory. You can also specify passwords on the command line.
4. Decide whether to keep your database to preserve WebSphere Portal Express information.
   - If you keep the database, no further steps are required.

Note: If you choose to keep the database information, you cannot use it with subsequent installations although you can still access the information through your database software. Also, if you keep the information, you can always delete the WebSphere Portal Express databases and database tables later with the database software.

- Complete the following steps to remove the information from the database:
  a. Stop all the servers. For specific instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
  b. Open a command prompt and change to the *wp_profile_root*`/ConfigEngine` directory.
  c. Run the `ConfigEngine.sh remove-schema -DWasPassword=`*`password`* `-Drelease.DbPassword=`*`password`* `-Dcustomization.DbPassword=`*`password`* `-Dcommunity.DbPassword=`*`password`* `-Djcr.DbPassword=`*`password`* `-Dfeedback.DbPassword=`*`password`* `-Dlikeminds.DbPassword=`*`password`* task.

  Note: Some tables remain in the IBM Java Content Repository database. Removing the database removes these tables.

IBM i: Uninstalling WebSphere Portal Express

If you have a complete and functional uninstallation program, you can uninstall IBM WebSphere Portal Express only or both WebSphere Portal Express and IBM WebSphere Application Server.

Procedure

1. Stop all the servers. For specific instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
2. Verify that you are not running any other installation or uninstallation programs.
3. Choose one of the following uninstallation commands to uninstall WebSphere Portal Express and WebSphere Application Server:
   - Graphical user interface: Start the Installation Manager and then select **Uninstall**.
   - Response file: From your installation source directory, run the `imcl input` *`pathtoresponse.xml`* `-log` *`pathtologfiles`* task.

     Important: Do not place the response file in a path that contains a space and do not put a space in the file name.
   - Console mode: Run the `imcl -c` task from the `install_root/Installation Manager/eclipse/tools` directory. Then, type `5`.

     Restriction: You can select only one package group to uninstall at a time. First, uninstall the WebSphere Portal Express package. Then, uninstall the WebSphere Application Server package.

   During the uninstallation, remove all profiles that you do not want to keep for future installations.
4. Remove any remaining WebSphere Portal Express directories from your directory structure.
5. If you uninstall WebSphere Portal Express only, go to the *AppServer_root* directory and remove the following files:
   - `lib/ext/commons-codec-1.3.jar`
   - `lib/ext/commons-httpclient-3.0.1.jar`
   - `lib/ext/openid4java-full-0.9.5.jar`

- lib/ext/wp.auth.base.sua_RedirectServletFilter.jar
- lib/ext/wp.auth.base.sua_loginmodule.jar
- lib/ext/wp.auth.tai.jar
- lib/wp.user.connections.jar
- lib/wp.wire.jar
- plugins/com.ibm.patch.was.plugin.jar
- plugins/com.ibm.wp.was.plugin.jar
- plugins/wp.ext.jar
- properties/jndi.properties

6. Examine all running processes and stop ones that contain the PortalServer_root directory. Restart the server, especially if you intend to reinstall WebSphere Portal Express on the same server.
7. Go to Deleting specific cluster members for information about how to delete a cluster member from the deployment manager.
8. Complete the following steps to delete the WebSphere Portal Express server from the deployment manager:
   a. Log on to the WebSphere Integrated Solutions Console.
   b. Click **Servers** > **Application Servers**.
   c. Select the check box for the WebSphere Portal Express server you want to delete.
   d. Click **Delete**.
9. After uninstalling WebSphere Portal Express and WebSphere Application Server, you can also delete the Installation Manager. Run the ./uninstallc command from the qibm/userdata/InstallationManager/uninstall directory.

Linux: Uninstalling WebSphere Portal Express

Use the IBM Installation Manager to uninstall IBM WebSphere Portal Express binary files.

   a. Log on to the Deployment Manager WebSphere Integrated Solutions Console.
   b. Go to **Servers** > **WebSphere application server clusters** > ***cluster_name*** > **Cluster members**, where *cluster_name* is the name of your cluster, click the server that you want to stop, and then click **Stop**.
   c. Go to **System Administration** > **Nodes**. Select the node that contains the server that you want to remove from the cell, and then click **Remove Node** to remove the node from the cell.

      Important: Make sure that you choose the **Remove Node** option to remove the node from cell and not the **Delete** option on the **Cluster members** view. The **Delete** option completely deletes the node, which removes the existence of the server from the deployment manager. It does not leave a means for

restoring the WebSphere Portal Express node to a stand-alone system. Using the **Delete** option can prevent the WebSphere Portal Express server from working after it is deleted from the cluster. If **Remove Node** does not successfully remove the node, click **Force Delete** to remove the node.

d. Click **Save** to save the changes to the cell's configuration.

e. Repeat the previous steps for each node in the cluster and cell that you want to uninstall.

f. Optional: Complete the following steps if you plan to convert the stand-alone server to a working portal:

1) Use a text editor to open the `wkplc.properties` file.

2) Change the value of the **`CellName`** property so that it matches the cell name of the node itself.

- The cell name for the node reverts to the cell name that was used before you federated the node.
- The cell name can be identified by the *wp_profile_root*`/config/cells/`*`cell_name`* directory on the node, where *cell_name* indicates the cell to which the node belongs.

3) Change the value of the **`ServerName`** property to the original WebSphere Portal Express server name.

4) Ensure that the value of the **`PrimaryNode`** property is set to `true`.

5) Save your changes.

3. Add passwords to the `wkplc.properties`, `wkplc_dbdomain.properties`, and `wkplc_dbtype.properties` files in the *wp_profile_root*`/ConfigEngine/properties` directory. You can also specify passwords on the command line.

4. Decide whether to keep your database to preserve WebSphere Portal Express information.

- If you keep the database, no further steps are required.

  Note: If you choose to keep the database information, you cannot use it with subsequent installations although you can still access the information through your database software. Also, if you keep the information, you can always delete the WebSphere Portal Express databases and database tables later with the database software.

- Complete the following steps to remove the information from the database:

  a. Stop all the servers. For specific instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

  b. Open a command prompt and change to the *wp_profile_root*`/ConfigEngine` directory.

  c. Run the `./ConfigEngine.sh remove-schema -DWasPassword=`*`password`* `-Drelease.DbPassword=`*`password`* `-Dcustomization.DbPassword=`*`password`* `-Dcommunity.DbPassword=`*`password`* `-Djcr.DbPassword=`*`password`* `-Dfeedback.DbPassword=`*`password`* `-Dlikeminds.DbPassword=`*`password`* task.

  Note: Some tables remain in the IBM Java Content Repository database. Removing the database removes these tables.

Linux: Uninstalling WebSphere Portal Express

If you have a complete and functional uninstallation program, you can uninstall IBM WebSphere Portal Express only or both WebSphere Portal Express and IBM WebSphere Application Server.

Procedure

1. If you uninstall as a non-root user, verify that all product directories and files have the correct permissions. If not, set their permissions to the non-root user.
2. Stop all the servers. For specific instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
3. Verify that you are not running any other installation or uninstallation programs.
4. Choose one of the following uninstallation commands to uninstall WebSphere Portal Express and WebSphere Application Server:
   - Graphical user interface: Start the Installation Manager and then select **Uninstall**.
   - Response file: From your installation source directory, run the `./imcl input` *`pathtoresponse.xml`* `-log` *`pathtologfiles`* task.

     Important: Do not place the response file in a path that contains a space and do not put a space in the file name.
   - Console mode: Run the `./imcl -c` task from the `install_root/Installation Manager/eclipse/tools` directory. Then, type `5`.

     Restriction: You can select only one package group to uninstall at a time. First, uninstall the WebSphere Portal Express package. Then, uninstall the WebSphere Application Server package.

   During the uninstallation, remove all profiles that you do not want to keep for future installations.
5. Remove any remaining WebSphere Portal Express directories from your directory structure.
6. If you uninstall WebSphere Portal Express only, go to the *AppServer_root* directory and remove the following files:
   - `lib/ext/commons-codec-1.3.jar`
   - `lib/ext/commons-httpclient-3.0.1.jar`
   - `lib/ext/openid4java-full-0.9.5.jar`
   - `lib/ext/wp.auth.base.sua_RedirectServletFilter.jar`
   - `lib/ext/wp.auth.base.sua_loginmodule.jar`
   - `lib/ext/wp.auth.tai.jar`
   - `lib/wp.user.connections.jar`
   - `lib/wp.wire.jar`
   - `plugins/com.ibm.patch.was.plugin.jar`
   - `plugins/com.ibm.wp.was.plugin.jar`
   - `plugins/wp.ext.jar`
   - `properties/jndi.properties`
7. Examine all running processes and stop ones that contain the `PortalServer_root` directory. Restart the server, especially if you intend to reinstall WebSphere Portal Express on the same server.
8. Go to Deleting specific cluster members for information about how to delete a cluster member from the deployment manager.
9. Complete the following steps to delete the WebSphere Portal Express server from the deployment manager:
   a. Log on to the WebSphere Integrated Solutions Console.
   b. Click **Servers** > **Application Servers**.

c. Select the check box for the WebSphere Portal Express server you want to delete.
d. Click **Delete**.

10. After uninstalling WebSphere Portal Express and WebSphere Application Server, you can also delete the Installation Manager. Run the `./uninstall` command from the `ibm/InstallationManager/uninstall` directory.

         - The cell name for the node reverts to the cell name that was used before you federated the node.

- The cell name can be identified by the *wp_profile_root*/config/cells/*cell_name* directory on the node, where *cell_name* indicates the cell to which the node belongs.

3) Change the value of the **ServerName** property to the original WebSphere Portal Express server name.
4) Ensure that the value of the **PrimaryNode** property is set to true.
5) Save your changes.

3. Add passwords to the wkplc.properties, wkplc_dbdomain.properties, and wkplc_dbtype.properties files in the *wp_profile_root*/ConfigEngine/properties directory. You can also specify passwords on the command line.
4. Decide whether to keep your database to preserve WebSphere Portal Express information.
   - If you keep the database, no further steps are required.

     Note: If you choose to keep the database information, you cannot use it with subsequent installations although you can still access the information through your database software. Also, if you keep the information, you can always delete the WebSphere Portal Express databases and database tables later with the database software.
   - Complete the following steps to remove the information from the database:
     a. Stop all the servers. For specific instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
     b. Open a command prompt and change to the *wp_profile_root*/ConfigEngine directory.
     c. Run the ConfigEngine.bat remove-schema -DWasPassword=*password* -Drelease.DbPassword=*password* -Dcustomization.DbPassword=*password* -Dcommunity.DbPassword=*password* -Djcr.DbPassword=*password* -Dfeedback.DbPassword=*password* -Dlikeminds.DbPassword=*password* task.

     Note: Some tables remain in the IBM Java Content Repository database. Removing the database removes these tables.

Windows: Uninstalling WebSphere Portal Express

If you have a complete and functional uninstallation program, you can uninstall IBM WebSphere Portal Express only or both WebSphere Portal Express and IBM WebSphere Application Server.

Procedure

1. Stop all the servers. For specific instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
2. Verify that you are not running any other installation or uninstallation programs.
3. Choose one of the following uninstallation commands to uninstall WebSphere Portal Express and WebSphere Application Server:
   - Graphical user interface: Start the Installation Manager and then select **Uninstall**.
   - Response file: From your installation source directory, run the imcl input *pathtoresponse.xml* -log *pathtologfiles* task.

     Important: Do not place the response file in a path that contains a space and do not put a space in the file name.

- Console mode: Run the `imcl -c` task from the `install_root/Installation Manager/eclipse/tools` directory. Then, type `5`.

  Restriction: You can select only one package group to uninstall at a time. First, uninstall the WebSphere Portal Express package. Then, uninstall the WebSphere Application Server package.

During the uninstallation, remove all profiles that you do not want to keep for future installations.

4. Remove any remaining WebSphere Portal Express directories from your directory structure.
5. If you uninstall WebSphere Portal Express only, go to the *AppServer_root* directory and remove the following files:
   - `lib/ext/commons-codec-1.3.jar`
   - `lib/ext/commons-httpclient-3.0.1.jar`
   - `lib/ext/openid4java-full-0.9.5.jar`
   - `lib/ext/wp.auth.base.sua_RedirectServletFilter.jar`
   - `lib/ext/wp.auth.base.sua_loginmodule.jar`
   - `lib/ext/wp.auth.tai.jar`
   - `lib/wp.user.connections.jar`
   - `lib/wp.wire.jar`
   - `plugins/com.ibm.patch.was.plugin.jar`
   - `plugins/com.ibm.wp.was.plugin.jar`
   - `plugins/wp.ext.jar`
   - `properties/jndi.properties`
6. Examine all running processes and stop ones that contain the `PortalServer_root` directory. Restart the server, especially if you intend to reinstall WebSphere Portal Express on the same server.
7. Go to Deleting specific cluster members for information about how to delete a cluster member from the deployment manager.
8. Complete the following steps to delete the WebSphere Portal Express server from the deployment manager:
   a. Log on to the WebSphere Integrated Solutions Console.
   b. Click **Servers** > **Application Servers**.
   c. Select the check box for the WebSphere Portal Express server you want to delete.
   d. Click **Delete**.
9. After uninstalling WebSphere Portal Express and WebSphere Application Server, you can also delete the Installation Manager. Run the `uninstall.bat` command from the `ibm\InstallationManager\uninstall` directory.

Chapter 5. Configuring

Run the following tasks after you install and deploy IBM WebSphere Portal Express. They address tasks that are typically run one time and have a global effect. Some configuration changes are made more frequently or do not have a global effect. These tasks are addressed in the Administering section.

About this task

Review the Performance Tuning Guide to tune your stand-alone or clustered environment. Even if you have a clustered environment, review the Base Portal Tuning scenarios and the Tuning a cluster environment chapter. In addition, the tuning guide provides information about caches for WebSphere Portal Express. Until the latest tuning guide is available, refer to the previous tuning guide.

"Configuration Wizard" on page 232
Use the Configuration Wizard to set up stand-alone servers and new deployments, create clusters, migrate and update to new versions, and add new capabilities to existing deployments.

"Setting up a stand-alone server" on page 239
Use the Configuration Wizard to set up a stand-alone server. A stand-alone server is useful for different environments, such as a content authoring environment, test environment, and more.

"Tune your environment" on page 240
Tuning the servers is important to the performance of your environment. By default, IBM WebSphere Portal Express is not tuned for a production environment. Therefore, to ensure optimal performance review and complete the steps in the IBM WebSphere Portal Tuning Guide. If a tuning guide is not available for the current release, use the tuning guide from the previous product version.

"Web servers" on page 242
IBM WebSphere Portal Express uses the internal HTTP transport within IBM WebSphere Application Server to handle requests. However, because WebSphere Application Server also supports the use of an external web server, you can access WebSphere Portal Express from your web server. You can use a local web server on the same server as WebSphere Portal Express or you can use a remote web server on a different server. A remote web server is typical for a production environment or other high-traffic configuration and is also typically placed in DMZ outside a firewall to protect portal ports.

"WebSphere Portal" on page 247
First, finish your IBM WebSphere Portal Express deployment with the Configuration Wizard. Then, you can configure your environment further. For example, you can tune your servers to improve performance. You can change the default context root.

"Web Content Manager" on page 392
Set up a content server by installing IBM Web Content Manager in various deployments to provide robust and flexible environments for web content development and delivery. After you install the content server, more configuration steps must be completed according to the role that the server plays in your web content environment.

"Syndication" on page 448
Use syndication to replicate web content library data from one server to

another server. Syndication is based on a syndicator and subscriber relationship. The syndicator has the current data. The subscriber received the current data from the syndicator.

"Database Management Systems" on page 466
Configure the connection between IBM WebSphere Portal Express and your database management system. The **Database Transfer** configuration option in the Configuration Wizard assigns users and permissions, creates databases, obtains support for database collation, and transfers your database.

"User registry" on page 562
User information is stored in your user registry. You can enable LDAP referrals, configure IBM WebSphere Portal Express to use dynamic groups, update your user registry, or delete your user registry configurations.

"Search" on page 608
You use Portal Search to search for text that is displayed in websites that are created by IBM Web Content Manager.

Chapter 6, "Document Conversion Services," on page 727
Document Conversion Services are used when you work with the Common Mail Portlet, IBM Web Content Manager authoring and previewing, and search.

Chapter 7, "IBM Connections," on page 747
IBM Connections portlets give the IBM WebSphere Portal Express users access to more collaboration and social networking features such as activities, blogs, and bookmarks.

Configuration Wizard

Use the Configuration Wizard to set up stand-alone servers and new deployments, create clusters, migrate and update to new versions, and add new capabilities to existing deployments.

In the Configuration Wizard, you answer questions about the environment that you are configuring. Based on your answers, the wizard prompts you for custom values that are needed to configure your environment. Finally, the wizard generates custom steps and scripts to set up your environment.

Configuration options in the Configuration Wizard

Using the following configuration options, you can configure the portal server that you are connected to in real time. You can also download scripts and instructions to run on other servers, create reusable scripts for common configuration patterns, and create scripts to compare to scripts created in previous releases.

Database Transfer
Select this option to transfer data from Apache Derby to any of the database types that are supported by WebSphere Portal Express.

This option is found in **Set Up a Stand-alone Server** and in **Set Up a Cluster**.

Documentation resource: Database transfer

Documentation resource: "Troubleshooting: Database Transfer" on page 3561

Enable Federated Security
Add an LDAP user registry to the default federated repository to store user account information for authorization.

This option is found in **Set Up a Stand-alone Server** and in **Set Up a Cluster**.

Documentation resource: “Enable federated security” on page 563

Documentation resource: “Troubleshooting: Enable federated security option” on page 3582

Create a Deployment Manager

Create a deployment manager profile that is augmented with WebSphere Portal Express resources.

This option is found in **Set Up a Cluster**.

Documentation resource: Create a deployment manager

Documentation resource: “Troubleshooting: Create a deployment manager” on page 3587

Create a Cluster

Use the Configuration Wizard to create the primary node in your cluster.

This option is found in **Set Up a Cluster**.

Documentation resource: Create a cluster

Documentation resource: “Troubleshooting: Create a cluster option” on page 3589

Create an Additional Cluster Node

Use the Configuration Wizard to add nodes to a cluster.

This option is found in **Set Up a Cluster**.

Documentation resource: Create an additional cluster node

Documentation resource: “Troubleshooting: Create an additional cluster node” on page 3591

Install and Uninstall Add-ons

You can install add-on functionality to your WebSphere Portal Express with the solution installer through the Configuration Wizard.

This option is found in **Add On New Capability**.

Documentation resource: “Install and uninstall add-ons using the Configuration Wizard” on page 212

Migrate a Stand-alone Server

Use the Configuration Wizard to migrate a stand-alone server environment.

This option is found in **Migrate to a New Version**.

Documentation resource: “Migrate a stand-alone server” on page 842

Documentation resource: “Troubleshooting: Migrate a stand-alone server” on page 3599

Migrate a Cluster Step 1: Migrate the Deployment Manager Profile

Use the Configuration Wizard to migrate the deployment manager profile for a cluster environment. These steps must be completed before you start the migration of any nodes.

This option is found in **Migrate to a New Version**.

Documentation resource: “Cluster: Migrate the deployment manager profile” on page 847

Documentation resource: “Troubleshooting: Migrate the deployment manager profile for a cluster environment” on page 3605

Migrate a Cluster Step 2: Migrate Node Profiles

Use the Configuration Wizard to upgrade the node profiles for a cluster environment. These steps must be completed on all portal nodes in the cell before you begin the next cluster migration step.

This option is found in **Migrate to a New Version**.

Documentation resource: "Cluster: Migrate node profiles" on page 850

Documentation resource: "Troubleshooting: Migrate node profiles for a cluster environment" on page 3608

Migrate a Cluster Step 3: Upgrade Node Profiles
Use the Configuration Wizard to upgrade the nodes profiles for a cluster environment. Start these steps only after you migrate node profiles on all portal nodes in the cell.

This option is found in **Migrate to a New Version**.

Documentation resource: "Cluster: Upgrade node profiles" on page 853

Documentation resource: "Troubleshooting: Upgrade node profiles for a cluster environment" on page 3612

Recycle a Managed IBM WebSphere Portal Express Cell
Select this option to recycle the deployment manager and node agents. This configuration option runs the **action-cluster-recycle-dmgr** task.

This option is found in **More Options**.

Remove the IBM WebSphere Portal ExpressProfile
Use the Configuration Wizard to remove a portal profile.

This option is found in **More Options**.

Documentation resource: "Remove a WebSphere Portal profile" on page 384

Documentation resource: "Troubleshooting: Remove a WebSphere Portal profile" on page 3598

Configuration Wizard and clusters

In clustered environments, you can use the configuration wizard from the primary node. You can use the scripts from the primary node on the other nodes. You do not need to deploy the configuration wizard to the deployment manager.

Configuration Wizard profile

The wizard has a unique profile, `cw_profile`, and administrator credentials.

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

"Creating scripts and instructions" on page 235
The Configuration Wizard creates multiple files to help you complete your configuration objectives in a three-step process (**Answer Questions**, **Customize Values**, and **Configure**). When you select an option to customize for a specific configuration scenario, you provide information about your environment. Instructions, scripts, and helper files with updated property values are created to guide you in completing your configuration goal. You can run your configuration in real time or you can save your settings to use on another server.

"Configuration wizard runtime properties" on page 237
The Configuration wizard reads a properties file at startup. You can change these values and restart the wizard to control runtime behaviors.

"Running the configuration wizard silently" on page 237
You can run the configuration wizard silently if you have multiple deployments or if you want to develop a common deployment template.

"Installing or uninstalling the configuration wizard" on page 238
Use these instructions for the configuration wizard when installing or uninstalling the configuration wizard to another server with WebSphere Application Server installed.

Related concepts:

Chapter 3, "Roadmaps," on page 69
Review the roadmaps to understand the common deployment patterns that are supported by the configuration wizard.

Accessing the Configuration Wizard

The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

About this task

Click < and > to move back or forward in the Configuration Wizard.

Procedure

1. To get the latest updates for the wizard, apply the most recent combined cumulative fix. For more information about applying the latest fix pack, see WebSphere Portal and Web Content Manager V8.5.0.0 combined cumulative fix overview.

   Note: Skip this step, if you have the most recent fix pack applied.
2. Optional: Restart server1 to ensure that the Configuration Wizard uses the updated environment variables. Go to *AppServer_home*/profiles/cw_profile/bin and stop the server:
   - Linux : ./stopServer.sh server1 -username *username* -password *password*
   - IBM i: stopServer cw_profile -username *username* -password *password*
   - Windows: stopServer.bat server1 -username *username* -password *password*

   Then, start the server:
   - Linux : ./startServer.sh server1
   - IBM i: startServer cw_profile
   - Windows: startServer.bat server1
3. Access the Configuration Wizard. Go to http://*your_server*:*10200*/ibm/wizard.
4. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, cw_profile.

   Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For details on the supported languages for all of the WebSphere Portal Express user interfaces, see "Supported languages" on page 3622.

Creating scripts and instructions

The Configuration Wizard creates multiple files to help you complete your configuration objectives in a three-step process (**Answer Questions**, **Customize**

Values, and **Configure**). When you select an option to customize for a specific configuration scenario, you provide information about your environment. Instructions, scripts, and helper files with updated property values are created to guide you in completing your configuration goal. You can run your configuration in real time or you can save your settings to use on another server.

Procedure

1. From the Configuration Wizard, click an option to customize your configuration goal.

Answer Questions

2. If you saved values from a previous session, click **Upload Saved Selections** to locate the `.xml` file with your values. Then, click **Load**.
3. Answer questions about your environment, configuration goals, and preferences. The Configuration Wizard uses these values to filter steps when it creates your scripts. For example, you can select the targeted operating system where portal is installed to customize the instructions and scripts that are created for your environment.
4. Click the forward arrow to proceed to **Customize Values**.

Customize Values

5. Review parameter and property values. Use the default values or enter new values. Default values are provided for some parameters. Sample values are also provided to guide you through the configuration process. To see more parameters that are not part of the basic configuration path, click **Advanced**.
6. Click the forward arrow to proceed to **Configure**.

Configure

You can start your configuration on the same system that you are using to access the configuration wizard or save your settings to use on another server.

7. Click **Download Wizard Selections** to save your configuration settings to configure similar environments. By saving your settings, you can reuse parameter values in the future. When you use this option, an XML file is created for you to download with the information that you provided.
8. Review parameter and property values. Some of the properties and parameters that display might not be relevant to your task.
9. Click **Download Configuration Scripts** to create a compressed file that contains scripts, instructions, and other files. This compressed file is downloaded to the location specified in your browser download settings. The configuration wizard creates the following files:

   Instruction file (html) named after your task
   The instruction file provides you with tailored steps for your configuration and your target operating system. Based on the information that you provided when customizing your task, an instruction file is created. This file guides you when you run scripts in combination with other manual configuration steps for your specific configuration goal.

   Scripts
   Depending on the conditions of your environment, the script files use a `.sh` or `.bat` file extension or are simple text files. Use the scripts, along with other manual configuration steps described by your instruction file, to run your configuration. For example, your script file might provide you with a script to run a ConfigEngine task rather than you running the task.

Updated properties
Configuration helper files with updated property values entered for your configuration are created when customizing your task. You can use these helper files to save time.

`.wfi` file
File used for troubleshooting your task.

10. Click **Start Configuration** to run your configuration.

Related concepts:

Chapter 3, "Roadmaps," on page 69
Review the roadmaps to understand the common deployment patterns that are supported by the configuration wizard.

Configuration wizard runtime properties

The Configuration wizard reads a properties file at startup. You can change these values and restart the wizard to control runtime behaviors.

The properties file is in the *wp_profile_root*`/WebSphere/AppServer/systemApps/isclite.ear/wizard.war/display.properties` directory. Any property change requires a restart of the wizard before they take effect.

The following actions are supported:

Run the wizard in non-execution mode
It is possible to run the wizard in a non-execution mode. The instance is created and the wizard proceeds through the steps. However, no commands are run. This method is useful with the **`printDebug`** parameter to debug issues. It is also useful to create the custom data that is used to run the wizard silently. Set the value to `false` to enable this mode.

Enable tracing
To enable tracing, add the **`printDebug`** parameter to the `display.properties` file. Set the value to `true`.

Running the configuration wizard silently

You can run the configuration wizard silently if you have multiple deployments or if you want to develop a common deployment template.

Procedure

1. Choose one of the following options to prepare to run the configuration wizard silently:
   - Generate the customization data file in the configuration wizard without running the tasks.
   - Modify the sample customization data file that matches your deployment. This file is in the *PortalServer_root*`/installer/samples/configwizard` directory.

     Important: The sample scenarios do not cover all deployment options. Therefore, if the samples do not match your deployment scenario, generate the customization data file.
2. Open a command prompt.
3. Change to the *wp_profile_root*`/ConfigEngine` directory.
4. Create a silent installation from a set of customization data:

Note: All parameters are necessary. Run this task once per deployment cycle.

- Linux : `./ConfigEngine.sh customize-workflow -DwfId=`*`workflow-identifier`* `-DwfData=`*`customization-data-file`* `-DwfOutput=`*`output-directory`* `-DWasPassword=`*`password`*
- IBM i: `ConfigEngine.sh customize-workflow -DwfId=`*`workflow-identifier`* `-DwfData=`*`customization-data-file`* `-DwfOutput=`*`output-directory`* `-DWasPassword=`*`password`*
- Windows: `ConfigEngine.bat customize-workflow -DwfId=`*`workflow-identifier`* `-DwfData=`*`customization-data-file`* `-DwfOutput=`*`output-directory`* `-DWasPassword=`*`password`*

Where *`workflow-identifier`* is the name in the repository.

Where *`customization-data-file`* is the name of the customization data file.

Where *`output-directory`* is the directory where resulting files are written. This directory includes the following content:

- The *`workflow-identifier`*`.wfi` file that represents the combination of silent installation tasks and the custom data. Subsequent tasks use this file.
- The *`workflow-identifier`* directory where scripts and related files are created.

5. Start the silent installation:
   - Linux : `./ConfigEngine.sh execute-workflow -DwfInstance=`*`workflow-instance`* `-DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh execute-workflow -DwfInstance=`*`workflow-instance`* `-DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat execute-workflow -DwfInstance=`*`workflow-instance`* `-DWasPassword=`*`password`*

   This task runs until:
   - A step in the silent installation fails. You must correct the error and then run the **`resume-workflow`** task.
   - A step is reached that requires manual action. You must finish the requested action and then run the **`resume-workflow`** task.
6. To resume the silent installation, run the **`resume-workflow`** task:
   - Linux : `./ConfigEngine.sh resume-workflow -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh resume-workflow -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat resume-workflow -DWasPassword=`*`password`*

   This task works in the following way:
   - If you resume the silent installation after an error, the task runs the failed step.
   - If you resume after you complete a manual step, the task runs the next step in the sequence.

Installing or uninstalling the configuration wizard

The configuration wizard is installed by default when you install IBM WebSphere Portal Express. As an alternative to using the default installation, you can install the configuration wizard on another server that already has IBM WebSphere Application Server installed.

Procedure

1. Change to the *AppServer_root*`/ConfigEngine` directory.
2. To install the configuration wizard, run the following command:

- Linux : **./ConfigEngine.sh deploy-wizard-war-standalone**
- IBM i: **ConfigEngine.sh deploy-wizard-war-standalone**
- Windows: **ConfigEngine.bat deploy-wizard-war-standalone**

3. To uninstall the configuration wizard, run the following command:
   - Linux : **./ConfigEngine.sh remove-wizard-war-standalone**
   - IBM i: **ConfigEngine.sh remove-wizard-war-standalone**
   - Windows: **ConfigEngine.bat remove-wizard-war-standalone**

Setting up a stand-alone server

Use the Configuration Wizard to set up a stand-alone server. A stand-alone server is useful for different environments, such as a content authoring environment, test environment, and more.

Before you begin

Roadmaps provide an overview of the steps that are required for common environment configurations. Select the roadmap that is most like the environment that you want to set up.

About this task

Use your selected roadmap and the Configuration Wizard to complete a new environment set up.

Procedure

1. Select the roadmap that is most like the configuration that you need to configure.
2. Access the Configuration Wizard. Go to `http://`*`your_server`*`:`*`10200`*`/ibm/wizard`.
3. Log in to the Configuration Wizard with the administrative ID for the configuration wizard profile, `cw_profile`.

   Note: The wizard user interface might not be available in all languages. If the language is not currently supported, you might see the English version. For details on the supported languages for all of the WebSphere Portal Express user interfaces, see “Supported languages” on page 3622.
4. Click **Set Up a Stand-alone Server**.
5. Complete each sub step in the order that is shown in the wizard. Use the Configuration Wizard in conjunction with your selected Roadmap.

Related concepts:

“Roadmaps for stand-alone servers” on page 69
A stand-alone server topology is useful for many environments. While the underlying topology is similar for many environments, the configuration steps to achieve a desired environment varies.

Database transfer
Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

"Enable federated security" on page 563
You can use the Configuration Wizard to configure WebSphere Portal to use a federated LDAP for security. Use the following information to get familiar with the information you must provide in the wizard and the configuration procedure that it generates.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

"Updating DB2 self-tuning memory manager (STMM) settings" on page 895
With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Tune your environment

Tuning the servers is important to the performance of your environment. By default, IBM WebSphere Portal Express is not tuned for a production environment. Therefore, to ensure optimal performance review and complete the steps in the IBM WebSphere Portal Tuning Guide. If a tuning guide is not available for the current release, use the tuning guide from the previous product version.

About this task

Tuning your environment involves tuning and configuring the various systems and components. The tuning guide provides general concepts and detailed configuration instructions. Instructions are included for the following areas:

- Configuring the application server and the resources that are defined for that application server
- Determining the cloning strategy for expanding or extending the environment
- Tuning the database and database server
- Tuning the directory server and its database
- Tuning the web server
- Tuning the operating system and network
- Tuning the WebSphere Portal Express services

Procedure

1. Use the performance tuning tool to tune the portal server.
2. Read the tuning guide for assistance with tuning other servers in your environment.

   "Portal server performance tuning tool"
   Run the performance tuning tool on a new deployment to tune the servers that are based on performance recommendations.

Portal server performance tuning tool

Run the performance tuning tool on a new deployment to tune the servers that are based on performance recommendations.

Note: The performance tuning tool does not tune the database, the LDAP user registry, the web servers, or the operating system. In a clustered environment, it tunes only the cluster members. For advanced tuning, refer to the performance tuning guides.

Properties files

If necessary, modify the following properties files before you run the **tune-initial-portal-performance** task:

Remember: Review the performance tuning guide for information first. Before you modify the properties files, make a local copy of the *PortalServer_root*\installer\wp.config\config\TuningTask directory. Modify the files in the local copy. Then, add the -DTuningPropertiesDirectory=*local_dir_path* parameter to the **tune-initial-portal-performance** task.

- *PortalServer_root*\installer\wp.config\config\TuningTask\tuning.properties
- *PortalServer_root*\installer\wp.config\config\TuningTask\portal\CacheManagerService.properties
- *PortalServer_root*\installer\wp.config\config\TuningTask\portal\CommonComponentConfigService.properties
- *PortalServer_root*\installer\wp.config\config\TuningTask\portal\ConfigService.properties
- *PortalServer_root*\installer\wp.config\config\TuningTask\portal\CPConfigurationService.properties
- *PortalServer_root*\installer\wp.config\config\TuningTask\portal\NavigatorService.properties
- *PortalServer_root*\installer\wp.config\config\TuningTask\portal\RegistryService.properties
- *PortalServer_root*\installer\wp.config\config\TuningTask\portal.8\VirtualPortalConfigService.properties
- *PortalServer_root*\installer\wp.config\config\TuningTask\wcm\WCMConfigService.properties
- *PortalServer_root*\installer\wp.config\config\TuningTask\authoring\AccessControlDataManagementService.properties

Note: Starting with CF02, you can add the **-DAuthoringServer** parameter to the **tune-initial-portal-performance** task. Set this parameter to either true or false. Setting this parameter to true turns off the Web Content Manager advanced cache feature and any tuning features that are specific to a Subscriber server.

Stand-alone and clustered environments

Use the following syntax to run the **tune-initial-portal-performance** task on a stand-alone or clustered environment:

Note: In a clustered environment, run this task on each clustered node.

- Linux :./ConfigEngine.sh tune-initial-portal-performance -DWasPassword=*password* -DPortalAdminPwd=*password* -DTuningPropertiesDirectory=*local_dir_path*
- IBM i: ConfigEngine.sh tune-initial-portal-performance -DWasPassword=*password* -DPortalAdminPwd=*password* -DTuningPropertiesDirectory=*local_dir_path*

- Windows: `ConfigEngine.bat tune-initial-portal-performance -DWasPassword=password -DPortalAdminPwd=password -DTuningPropertiesDirectory=local_dir_path`

Vertical cluster member servers

Use the following syntax to run the **tune-initial-portal-performance** task on vertical cluster members:

Note: Run this task on each vertical cluster member on each node in the cluster.

- Linux :`./ConfigEngine.sh tune-initial-portal-performance -DServerName=vertical_cluster_servername -DWasPassword=password -DPortalAdminPwd=password -DTuningPropertiesDirectory=local_dir_path`
- IBM i: `ConfigEngine.sh tune-initial-portal-performance -DServerName=vertical_cluster_servername -DWasPassword=password -DPortalAdminPwd=password -DTuningPropertiesDirectory=local_dir_path`
- Windows: `ConfigEngine.bat tune-initial-portal-performance -DServerName=vertical_cluster_servername -DWasPassword=password -DPortalAdminPwd=password -DTuningPropertiesDirectory=local_dir_path`

Web servers

IBM WebSphere Portal Express uses the internal HTTP transport within IBM WebSphere Application Server to handle requests. However, because WebSphere Application Server also supports the use of an external web server, you can access WebSphere Portal Express from your web server. You can use a local web server on the same server as WebSphere Portal Express or you can use a remote web server on a different server. A remote web server is typical for a production environment or other high-traffic configuration and is also typically placed in DMZ outside a firewall to protect portal ports.

Configure your remote web server. Then, configure your web server to work with features such as IBM Web Content Manager.

"Configuring a remote web server" on page 243
To enable communication between the web server and WebSphere Application Server, a web server plug-in is required. The web server plug-in determines whether a request is handled by the web server or by the application server. The plug-in can be installed into a web server that is located either on the same server as WebSphere Application Server or on a separate server. The web server plug-in uses an XML configuration file (`plugin-cfg.xml`) that contains settings that describe how to handle and pass on requests to the WebSphere Application Server made accessible through the plug-in.

"Accessing WebSphere Portal Express through another HTTP port " on page 246
By default WebSphere Portal Express is configured to be accessed through the internal HTTP port in WebSphere Application Server. For example, `http://hostname.example.com:10039/wps/portal`, where *hostname.example.com* is the fully qualified host name of the server where Portal is running and *10039* is the default transport port that is created by WebSphere Application Server. The port number might be different for your environment. The default host name and port that is used by WebSphere Portal Express are specified by the **WpsHostName** and **WpsHostPort** properties in the `wkplc.properties` file.

Configuring a remote web server

To enable communication between the web server and WebSphere Application Server, a web server plug-in is required. The web server plug-in determines whether a request is handled by the web server or by the application server. The plug-in can be installed into a web server that is located either on the same server as WebSphere Application Server or on a separate server. The web server plug-in uses an XML configuration file (`plugin-cfg.xml`) that contains settings that describe how to handle and pass on requests to the WebSphere Application Server made accessible through the plug-in.

About this task

In the WebSphere Integrated Solutions Console, the web server is represented as a specific server type, and you can view or modify all of the configuration properties that are used in the `plugin-cfg.xml` file for the web server plug-in from the WebSphere Integrated Solutions Console.

Note: For some portal functions to work, you must make sure that the web server write and delete operations are allowed. These operations enable the HTTP operations POST, PUT, and DELETE. For example, these operations are required for the toolbar.

Choose the type of web server to configure:

"Configuring your Apache web server"
Configure the communication between IBM WebSphere Portal Express and your Apache web server.

"Configuring your Domino web server" on page 244
Configure the communication between IBM WebSphere Portal Express and your IBM Domino web server.

"Configuring your Oracle iPlanet web server" on page 245
Configure the communication between IBM WebSphere Portal Express and your Oracle iPlanet web server.

"Configuring your OnDemand Router" on page 245
Configure the communication between IBM WebSphere Portal Express and your OnDemand Router (ODR).

Configuring your Apache web server

Configure the communication between IBM WebSphere Portal Express and your Apache web server.

Procedure

1. If you are using IBM HTTP Server or Apache Server, edit the `httpd.conf` file on the web server. Set the **`AllowEncodedSlashes`** directive to `On`. Add the directive to the root level as a global directive.

HTTP server type	Documentation link
Read the appropriate HTTP Server documentation	IBM HTTP Server
Read the appropriate Apache Server documentation	**`AllowEncodedSlashes`** directives

2. Stop the web server.

3. Install and configure the web server plug-in on the system where the web server is located. Use the plug-ins installation wizard that is provided with WebSphere Application Server. Refer to the following topic for information:
   - Linux Windows: Selecting a Web server topology diagram and road map
   - IBM i: Selecting a Web server topology diagram and road map

   Important: Depending on how you use the web server, you must adjust the **ServerIOTimeout** parameter. It defines how long the plug-in must wait for a response from the application. The minimum value is `60` but you must increase this value if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set **ServerIOTimeout** to an appropriate value. For information, read Common questions about the Web server plug-in.
4. Web 2.0 REST features in portal might require an enabled PUT and DELETE method. If your web server has these methods disabled, complete one of the following options:
   - Enable HTTP tunneling to simulate PUT and DELETE requests, which means that POST requests are used instead. See the "Switch for tunneling of HTTP methods" link for information.
   - Follow the instructions for your web server to enable PUT and DELETE requests.
5. Start the web server.
6. Optional: If you want to use the short version of vanity URLs, add a rewrite rule to your web server. For more information, read *Providing short vanity URLs*.

Configuring your Domino web server

Configure the communication between IBM WebSphere Portal Express and your IBM Domino web server.

Procedure

1. Edit the `NOTES.INI` file on the web server. Set the **HTTPEnableConnectorHeaders** and **HTTPAllowDecodedUrlPercent** parameters to 1. Also, if you are using WebDAV, enable it in the Domino web server administrative console.
2. Stop the web server.
3. Install and configure the web server plug-in on the system where the web server is located. Use the plug-ins installation wizard that is provided with WebSphere Application Server. Refer to the following topic for information:
   - Linux Windows: Selecting a Web server topology diagram and road map
   - IBM i: Selecting a Web server topology diagram and road map

   Important: Depending on how you use the web server, you must adjust the **ServerIOTimeout** parameter. It defines how long the plug-in must wait for a response from the application. The minimum value is `60` but you must increase this value if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set **ServerIOTimeout** to an appropriate value. For information, read Common questions about the Web server plug-in.
4. Web 2.0 REST features in portal might require an enabled PUT and DELETE method. If your web server has these methods disabled, complete one of the following options:
   - Enable HTTP tunneling to simulate PUT and DELETE requests, which means that POST requests are used instead. See the "Switch for tunneling of HTTP methods" link for information.

- Follow the instructions for your web server to enable PUT and DELETE requests.

5. Start the web server.
6. Optional: If you want to use the short version of vanity URLs, add a rewrite rule to your web server. For more information, read *Providing short vanity URLs*.

Configuring your Oracle iPlanet web server

Configure the communication between IBM WebSphere Portal Express and your Oracle iPlanet web server.

Procedure

1. Install and configure the web server plug-in on the system where the web server is located. Use the plug-ins installation wizard that is provided with WebSphere Application Server. Refer to the following topic for information:
   - Linux Windows: Selecting a Web server topology diagram and road map
   - IBM i: Selecting a Web server topology diagram and road map

   Important: Depending on how you use the web server, you must adjust the **ServerIOTimeout** parameter. It defines how long the plug-in must wait for a response from the application. The minimum value is `60` but you must increase this value if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set **ServerIOTimeout** to an appropriate value. For information, read Common questions about the Web server plug-in.
2. If you are using an Oracle iPlanet web server, some portlets require that you disable the **unix-uri-clean** or **nt-uri-clean** directives. Edit the `obj.conf` file to enable or disable these directives. Refer to the Oracle iPlanet web server documentation to determine the appropriate setting for your environment.

   Note: If you are using Oracle iPlanet web server Version 7, you must disable **uri-clean**.
3. Web 2.0 REST features in portal might require an enabled PUT and DELETE method. If your web server has these methods disabled, complete one of the following options:
   - Enable HTTP tunneling to simulate PUT and DELETE requests, which means that POST requests are used instead. See the "Switch for tunneling of HTTP methods" link for information.
   - Follow the instructions for your web server to enable PUT and DELETE requests.
4. Start the web server.
5. Optional: If you want to use the short version of vanity URLs, add a rewrite rule to your web server. For more information, read *Providing short vanity URLs*.

Configuring your OnDemand Router

Configure the communication between IBM WebSphere Portal Express and your OnDemand Router (ODR).

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Go to **Servers** > **Server Types** > **Web server**.
3. Select your ODR.

4. Expand **On Demand Router Properties** in the **On Demand Router Settings** section.
5. Click **Custom Properties** in the **Additional Properties** section.
6. Add a new custom property with the following information:

   Name
   `cache.query.string`

   Value
   `true`
7. Save your changes.
8. Restart your ODR server.

Accessing WebSphere Portal Express through another HTTP port

By default WebSphere Portal Express is configured to be accessed through the internal HTTP port in WebSphere Application Server. For example, `http://`*`hostname.example.com`*`:`*`10039`*`/wps/portal`, where *hostname.example.com* is the fully qualified host name of the server where Portal is running and *10039* is the default transport port that is created by WebSphere Application Server. The port number might be different for your environment. The default host name and port that is used by WebSphere Portal Express are specified by the **WpsHostName** and **WpsHostPort** properties in the `wkplc.properties` file.

About this task

After you configure WebSphere Portal Express to use an external web server, you access the portal with the web server host name and port (for example, *80*). For stand-alone servers or vertical cluster members, you are unable to access the portal with the WebSphere Portal Express host name and port (for example, *10039*). You can access it if there is a corresponding virtual host definition for port *10039* in the WebSphere Application Server configuration.

Many of the WebSphere Portal Express configuration tasks rely on the **WpsHostName** and **WpsHostPort** properties from the `wkplc.properties` file. You must ensure that WebSphere Portal Express can be accessed with the host name and port that is specified by these property values. Choose one of the following methods:

- Modify the **WpsHostName** and **WpsHostPort** property values to specify the web server host name and port.
- Add the appropriate virtual host definition.

If you want to access WebSphere Portal Express with a host name and port different from your web server, add the required virtual host definition with the WebSphere Integrated Solutions Console. In a clustered environment, use the deployment manager WebSphere Integrated Solutions Console to complete these steps.

Procedure

1. Log on to the WebSphere Integrated Solutions Console.
2. Go to **Environment** > **Virtual Hosts**.
3. Select the **default_host** entry or the entry for the virtual host that is being used to access the WebSphere Portal Express application.
4. Select **Host Aliases**, and verify whether there is a host name and port entry corresponding to the values used to access WebSphere Portal Express. If the

entry does not exist, select **New**, and enter the information for the host name and port you want to use. The following information is the host alias examples:

- IBM i Linux Windows: `*:10039`

5. Save your changes.
6. Regenerate the web server plug-in.
7. If you are using a remote web server, copy the updated `plugin-cfg.xml` file to the web server in the web server home directory.
8. If you are running a system under stress and are expecting requests to take longer than the **ServerIOTimeout** default value, increase this value to avoid sending requests twice.
9. Recycle your web server, and your portal.
10. In a clustered environment, resynchronize the nodes and restart the cluster.

WebSphere Portal

First, finish your IBM WebSphere Portal Express deployment with the Configuration Wizard. Then, you can configure your environment further. For example, you can tune your servers to improve performance. You can change the default context root.

"Configuring portal behavior" on page 248
Configure various options related to your portal.

"Changing ports" on page 361
You can change the IBM WebSphere Portal Express ports values after installation if there are port conflicts with other cells on the system.

"Completing the portal URI change started during installation" on page 362
If you changed the context root on the **Configuration for IBM WebSphere Portal: Profile configuration details: Advanced** pane during installation, there are more steps to take to complete the change.

"Changing the portal URI after an installation" on page 368
You can change the default portal Uniform Resource Identifier (URI) any time after you install IBM WebSphere Portal Express. Some applications have a fixed context root that cannot be changed.

"Configuring managed pages" on page 375
When you create a new installation of IBM WebSphere Portal Express 8.5, managed pages are enabled by default. However, you can also manually disable and enable the feature as needed.

"Create a WebSphere Portal profile" on page 382
During the installation process, the IBM Installation Manager creates the WebSphere Portal Express profile. If you are on WebSphere Portal Express Version 8.5 without a combined cumulative fix applied, then you can use this option in the Configuration Wizard to create an additional profile.

"Remove a WebSphere Portal profile" on page 384
Use the Configuration Wizard to remove a portal profile.

"Managing your WebSphere Portal Express environment" on page 386
After you install IBM WebSphere Portal Express, you can use the IBM Installation Manager function to manage your environment. The Installation Manager function consists of updating and modifying the environment. You can also uninstall or roll back the modifications you made to your environment.

"Configuring the IBM License Metric Tool" on page 389
IBM License Metric Tool monitors license compliance. It recognizes and monitors what product offerings and their versions, releases, and fix packs are

installed and used on the system. It measures the processor value units (PVU) available to and used by these assets. The tool ensures compliance with IBM subcapacity licensing requirements and to demonstrate good IT governance. Information about installed software is collected from monitored computers by an agent that can be deployed on a range of operating systems. It is stored on a central server in a DB2 database and can be accessed through pre-configured reports that are available from a web user interface.

"Upgrading your existing product offering" on page 391
After your initial WebSphere Portal Express installation, you can purchase a license for an upgraded product offering.

Configuring portal behavior

Configure various options related to your portal.

"Setting the language of the portal" on page 249
Specify the default language in which the portal appears with the Global Settings portlet.

"Renaming the HTTP session cookie" on page 250
The Java Servlet API up to Version 2.5 states that the session identification cookie must be named `JSESSIONID` . WebSphere Application Server Version 8 supports the Java Servlet API 3.0 that offers applications the option to rename the JSESSIONID cookie name. Therefore WebSphere Portal Express Version 8.5 also supports this option.

"Customizing the home page login URL with the theme " on page 251
In the theme the login link points to a protected URL to the home page of the default portal installation. If you remove this page, or if you want your users to be directed to a different page after login, modify the theme by the following procedure.

"Using portal light mode" on page 251
Portal now provides a portal light mode which can improve portal startup time and reduce memory consumption in production environments.

"Creating or editing a custom unique name" on page 254
You can create a new custom unique name for a portal resource or update an existing custom unique name.

"Setting the portal entry page" on page 254
Use the **Global Settings** portlet to specify the page that a user sees when the user logs in to IBM WebSphere Portal Express.

"Configuring your time settings" on page 255
Some applications, like Calendar, are capable of adapting to the time zone settings of a user. By default, this functionality is disabled. If you want to enable your system to adjust to your local time settings, you must add a mapping to the **ibm-timeZone** attribute. See Adapting the attribute configuration in the Installing section in the Configuring portal to use a user registry topic.

"Setting the search engine that opens when users select Find" on page 255
Specify the search engine that is used when users click **Find** with the Global Settings portlet.

"Configuring how to handle portlets that a user is not authorized to view" on page 256
Specify how you want the portal to display portlets that a user is not authorized to view with the Global Settings portlet.

"Configuring user session persistence" on page 256
With the persistent session state feature, portal users can resume and continue a previously interrupted working session at the same state where they ended the session. When the user logs out or the session times out, the portal stores the

current navigational state into the database. As a portal administrator, you can give users the option to resume the navigational state of their last session when they log in again. When the user chooses to resume the last session, the navigational state that is stored previously is restored, and the user can continue working where the user stopped before.

"Configuring dynamic fragment cache" on page 260
Dynamic fragment cache (also known as servlet caching) is a component of WebSphere Application Server that provides content caching. You configure and enable dynamic fragment cache by using the WebSphere Integrated Solutions Console.

"Configuring portlet filtering" on page 260
A portlet filter enables the administrator of a portal to intercept and modify the output of a portlet before it is aggregated to the entire portal page. This way you can support different languages and markups other than those for which the portlet was originally designed. You can use portlet filters also for adding additional information to the portlet output, for example, a copyright statement, deleting unimportant or restricted content, and for parsing destructive JavaScript.

"Configuring authentication filters" on page 265
The portal authentication filters are a set of plug-in points. You can use them to intercept or extend the portal login, logout, session timeout, and request processing by custom code, for example to redirect users to a specific URL.

"Caching" on page 267
Caching affects the performance of your IBM WebSphere Portal Express environment. Learn about some simple ways to improve the caching performance. After you have reviewed this content, you should also review the WebSphere Portal Express and Web Content Manager Performance Tuning Guide which provides more information about caches for both WebSphere Portal Express and Web Content Manager.

"URL mapping" on page 277
URL mappings were deprecated starting with WebSphere Portal Express Version 8.5. Instead, you can now use friendly URLs or Vanity URLs as an alternative to URL mapping.

"HTTP proxy configuration" on page 278
Some portlets use IBM WebSphere Portal Express resources to support HTTP proxy. Loading and caching remote URLs (such as RSS streams or HTML files) is done in the portal by the URL Manager service. If you specify an HTTP proxy in the configuration of the service, all remote requests are loaded using this HTTP proxy. This feature enables servers behind a firewall with no direct access to the Internet to load external data, such as news or stock information.

"Delayed cleanup of deleted portal pages" on page 278
Get an overview of the cleanup service for portal pages and their dependent resources.

"Deleting orphaned data" on page 280
You use the SLCheckerTool to delete orphaned data in the database.

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Setting the language of the portal

Specify the default language in which the portal appears with the Global Settings portlet.

About this task

Note: The Global Settings portlet does not work in portal cluster configurations. For portal clusters set the portal default language in the portal Localizer service by using the WebSphere Integrated Solutions Console. For details about how to set the language see *Setting service configuration properties*.

Procedure

1. Click the **Administration menu** icon. Then, click **Portal Settings** > **Global Settings**.
2. Select the language for the portal from the **Default portal language** list.
3. Click **Save**.

What to do next

For a list of the languages that are supported by the portal, see *Language support*.

Related concepts:

"Language support" on page 1419
To reach as many users as possible, WebSphere Portal Express supports different languages for different locations. For instance, a large, international corporation might address users in different countries or regions through multilingual Web sites. In this context the portal can concurrently serve portal views to large numbers of users, each in the user's preferred language.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Renaming the HTTP session cookie

The Java Servlet API up to Version 2.5 states that the session identification cookie must be named `JSESSIONID` . WebSphere Application Server Version 8 supports the Java Servlet API 3.0 that offers applications the option to rename the JSESSIONID cookie name. Therefore WebSphere Portal Express Version 8.5 also supports this option.

About this task

A common use case for changing the JSESSIONID cookie name results from cookie name clashes due to HTTP proxy server usage. You can avoid such conflicts by either of the following methods:

Enable HTTP session ID reuse
: This prevents cookie name clashes by reusing the session ID values across different servers. To protect WebSphere Portal Express user sessions, you need to enable security integration in conjunction with session ID reuse. For details see the topic about Session management custom properties under the section about Http Session ID Reuse and the topics about Session security support and Session management settings in the appropriate WebSphere Application Server information center for your portal environment.

Procedure

1. Rename the HTTP session cookie on WebSphere Application Server. To do this, proceed as follows:
   a. Open the WebSphere Integrated Solutions Console.
   b. Select **Servers** > **Application Servers** > **Server_Name** > **Web Container Settings** > **Session management** > **Enable Cookies**.
   c. Change the value for session cookie name as required.
   d. Click **OK**.
   e. Save your changes.
   f. Restart WebSphere Application Server
   g. Regenerate the plug-in configuration file.
   h. If you are running a remote system, copy the plug-in configuration file to the remote server.
2. To synchronize your portal with the changes you made in the previous step, add the required properties to the Resource Environment Providers for your portal:
   a. Open the WebSphere Integrated Solutions Console.
   b. Add the following properties to the Resource Environment Providers:
      - In the **WP ConfigService**, add the following property:
        `cookie.sessionid.name=`*`cookiename`*
      - In the **WP PortletServiceRegistryService**, add the following property:
        `com.ibm.wps.pb.service.PropertyBrokerServiceImpl.sessionid.cookie.names=`*`cookiena`*

      For both properties, replace the variable *`cookiename`* by the new name of the JSESSIONID cookie.

Customizing the home page login URL with the theme

In the theme the login link points to a protected URL to the home page of the default portal installation. If you remove this page, or if you want your users to be directed to a different page after login, modify the theme by the following procedure.

Procedure

1. Open the file *PortalServer_root*`/theme/wp.theme.themes/default80/installedApps/DefaultTheme80.ear/DefaultTheme80.war/themes/html/dynamicSpots/commonActions.jsp` .
2. Locate the line: `<portal-navigation:urlGeneration allowRelativeURL="true" keepNavigationalState="false" contentNode="wps.content.root" home="protected" >`
3. Change `wps.content.root` to the unique name of the page to which you want your users to be directed after logging in.

Using portal light mode

Portal now provides a portal light mode which can improve portal startup time and reduce memory consumption in production environments.

About this task

When you enable portal light mode, specific portlet applications are not started at portal start up. Instead they are started later by the first standard HTTP request that occurs and renders a portal page with the portlet application on the server. This occurs, for example, when a user accesses the portlet application.

The default list of these applications whose initialization is deferred until first use (sometimes called "lazy applications"), contains administrative and sample portlet applications.

To benefit from a higher performance improvement, you can adapt the default list of these applications to your needs.

"Configuring portal light mode"
To benefit from a higher performance improvement, you can adapt the default list of lazy applications to your needs.

"Enabling and disabling portal light mode" on page 253
When you enable portal light mode, a portlet application is not started by a user request, but by the first standard HTTP request that occurs and renders a portal page that contains the portlet application on the server. Direct access to the portlet, for example an Ajax request, does not start the portlet.

Configuring portal light mode:

To benefit from a higher performance improvement, you can adapt the default list of lazy applications to your needs.

Procedure

1. Determine which of the applications that are deployed in your portal you want to configure as lazy applications. To do this procedure, perform the following steps:
   a. Log on to the WebSphere Integrated Solutions Console.
   b. Select **Applications** > **Application Types** > **WebSphere Enterprise Applications**.
   c. Write down the names of the applications that you want to add to the list of lazy applications. Add only applications to the list that are not used by your usual scenarios and that are not required for portal start.
2. Stop the portal server.
3. Make sure that portal light mode is disabled. To disable portal light mode, change to the directory *wp_profile_root*/ConfigEngine and run the configuration task

   ```
   ConfigEngine.sh|bat disable-portal-light-startup-performance -DWasPassword=password
   ```
4. Change to the directory *wp_profile_root*/PortalServer/config/StartupPerformance.
5. Modify the file wp.base_TargetMapInclList.properties. This file contains the list of applications that are not loaded when the portal server is started.
   - To add an application to this list, type the required application names from the **WebSphere Enterprise Applications** list.
   - To remove an application, comment out the appropriate application name or delete it from the list.

   Note: Make sure that your list of lazy applications does not contain any applications that are either required for portal startup or frequently used. Do not add portlet applications to the list that hold portal services or a plug-in for an Eclipse extension point. You can use the white list in the wp.base_TargetMapExclList.properties file as a reference. Never disable any of the applications that are listed in that properties file. For more information, see *Configuring developer mode on Windows*.
6. Save your changes.

7. Enable portal light mode. To do this step, change to the directory *wp_profile_root*/ConfigEngine and run the configuration task
   ConfigEngine.sh|bat **en**able-portal-light-startup-performance -DWasPassword=*password*
8. Restart the portal server.
9. After this adaptation, verify that your scenarios are still running.

What to do next

Limitations:

1. If you have portal light mode that is enabled and you stop an application manually, for example by using the WebSphere Integrated Solutions Console or the wsadmin command-line interface, and a user then accesses that application, that applications are restarted.
2. If you have portal light mode enabled and you use the activation task ConfigEngine.sh|bat activate-portlets to activate all portlets, all portlets are indeed started, even if they are set for lazy load.

Enabling and disabling portal light mode:

When you enable portal light mode, a portlet application is not started by a user request, but by the first standard HTTP request that occurs and renders a portal page that contains the portlet application on the server. Direct access to the portlet, for example an Ajax request, does not start the portlet.

About this task

Follow the appropriate procedures to enable or disable portal light mode.

Procedure

- Enable: To enable portal light mode, change to the directory *wp_profile_root*/ConfigEngine and run the configuration task
  - Linux : ./ConfigEngine.sh enable-portal-light-startup-performance -DWasPassword=*password*
  - Windows: ConfigEngine.bat enable-portal-light-startup-performance -DWasPassword=*password*
  - IBM i: ConfigEngine.sh enable-portal-light-startup-performance -DWasPassword=*password*
- Disable: To disable portal light mode, change to the directory *wp_profile_root*/ConfigEngine and run the configuration task
  - Linux : ./ConfigEngine.sh disable-portal-light-startup-performance -DWasPassword=*password*
  - Windows: ConfigEngine.bat disable-portal-light-startup-performance -DWasPassword=*password*
  - IBM i: ConfigEngine.sh disable-portal-light-startup-performance -DWasPassword=*password*

What to do next

Limitations: When portal light mode is enabled, the following limitations apply:

1. If you manually stop applications, for example by using the WebSphere Integrated Solutions Console or the wsadmin user ID, and they are then accessed by users, the applications are automatically started again.

2. When you use the activation task **activate-portlets** to activate all portlets, it starts all portlets, including the portlets that are set for lazy load.

Creating or editing a custom unique name

You can create a new custom unique name for a portal resource or update an existing custom unique name.

Before you begin

Proceed by the following steps:

About this task

Procedure

1. Select a resource type. Manage Custom Unique Names initially displays a list of resource types. Select a resource type by clicking it, for example, **Portlets**. Manage Custom Unique Names then lists all portal resources of the selected type, for example, all portlets of the portal.
2. Select a resource. From the list of resources, click the **Edit** icon for the portal resource for which you want to assign or change the custom name. Manage Custom Unique Names displays the **Unique name:** entry field for specifying the unique name, together with the identifying information for the selected resource. For example, this can be the portlet title and the Unique Identifier used internally by the portal.

   Note: To select a portlet instance as the resource, click **Pages**, navigate to the page containing the portlet instance, and click **Edit** by the portlet name.
3. Type the unique name that you want to assign to the selected portal resource or update the name as required.

   Notes:

   a. This name must be unique within the portal.
   b. A unique name must not exceed 255 characters in length.
   c. A unique name must not start with an IBM internal prefix, such as `ibm` or `com.ibm` . Otherwise clashes with internal unique names might occur, for example with pages provided with the default portal installation.

   If you want to remove the unique name from the resource, delete the name from the field.
4. Click **OK** to save your updates, or click **Cancel** if you do not want to save the updates. Manage Custom Unique Names returns to the previous panel. If you clicked **OK**, it displays the new name with the resource in the table.
5. Return to the resource type list by clicking **Select type**.

Setting the portal entry page

Use the **Global Settings** portlet to specify the page that a user sees when the user logs in to IBM WebSphere Portal Express.

About this task

Note: The Global Settings portlet does not work in portal cluster configurations.

Procedure

1. Click the **Administration menu** icon. Then, click **Portal Settings** > **Global Settings**.
2. Make a selection from the field **When a user logs in, the first page displayed**:

   Will always be the user's default page (portal session will not resume)
   Choose this option if you want users to always return to the default page after login.

   Will be the page the user most recently visited (portal session will resume)
   Choose this option if you want users to return to the page from their last visit. This option is helpful when users lose their portal session in the middle of a task and need to login to return.

   Will be dependent upon the choice the user makes at login
   Choose this option to let users determine the initial view by their choice after login.
3. Click **Save**.

Results

If you have a portal cluster configuration, use the WebSphere Integrated Solutions Console to set the properties `persistent.session.level` and `persistent.session.option` in the portal configuration service. For more information, refer to the topics about *Configuring user session persistence*, *Portal configuration services, and Setting service configuration properties*.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

"Configuring user session persistence" on page 256
With the persistent session state feature, portal users can resume and continue a previously interrupted working session at the same state where they ended the session. When the user logs out or the session times out, the portal stores the current navigational state into the database. As a portal administrator, you can give users the option to resume the navigational state of their last session when they log in again. When the user chooses to resume the last session, the navigational state that is stored previously is restored, and the user can continue working where the user stopped before.

Configuring your time settings

Some applications, like Calendar, are capable of adapting to the time zone settings of a user. By default, this functionality is disabled. If you want to enable your system to adjust to your local time settings, you must add a mapping to the **`ibm-timeZone`** attribute. See Adapting the attribute configuration in the Installing section in the Configuring portal to use a user registry topic.

About this task

Setting the search engine that opens when users select Find

Specify the search engine that is used when users click **Find** with the Global Settings portlet.

About this task

The Global Settings portlet does not work in portal cluster configurations.

Procedure

1. Click the **Administration menu** icon. Then, click **Portal Settings** > **Global Settings**.
2. In the field **Use this URL for "Find:"**, enter the URL for the search engine that you want to open when a user selects **Find**.
3. Restart the portal.

   The portal now displays a **Find:** button in the theme action bar of user pages.

   Note: If you use any themes with WebSphere Portal Express, you must modify these themes to make the Find function available. To complete this step, include the `<portal:find/>` tag in your theme.
4. Click **Save**.

Configuring how to handle portlets that a user is not authorized to view

Specify how you want the portal to display portlets that a user is not authorized to view with the Global Settings portlet.

About this task

Note: The Global Settings portlet does not work in portal cluster configurations.

Procedure

1. Click the **Administration menu** icon. Then, click **Portal Settings** > **Global Settings**.
2. Make a selection from the field **If a user is not authorized to view a portlet**:

   Portlet is not displayed
   Choose this option if you want nothing to display.

   Portlet is not displayed, replaced by an informative message
   Choose this option if you want a message to be displayed instead of the portlet.
3. Click **Save**.

Results

If you have a portal cluster configuration, use the WebSphere Integrated Solutions Console to set the property `portlets.unauthorized.visible` in the portal Configuration Service.

Configuring user session persistence

With the persistent session state feature, portal users can resume and continue a previously interrupted working session at the same state where they ended the session. When the user logs out or the session times out, the portal stores the current navigational state into the database. As a portal administrator, you can give users the option to resume the navigational state of their last session when they log in again. When the user chooses to resume the last session, the navigational state that is stored previously is restored, and the user can continue working where the user stopped before.

About this task

Example: A user logs in and maximizes some portlets. Afterwards the user logs out. When the user logs in again, all of the previously maximized portlets are still maximized.

"Session settings stored by the portal"
After a user logs out or the session times out, the portal stores the complete navigational state into the database.

"User option during login"
Depending on the configuration defined by the administrator, the user can choose whether to resume the last session or not.

"How administrators define persistent session options" on page 258
As an administrator, you can configure the persistent session behavior

Session settings stored by the portal:

After a user logs out or the session times out, the portal stores the complete navigational state into the database.

The settings include the following navigational state information:

Note: Authenticated and remembered users must have cookies enabled on their browser. Users can access portal sites without cookies enabled if they are anonymous users. If you turn on session tracking for anonymous users, then anonymous users also require cookies.

- Portlet states:
  - Normal
  - Minimized
  - Maximized
- Portlet modes:
  - `config`
  - `edit_defaults`
  - `edit`
  - `view`
  - `help`
- Page selection:
  - The last page that was active before the user logged out.

Note: Resuming the session state is only possible if either the portal theme login link or WebSphere Application Server TAI-based authentication is used to log in to the portal. Logging in or addressing a resource with a URL overwrites the complete session state that is to be resumed and addresses the named resource with the default states and modes for its portlets. For example, this occurs when users use `../wps/myportal/` or `../wps/myportal/`*`name`*`/` for a URL mapping or friendly name.

User option during login:

Depending on the configuration defined by the administrator, the user can choose whether to resume the last session or not.

If the portal administrator has enabled the resume option for users, the login page displays a check box **Resume last session**. If the user selects this check box, the previous session is resumed. Otherwise the previous session is not resumed and the user starts as if logging in for the first time. The options that administrators can set are described in the following sections.

How administrators define persistent session options:

As an administrator, you can configure the persistent session behavior

About this task

You do this by setting the following properties:

persistent.session.option
: This property determines whether the login portlet displays a check box that enables the user to decide whether to resume the session or not. For details refer to the topic about *Giving users the resume option*.

persistent.session.level
: This property determines which navigational state information should be restored when resuming the session. The administrator can choose from three predefined levels. For details refer to the topic about *Setting the session resume level for users*.

timeout.resume.session = (false)
: This property determines whether resuming the session after a session timeout requires user authentication. The default value is `false`. If this property is set to `false` and the user tries to continue working after a session timeout, the portal shows an error message stating that the session has timed out and the user has to log in again. If you set this property to `true`, the portal ignores the session timeout and does not show the error message. The user can resume the previous session without authentication and continue to work. In both cases the previous session is resumed according to the setting of the `persisted.session.level` property described previously.

You set these properties in the portal Configuration Service as described in the topic about *Setting service configuration properties*. The following sections describe the persistent session properties in more detail.

"Giving users the resume option"
As a portal administrator, you can define if users can resume their last session during login.

"Setting the session resume level for users" on page 259
The session resume level specifies which navigational state information is resumed (if any) when the respective user logs in again. As a portal administrator you can configure the session resume level.

Giving users the resume option:

As a portal administrator, you can define if users can resume their last session during login.

About this task

To set the resume option, you set the property `persistent.session.option` in the Portal Configuration Service, as described in the topic about *Setting service configuration properties*. You can configure the property to one of two settings: `0` or `1`.

The two persistent session option values have the following effects:

`persistent.session.option = 0`
This value means that the user does not have the choice to resume the last session or not.

`persistent.session.option = 1`
This value means that at login the user is presented with the option to resume the session in the navigational state of the last session.

The default setting is `0`, that is, users cannot resume their last session.

Notes:

- The defined session preservation settings as described in the topic about *Setting the session resume level for users* are in effect, independent of whether the administrator gave the users the resume option.
- If you give users the resume option, set the session resume level to `1` or higher. Otherwise, the `persistent.session.option` property setting has no effect.

Setting the session resume level for users:

The session resume level specifies which navigational state information is resumed (if any) when the respective user logs in again. As a portal administrator you can configure the session resume level.

About this task

You configure the session resume level by setting the property `persistent.session.level` in the Portal Configuration Service as described in the topic about *Setting service configuration properties*. You can configure the property to one of four predefined values: `0`, `1`, `2`, and `3`.

Note: If you want the user to benefit from the setting, give users the resume option as described in the topic about *Giving users the resume option*. However, the defined setting is in effect, independent of whether you give users the resume option or not.
The four persistent session level values have the following effects:

`persistent.session.level = 0`
This setting means that no persistent session state at all applies to the user session. During logout or session timeout no navigational state information is stored into the database. After a login no navigational state is restored. This value is the default setting.

`persistent.session.level = 1`
The portlet states and the portlet modes are stored in the database and are restored to the user session when the respective user logs in again. For example, all maximized portlets are still maximized. However, no information is stored about the last active page or its render parameters. With this setting, the user starts with the default page after a login.

persistent.session.level = 2
This setting is the maximum level of persistent session state. Using this level, the complete navigational state information is stored. This information includes page selection information and portlet-specific navigational state, such as portlet states, portlet modes, and render parameters. In contrast to persistent session level 1, the session now starts with the last page that was active before the user logged out.

persistent.session.level = 3
If you choose the setting 3, users will stay on the login page after they log in, rather than being redirected to another page. If you set this parameter to 3, this setting does not affect implicit logins, such as single sign-on with LTPA token or through an external security manager.

The default setting is 0, that is, no persistent session state is stored or restored.

The following table gives an overview of the settings and their effect on the user session when the user logs back in to the portal:

Table 28. Persistent session state settings and their effect on resuming user sessions

	Portal navigational state	Session persistence level 0	Session persistence level 1	Session persistence level 2	Session persistence level 3
Portlet states	Normal, minimized, maximized	Not restored	Restored	Restored	Not restored
Portlet modes	configure, edit_defaults, edit, view, help	Not restored	Restored	Restored	Not restored
Render parameters	Not applicable	Not restored	Not restored	Restored	Not restored
Pages	The last active page before the user logged out	Not restored	Not restored	Restored	Not restored

Configuring dynamic fragment cache
Dynamic fragment cache (also known as servlet caching) is a component of WebSphere Application Server that provides content caching. You configure and enable dynamic fragment cache by using the WebSphere Integrated Solutions Console.

About this task

For information about how to enable and configure dynamic fragment cache, go to the WebSphere Application Server topics in the following list. However, complete only the steps in the *Procedure*. Do not proceed with the **What to do next** instructions. Do not configure cacheable objects with the cachespec.xml file.

- Linux : Configuring portlet fragment caching
- IBM i: Configuring portlet fragment caching
- Windows: Configuring portlet fragment caching
- IBM WebSphere Developer Domain - Portal Zone: WebSphere Portal Zone

Configuring portlet filtering
A portlet filter enables the administrator of a portal to intercept and modify the output of a portlet before it is aggregated to the entire portal page. This way you can support different languages and markups other than those for which the portlet was originally designed. You can use portlet filters also for adding

additional information to the portlet output, for example, a copyright statement, deleting unimportant or restricted content, and for parsing destructive JavaScript.

About this task

To use portlet filters, you need to perform all of the following procedures:

- Enable portlet filtering for the portal
- Register the portlet filters, that is define and activate them in a properties file
- Assign the filters to the portlet.

Note: Using this portlet filter only applies to the IBM portlet API. For portlets written against the JSR 286 specification, portlet filtering is already defined within the JSR 286 standard and is configured differently.

"Enabling portlet filtering"
You enable the usage of portlet filters by setting the `legacy.portlet.enable.filtering` property in the Portlet Container Service.

"Registering portlet filters"
Before you can use a portlet filter and assign it to a portlet, you must register it in the `PortletFilterService`.

"Assigning filters to a portlet" on page 262
After you have registered a portlet filtered, you can assign it to a portlet. You can assign multiple portlet filters to a portlet.

"Portlet filter life cycle" on page 263
For performance reasons, portlet filters have a limited life cycle.

"Supported filter targets" on page 263
Calls to the portlet that do not have a request attached are not available to the portlet filter.

"Programming tips: wrapper objects" on page 264
To enable the easy usage of portlet filters, WebSphere Portal Express provides a predefined set of wrapper objects. You can use these wrapper objects to modify the standard behavior of the wrapped components.

"Request flow of portlet filters" on page 264
On server startup, all portlet filters that are registered in the `PortletFilterService` are initialized and are made available for filter registration. After that, the portlet filters go through a sequence of processing steps.

Enabling portlet filtering:

You enable the usage of portlet filters by setting the `legacy.portlet.enable.filtering` property in the Portlet Container Service.

About this task

To enable portlet filtering for the portal, set this property value to `true`:

```
legacy.portlet.enable.filtering = true
```

The default value is `true`.

Registering portlet filters:

Before you can use a portlet filter and assign it to a portlet, you must register it in the `PortletFilterService`.

About this task

The following example code snippet shows the declaration of a filter:

```
1: # Example:
2: filter.SampleFilter.class = com.example.SampleFilter
3: filter.SampleFilter.configValue = some configuration value
4: filter.SampleFilter.transcodeMarkup.1 = html->wml
5: # methods to be filtered
6: filter.SampleFilter.method.1 = service
7: filter.SampleFilter.method.2 = doTitle
```

In this example, the portlet filter `SampleFilter` is defined as follows:

- Line 2 defines the filter name to be `SampleFilter`. This name is later used in the portlet settings to attach the filter to the portlet. Line 2 also defines the class that implements the filter interface.
- Line 3 is a filter specific setting that is given to the filter during initialization. The filter name is removed from the parameter name for later use. For example, the parameter defined in line 4 is later seen by the filter with the name `configValue` and the value `some configuration value`. Several settings of this type can exist.
- Line 4 declares this filter as a transcoding filter that can transcode from HTML to a WML markup. Several settings of this type can exist. If this filter is attached to a portlet that can render HTML, you can now also place this portlet on pages for WML devices. The filter is invoked to transcode the html output to wml as soon as a WML device connects to the portal.
- Line 6 specifies that the filter is called when the `service` method of the portlet is called.
- Line 7 specifies that the filter is called when the `doTitle` method of the portlet is called.

The information in lines 6 and 7 is used to call the filter only for the specified methods to improve the performance. The possible methods for the filter are the following: `login`, `beginPage`, `service`, `endPage`, `doTitle`, `ActionEvent`, `MessageEvent`, and `WindowEvent`. If you want the filter to be called for every method, you do not need to define any method in the properties file.

Assigning filters to a portlet:

After you have registered a portlet filtered, you can assign it to a portlet. You can assign multiple portlet filters to a portlet.

About this task

To assign multiple portlet filters to a portlet, you define the portlet setting `FilterChain` and specify a list of filters separated by commas or semicolons as the value.

To add this setting to the relevant portlet during run time, use the Modify Parameters option in the Manage Portlets portlet.

The request will pass to the filters in the list in sequential order and then proceed to the portlet. The portlet response will then traverse back through all filters in reverse order. Refer to the following example:

```
FilterChain = MyTranscodingFilter, MyAdStripper
```

In this filter chain example, the filters perform the following actions:

- `MyTranscodingFilter` can transcode HTML to WML.
- `MyAdStripper` removes the advertisement from the output of the portlet.

The request processes the following steps:

1. `MyTranscodingFilter` is called first. This filter checks the requested markup and detects that WML is requested. Since the portlet supports only HTML, the client in the request is wrapped by this filter with a client-wrapper, which mimes an HTML client for the portlet. In addition, the response must be wrapped with a wrapper that intercepts the output of the following portlet or filters, in order to work on their output.
2. `MyAdStripper` does not have to modify the request because it only works on the output, but the response must be wrapped to store the output of the portlet.
3. The portlet generates its HTML output.
4. `MyAdStripper` on the output of the portlet and will remove the advertisement.
5. `MyTranscodingFilter` then works on the output of the previous filter and transcodes this output to WML.

You cannot use multiple filters that can transcode from one markup to another in a single filter chain.

You can also declare the filter chain or parts of the filter chain on a global level for all portlets written against the IBM API. To achieve this, you can edit or add a property `FilterChain` containing a comma-separated list of filters in the `PortletFilterService.properties` file, just like in the example given previously (`FilterChain = MyTranscodingFilter, MyAdStripper`). This global filter chain is merged with the one defined on a per-portlet basis, while the global ones are applied before the local ones.

Portlet filter life cycle:

For performance reasons, portlet filters have a limited life cycle.

All filters have the following stages:

Init The filter will be initialized. To get information about the specific filter settings and portal information, the `FilterConfig` is given to the `init` method of the filter. After the call of the init method, the filter will switch to the use mode.

Use Filter requests are handled by the `doFilter` method.

Destroy
The filter is taken out of service and the `doFilter` method will not be called again. This way, system resources can be given back to the portal.

Supported filter targets:

Calls to the portlet that do not have a request attached are not available to the portlet filter.

The following calls to the portlet are available to the filter:

- SERVICE
- DOTITLE
- ACTIONEVENT

- MESSAGEEVENT
- WINDOWEVENT
- LOGIN
- BEGINPAGE
- ENDPAGE

The following calls to the portlet are **not** available to the filter:

- Logout
- AttributeAdded
- AttributeReplaced
- AttributeRemoved
- Init
- InitConcrete
- Destroy
- DestroyConcrete

Programming tips: wrapper objects:

To enable the easy usage of portlet filters, WebSphere Portal Express provides a predefined set of wrapper objects. You can use these wrapper objects to modify the standard behavior of the wrapped components.

Wrappers are defined for the following objects:

Table 29. The wrappers defined for three objects

Object	**Predefined wrapper**
PortletRequest	PortletRequestWrapper
PortletResponse	PortletResponseWrapper
Client	ClientWrapper

A transcoding filter for markups, for example, from HTML to WML needs to use all of these wrappers to emulate the HTML environment that an HTML portlet assumes.

Request flow of portlet filters:

On server startup, all portlet filters that are registered in the `PortletFilterService` are initialized and are made available for filter registration. After that, the portlet filters go through a sequence of processing steps.

1. When a portlet is dispatched, the portlet container gets the required filters from the filter registration and calls these filters successively in the specified order.
2. Before the portlet is rendered, the portlet request and portlet response is forwarded through this chain of portlet filters.
3. Afterwards, the portlet container passes the request and response back through the chain of filters in the reverse order.

If a filter is to manipulate the output of a portlet, it must exchange the actual writer in the portlet response with one that stores data for later changes. This can be implemented by using the wrapper classes delivered with the portal. After the portlet is called and the response is returned, the filter can then manipulate the output of the portlet and write the resulting output to the original writer.

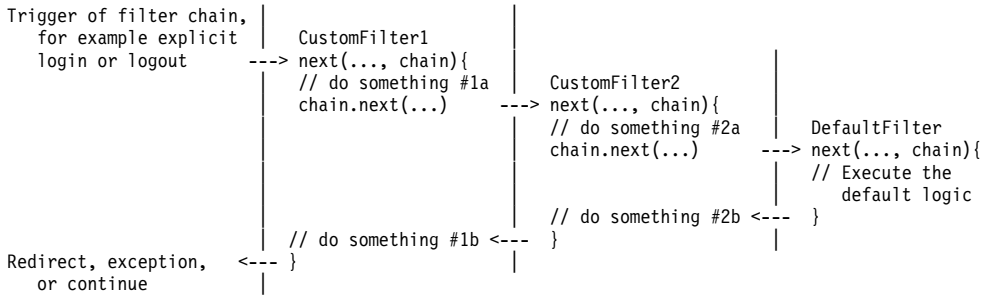
Configuring authentication filters

The portal authentication filters are a set of plug-in points. You can use them to intercept or extend the portal login, logout, session timeout, and request processing by custom code, for example to redirect users to a specific URL.

- "The authentication filter chain concept"
- "Available authentication filter chains "
- "Configuring the filter chains" on page 266
- "Example of a custom authentication filter" on page 266

The authentication filter chain concept

The authentication filters in the portal use the same pattern as defined by the J2EE servlet filter facility. For more information see the web article about The Essentials of Filters. The following example of a code flow shows how this pattern is applied to the authentication filters described in this section.



A default filter performs the default logic for a particular use case, for example, login. You can chain a set of custom filters to be executed before that default filter. When the filter chain is invoked, it calls the first element in the chain (in the example `CustomFilter1`) and passes a chain object as an argument to the call. The filter implementation can then perform some operations before calling the appropriate method on the chain object to trigger the next element in the chain (`CustomFilter2`). This filter again can implement some individual logic that is executed before calling the next element. The last element of the chain is the predefined `DefaultFilter` that makes sure that the default logic for the respective use case is executed.

After a filter has been executed or if an exception is thrown, each filter returns to the one that has called it, so it is possible to implement a customized exception handling or perform additional operations after having called the successor. This way you can chain a custom set of filters. Each custom filter can perform operations before and after the following element(s) in the chain. You can specify the order and the fully qualified class names of the custom filters by portal configuration properties. For details see the topic about the portal WP Authentication Service. The portal provides only the DefaultFilter implementations and enforces that they are always the last element in the chains; if there are no custom login filters defined, the default filters are the only element.

Available authentication filter chains

The filter chain concept described in the previous section is applied to six types of events that concern the flows of Portal login, logout, and session handling. This provides a flexible approach to plug custom logic to each of those flows. In particular, there are filter chains for the following events:

- Explicit login: This is a login by user name and password as represented by the interface `com.ibm.portal.auth.ExplicitLoginFilter`. For example, this can be a login by using the login portlet or the login URL.
- Implicit login: For example, this can be when a user is already authenticated by WAS, but not yet to Portal. This is represented by the interface `com.ibm.portal.auth.ImplicitLoginFilter`.
- Explicit logout: This means that the user triggers a logout action directly, for example by clicking the **Logout** button in the user interface, `interface com.ibm.portal.auth.ExplicitLogoutFilter`.
- Implicit logout: For example, this can be after a session timeout, or if an authenticated user accesses a public page, or if the user navigates to a virtual portal without being member of the associated user realm. This is represented by the interface `com.ibm.portal.auth.ImplicitLogoutFilter`.
- Session Timeout: This is called immediately after an idle timeout of the user session occurred. This is represented by the interface `com.ibm.portal.auth.SessionTimeoutFilter`.
- Session Validation: This is called for every request before actions are triggered and the page is rendered. This is represented by the interface `com.ibm.portal.auth.SessionValidationFilter`.

Besides the session timeout filter, each of the previous filters has access to the HTTP request and response objects. A special context object can be used to share information between filters and set redirects that are executed after the filter chain has been processed. For more detailed information about each of the filter and the filter chain interfaces see the documentation for both WebSphere Portal Express and the API JavaDoc. For a filter chain example see the topic with the Example of a custom authentication filter.

Configuring the filter chains

You can specify the order of filters for each filter chain by setting the following properties in the portal WP Authentication Service:

```
login.explicit.filterchain    = colon or semicolon-separated list of fully qualified class names
login.implicit.filterchain    = colon or semicolon-separated list of fully qualified class names
logout.explicit.filterchain   = colon or semicolon-separated list of fully qualified class names
logout.implicit.filterchain   = colon or semicolon-separated list of fully qualified class names
sessiontimeout.filterchain    = colon or semicolon-separated list of fully qualified class names
sessionvalidation.filterchain = colon or semicolon-separated list of fully qualified class names
```

Note: Use the properties to specify only the custom filter elements, as the default filter implementation is added implicitly by the Portal infrastructure. Thus, by default no value is set for the properties.
In addition, you can set properties in the portal WP Authentication Service according to the following pattern:

`filterchain.properties.`*`fully qualified class name of the filter implementation.property name`*

This makes the value of this property available in the filter configuration object of the specified class by using the key `property name` .

For details about setting portal configuration properties see the topic about Setting service configuration properties.

Example of a custom authentication filter

The following gives an example of a custom filter plugged into the filter chain for the explicit Portal login. The custom filter holds properties that define particular

redirect URLs for particular user IDs and triggers the corresponding redirect if one of those users logged in successfully. To implement such an example, proceed by the following steps:

1. Implement the `com.ibm.portal.auth.ExplicitLoginFilter` interface and make your class available to the portal class path by adding the JAR file to the extended classpath directory of the WebSphere Portal Express application: *PortalServer_root*`/shared/app` . For an example for how to implement the methods of the interface refer to the following code sample:

```
package com.ibm.portal.example;

public class UserRedirectLoginFilter implements ExplicitLoginFilter {

    // hash map to store the mappings from user id to redirect URL
       private java.util.Map userToRedirectURLs = new java.util.HashMap();

public void init(SecurityFilterConfig filterConfig)
       throws SecurityFilterInitException {
    // iterate the list of init parameters and store
       the mappings of user to redirect urls for
       (java.util.Iterator it = filterConfig.getInitParameterNames(); it.hasNext(); ) {
           String currentParameter = (String)it.next();
           userToRedirectURLs.put(currentParameter,
           filterConfig.getInitParameter(currentParameter));
        }
    }

    public void login(HttpServletRequest req, HttpServletResponse resp,
                String userID, char[] password,
                FilterChainContext portalLoginContext, Subject subject,
                String realm, ExplicitLoginFilterChain chain)
                throws LoginException, WSSecurityException,
                PasswordInvalidException, UserIDInvalidException,
                AuthenticationFailedException, AuthenticationException,
                SystemLoginException, com.ibm.portal.auth.exceptions.LoginException {
        // call the next element in the filter chain to trigger the default login
           chain.login(req, resp, userID, password, portalLoginContext, subject, realm);

        // if no exception occured, the login was successful
           if (userToRedirectURLs.containsKey(userID)) {
        // set the redirect url for the user if we have an entry
           portalLoginContext.setRedirectURL((String)userToRedirectURLs.get(userID));
        }
    }

    public void destroy() {
           // nothing to do here
    }
 }
```

2. Specify the class name of the custom filter in the WP Authentication Service properties:

   ```
   login.explicit.filterchain=com.ibm.portal.example.UserRedirectLoginFilter
   ```

3. To define the redirect URLs for individual user IDs, specify your custom set of properties for this class accordingly. Example:

   ```
   filterchain.properties.com.ibm.portal.example.UserRedirectLoginFilter.alice=/wps/myportal/pageA
   filterchain.properties.com.ibm.portal.example.UserRedirectLoginFilter.bob=/wps/myportal/pageB
   ```

4. Restart the portal.

The new filter for the explicit login is now available. Users defined in the properties will be redirected to the specified URL after logging in through the login portlet or login URL.

Caching

Caching affects the performance of your IBM WebSphere Portal Express environment. Learn about some simple ways to improve the caching performance. After you have reviewed this content, you should also review the WebSphere Portal Express and Web Content Manager Performance Tuning Guide which provides more information about caches for both WebSphere Portal Express and Web Content Manager.

The WebSphere Portal and Web Content Manager Performance Tuning Guide provides information about caches for WebSphere Portal Express and Web Content Manager. Choose the latest tuning guide for information:

Essential tuning and performance resources

Use the following files to create an effective cache for your environment:

"Caching pages shared by multiple users"
If you use a proxy server such as WebSphere Edge Server and your system has content that can be shared among multiple users, you can improve performance by caching this shared content.

"**cookie.ignore.regex** parameter" on page 269
Use the **cookie.ignore.regex** parameter to configure which cookies to ignore from the header field. Ignoring these cookies excludes them from the digest computation.

"Cache scope" on page 270
The cache scope determines where the content is cached.

"Expiry time" on page 270
The expiry time determines how long the page is stored in a cache.

"Cache scope and expiry time settings" on page 271
There are resources that contribute to the overall remote cache information on a page.

"Default cache scope and expiry time settings" on page 274
You can set the default cache scope and expiry time settings for WebSphere Portal Express in the portal WP Navigator Service.

"Factors affecting cache scope and expiry time" on page 276
Multiple factors can affect the cache scope and expiry time for a page.

"Cache limitations" on page 276
When tuning your environment to improve performance, review the limitations to ensure success.

"Security Issues" on page 277
Storing authenticated pages in a shared cache introduces security holes. If a malicious user discovered the URL for an authenticated page, that user could read pages containing private information.

"Troubleshooting the cache" on page 277
In general, you should monitor the cache hit rate on the proxy server and adjust the cache size appropriately. If the hit rate is not what you expected, increase the cache size.

Caching pages shared by multiple users:

If you use a proxy server such as WebSphere Edge Server and your system has content that can be shared among multiple users, you can improve performance by caching this shared content.

WebSphere Portal Express allows you to configure the cache scope and the cache expiry time of the specified content. The cache scope and cache expiry time are configured by page, portlet, and theme. WebSphere Portal Express combines this information to produce a final cache scope and expiry time for each page it serves. You can configure these cache settings in one of the following two ways:

The XML configuration interface
See the XML configuration interface for information.

Portlets

The Manage Pages, Manage Portlets, and Properties portlets allow you to configure cache settings. For detailed information, refer to the portlet helps.

Note: When caching JSR portlets, the cache scope is only for proxy server caching policies and requires the use of an edge server cache. Local display caching policies are not affected by this setting. The cache expiration setting is used for both local and remote caching policies.

cookie.ignore.regex parameter:

Use the **cookie.ignore.regex** parameter to configure which cookies to ignore from the header field. Ignoring these cookies excludes them from the digest computation.

About this task

Complete the following steps to add the **cookie.ignore.regex** parameter to the portal resource environment provider:

Procedure

1. If necessary, start the WebSphere_Portal server.
2. Log in to the WebSphere Integrated Solutions Console.
3. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
4. Select **WP ConfigService**.
5. Under Additional Properties, select **Custom Properties**.
6. Click **New**.
7. Specify the name of the required property and set the value of the property to the appropriate value as needed.

   To specify cookies that are NOT included in the digest computation, specify `cookie.ignore.regex = digest\.ignore.*|Item1|Item2|Item3|Item4,` where Item1, Item2, Item3, Item4 are the items that you want to exclude from getting cached. The default value is:

   `digest\.ignore.*|${com.ibm.websphere.security.customLTPACookieName}|${com.ibm.websphere.security.customSSOCookieName}|${cookie.session`

   The variables are defined such that the variables resolve to the values listed. For example,

   `digest\.ignore.*|LTPAToken|LTPAToken2|JSESSIONID|WASReqURL` where

   `${com.ibm.websphere.security.customLTPACookieName}= LTPAToken`
   `${com.ibm.websphere.security.customSSOCookieName}= LTPAToken2`
   `${cookie.sessionid.name}=JSESSIONID`

   Important: Any cookie that is set or modified by any component causes the digests in the URL to change, directly affecting the cache of those resources. If a particular cookie is required for some custom code or feature to work but it is not designed to invalidate the cache, that cookie name must be included in the **cookie.ignore.regex** list or at least matched successfully by the regular expression in that property. This process ensures that changes to the cookie value do not have any adverse impact on performance by prematurely invalidating cache entries.
8. Click **Apply** and save your changes.

9. Log out of the WebSphere Integrated Solutions Console.
10. Restart the WebSphere_Portal server.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Cache scope:

The cache scope determines where the content is cached.

There are two types of caching:

Shared cache across users
This type of caching provides the biggest performance improvement. A proxy server caches content and serves requests for the content. This caching eases the load on the server because requests that are served by the proxy do not reach WebSphere Portal Express. If most requests are for customized content, this type of caching provides no performance improvement. The following default values exist for portlet definitions and themes if nothing is provided:

Note: This type of caching should be used only for pages that contain public content that is not personalized.

- Remote cache scope is `non-shared`
- Remote cache expiry is `0 seconds`

Non-shared cache for a single user (Web browser cache)
This type of caching provides a much smaller performance improvement. The cache is typically located in each user's Web browser. This type of caching can be used for all content, including content that is personalized. If the computer is shared among multiple users, a user may see personalized content from other users if served from the browser cache. To prevent this from happening, do not enable private caching, even for personalize content.

Expiry time:

The expiry time determines how long the page is stored in a cache.

WebSphere Portal Express allows three options for specifying expiry time:

Cache always expires
The content is never cached in either a shared or a private cache; set the remote cache expiry to **0**.

Cache never expires
The content can be stored indefinitely in either a shared or a private cache; set the remote cache expiry to **-1**.

Cache expires after this many seconds
The content is stored for the number of seconds specified in either a shared or a private cache; set the remote cache expiry to a positive integer up to `2^31 -1`.

Cache scope and expiry time settings:

There are resources that contribute to the overall remote cache information on a page.

The following information lists the resources that contribute to the overall remote cache information on a **Page**:

remote cache scope

Key com.ibm.portal.remote-cache-scope

Possible values
SHARED, NON_SHARED

Set with XML Access
Yes

Set with user interface
Yes

remote cache expiry

Key com.ibm.portal.remote-cache-expiry

Possible values
Time in seconds, given as an integer between -1 and the value ((2 to the power of 31)-1)

Note: Use the value -1 if you never want the cache to expire.

Set with XML Access
Yes

Set with user interface
Yes

Ignore Access Control in Caches

Key com.ibm.portal.IgnoreAccessControlInCaches

Possible values
True false

Set with XML Access
Yes

Set with user interface
Yes

Example for XML access:

```
<parameter update="set" name="com.ibm.portal.remote-cache-scope" type="string">SHARED</parameter>
<parameter update="set" name="com.ibm.portal.remote-cache-expiry" type="string">3000</parameter>
<parameter update="set" name="com.ibm.portal.IgnoreAccessControlInCaches" type="string">true</parameter>
```

The following information lists the resources that contribute to the overall remote cache information for **Themes**:

remote cache scope

Key com.ibm.portal.remote-cache-scope

Possible values
SHARED NON_SHARED

Set with XML Access
Yes

Set with user interface
No

remote cache expiry

Key com.ibm.portal.remote-cache-expiry

Possible values
Time in seconds, given as an integer between -1 and the value ((2 to the power of 31)-1)

Note: Use the value -1 if you never want the cache to expire.

Set with XML Access
Yes

Set with user interface
No

Example for XML access:

```
<parameter update="set" name="com.ibm.portal.remote-cache-scope" type="string">SHARED</parameter>
<parameter update="set" name="com.ibm.portal.remote-cache-expiry" type="string">3000</parameter>
```

The following information lists the resources that contribute to the overall remote cache information on a **Portlet Definition**:

remote cache scope

Key remote-cache-scope

Possible values
SHARED NON_SHARED

Set with XML Access
Yes

Set with user interface
No

expiration cache

Key EXPIRATION_CACHE

Possible values
Time in seconds, given as an integer between -1 and the value ((2 to the power of 31)-1)

Note: Use the value -1 if you never want the cache to expire.

Set with XML Access
Yes

Set with user interface
Yes

remote cache dynamic

Key remote-cache-dynamic

Possible values
True falso

Set with XML Access
Yes

Set with user interface
No

Note: The Standard Portlet API specification defines the meaning of the `EXPIRATION_CACHE` value. WebSphere Portal Express uses this value to determine the lifetime of the portlet's output in a remote cache, just like the remote cache expiry for themes. The remote cache dynamic setting is an optimization to notify the container whether a portlet window can publish remote cache information at render time. The deployment descriptor specification shows how to deal with these settings.

The following information lists the resources that contribute to the overall remote cache information on a **Portlet Window**:

remote cache scope

Key remote-cache-scope

Possible values
SHARED NON_SHARED

Set with XML Access
No, only published during render time

Set with user interface
No

expiration cache

Key EXPIRATION_CACHE

Possible values
Time in seconds, given as an integer between -1 and the value ((2 to the power of 31)-1).

Note: Use the value -1 if you never want the cache to expire.

Set with XML Access
No, only published during render time.

Set with user interface
No

Note: The portlet definition describes the portlet at a deployment time level given in the portlet deployment descriptor. Thus, attributes specified in the deployment descriptor are valid on all occurrences on all pages of this portlet. The portlet window describes the runtime entity for a portlet. While in the rendering phase of a portlet, the portlet can publish values or attributes via an API. Thus, attributes specified while rendering the portlet is portlet instance specific.
Example code snippet for publishing the information at render time:

```
String paramExpiry = "3000";
String paramScope = "SHARED";
renderResponse.setProperty( "portlet.remote-cache-scope", paramScope );
renderResponse.setProperty( RenderResponse.EXPIRATION_CACHE, paramExpiry );
```

The following information lists the resources that contribute to the overall remote cache information on **Portlet Wide Settings**:

remote cache expiration

Key remote.cache.expiration

Possible values
no, property in `WP NavigatorService`

Set with XML Access
No

Set with user interface

vary

Key vary

Possible values
List of HTTP header fields that can be put into the vary response header

Set with XML Access
No, property in `WP NavigatorService`

Set with user interface
No

Default cache scope and expiry time settings:

You can set the default cache scope and expiry time settings for WebSphere Portal Express in the portal WP Navigator Service.

The following list shows the properties of the portal WP Navigator Service:

`public.session`
Use this property to specify whether an anonymous user always has a public session. This may be useful when a portlet requires a session for anonymous users. the default value is `false` . To enable public sessions for pages that anonymous users can view without logging in, set this property to `true`.

The setting of `public.session` influences the remote cache scope for public pages. If `public.session` is set to `true`, then the cache scope is set to non-shared (private). If `public.session` is set to `false`, then the cache scope is set to shared (public).

Note: Setting `public.session` to `true` might reduce performance.

`public.expires`
Use this property to specify the cache expiration time (in seconds) for caches outside of WebSphere Portal Express and for unauthenticated pages only. These caches must adhere to the HTTP 1.1 specification (RFC 2616). The `public.expires` key specifies the time after which HTTP caches should drop the response. You can further restrict this time by the `remote.cache.expiration` key.

This value is used as a maximum value for the cache expiration time and as a global default value for unauthenticated pages. If you also set the property `remote.cache.expiration` to a value greater than or equal to zero (`0`), the smaller one of the two values is used.

WebSphere Portal Express calculates and aggregates the remote cache information, that is the scope and expiration time, by a number of properties contributed by themes, pages, and portlets besides the properties described here. Therefore WebSphere Portal Express can do any of the following internally while processing a request:

- Reduce the cache lifetime
- Reduce the cache scope, for example, from public (shared) to private (non-shared)
- Switch off the overall cachability of pages.

Therefore this value might not be static for all responses resulting from requests to unauthenticated pages.

The response of WebSphere Portal Express sets the following header fields:

- The `Expires` header with the expiration time added to the system date and time.
- The `Cache-Control : max-age =` header with the expiration time as its parameter.

The default value specified for this property is `60` seconds. If no value is specified, WebSphere Portal Express defaults the value to `60` seconds.

`remote.cache.expiration`
This property specifies the maximum cache lifetime of a page, both public and private, in seconds. Use this property to specify a global value for the expiration of pages in remote caches. Setting this value to zero (`0`) switches caching off in remote caches. If the legacy setting is not available, this property is used for authenticated and unauthenticated pages. If the legacy setting is available, then the smaller of the two values is used for unauthenticated pages only. In this case the `remote.cache.expiration` property is used for authenticated pages in general. If theme, composition, and portlets contribute remote cache information, then the global settings also contribute to the information. In this case the lowest of the values of all contributors is used, including the global settings.

The default value for this property is `60` seconds. If no value is specified, WebSphere Portal Express defaults the value to zero (`0` seconds).

`remoteCacheInfo.response.header.vary`
This property specifies the HTTP headers that force a proxy to cache different variants of the same URL. Use this property to specify a comma separated list of HTTP header fields to which WebSphere Portal Express should refer in its vary field of the generated HTTP response. This is required to ensure that proxy caches can invalidate entries in their cache if the specified header fields do not match from request to request. The default for this property is `User-Agent` .

`public.cache-control`
This property specifies the HTTP headers that force a proxy to cache different variants of the same URL. Use this property to specify a comma separated list of HTTP header fields to which WebSphere Portal Express should refer in its vary field of the generated HTTP response. This is required to ensure that proxy caches can invalidate entries in their cache if the specified header fields do not match from request to request. The default for this property is `no-cache` .

`private.cache-control`
This property specifies the value that is set for the `cache-control` HTTP header field when the portal generates a response in request for private pages. This header field controls the behavior of all caching mechanisms along the request-response chain. The default for this property is `no-cache` .

Factors affecting cache scope and expiry time:

Multiple factors can affect the cache scope and expiry time for a page.

The remote-cache-scope and remote-cache-expiration of a rendered page view is calculated as the minimum of the following factors:

- Cache scope and expiry time specified for the page
- Cache scope and expiry time of the portlets on the page

  Note: If any of the portlets on a page can only be cached in a private cache, then the entire page can only be cached in a private cache. A page cannot be stored in a shared cache unless all portlets on the page can also be stored in a shared cache. Make sure cache settings for portlets and pages are consistent.
- Cache scope and expiry time of the theme
- Global values as defined in the Navigator Service in the WebSphere Integrated Solutions Console.

Cache limitations:

When tuning your environment to improve performance, review the limitations to ensure success.

- For best results, use WebSphere Application Server Edge Components version 6.0.0.1 (or later), version 5.1.0.7 (or later), version 5.0.2.30 (or later) for the proxy server. Previous versions do not serve multiple markup types from the same cache. If there are multiple requests for the same page, but with different markup, the cache is not used. These versions of WebSphere Application Server Edge Components correct this problem.
- If your WebSphere Portal Express serves only one markup, make sure the vary is set appropriately. If your WebSphere Portal Express serves multiple markups, set the vary appropriately and use a larger cache size. Use `remoteCacheInfo.response.header.vary = space separated list of other http header fields` to appropriately set the vary.

  Note: Enter any HTTP header field names; you must use the HTTP 1.1 specification. The two most common HTTP headers to specify here are `vary = accept-language user-agent`.

  Note: The Vary value indicates the set of request-header fields that force a proxy to cache different variants of the same URL.
- If your WebSphere Portal Express serves only one language, make sure the vary is set appropriately. If your WebSphere Portal Express serves multiple languages, set the vary appropriately and use a larger cache size. Use `remoteCacheInfo.response.header.vary = accept-language` to appropriately set the vary.
- Only JSR portlets can override the cache lifetime setting at run time.

Note: With the previous settings, it is possible to generate an HTTP response header like `Cache-Control: max-age=-1`, which indicates an unlimited cache expiration when a page is rendered. This is beyond the HTTP 1.1 specification but if a proxy cache does not support an unlimited cache expiration, WebSphere Portal Express supports it. If the cache infrastructure does not properly work with this response header, set the `remote.cache.expiration` value in the **`WP NavigatorService`** to a large value. To set an unlimited cache expiration is not possible if the cache infrastructure does not support it.

Security Issues:

Storing authenticated pages in a shared cache introduces security holes. If a malicious user discovered the URL for an authenticated page, that user could read pages containing private information.

By default, WebSphere Portal Express does not permit shared caching for authenticated pages. You can use the Properties portlet or the XML configuration interface to override these default settings using the **com.ibm.portal.IgnoreAccessControlInCaches** parameter, but in most cases this is not recommended.

Note: In some rare circumstances, it might be useful to store authenticated pages in a shared cache. For example, if all authenticated users receive identical content, then storing authenticated pages in a shared cache might be acceptable.

Troubleshooting the cache:

In general, you should monitor the cache hit rate on the proxy server and adjust the cache size appropriately. If the hit rate is not what you expected, increase the cache size.

You can also check the following item:

Ensure that the cache settings for all portlets on the page are consistent with the cache settings for the page. For example, if one portlet on a page is set to only be cached in a private browser cache, then the entire page can only be cached in a private browser cache, and performance is not optimal.

URL mapping

URL mappings were deprecated starting with WebSphere Portal Express Version 8.5. Instead, you can now use friendly URLs or Vanity URLs as an alternative to URL mapping.

About this task

Depending on your requirements, you can use vanity URLs, or friendly URLs:

- If you want to have a short URL as an entry point to a specific portal page or content item, use a vanity URL.
- If you want to have a friendly URL that your site visitors see when the portal shows the page, use a friendly name.
- If you want to be able to publish the page through the Web Content Manager workflow, use a vanity URL. For example, this URL can be useful for a marketing campaign.
- If you want to address a specific portal page through URL generation tags or APIs, use unique name IDs. For more information, see *URL generation in WebSphere Portal*.

You can create both vanity URLs and friendly URLs for the same portal page.

Related concepts:

"Vanity URLs" on page 2094
You can associate vanity URLs with portal pages and labels. Vanity URLs are short URLs that people can easily remember. They are shorter than full WebSphere Portal Express URLs. They are sometimes also called marketing URLs. You can publish vanity URLs for marketing campaigns through different channels, such as email or print. This way, you can use vanity URLs to direct customers to a specific portal page or content item. Interested site visitors who want to view your campaign can then remember or copy the short vanity URL and type it into the browser address field.

Related tasks:

"Using friendly URLs" on page 1280
You can associate friendly URLs with portal pages and labels. You and your users can use these friendly URLs to access specific portal pages or labels by using a human readable path, which is easy to remember.

HTTP proxy configuration

Some portlets use IBM WebSphere Portal Express resources to support HTTP proxy. Loading and caching remote URLs (such as RSS streams or HTML files) is done in the portal by the URL Manager service. If you specify an HTTP proxy in the configuration of the service, all remote requests are loaded using this HTTP proxy. This feature enables servers behind a firewall with no direct access to the Internet to load external data, such as news or stock information.

To configure WebSphere Portal Express for HTTP proxy, you use the `WP PortletServiceRegistryService` property in the portal WP Content Access Service in the WebSphere Integrated Solutions Console. For more information, see the topic about Content Access Service and go to the section about Proxy protocol and port settings.

Delayed cleanup of deleted portal pages

Get an overview of the cleanup service for portal pages and their dependent resources.

Portal resources, such as pages, components or portlet instances are kept persistent in the portal database. When an administrator deletes a page, all its derived pages and dependent resources and content are deleted with it. The actual deletion can take considerable time, depending on the size of the portal and the number of resources affected by the deletion. Therefore, if the deletion takes place immediately after the user completes the deletion task, this might impact portal performance for users. On the other hand, if the deletion is delayed and scheduled for an off peak time, it will not affect portal response time and thereby user experience.

The delayed deletion of pages is performed by a cleanup service.

"Configuring immediate or delayed deletion of portal pages" on page 279
You can configure the deletion cleanup to happen either immediately when you delete the page or later.

"Configuring your own delayed deletion schedule by using the XML configuration interface" on page 279
You can use the IBM WebSphere Portal Express XML configuration interface to configure the delayed deletion schedule according to your requirements. You can define a daily, weekly, or monthly schedule. You can also use the XML configuration interface to run individual cleanup tasks at arbitrary intervals.

Configuring immediate or delayed deletion of portal pages:

You can configure the deletion cleanup to happen either immediately when you delete the page or later.

About this task

- **Immediate deletion**. This means that the page and all resources that depend on it are deleted immediately after the user completes the action for the deletion.
- **Delayed deletion**. This means that the page is marked for deletion, but the page and all dependent resources are actually deleted later.

  Note: Once the page has been marked for deletion, users cannot view or otherwise access the page any longer.

You can change between the immediate and delayed deletion of portal pages by configuring the property value `scheduler.cleanup.enabled` in the portal Data Store Service in the WebSphere Integrated Solutions Console. Set the following Data Store Service configuration parameters as required:

scheduler.cleanup.enabled = (true)

Determines whether deletion of portal pages is performed later by the scheduled cleanup service, or immediately after the user completes the deletion task. This affects the deletion of portal pages and all their dependent resources, such as components and portlet instances.

true This setting enables delayed deletion of portal pages by the scheduled cleanup service. Pages and dependent resources are deleted by the scheduled cleanup service.

false This setting disables deletion of portal pages by the scheduled cleanup service. Deletion of the pages and their dependent resources is triggered immediately when the administrative user runs the cleanup task.

Set this property to `true` if you want the deletion of pages to be delayed and performed by the scheduled cleanup service. This property defaults to true, if the portal installation is based on a version of WebSphere Application Server that includes the Scheduler service.

By its default schedule configuration, the cleanup service runs weekly, on Saturdays at 8 pm.

Configuring your own delayed deletion schedule by using the XML configuration interface:

You can use the IBM WebSphere Portal Express XML configuration interface to configure the delayed deletion schedule according to your requirements. You can define a daily, weekly, or monthly schedule. You can also use the XML configuration interface to run individual cleanup tasks at arbitrary intervals.

Procedure

1. Edit the following sample XML configuration file:
   - IBM i: *PortalServer_root*`/PortalServer/doc/xml-samples/Task.xml`
   - Linux: *PortalServer_root*`/PortalServer/doc/xml-samples/Task.xml`
   - Windows: *PortalServer_root*`\PortalServer\doc\xml-samples\Task.xml`
2. Uncomment and edit the entry that corresponds to the scheduled time that you want to set.

Note: By default, the `Task.xml` file is set to run the scheduler immediately one time.

3. Save your changes.
4. Import the modified `Task.xml` file by using the XML configuration interface (XMLAccess).

What to do next

Notes:

1. For your customized schedule to be observed by the portal, you must enable the **`scheduler.cleanup.enabled`** property by setting it to `true` in the WP Data Store Service. You do so in the resource environment providers in the WebSphere Integrated Solutions Console. For more information, read *Configuring immediate or delayed deletion of portal pages*. For more information about portal configuration properties and how to set them, read *Setting service configuration properties* and *Portal service configuration*.
2. If you delete a page with an object ID and then re-create it with XML configuration interface, you might receive an error message. The message indicates that the operation was canceled because it would cause a duplicate key value.
3. When you run the cleanup task, the XML configuration interface schedules only the task to be run in WebSphere Application Server and returns. It does not mean that WebSphere Application Server runs the task immediately. To determine when a task started and ended, check the `SystemOut.log` log file for the messages EJPDE0005I and EJPDE0006I. These messages confirm that the cleanup task successfully completed. After you confirm, you can run the XML script for re-creating a page with the same object ID as it had before the deletion.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

IBM WebSphere Portal Express comprises a framework of configuration services to accommodate the different scenarios that portals of today need to address. You can configure some of these services.

Deleting orphaned data

You use the SLCheckerTool to delete orphaned data in the database.

Before you begin

When portal resources are deleted, dependent resources that are stored in a different database domain are not deleted at the same time. These remaining resources are still available for backup scenarios or other production lines that might share the database domain. For example, when an administrator deletes pages, the user customization to the deleted pages are not deleted. The SLCheckerTool enables the detection of orphaned data that is not needed any more by any of the production lines that share the domain. You can use the SLCheckerTool to prepare an XML script for later deletion of the orphaned data by the XML configuration interface.

The SLCheckerTool is included in the file wp.db.slchecker.jar in the following directory:

- Linux : *wp_profile_root*/PortalServer/bin/slcheckertool.sh
- IBM i: *wp_profile_root*/PortalServer/bin/slcheckertool.sh
- Windows: *wp_profile_root*\PortalServer\bin\slcheckertool.bat

You start the SLCheckerTool by using the following shell scripts:

- Linux : *wp_profile_root*/PortalServer/bin/slcheckertool.sh
- IBM i: *wp_profile_root*/PortalServer/bin/slcheckertool.sh
- Windows: *wp_profile_root*\PortalServer\bin\slcheckertool.bat

To prepare and complete deleting orphaned data, you also complete some steps by using the XML configuration interface. For details about the XML configuration interface and how to use it refer to the appropriate topics. A sample XML script for exporting orphaned data that are listed enables the preparation of the orphaned data for work with the SLCheckerTool.

About this task

Notes:

1. Before you delete the orphaned data by using the SLCheckerTool, secure your databases by making a backup.
2. To delete all orphaned data, you must include every production line that shares the database domain. Otherwise, resources that are still valid in a skipped production line might be unintentionally removed.

To delete the orphaned data, proceed by the following steps. For each step, use the target file from the previous step as the source file.

Procedure

1. Run the cleanup service to delete resources that are marked for delayed deletion. To run the cleanup service, use the XML configuration interface and the XML sample file Task.xml as the input.
2. Create a full export that includes orphaned data of each production line that shares the particular domain. To complete this step, use the XML configuration interface and the XML sample file ExportIncludingOrphanedData.xml.
3. Use the SLCheckerTool to create an XML script file to delete the orphaned data. Complete this step with the substeps given later. Observe the following rules:
   - For each step, start the SLCheckerTool with the appropriate parameters as described under that step.
   - Replace all file name variables (given in italics) by the complete directory path location and file name.
   - For each step, use the target file or files from the previous step as the source file or files.

   Start the SLCheckerTool by using the following shell scripts:
   - Linux : *wp_profile_root*/PortalServer/bin/slcheckertool.sh
   - IBM i: *wp_profile_root*/PortalServer/bin/slcheckertool.sh
   - Windows: *wp_profile_root*\PortalServer\bin\slcheckertool.bat

a. Find candidates for orphaned data in each production line. Repeat this step for each production line, but specify a different output file for each iteration. Otherwise, the results are overwritten. Use the following parameters:

   --find-candidates -s *xml_source_file* **-d** *cand_target_file* **-domain** *domain_identifier*

   Use these parameters to find the candidates for orphaned data within one production line. Replace the variables as follows:

   xml_source_file

   Specify a full XML export file that you created in step 2, the step for creating the XML export including orphaned data.

   cand_target_file

   Specify the target file. The orphaned data candidates are saved to that file.

   domain_identifier

   Specify the database domain in which you want candidates to be searched. Valid values are `comm` for the community database domain, `cust` for the customization database domain or `all` for both database domains.

b. Identify the orphaned data. Complete this step once, but with all the candidate files generated by previous step at the same time. This step determines the intersection of all result files, that is, the data that are orphaned in all production lines. Use the following parameters:

   --identify-orphans -s cand_source_files_and_directories -dorph_target_file

   Use these parameters to identify the orphaned data by matching the information from all the candidate files. Replace the variables as follows:

   cand_source_files_and_directories

   Specify all files that were generated as `cand_target_files` by the substep for finding the candidates. If you specify one or more directories with the files, make sure that these directories contain only candidate files and no other files.

   orph_target_file

   Specify the target file. The identified orphaned data is saved to that file.

c. Generate an XML script file. You can later use that script for deleting the orphaned data. Use the following parameters:

   --delete-orphans -s *orph_source_ file* **-d** *xml_target_file*

   Use these parameters to generate an XML script file for deleting the orphaned data. Replace the variables as follows:

   orph_source_ file

   Specify the file that was generated as the `orph_target_file` in the substep for identifying the orphaned data.

   xml_target_file

   Specify the target file. This file will be the XML script file that contains the information about the orphaned data. You can later use this file to delete the orphaned data.

4. Optional: You can check whether all production lines were considered during the creation of the XML script file. To check, review the comment in the file header. The header contains information about all full exports that were used.
5. Delete the orphaned data by starting the XML configuration interface with the XML script that you obtained as the `xml_target_file` with the orphaned data in the substep for generating the XML script. You must start the XML configuration interface with the XML script only on one production line that shares the database domain. This step deletes the orphaned data for all production lines that share that database domain.

Results

You removed all orphaned data from your portal database.

Related tasks:

"Preparing the deletion of orphaned resources" on page 1081
You can use the XML configuration interface to delete orphaned data from your WebSphere Portal Express.

Setting service configuration properties

IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

About this task

The configuration for each service is stored in and accessible through the WebSphere Integrated Solutions Console. Each service is registered as a separate resource environment provider with custom properties that represent the service configuration. Initially in a default installation, only the most common properties are shown as custom properties. You might need to add more properties with key and value as required. Or you might want to remove properties that can be used with their default values or are no longer required.

Procedure

To set configuration service properties, proceed as follows:

1. Select the appropriate WebSphere Integrated Solutions Console, depending on your environment:
   - If your portal runs stand-alone, use the local console.
   - If your portal is installed in a cluster, use the console of the deployment manager.
2. Start the WebSphere Integrated Solutions Console by entering the following string in the **URL location** field of a web browser:

   `http://example.com:admin_port/ibm/console`

   where *example*`.com` is the name of your server and *admin_port* is the port that is assigned to the WebSphere Integrated Solutions Console.
3. Go to **Resources** > **Resources Environment** > **Resource Environment Providers**.
4. In the Resource Environment Providers page, make the appropriate selection. Select the appropriate node or cluster from the scopes list, or clear the **Show Scope** check box and select one of the following options, depending on your portal environment:

- If your portal is running as a single server, select **Browse Nodes** and select the node.
- If your portal is installed in a cluster, select **Browse Clusters** and select the portal cluster.

5. Select the service in which you want to change a property.

   Note: In the list, the service names are preceded by a product prefix and a blank space. For example, the WebSphere Portal Express configuration service is identified as `WP ConfigService`. The Web Content Manager configuration service is identified as `WCM WCMConfigService`.
6. Click **Custom Properties**.
7. Do one of the following tasks as needed:
   - To set a property, select that property and change its value.
   - If the property that you want to set does not exist yet, create it new. When you create a new property, use `java.lang.String` as its type and do not mark the property as **required**. Otherwise, you might not be able to delete it later.
   - Select one or more properties for removal.
8. When you are done, click **Save** at the start of the page under **Message(s)**.
9. Click **Save** again when prompted to confirm your changes.
10. If you have a cluster configuration, replicate your changes to the cluster.
11. Restart the server for the changes to become effective.

By alternative, you can also set the properties in the properties files and then enable them by using a configuration task.

Notes:

- This option for setting service configuration properties is not available for all properties.
- Changes to properties configuration files do not affect runtime properties until you run the configuration tasks that are described in the following procedure.

12. Locate the properties file for the appropriate Resource Environment Provider. The properties files are in the directory *wp_profile_root*`/PortalServer/config`. If there is no default properties file for a Resource Environment Provider, for example, WP_DynamicContentSpotMappings, create a new properties file as follows:
    a. Create a properties file by using a text editor.
    b. Give the file the name of the Resource Environment Provider without the `WP` prefix. Save the file in the directory *wp_profile_root*`/PortalServer/config`. Example:

       wp_profile_root`/PortalServer/config/DynamicContentSpotMappings.properties`
13. Edit the properties file and modify or add configuration properties as needed. Example:

    ```
    newDynamicContent=res:/CustomThemeContext/themes/html/MyTheme/dynamicContent.jsp
    ```
14. Save the updated properties file.
15. Run the appropriate configuration task to update the configuration properties: For changes to WebSphere Portal Express properties files to take effect, run the following task from the *wp_profile_root*`/ConfigEngine` directory.
    - Windows: `ConfigEngine.bat update-properties -DPortalAdminPwd=`*password* `-DWasUserid=`*username* `-DWasPassword=`*password*

- Linux : `./ConfigEngine.sh update-properties -DPortalAdminPwd=password -DWasUserid=username -DWasPassword=password`
- IBM i: `ConfigEngine.sh update-properties -DPortalAdminPwd=password -DWasUserid=username -DWasPassword=password`

For changes to Web Content Manager properties files, run the following task from the *wp_profile_root*/ConfigEngine directory.

- Windows: `ConfigEngine.bat update-wcm-service-properties -DPortalAdminPwd=password -DWasUserid=username -DWasPassword=password`
- Linux : `./ConfigEngine.sh update-wcm-service-properties -DPortalAdminPwd=password -DWasUserid=username -DWasPassword=password`
- IBM i: `ConfigEngine.sh update-wcm-service-properties -DPortalAdminPwd=password -DWasUserid=username -DWasPassword=password`

Results

Your service configuration properties updates are now in effect.

"Overview of configuration services" on page 287
Get an overview of the WebSphere Portal Express configuration services available for the portal.

"Portal service configuration" on page 289
IBM WebSphere Portal Express comprises a framework of configuration services to accommodate the different scenarios that portals of today need to address. You can configure some of these services.

"Web Content Manager service configuration" on page 353
Configuration services for IBM Web Content Manager contain settings for the general operation of the web content system, including settings for messaging, pre-rendering, and searching.

Related concepts:

"Pre-render methods" on page 2090
Pre-rendering can be configured to run automatically, or you can manually pre-render a website by using a URL.

"Syndication properties" on page 454
You can tailor the syndication behavior of your web content environment by changing configuration settings such as the syndication interval and automatic syndication.

"Web content authoring options" on page 396
You can tailor the authoring behavior of your web content environment by changing configuration settings such as workflow, profiling, and version control.

"Data cache configuration" on page 425
Data caching is used to cache data that is retrieved by the IBM Web Content Manager application from external sources that use connect tags or by requests that are made through URLs.

http://www-10.lotus.com/ldd/portalwiki.nsf/dx/Web_content_cache_configuration_wcm8

"How to configure authoring tools components" on page 1895
Authoring tools components that are rendered in a web content viewer allow you to create, read, edit, delete, approve, or reject content items directly in the web content viewer, instead of requiring you to browse to the IBM Web Content Manager authoring portlet to run the same action. The web content viewer either opens a window from the current page or redirects the user to another portal page that contains the authoring portlet.

"How to configure authoring portlet search" on page 402
You can change the configuration of the authoring portlet to change how search works.

"How to access the pre-rendered site" on page 2091
Pre-rendered sites are accessed either through IBM Web Content Manager, or through a web server.

"Pre-rendering options" on page 425
You can enable pre-rendering so that content can be viewed either through a IBM Web Content Manager application or as a stand-alone site that is accessed through a web server.

"Creating category selection trees" on page 1823
You use category selection trees to allow users to personalize menus.

"Text, rich text and HTML elements" on page 1812
You use the short text, text, rich text, and HTML elements to store blocks of text, but each has slightly different properties.

"Syndication troubleshooting" on page 459
If you encounter issues when syndicating, there are some common methods available to troubleshoot these issues.

"User roles and access" on page 1560
Different users will have different access to items and functions in your system depending on the role they are assigned. Roles can be assigned at the library level, and also assigned on individual items.

 Using the web content member fixer task

"Cache tuning for federated documents" on page 410
The federated documents feature uses the document list cache, the document data cache, and the feed type cache to manage information about the list of documents, the document data, and the types of feeds a server provides.

Related tasks:

"Enabling connect tags" on page 435
Enable connect tags to reference web content components and apply customized caching to the components.

"Enabling email" on page 435
To use the email workflow action, you must configure Web Content Manager to use your SMTP server.

Using a page navigation element
A page navigation element provides navigation controls that are used to browse through a set of results that are generated by menus, navigators, personalization, and search elements.

"Web Content Manager" on page 392
Set up a content server by installing IBM Web Content Manager in various deployments to provide robust and flexible environments for web content development and delivery. After you install the content server, more configuration steps must be completed according to the role that the server plays in your web content environment.

"Configuring remote server access for links" on page 404
Before you can add links to files and documents that are stored in remote content management systems into web content elements, you must configure your server with information about the remote system and the settings that are used to handle communication with the system.

"Configuring access to remote systems for federated documents" on page 406
To retrieve metadata information for documents on remote content management systems, configure the federated documents feature with information about the remote system and the settings that are used to handle communication with the system.

"Filtering the content model" on page 2869
By applying filters to the content model, you can exclude parts of the page hierarchy from the content model. Filtering is performed based on request data and metadata assigned to the pages.

Overview of configuration services:

Get an overview of the WebSphere Portal Express configuration services available for the portal.

The following table lists the configuration services:

1. The first column gives the names of the services and provides links to the respective topics for those services that you can configure in the WebSphere Integrated Solutions Console.
2. The second column gives the name of each service by which you can access the service in the WebSphere Integrated Solutions Console.
3. The third column lists the related properties files.

Note: The configuration for each service is stored in the WebSphere Integrated Solutions Console. You can change the configuration only there.

"Web Content Manager service configuration" on page 353	Service name in the WebSphere Integrated Solutions Console	Properties file
"Web Content Manager search service" on page 359	WCM_SearchService	SearchService.properties

There is a number of other Web Content Manager configuration services. The Web Content Manager properties files are located in the *wp_profile_root*/PortalServer/wcm/shared/app/config/wcmservices directory.

Portal service configuration:

IBM WebSphere Portal Express comprises a framework of configuration services to accommodate the different scenarios that portals of today need to address. You can configure some of these services.

The configuration for each service is stored in and accessible for configuration through the WebSphere Integrated Solutions Console. In the WebSphere Integrated Solutions Console, the portal configuration services are spelled as one word, for some services abbreviated, and preceded by the letters WP. Example: In the WebSphere Integrated Solutions Console, the portal Configuration Service is listed as **WP ConfigService**. For more information about how to set properties see the topic about Setting service configuration properties.

Notes:

- The following topics describe the services that can be of interest to the portal administrator. Services that are not described in the following are purely for portal internal usage. Do not modify them in any way.
- The following topics describe the portal services and their configuration properties. In these lists, the values given in parentheses are the default values. Properties given with a value of <none> have no default values.
- You configure the portal configuration services in the WebSphere Integrated Solutions Console. You cannot set the service configuration properties by simply changing the property value in the properties file and restarting the portal.
- For details about how to export a configuration from an existing portal and import it to another portal, refer to the documentation about the portal XML configuration interface.

  "Administrator Unique Names Mapping Service" on page 291
  Administration portlets and themes create URL links to other administration portlets and pages. If these links were hardcoded, they would no longer be usable if you changed the unique names of these pages. Therefore a service for obtaining those unique names is provided in the portal Administrator Unique Names Mapping Service. This service contains properties with key-value pairs that map internal keys to the actual unique names that are assigned to the referenced pages.

  "Cache Manager Service" on page 292
  The portal Cache Manager Service is responsible for managing the different caches used in WebSphere Portal Express.

  "Common Component Configuration Service" on page 295
  You can use the Common Component Configuration service to configure the behavior of the common components framework, the enabler widget container, and the client-side APIs.

  "Configuration Service" on page 297
  The portal Configuration Service is responsible for collecting the most essential configuration data of the IBM WebSphere Portal Express engine.

"Portlet Container Service" on page 346
The portal Portlet Container service provides properties for portlet filtering.

"Project Identification Service" on page 346
The Project Identification Service provides access to the identifier for a currently selected project in IBM Web Content Manager. Projects enable you to make changes to a set of items and publish those changes at the same time.

"Registry Service" on page 346
The portal Registry Service loads and caches a small number of objects that are regularly accessed in the engine. This improves performance. However the trade off is that the cached objects can be stale compared to their database counterparts. This applies particularly in a cluster environment.

"State Manager Service" on page 347
The portal State Manager Service is the access point for managing the navigational state of the portal. The navigational state represents the current view of portal resources as displayed to a user.

"Virtual Portal Configuration Service" on page 352
The Virtual Portal configuration service (WP VirtualPortalConfigService) enables you to specify properties for the default virtual portal and for specific virtual portals.

Administrator Unique Names Mapping Service:

Administration portlets and themes create URL links to other administration portlets and pages. If these links were hardcoded, they would no longer be usable if you changed the unique names of these pages. Therefore a service for obtaining those unique names is provided in the portal Administrator Unique Names Mapping Service. This service contains properties with key-value pairs that map internal keys to the actual unique names that are assigned to the referenced pages.

In the WebSphere Integrated Solutions Console, the portal Administrator Unique Names Mapping Service is listed as **WP AdminUniqueNamesMappingService**.

Note: If you change the unique name of a portal administration page by using the Manage Unique Names portlet, you also need to update that name in the properties. This is required so that the theme and administration portlets still function.
The available mappings are defined as follows:

```
# ------------------------------------------------ #
# Portal administration page unique names mapping #
# ------------------------------------------------ #
# Internal key           unique name               #
# ------------------------------------------------ #
#
#CONTENT_LAYOUT          = ibm.portal.Content
#APPEARANCES             = ibm.portal.Appearance
#MANAGE_PAGES            = ibm.portal.Manage Pages
#UNIQUE_NAMES            = ibm.portal.Custom Unique Names
#ASSIGN_ROLES            = ibm.portal.Resource Permissions
#PROPERTIES_PORTLET      = ibm.portal.Page Properties
#MY_FAVORITES            = wps.My Favorites
#ORGANIZE_FAVORITES      = wps.Organize Favorites
#SET_PERMISSIONS         = ibm.portal.Locks
#MANAGE_LOG              = ibm.portal.Enable Tracing
#MY_PORTAL               = ibm.portal.Home
#ADMINISTRATION          = ibm.portal.Administration
#PAGE_CUSTOMIZER         = ibm.portal.Page Customizer
#PORTLET_MANAGER         = ibm.portal.Web Modules
#MANAGE_MY_PORTLETS      = ibm.portal.Portlets
```

```
#MANAGE_MY_PORTLET_APPS  = ibm.portal.Applications
#MANAGE_WEBSERVICES      = ibm.portal.Web Services
#IMPORTXML               = ibm.portal.Import XML
#SEARCH_CENTER           = ibm.portal.Search Center
#VIRTUAL_PORTAL          = ibm.portal.Virtual Portal
#LOGIN                   = wps.Login
#SELFCARE                = wps.Selfcare
#APP_PROPERTIES          = ibm.portal.Template and Application Properties
#APP_PARAMETER           = ibm.portal.Template Parameters
#APP_ROLES               = ibm.portal.Application Roles
#APP_TEMPLATES           = ibm.portal.Templates
#APP_MEMBERSHIP          = ibm.portal.Application Membership
#APP_CATALOG             = ibm.portal.Catalog
#APP_LAYOUT              = ibm.portal.Template and Application Layout
#PZN_PICKER_PAGE         = ibm.portal.Personalization.Picker
```

Examples of where these unique names are used are: Theme links for New Page, Edit Page, and Assign Permissions.

Cache Manager Service:

The portal Cache Manager Service is responsible for managing the different caches used in WebSphere Portal Express.

In the WebSphere Integrated Solutions Console, the portal Cache Manager Service is listed as **WP CacheManagerService**.

The portal provides two different types of caches: **shared** and **non-shared**:

Shared caches
The shared caches are cluster aware. This means that deleting an element from the cache on one cluster node results in deleting that element from the corresponding cache instances on all other nodes. This ensures that frequently changing data are kept consistent over the whole cluster installation.

Non-shared caches
The non-shared caches are used for data where cluster awareness is of no concern. This avoids unnecessary network communication overhead.

Plan well ahead and apply special care when modifying these properties. There are two levels of properties:

cacheglobal properties
They specify the default setting which is to be used for all caches unless explicitly overridden by the corresponding cache instance property.

cacheinstance.*cacheidentifier* properties
They are used to override a global setting, for example the size of the cache, for a specific instance of a cache.

Changing some or all of these properties can dramatically improve or impair portal performance. Therefore it is recommended not to change the shared setting for any cache unless the consequences are absolutely understood and agreed. If you want to determine the optimal values for the `size`, `lifetime`, `admit-threshold` and `replacement` properties, monitor the cache properties during the staging phase of your portal installation. Use the Tivoli Performance viewer, that is the WebSphere Application Server PMI client (PMI = Performance Monitoring Interface) to find the optimal settings for your environment.

The properties for the Cache Manager Service for both shared and non-shared caches are listed in the following:

cacheglobal.enabled = [true | false]
cacheinstance.*cacheidentifier*.enabled = [true | false]
Use this property to control whether caching is enabled or not. Use this property with care !

cacheglobal.size = *number*
cacheinstance.*cacheidentifier*.size = *number*
Use this property to define the number of elements that can be put into the cache before eviction takes place. The eviction uses a "near LRU" algorithm.

cacheglobal.shared = [true | false]
cacheinstance.*cacheidentifier*.shared = [true | false]
Use this property to define whether a cluster-aware cache is to be used or not.

cacheglobal.lifetime = *number*
cacheinstance.*cacheidentifier*.lifetime = *number*
Use this property to specify the lifetime of elements in the cache in seconds. When the specified lifetime is up, elements are not discarded from the cache immediately. They are evicted when the next element is inserted. Specifying `-1` means an infinite lifetime. In this case no timeout is applied and the cache entry is never evicted.

randomizePercent = *number*
cacheinstance.*cacheidentifier*.randomizePercent= *number*

Use this property to randomize cache entry lifetimes to some extent. If all entries in a cache have the same lifetime, this can result in high loads on the database when reloading entries, as large amounts of entries are evicted at the same time.

Specify the value for this property as a numeric value given in percent. For example, a value of `25` means that all cache entry lifetimes are up to 25% more or less than the default lifetime (given by the lifetime parameter). No cache entry will have a lifetime less than 50% of the default value, no matter how large you specify the value for this property. By default no value is specified. In this case lifetimes are not randomized, and all cache entries have the default lifetime.

If you set the default lifetime property to infinite by the value `-1` , the lifetime randomization setting is not applied, even if you specify a value for the `randomizePercent` property.

You can view the actual randomized lifetime of a cache entry by enabling tracing for class `com.ibm.wps.services.cache.AbstractCache`.

You can set the following additional properties for non-shared caches. (Setting them for shared caches does no harm, they will be ignored.)

cacheglobal.replacement= [aggressive | moderate | conservative]

cacheinstance.*cacheidentifier*.replacement= [aggressive | moderate | conservative]
Controls the eviction algorithm behavior.

cacheglobal.admin-threshold = *number*

cacheinstance.*cacheidentifier*.admin-threshold = *number*
Admittance threshold. Use this to keep unwanted entries from the cache. An

entry is cached only if it is put into the cache as often as specified by the value for this property. If you want each entry to be cached, set this to zero (`0`).

The cache identifiers are described in the following:

com.ibm.wps.pe.deployedresources
Use this cache instance to cache servlet configuration information and the database representation of all web modules stored in the database.

com.ibm.wps.pe.portletregistry
Use this cache instance to cache the database representation of all portlets stored in the database.

com.ibm.wps.pe.portletdefinition
Use this cache instance to cache the database representation of all portlet applications stored in the database.

The following caches are for social rendering and the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework:

com.ibm.workplace.wcm.pzn.plr.BeanListCache
The bean list cache caches the bean list Java objects that the Digital Data Connector plug-ins return. The DDC plug-ins control the cache key generation for the individual entries and whether the bean lists are automatically removed from the cache during user login. By default, this cache is enabled.

Note: Single entries of this cache can have a size of several MB. Therefore, the default number of cache entries for this cache is much lower than the default of other portal caches. When you use the bean list cache, closely monitor the cache and tune it as required. You might also consider the size of individual cache entries and how to influence it. For more information, read *Configuring the maximum number of items loaded from Connections*.

com.ibm.workplace.wcm.pzn.plr.xml.DocumentCache
The document cache is used by the generic XML DDC plug-in for caching the Document Object Model (DOM) objects for individual source URIs. This cache specifically caches the DOMs for associated item attributes. If an individual associated item attribute is flagged as `shared` in the list-rendering profile, the cache entries are shared between different users. Such shared documents do not get invalidated on user login. Documents that are loaded through non-shared associated item attributes are cached separately per user. These cache entries are automatically invalidated during login. By default, this cache is enabled.

com.ibm.workplace.wcm.pzn.plr.json.DocumentCache
The document cache is used by the generic JSON DDC plug-in for caching the Document Object Model (DOM) objects for individual source URIs. This cache specifically caches the DOMs for associated item attributes. If an individual associated item attribute is flagged as `shared` in the list-rendering profile, the cache entries are shared between different users. Such shared documents do not get invalidated on user login. Documents that are loaded through non-shared associated item attributes are cached separately per user. These cache entries are automatically invalidated during login. By default, this cache is enabled.

com.ibm.workplace.wcm.pzn.plr.ListRenderingCache
The list-rendering cache caches the markup that a specific appearance component generates for a specific bean list instance. If you enable this cache, the updates in the appearance component might not become visible

immediately, as updates to the corresponding IBM Web Content Manager design components do not invalidate this cache. In general, the entries in this cache are invalidated together with the corresponding bean list objects in the bean list cache that is listed earlier. As a result, it is good practice to disable this cache on authoring systems and enable it on delivery systems.

To use this cache, you must use the `ListRenderingCache` rendering plug-in to instrument the Web Content Manager design components that are involved in the markup generation for this cache. For more information, read *Using the list-rendering cache*.

For more information about these caches, read *Digital Data Connector cache tuning*.

Related tasks:

"Configuring the maximum number of items loaded from Connections" on page 2123
You can define a value for the maximum number of social objects that you want the IBM Connections to return when data for a list of social objects is requested.

Related reference:

"Digital Data Connector cache tuning" on page 3297
To improve performance, you can tune the caches for the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

Common Component Configuration Service:

You can use the Common Component Configuration service to configure the behavior of the common components framework, the enabler widget container, and the client-side APIs.

In the WebSphere Integrated Solutions Console, the portal Common Component Service is listed as **WP CommonComponentService**. It provides the following configuration properties:

cc.multipart.enabled = true|false
Use this property to specify whether multipart requests can be used for batch processing. This property applies to using the enabler client-side APIs. The portal theme uses this property primarily during bootstrap when it loads remote data.

cc.multipart.correlatehosts = true|false
Use this property to specify whether you want hosts in multipart requests to be correlated.

cc.multipart.pageLoadOptimization
This property is optional. You can use it for user interface components to modify page loading for optimization if required. If you do not specify a value for this property, it defaults to `false`.

cc.multipart.pageLoadOptimizationTheme
This property is optional. You can use it for user interface components to modify theme loading for optimization if required. If you do not specify a value for this property, it defaults to `false`.

cc.multipart.pageLoadOptimizationAppWidgets
This property is optional. You can use it for user interface components to modify widget loading for optimization if required. If you do not specify a value for this property, it defaults to `false`.

cc.theme.context
Use this property to specify the context root of the default theme.

cc.theme.id
Use this property to specify the ID of the default common component theme.

cc.enabler.sandboxenabled
Use this property to specify whether the sandbox is enabled. If you have widgets that are loaded in a sandbox, the widgets are loaded inside an iFrame. Loading them inside an iFrame keeps them from interacting with the other JavaScript and DOM resources on the same page.

cc.enabler.subdomains
Use this property to specify an array of strings with the names of the subdomains that are used to create sandboxed widgets. iFrames that load sandboxed iWidgets use subdomains to create an alternative domain rather than the default one so that cross-domain browser security settings are put in place. Use this property to specify the subdomains that you set up that can be resolved correctly through DNS.

cc.enabler.serverdomain
Use this property to specify the name of the server domain that you use with the sandbox.

cc.enabler.useridattribute
Use this property to specify the user registry attribute that uniquely identifies users.

cc.enabler.user.displaynameattribute
Use this property to specify the user registry attribute that is used to display the name of users. The user registry attribute is the attribute on the object that represents a user in the user registry. For example, LDAP or other, that refers to the user's name to display.

cc.enabler.groupidattribute
Use this property to specify the user registry attribute that uniquely identifies groups.

cc.enabler.group.displaynameattribute
Use this property to specify the user registry attribute to is used to display the name of groups.

cc.enabler.acceptedPagesParentNode
Use this property to specify the navigation node that becomes the parent of shared pages that users accept. However, the shared pages parameters were deprecated in WebSphere Portal Express 8.5.

cc.enabler.remote-cache-expiry
Use this property to specify the number of seconds for the remote expiration time for new pages. The amount of time specifies how long cache entries for newly created pages can be cached.

cc.page.autowiredefaultenabled
Use this property to specify whether widgets are autowired automatically.

cc.isDebug = true|false
Use this property to specify whether you want debugging to be enabled or not.

cc.traceConfig
Use this property to specify an array of strings that are used to set client side tracing on user interface components. Use the exact syntax of a JavaScript array, including brackets and double or single quoted values for each item. Example: `["com.ibm.mashups.enabler.*","com.ibm.pb.*"]`

cc.productname = *product name*
Use this property to specify the product name; user interface components such as themes can use the value from this property. Themes or other user interface components can use this property to display a global brand name. For example, in a default portal installation this property is used to specify the product display name WebSphere Portal Express.

cc.theme.autoEditNewPages = true|false
Use this property to specify whether you want blank pages to go into edit mode automatically (`true`) or not (`false`).

cc.theme.alwaysRefreshOnPageSave
Use this property to specify whether you want the page always to refresh when it is saved (`true`) or not (`false`).

The following list gives the navigational state parameters. Use them to set the configuration for the navigational state model. By default the `w` (width), `h` (height), and `st` (state) attributes are persisted to persistence store and are not included in the URL. The page identifier (PID) of the current page and the space identifier (SID) of the current space are added to the URL. In general all navigational state parameters that are not defined in the parameter `navstate.persistence.pstore` are added to the URL. This way all widget navigational state parameters are added to the URL.

cc.enabler.navstate.persistence.url = ['sid','pid']
Use this property to specify an array of strings that specify which attributes of the navigation state are stored in the URL.

cc.enabler.navstate.persistence.pstore = ['w','h','st']
Use this property to specify an array of strings that specify which attributes of the navigation state are stored in the persistence store.

cc.enabler.navstate.persistence.url.limit = 10
Use this property to specify the limit on how many widgets can store their navigation state in the URL.

cc.enabler.navstate.persistence.url.splimit = 10
Use this property to specify the limit on how many shared parameter sets can be stored through encoding in the URL.

Adding new parameters

You can add new parameters by prefixing the key with `dyn:`, for example: `dyn:com.ibm.mashups.`*`someKey`* `=` *`someValue`*. The new name-value pair must be of type string. Restart the server after you add the new parameter.

Configuration Service:

The portal Configuration Service is responsible for collecting the most essential configuration data of the IBM WebSphere Portal Express engine.

In the WebSphere Integrated Solutions Console, the portal Configuration Service is listed as **WP ConfigService**.

Notes:

- Many of the properties that are listed here are set by the installation procedure. Therefore, plan ahead and apply special care when you modify these properties.

- WebSphere Portal Express and the WebSphere Integrated Solutions Console also provide a CP Configuration Service; this service has properties for tagging and rating only.
- The Configuration Service also includes the configuration properties for WSRP services. They are listed and described in the context of the respective WSRP topics for which they are relevant.

was.home = (${WAS_INSTALL_ROOT})
This path is the absolute path to the installation directory of WebSphere Application Server.

wps.home = (${WPS_INSTALL_ROOT})
This path is the home (or install) directory of the WebSphere Portal Express.

redirect.login = (true)
Turns on user-defined redirection after successful login. If a URL is specified under `redirect.login.url` listed later, that URL is used as the URL for the redirection. If no URL is specified, the portal determines the default page for the current user and sends a redirect to that page in the protected portal area.

redirect.login.ssl = (false)
Turns on SSL in the system-defined redirection after successful login. If no URL is specified for the property `redirect.login.url` listed in the following, the redirect URL uses HTTPS for the protocol.

redirect.login.url [optional] = <none>
Specifies the URL for redirection after successful login. If no URL is specified, the portal determines the default page for the current user and sends a redirect to that page in the protected portal area. This setting does not affect implicit logins, such as single sign-on with LTPA token or through an external security manager.

redirect.login.authenticated.url [optional] = <none>
Specifies the URL for redirection after the first access to a protected page when the user is authenticated by an external security manager (TAI) and a portal session does not exist yet. If no URL is specified, the portal either displays the protected page that was originally requested, or, if session resume is enabled, the last page that the user accessed in the previous session.

redirect.logout = (false)
Turns on user-defined redirection after successful logout. If a URL is specified under `redirect.logout.url` listed later, that URL is used as the URL for the redirection. If no URL is specified, the portal determines the default page in the public portal area and sends a redirect to that page.

redirect.logout.ssl = (false)
Turns on SSL in system-defined redirection after successful logout. If no URL is specified, the redirect URL uses HTTPS.

redirect.logout.url = <none>
Specifies the URL for redirection after successful logout. If no URL is specified, the portal determines the default page in the public portal area and sends a redirect to that page.

ldapserviceattributename.attribute [optional] = (*uid*)
Use this property to determine that portal workflow integration uses a dedicated user attribute when individual users on WebSphere Process Server are identified. Set this property to the user attribute that is used by WebSphere Process Server during task authorization. WebSphere Process Server uses the J2EE principal name for this purpose. By default the J2EE principal name maps to the `uid` user attribute in most LDAP servers, except for Domino servers.

Domino LDAP servers use the `cn` attribute by default, therefore for such a configuration set the `ldapserviceattributename.attribute` to the value `cn`. This property is optional.

multiple.realms.enabled = (false)
Multiple Realms Support properties to allow login with uid@realm.

multiple.realms.login.default.realm = <none>
Multiple Realms Support properties to allow login with uid@realm.

multiple.realms.user.dn.template = <none>
Multiple Realms Support properties to allow login with uid@realm.

host.name = <none>
The default is that no value exists for `host.name.`. In this case, portal URLs start with the host name of the incoming request. If you want the host name in URLs be static, you enter a host name here. For example, in a cluster installation you can enter the name of the network traffic dispatcher here. If a host name is entered, this entry is used to create the portal URLs.

host.port.http = <none>
The HTTP port (normally 80).

host.port.https = <none>
The HTTP-SSL port (normally 443).

security.css.protection = (true)
This property determines whether Cross-Site-Scripting security protection is turned on. The default is `true` for enabling the protection.

redirect.commands = (false)
Specifies that a portal command is followed with an HTTP redirect. This way URLs can be bookmarked. Using this feature results in a certain performance. Therefore, it must be used only if needed.

uri.context.path = (/wps)
The context path under which the portal is running.

uri.context.path.facade = (/wsrp)
The context path for the additional WAR file that is used as a facade web application for your WSRP implementation. With this path, you can use Secure Socket Layer (SSL) with Client Authentication for WSRP and simultaneously use other means of authentication for the portal, for example form based authentication. This separation is required as J2EE allows only for one authentication mechanism per WAR file.

uri.home.public = (/portal)
The servlet context of the portal engine for public (or anonymous) pages, that is, pages that users can view without entering a user ID or password.

uri.home.protected = (/myportal)
The servlet context portal engine for protected (or personal) pages, that is, pages that users can view only by entering a user ID and password.

uri.home.doc = (/doc)
The servlet context of the portal engine for the documentation area.

uri.home.substitution = (false)
Determines whether a public URL must be translated to a protected URL if a user session exists.

Important: To preserve the original behavior and design assumptions of WebSphere Portal Express URLs, set the value of the **uri.home.substitution** property to `true`.

Uri.home.substitution controls the behavior of WebSphere Portal Express when a user who is already logged on to the IBM WebSphere Application Server environment on which WebSphere Portal Express is running uses a `/portal` URL to access WebSphere Portal Express.

The original default behavior of WebSphere Portal Express when a logged-in user made a `/portal` request and the **uri.home.substitution** property was either not set or set to `false` was to log out the user and redirect them to the login page. Setting the **uri.home.substitution** property to `true` changes the behavior so that WebSphere Portal Express translates the public URL to a protected URL by redirecting the user to a `/myportal` URL version of the same request without logging out the user. This behavior is how most users want WebSphere Portal Express to function.

A setting in WebSphere Application Server security, called **use available authentication**, affected the behavior of WebSphere Portal Express URLs. The **use available authentication** setting is now set to `true` by default in WebSphere Application Server. When set to `true`, this setting directs WebSphere Application Server to build a security context for requests to unprotected URLs, specifically the `/portal` URL, if possible. More specifically, WebSphere Application Server builds this security context when valid credentials such as an LtpaToken are recognized on the inbound request. In this case, a request to the `/portal` URL by a logged in user does not automatically log out the user and redirect them to the login page. Instead, the request is processed, but in an inconsistent manner. Many things appear to work properly as if the user was recognized as logged in. However, some subtle functional errors might occur, specifically when the rendering of the response embeds secondary requests to the WebSphere Portal Express **contenthandler** function. Therefore, to achieve the most correct operation, set the **uri.home.substitution** property in the **WP ConfigService Resource Environment Provider** to `true`.

Setting the **uri.home.substitution** property to `true` ensures that even when a request to the `/portal` URL is forwarded by WebSphere Application Server with a security context, WebSphere Portal Express still redirects the user to a `/myportal` version of that same URL. This behavior maintains the original design assumption of using two URL entry points into WebSphere Portal Express, one for anonymous access and one for authenticated access.

Note: If you want to preserve the original behavior of WebSphere Portal Express when **uri.home.substitution** is not set or is set to `false`, see the property **logout.user.onpublic** and the following technote, Default triggers for implicit logouts changed in WebSphere Portal v8.

wsrp.resourceproxy.basic.auth.credentialslot = <none>
On a WSRP Consumer portal, you can use this property to specify a credential vault slot that contains the user ID and password credentials. The resource proxy servlet uses the credentials from the credential vault slot when resources that are protected by HTTP basic authentication are fetched. The user ID and password are sent to all remote resources that are referenced in the markup of the remote WSRP portlet.

wsrp.resourceproxy.no.header.forwarding = <none>
On a WSRP Consumer portal, you can use this property to specify the list of HTTP headers that are not forwarded from the client request in addition to the

host header and cookie headers. The host header and cookie headers are never forwarded independent of how this property is set.

Persistent session properties

Use these properties to configure session persistence for users. For more information about persistent session state and its possible options, see the topics about *Configuring user session persistence*.

persistent.session.level = (0)

Determines the level on which the persistent session must operate. If you set this property to a value of 3, this setting does not affect implicit logins, such as single sign-on with LTPA token or through an external security manager.

persistent.session.option = (0)

Determines whether the user gets the option to resume the session. If you set this property to 0, the level setting for the property **persistent.session.level** is applied during login, and the user has no choice whether to resume the previous session or not. If you give users the resume option by setting this property to 1, you must configure the persistent session preservation level by setting the property **persistent.session.level** to 1 or 2.

timeout.resume.session = (false)

Determines whether resuming the session after a session timeout requires user authentication. The default value is false. If this property is set to false and the user tries to continue working after a session timeout, the portal shows an error message that states the session is timed out and the user must log in again. If you set this property to true, the portal ignores the session timeout and does not show the error message. The user can resume the previous session without authentication and continue to work. In both cases, the previous session is resumed according to the setting of the persisted.session.level property.

session.security.use.errorcode = (true)

Use this property to specify whether the portal does a redirect or displays an HTTP error, if session security support is enabled for the portal server and the user in the session does not correspond to the authenticated user in the request. Session security support is a hardening feature of WebSphere Application Server. You can activate it for each application server in the WebSphere Integrated Solutions Console under the **Web Container Settings** > **Session Management** section. If this session security support is active, the application server checks for each authenticated request whether the user who owns the current session matches the user who originated the request. For example, this authentication can be determined by the LTPA token. The portal service configuration property specifies how the portal behaves, if it detects a mismatch between the session user and the authenticated user.

If you set this property to true, the portal returns the HTTP error code that you define by the property session.security.errorcode listed later. This typically results in an appropriate error message to be displayed.

If you set this property to false, you can specify a redirect URL by using the property session.security.redirecturl listed later. For example, you can redirect to a specific error page, which is then displayed to the user.

By default this property is set to true.

For more information about session security support in general, see the appropriate version of the *WebSphere Application Server information center* for your installation.

session.security.errorcode = (409)
Use this property to specify the HTTP error code that is returned if all of the following conditions apply:

1. Session security support is enabled in the WebSphere Application Server.
2. The property `session.security.use.errorcode` listed earlier is set to `true`.
3. A mismatch of the user in the session and the authenticated user is detected.

You must specify a valid HTTP error code. The default is error code 409.

session.security.redirecturl = <none>
Use this property to specify the redirect URL to which portal redirects if all of the following conditions apply:

1. Session security support is enabled in the WebSphere Application Server.
2. The property `session.security.use.errorcode` listed earlier is set to `false`.
3. A mismatch of the user in the session and the authenticated user is detected.

If the property `session.security.use.errorcode` listed earlier is set to `false`, you must specify a value for this property. This property has no default.

portal.session.protection = (true)
Use this property to specify that, for each authenticated portal request, portal checks whether the user in the portal session matches the calling user of the current request. If this portal check results in a mismatch, the portal invalidates the existing session and creates a new one for the calling user to make sure that both identities match. The portal provides this hardening feature, which is independent of the session security support that is provided by WebSphere Application Server. By default this property is set to `true`, therefore the portal checks by default.

portal.enable.filtering = (true)
This flag determines whether the portal must use Portal Filtering or not. The default is `true`.

portlet.url.find = <none>
URL that is used for find and set in global settings portlet.

portlets.unauthorized.visible = (false)
Determines what a user sees whether they are not authorized to view a portlet.

portletcontainer.std.custom.windowStates = <none>
This property defines custom window states that are handled by the portal. This action allows portlets to specify custom window states as defined in the Java Portlet Specification 1.0. The portal allows portlets to generate URLs and so start other portlets with a custom window state if both of the following preconditions apply:

- The started portlet specifies a custom window state in its deployment descriptor (`portlet.xml`).
- That window state is registered by using this property.

The property value is a comma-separated list of custom window states. For example, `portletcontainer.std.custom.windowStates = winState1, myWinState`.

allow.derived.titles = (true)
Determines whether the title and description of derived pages can be redefined by users. If the value is set to `false`, titles and description of pages can be changed only on non-derived pages.

wps.mappingurl.portal_url_identifier = (/!ut/p)
This property determines an identifier for Portal URLs. For the specification of the format of this property, refer to the topic about URL mapping.

Note: With WebSphere Portal Express Version 8.5, URL mappings are deprecated.

wps.mappingurl.enabled = (true)
This property determines whether URL mapping is enabled or not. Possible values are `true` to enable URL mapping, or `false` to disable URL mapping. The default value is `true`.

Note:

- With WebSphere Portal Express Version 8.5, URL mappings are deprecated.
- When you create a URL mapping or create or modify a page, make sure that URL mappings and friendly URLs in your portal do not match, partially overlap, or otherwise interfere with each other. For example, do not use strings such as `home`, `ibm`, `ibm.com`, and do not use strings that are used as URL mappings or friendly URLs in your portal already. Otherwise, several browser redirect loops might occur, sometimes without an error message. To determine such strings, create an export from your portal by using the XML configuration interface and scan the exported XML result output file for the string that you want to use for your URL mapping or for your friendly URL.

wps.mappingurl.invalid = (false)
This property determines how the portal responds to a URL mapping that contains path information. Specify one of the following two values:

true
If you set this property to `true` and the portal gets a request for a URL mapping that contains path information, the portal returns either an HTTP 404 error or redirects the user to the default portal page.

false
This value is the default value. If you set this property to `false` and the portal gets a request for a URL mapping that contains path information, the portal responds as defined by the property `friendly.pathinfo.enabled`.

Notes:

- With WebSphere Portal Express Version 8.5, URL mappings are deprecated.
- The property `friendly.pathinfo.enabled` applies to both friendly URLs and URL mappings.
- The property `state.decoding.fallback` is not applied to URLs that the portal interprets as URL mappings or friendly URLs. If you use friendly URLs or URL mappings, consider setting the parameters `state.decoding.fallback`, `wps.mappingurl.invalid`, and `friendly.pathinfo.invalid` in a consistent way. This action can help provide a consistent user experience. Example: If you set `state.decoding.fallback = false`, consider setting `wps.mappingurl.invalid = true` and `friendly.pathinfo.invalid = true`.

navigation.portletmenu.mode = (0)
The `navigation.portletmenu.mode` property defines in which way portlet

menus are integrated in the overall portal navigation menu structure. Portlet menus are navigation parts that are provided by the portlet itself. They can be added as a subtree to the navigation menu item that references the page in which the portlet is found. This property has the following three options:

0 Disabled: Portlet menus are not displayed in the navigation menu at all. This value is the default value.

1 Current selection: Only the portlet menus of the portlets that are found on the currently selected page are added under the navigation menu item for that page.

2 Everything: The portlet menus of all portlets on all pages are added under the appropriate navigation menu items in the navigation tree.

navigation.expansion.defaultstate = (false)
This value determines whether the nodes in the navigation tree are expanded or collapsed by default. The default is `false`, which means that the nodes are collapsed. Some exceptions apply; for example, the Portal Administration navigation tree is expanded by default.

Note: Setting this value to true does not affect Web 2.0 themes, as the expansion state is not returned from the portal REST service.

page.reload.interval = (0)
This value defines the page reload interval for unauthenticated users. Use it to specify the interval in minutes after which the portal page hierarchy must be reloaded for an unauthenticated user. The reload respects the most current access control settings for that user. If this value is set to zero, no automatic reload occurs during the session.

wsrp.caching.enabled = (true)
Use this property to enable or disable WSRP markup caching. The default for this property is `true`. This value means that WSRP markup caching is enabled, if no value is specified for this property. For more information, see the topic about *WSRP Markup Caching*.

friendly.enabled = (true)
This property determines whether friendly URL names can be set for portal pages in the Manage Pages portlet. The default value is `true`. If you set this property to `true`, you can add friendly URLs for portal pages in the Manage Pages portlet. "Friendly" means that you can use a name that is concise and easy to remember to address a specific portal page. To add a friendly URL for a portal page, click the **Edit Page Properties** icon for the page for which you want to add a friendly URL. You can then give your portal users that URL, and they can access that page by entering the URL in the Address field of their browser.

Note: When you create a URL mapping or create or modify a page, make sure that URL mappings and friendly URLs in your portal do not match, partially overlap, or otherwise interfere with each other. For example, do not use strings such as `home`, `ibm`, `ibm.com`, and do not use strings that are used as URL mappings or friendly URLs in your portal already. Otherwise, several browser redirect loops might occur, sometimes without an error message. To determine such strings, create an export from your portal by using the XML configuration interface and scan the exported XML result output file for the string that you want to use for your URL mapping or for your friendly URL.

If this property is set to `true`, you can use the property `friendly.redirect.enabled` listed later to determine whether a redirect must be sent if the incoming URL did not contain the friendly URL prefix of the addressed page.

`friendly.redirect.enabled = (true)`

Use this property to determine whether a redirect must be sent if the incoming URL did not contain the friendly URL prefix of the addressed page. This property does not take any effect if friendly URLs are disabled by setting the property `friendly.enabled` to `false`. Valid values for this property are as follows:

`true`

Set this property to `true` if you use an External Security Manager in your portal deployment that is configured to protect URLs based on their prefixes. This value is the default value of this property.

`false`

If you set this property to `false`, no redirect is sent in the previous case.

CF03 **`friendly.pathinfo.validation.redirect.onsuccess.enabled = (true)`**

This key specifies whether portal sends required friendly URL redirects if the path information of an incoming friendly URL is valid. Specify one of the following two values:

`true`

This value is the default value. If you set this property to `true` and portal gets a request for a friendly URL that contains path information, portal sends a required friendly URL redirect as if **`friendly.redirect.enabled`** was set to `true`. A required friendly URL redirect is only suppressed if the response indicates that the path information does not identify an available content item to ensure that the configured HTTP status code is sent.

`false`

If you set this property to `false`, portal sends friendly URL redirects as defined by the property **`friendly.redirect.enabled`**.

`friendly.pathinfo.invalid = (false)`

This property determines how the portal responds to a friendly URL that contains path information. Specify one of the following two values:

`true`

If you set this property to `true` and the portal gets a request for a friendly URL that contains path information, the portal returns either an HTTP 404 error or redirects the user to the default portal page. The portal response depends on the setting of the property `state.decoding.fallback`.

`false`

This value is the default value. If you set this property to `false` and the portal gets a request for a friendly URL that contains path information, the portal responds as defined by the property `friendly.pathinfo.enabled`.

Note: The property `state.decoding.fallback` is not applied to URLs that the portal interprets as URL mappings or friendly URLs. If you use friendly URLs or URL mappings, consider setting the parameters `state.decoding.fallback`, `wps.mappingurl.invalid`, and `friendly.pathinfo.invalid` in a consistent way. This action can help provide a consistent user experience. Example: If you set `state.decoding.fallback = false`, consider setting `wps.mappingurl.invalid = true` and `friendly.pathinfo.invalid = true`.

friendly.pathinfo.enabled = (true)

This property determines whether URL mappings and friendly URLs can contain path information to a content item as part of the URL. Specify one of the following two values:

true

This value is the default value. If you set this property to `true` and the portal gets a request for a URL that contains path information, the portal respects that path information and takes the user to the specified portal page.

Note: The property `friendly.pathinfo.enabled` applies to both friendly URLs and URL mappings.
Support for path information in friendly URLs also requires that the property `friendly.enabled` is set to `true` and the property `friendly.pathinfo.invalid` is set to `false`.
Support for path information in URL mappings also requires that the property `wps.mappingurl.enabled` is set to `true` and the property `wps.mappingurl.invalid` is set to `false`.

false

If you set this property to `false` and the portal gets a request for a URL that contains path information, the portal ignores the path information and takes the user only to the requested page.

CF03 **friendly.pathinfo.validation.errorCode = (404)**

This key specifies the HTTP status code that the portal returns if the path information of a friendly URL cannot be resolved to a content item for the requested page. You can specify one of the following values:

404

The default value. This HTTP status code tells a caller, such as a search crawler or web browser, that no content is found for the friendly URL. The missing content might be temporarily or permanently missing.

410

This HTTP status code informs a caller, such as a search crawler or a web browser, that the resource for the friendly URL is no longer available. This missing resource is permanently gone.

Portal can identify conditions that require a different HTTP status code than the one you configure by using **friendly.pathinfo.validation.errorCode**. For example, friendly URL redirects require the HTTP status code 302. To support the most common use cases, see the topic *Preventing friendly URL redirects for invalid friendly URLs for web content*.

CF03 **friendly.pathinfo.validation.errorTextProvider**

This key specifies the text provider of the localized HTTP status message to send as well as the configured HTTP status code. If you configure a text provider and a request URL has invalid path information, portal responds with a blank page that displays only the HTTP status code and the corresponding localized message that is specified by the text provider. The value of this parameter must be the ID of an implementation of the `com.ibm.workplace.wcm.api.plugin.textprovider.TextProvider` interface. To use the default messages of WebSphere Portal Express, specify the text provider with the ID `PathInfoValidationTextProvider`. If you implement a custom text provider, make sure that it supports message keys that are

composed of the prefix HTTP_STATUS_MESSAGE_ and the configured HTTP status code, for example: HTTP_STATUS_MESSAGE_404.

Important: Portal ignores this setting if you also specify the **friendly.pathinfo.validation.errorURI** property or page parameter.

CF03 **friendly.pathinfo.validation.errorResourceBundle**
This key specifies a Java resource bundle as an alternative to implementing a custom text provider. If you configure a Java resource bundle and a request URL has invalid path information, portal responds with a blank page displays only the HTTP status code and the corresponding localized message from the Java resource bundle. The value of this setting must be the fully qualified name of the Java resource bundle. If you provide a custom Java resource bundle, make sure that it contains message keys that are composed of the prefix HTTP_STATUS_MESSAGE_ and the configured HTTP status code, for example: HTTP_STATUS_MESSAGE_404.

Important: Portal ignores this setting if you also specify the **friendly.pathinfo.validation.errorURI** property or page parameter. Portal also ignores this setting if you set the value of the **friendly.pathinfo.validation.errorTextProvider** property or page parameter to a custom text provider ID.

CF03 **friendly.pathinfo.validation.errorURI**
This key specifies the piece of content URI that portal resolves if the request URL has invalid path information. The value of this parameter must be a piece of content URI that portal can resolve, for example:

nm:oid:*unique_page_name*
This navigation model URI redirects the request to a specific portal page based on the unique name of the target page.

custom:resolutionserviceuri
This custom implementation of the com.ibm.portal.resolver.ResolutionService interface resolves invalid path information to a dynamically determined navigational state. When portal resolves the piece of content URI, the content path that failed the portlet validation is passed to the resolution service as the **wcmContentPath** parameter.

CF03 **friendly.pathinfo.validation.errorContentPath**
This key specifies the full content path that portal sets as public Web Content Manager context of the resolved page if the request URL has invalid path information. Web Content Viewer portlets on the resolved page that are configured to listen to other portlets can then render the content with the specified path. The value of this setting must be the path of a content item that is available to users, for example: /Web Content/home/human_resources/health/topic_not_found.

CF03 **friendly.pathinfo.validation.enabled = (false)**
This key specifies whether portal validates the path information of friendly URLs. Specify one of the following two values:

true
If you set this property to true and portal gets a request for a friendly URL that contains path information, portal validates that path information. If it does not identify an available content item, portal responds based on

its configuration and the configuration of the resolved page. For more information, see *Configuring the validation of friendly URLs for web content*.

false
This value is the default value. If you set this property to false and portal gets a request for a friendly URL that contains path information, portal responds based on the properties **friendly.pathinfo.enabled** and **friendly.pathinfo.invalid**. For more information, see *Enabling the validation of friendly URLs for web content*.

friendlyname.uniqueness.enforcement = (true)
This property determines whether the portal enforces that new friendly names are unique across existing non-private sibling nodes. The default value is `true`. The enforcement does not include derived pages with an inherited friendly name and siblings that are moved in by a personalization rule.

com.ibm.wps.resolver.servlet.AbstractServlet.enableWebDAV[optional]=(true)
This property specifies whether the WebDAV feature is enabled in WebSphere Portal Express. By default, this property is set to the value `true`, by which WebDAV is enabled. To disable WebDAV, specify the value `false`. To re-enable WebDAV, specify the value `true`.

portlet.iwidget.markup.prefetching = (true)
This property determines whether the markup of portlets on pages in Client-side rendering mode must be loaded together with the markup for the portal page. The default value is `true`. This property defines the default markup prefetching behavior for pages that are configured to use the Client-side rendering mode. The default behavior can be overridden on a per portlet basis by declaring the same property as a portlet init property in the deployment descriptor file (`portlet.xml`) of the portlet. To disable portlet markup prefetching by default, set the value of this property to `false`. In this case, the markup of portlets on pages in Client-side rendering mode is fetched by using separate HTTP requests.

portlet.enable.transcoding = (true)
Determines whether transcoding is enabled.

portlet.automaximize = (false)
If you set this value to `true`, the portlet window is maximized when a portlet is set into edit, configure, or help mode.

proxy.enable.app.config = (false)
If you set this property to `true`, the Ajax proxy ignores all `proxy-config.xml` files inside portlets.

content.topology.writelock.timeout = *milliseconds* (default=25000)
This setting controls the maximum wait time to obtain a writable model before a timeout warning. To add or change the settings, open **Resource Environment Providers** in the WebSphere Integrated Solutions Console. Restart the portal server after you make your changes.

content.topology.writelock.dump = true|false (default=false)
This setting controls if a Java core memory dump is written in a timeout event for debugging. To add or change the settings, open **Resource Environment Providers** in the WebSphere Integrated Solutions Console. Restart the portal server after you make your changes.

com.ibm.wps.filestore.JCRWebdavTreeModelFactory.cacheClearOnRestart = true|false (default=true)
This setting defines whether the file cache content is invalidated and fetched again after server starts or not. The default value is `true`.

***actual.SSO.tokenUrl* = *your_URL_for_SAP_integration* (no default)**
This property is optional. Use it to specify a referenced property of SAP integration. Change the property name according to your chosen reference in the SAP integration page properties. Specify the URL for SAP integration as the value.

enable.default.social.object.resolution.mode.request.param = (true)|false
This property is optional. The default setting is `true`. If you set this property to `false`, the parameter `ibm.portal.default.social.object.resolution.mode` is disabled. This setting influences how social object links in social lists are resolved. For more information, see *Configuring globally how social object links are resolved*.

content.topology.writelock.dump = true|false (default=false)
This setting controls if a Java core memory dump is written in a timeout event for debugging. To add or change the settings, open **Resource Environment Providers** in the WebSphere Application Server administrative console. Restart the Portal Server after you make your changes.

com.ibm.wps.filestore.JCRWebdavTreeModelFactory.cacheClearOnRestart = true|false (default=true)
This setting defines whether the file cache content is invalidated and fetched again after server starts or not. The default value is `true`.

proxy.cv.slot.regex = *your regular expression with allowed slot IDs*
This property is optional. You can use it to define a subset of available slots in the Credential vault to which you want to limit the access of outbound HTTP connections. For details, read *Authenticating outbound HTTP connections*.

state.decoding.fallback [=true]
Use this property to control how the portal responds to requests for URLs that it cannot decode. Set it to one of the following two values:

true
This value is the default value. If you set this parameter to `true`, the portal renders the default or home page. This action is the fallback solution in scenarios with portal site visitors.

false
If you set this parameter to false, then the portal serves an HTTP 404 error to requests that it cannot decode. This action can be the preferred solution for other scenarios.

Note: The property `state.decoding.fallback` is not applied to URLs that the portal interprets as URL mappings or friendly URLs. If you use friendly URLs or URL mappings, consider setting the parameters `state.decoding.fallback`, `wps.mappingurl.invalid`, and `friendly.pathinfo.invalid` in a consistent way. This action can help provide a consistent user experience. Example: If you set `state.decoding.fallback = false`, consider setting `wps.mappingurl.invalid = true` and `friendly.pathinfo.invalid = true`.

search.service.suppress_automatic_creation = (false)
Use this property to determine whether the automatic creation of search services and search collections is suppressed. Specify one of the following two values:

false
To not suppress the automatic creation of search services and search collections, set this property to `false`. This is the default value.

true
To suppress the automatic creation of search services and search collections, set this property to `true`.

x-method-override.enabled = (false)
Use this property to specify whether you want to have PUT and DELETE requests simulated by tunneling that is by using POST requests instead. To enable this type of tunneling, set this property to `true`. If you set the property `x-method-override.enabled` to `true`, then the Config Service considers the `x-method-override` request header, when a request comes in. Whether to send this header is a decision of the HTTP client. By default, this property is set to `false`, and tunneling is disabled.

wcm.pages.enabled = (true)
This property specifies whether web content pages are enabled. The default value is `true`.

wcm.config.seedlist.version = (1.0)
This property specifies the version of the search seedlist format that is used by the portal. Search seedlist format 1.0 is the only supported search seedlist format, so the default and only supported value is `1.0`.

wcm.config.seedlist.servletpath = (/seedlist)
This property specifies the path to the servlet that generates the search seedlist. The default value is `/seedlist`.

delete.empty.portlet.locales = (false)
This property specifies whether the portal deletes the `localedata` element for a portlet after you set the locale to an empty value.

digest.seed

In WebSphere Portal Express, all resources that are served through the *contenthandler* framework, for example through the entries `/wps/contenthandler` and `/wps/mycontenthandler`, contain a digest token in their URLs. This digest token controls the cacheability of the resources by encoding request dependencies of the resource in the digest. Different dependencies result in a different digest, therefore a different URL, and a different entry in HTTP caches is generated. The digest computation algorithm also takes a seed value into account. This seed is a constant value, identical for all resources on a server. You can control this seed value by setting the *digest.seed* property in the WP ConfigService. You can control the seed value to make sure that all resources served through the *contenthandler* framework get fresh URLs, so eventual cache hits are avoided.

"Portlet Response headers" on page 311
The portlet response headers are part of the portal Configuration Service.

Related concepts:

CF03 "How to enable the validation of friendly URLs for web content" on page 2046
Learn about the properties and values that are required in WebSphere Portal Express Configuration Service Resource Environment Provider to validate friendly URLs for web content.

CF03 “Configuring the validation of friendly URLs for web content” on page 2046
After you enable the validation of friendly URLs for web content, you can choose from various configuration options. These options enable you to specify how the portal responds to friendly URLs that contain path information that does not identify an available content item. Learn about the parameter combinations you can specify and how the portal response varies based on these combinations.

CF03 “How to prevent friendly URL redirects for invalid friendly URLs for web content” on page 2051
If the validation of friendly URLs for web content is enabled and the path information of an incoming friendly URL is not valid, portal responds with the HTTP status code as defined by the portal Configuration Service property and page parameter **friendly.pathinfo.validation.errorCode**. However, depending on the configuration, portal does not always send the configured HTTP status code. Portal can identify conditions that require a different HTTP status code.

Related tasks:

“Configuring globally how social object links are resolved” on page 2127
You can include one or many attributes of social objects in the design component that defines the visual design of your social list. Among other features, social objects have different resolvable links that enable users to open details views of the social objects or the community to which the social objects belong. If you plan to add these links to your social list, you can decide how you want the social objects and their home community to be resolved when users click the corresponding links. IBM WebSphere Portal Express can either resolve the links in the context of the portal itself, or redirect the user to the IBM Connections user interface. You can globally configure how these types of links of social objects are resolved for the users. To do so, you use a setting in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console.

“Authenticating outbound HTTP connections” on page 3031
You can protect the access to the remote host by an authentication mechanism.

Portlet Response headers:

The portlet response headers are part of the portal Configuration Service.

portletcontainer.response.headers.additionallyNotAllowed = <none>
There is a predefined set of response header fields that you cannot use in portlet response fields. These unallowable header fields are listed later in this topic. In addition to these predefined header fields you can define additional fields that are then also not allowed to be included into a portlet response header. If you specify more than one field, you must separate the values by commas.

portletcontainer.response.headers.forceAllowed = (none)
This property enables you to re-enable the usage of the header fields that are by default prohibited header fields. If you specify more than one field, you must separate the values by commas.

The following list shows the header fields of the HTTP 1.1 (RFC 2616) specification that are by default **not** allowed to be set:

6.2 Response Header Fields:

The response-header fields allow the server to pass additional information about the response that cannot be placed in the Status-Line. These header

fields give information about the server and about further access to the resource identified by the Request-URI.

- Accept-Ranges (Section 14.5)
- Location (Section 14.30)
- Proxy-Authenticate (Section 14.33)
- Server (Section 14.38)
- Vary (Section 14.44)
- WWW-Authenticate (Section 14.47)

7.1 Entity Header Fields:

Entity-header fields define meta information about the entity-body or, if no body is present, about the resource identified by the request. Some of this meta information is **optional**; some might be **required** by portions of this specification.

- Allow (Section 14.7)
- Content-Encoding (Section 14.11)
- Content-Language (Section 14.12)
- Content-Length (Section 14.13)
- Content-Location (Section 14.14)
- Content-MD5 (Section 14.15)
- Content-Range (Section 14.16)
- Content-Type (Section 14.17)
- Expires (Section 14.21)
- Last-Modified (Section 14.29)

4.2 Message Headers:

HTTP header fields, which include general-header (section 4.5), request-header (section 5.3), response-header (section 6.2), and entity-header (section 7.1) fields, follow the same generic format as that given in Section 3.1 of RFC 822 [9]. Each header field consists of a name followed by a colon (**:**) and the field value. Field names are **case-insensitive**.

CP Configuration Service for tagging and rating:

The CP Configuration Service provides the properties for tagging and rating.

Usage notes for this topic:

1. The CP Configuration Service has properties for tagging and rating only. WebSphere Portal Express also has a portal Configuration Service (without "CP") that provides general portal configuration properties. The WebSphere Integrated Solutions Console lists that service as WP ConfigService.
2. The settings for the properties listed here apply to tagging and rating portal wide. Some of these properties have corresponding parameters that you can apply to individual tag or rating widget instances by the code that calls the widget instance. A setting applied to an individual widget instance overwrites the portal wide setting specified in the CP Configuration Service property listed here. For more details, read the topics about tagging and rating and the parameter reference topics for the widgets for tagging and rating.
3. In the following lists of properties, the values given in parentheses are the default values. Properties marked with **<none>** have no default values.

4. After you modify properties of one of the portal configuration services in the WebSphere Integrated Solutions Console, restart the portal server for your updates to take effect.
5. The parameters listed here are specific to the inline tag and rating widgets that were introduced with IBM WebSphere Portal Express Version 8.5. The dialog and inline widgets of earlier portal versions were deprecated with portal V 8.5. For information about the earlier widgets and their parameters, read the appropriate topics in the WebSphere Portal Express Version 8.0 product documentation.

General properties for tagging and rating:

View the general properties for tagging and rating.

Note: The parameters listed here are specific to the inline tag and rating widgets that were introduced with IBM WebSphere Portal Express Version 8.5. The dialog and inline widgets of earlier portal versions were deprecated with portal V 8.5. For information about the earlier widgets and their parameters, read the appropriate topics in the WebSphere Portal Express Version 8.0 product documentation.

com.ibm.wps.cp.tagging.isTaggingEnabled = (true)
com.ibm.wps.cp.rating.isRatingEnabled = (true)
Use these properties to enable or disable tagging or rating in the portal user interface. The default value is `true`.

com.ibm.wps.cp.tagging.contextMenu.isTaggingEnabled = (true)
com.ibm.wps.cp.rating.contextMenu.isRatingEnabled = (true)
Use these properties to enable or disable the page menu entries for tagging and rating. The default value is `true`.

com.ibm.wps.cp.tagging.portletContextMenu.isTaggingEnabled = (true)
com.ibm.wps.cp.rating.portletContextMenu.isRatingEnabled = (true)
Use these properties to enable or disable the portlet menu entries for tagging and rating. The default value is `true`.

com.ibm.wps.cp.default.feed.expiration = (600000)
Use this property to configure the default feed expiration time. Specify a value in milliseconds. The default is 600000 milliseconds = 10 minutes.

com.ibm.wps.cp.tagging.tagspace.TimeStampRange = (500)
Use this property to specify the range in which you want the time stamps of a tag space to be considered equal in milliseconds. Setting this property to a low value might affect performance.

com.ibm.wps.cp.tagging.normalization.displayNormalizedNames = (false)
Use this property to define whether the normalized tag names are shown in the tag cloud. Accepted values are `false|true`. The default value is `false`. Example: If there are three tags named `cot?`, `cote`, and `c?te`, the values for this property have the following meaning:

false If this property is set to the default `false`, all three tags show up separately in the tag cloud with a count of 1 each. Search suggestions for `c` are `cot?`, `cote`, and `c?te`; search suggestions for `co` are `cot?` and `cote`; search suggestion for `c?` is only `c?te`.

true If you set this property to `true`, all three tags are normalized to the tag name `cote`. Only this tag name `cote` is shown in the tag cloud or suggested by the search service.

com.ibm.wps.cp.tagging.normalization.typeAhead = (nonnormalized)
Use this property to determine which tag names the type-ahead feature **for tag creation** shows to the user. Accepted values are `nonnormalized|normalized`. The default value is `nonnormalized`. Example: If there are three tags: `cot?`, `cote`, and `c?te`, the values for this property have the following meaning:

nonnormalized
If this property is set to the default `nonnormalized`, the suggestions from the type-ahead feature are as follows:

- If a user types the characters `c?`, the type-ahead service suggests `c?te`.
- If a user types the characters `co`, the type-ahead service suggests `cot?` and `cote`.

normalized
If you set this property to `normalized`, the suggestions from the type-ahead feature are as follows:

- If a user types the characters `c?` or `co`, the type-ahead service shows all three tags as suggestions: `c?te`, `cot?`, and `cote`.

Note: The type-ahead feature works only with the dialog tag widget of the default tagging user interface of portal versions earlier than V 8.5. With WebSphere Portal Express V 8.5, the tag and rating widgets of earlier portal versions are deprecated.

com.ibm.wps.cp.filter.tagging.blacklist = (false)
Use this property to exclude unwanted tags, that is tags that might be seen as offending. If you enable this property, the blacklist filter checks every term that a user enters as a tag, before it is applied and stored. If the term that is used is listed on the blacklist, the portal does not allow this tag to be used and responds with an error message.

com.ibm.wps.cp.filter.tagging.whitelist = (false)
Use this property to check every term that users want to use as a tag before it is applied and stored. If the term that the user types is not listed on the whitelist, the portal does not allow this tag to be used and responds with an error message. This way operators can specify a controlled vocabulary from which users need to chose when they want to tag resources.

com.ibm.wps.cp.tagging.validation.regex = [^\<\>\(\)\[\]:]{1,50}
Use this property to specify a regular expression that the portal uses to validate the tag names that users type. The default is `[^\<\>\(\)\[\`

]:]{1,50}"}. As a result, users can type tag names that are from 1 to 50 characters long and do not contain any angled brackets, parentheses, brackets, or colons: < > ( ) [ ] :.

Limitation note: Angled brackets (< and >) are not allowed within tag names. Therefore, no matter how you customize the regular expression, angled brackets are not accepted.

com.ibm.wps.cp.rating.average.expected.averagerating = (3.0)
Use this property to specify the expected rating average per rated item. An item can be a single resource, or a search scope, such as all resources of type A or category B.

com.ibm.wps.cp.rating.averagel.expected.numberofratings = (10)
Use this property to specify the expected number of ratings per item. This value influences the credibility of the rating instances. The higher this value is, the more the average value is influenced by the value of the property com.ibm.wps.cp.rating.average.expected.averagerating.

com.ibm.wps.cp.rating.maxratingvalue = (5)
Use this property to specify the maximum value that a rating can have. The default is 5.

Related reference:

"Properties for the rating widget" on page 317
View the properties for the rating widget.

"Rating widget parameter reference" on page 1334
You configure rating widget instances by setting the Javascript parameters listed here.

Related information:

IBM WebSphere Portal V 8 Product Documentation

Properties for the tag widget:

View the properties for the tag widget.

Note: The parameters listed here are specific to the inline tag widget that was introduced with IBM WebSphere Portal Express Version 8.5. For information about the earlier widgets and their parameters, read the appropriate topics in the WebSphere Portal Express Version 8.0 product documentation.

com.ibm.wps.cp.tagging.inline.countsEnabled = (false)
Use this property to specify whether the count of each community tag is displayed. The count shows how often the tag was applied by users. The default value is false. To have the count of each community tag that is displayed, specify true. The count is then displayed in parentheses.

com.ibm.wps.cp.tagging.inline.customLabel
Use this property to specify a non-localized custom label to describe the displayed tags. If you do not want any further labeling or if you want to keep the label short, you can specify an empty string. This property has no default value.

com.ibm.wps.cp.tagging.inline.customMessageNoTags
Use this property to specify a non-localized custom label that you want to be displayed if no tags are available. This case can occur when users did not assign tags to the piece of content yet. Non-localized means that the label does not change with the browser language. This property has no default value.

com.ibm.wps.cp.tagging.inline.maxResults = (5)
Use this property to specify the number of tags that are shown per resource. The default value is 5.

com.ibm.wps.cp.tagging.inline.order = (DESC)
Use this property to specify the order direction for displaying the tags. This property is related to the property com.ibm.wps.cp.tagging.dialog.orderMetric listed later. Specify one of the following values:

DESC
This value is the default value. It specifies descending order. For example, when the default TAG_SPACE_COUNT_REVERSE_NAME is specified for the orderMetric property, tags with the highest count and the lowest character in the alphabet are listed first.

ASC
This value specifies ascending order. For example, if the order metric property is specified as orderMetric = TAG_SPACE_COUNT, tags with the lowest count are listed first.

com.ibm.wps.cp.tagging.inline.orderMetric = (TAG_SPACE_COUNT_REVERSE_NAME)
Use this property to specify the order metric for the order by which the tags are displayed. To determine the actual order, use the property com.ibm.wps.cp.tagging.dialog.order . The default value is TAG_SPACE_COUNT_REVERSE_NAME. This default means that tags are shown first by the tag count, with resources with more tags shown before resources with fewer tags, then, if resources have the same number of tags, alphabetically. Specify one of the following values:

- TAG_SPACE_COUNT_REVERSE_NAME. This value is the default value.
- TAG_SPACE_NAME
- TAG_SPACE_COUNT
- TAG_SPACE_CREATION_DATE
- TAG_SPACE_LAST_MODIFIED_DATE
- TAG_SPACE_COUNT_NAME

For more details, read the class com.ibm.portal.cp.Constants.OrderMetric in the portal Javadoc and to the *Inline tag widget parameter reference* in this documentation.

com.ibm.wps.cp.tagging.inline.privateTaggingEnabled = (false)
Use this parameter to enable private tagging. To do so, specify the PERSONAL_PRIVATE scope for the tags that you want to show in this inline widget. The default value is false.

com.ibm.wps.cp.tagging.inline.showDialogLauncher = (true)
Use this property to control whether a plus (**+**) sign for starting the corresponding dialog widget is shown. The default is true.

Note: This property applies only in case of Dojo based inline tagging widgets.

com.ibm.wps.cp.tagging.inline.tagClickActionMode = (TAG_CENTER)
Use this property to determine what happens when a user clicks a tag. Specify one of the following values:

TAG_CENTER
With this value, the widget redirects the user to the tag center. This value is the default value.

PUBLIC_RENDER_PARAMETER
With this value, the widget shows a public render parameter with the tag name.

Related concepts:

"The tag widget" on page 1311
Users can use the tag widget to view, apply, and update tags that were applied to a resource.

Related reference:

"Tag widget parameter reference" on page 1331
You configure specific tag widget instances by setting the JavaScript parameters that are listed here.

Properties for the rating widget:

View the properties for the rating widget.

Note: The parameters listed here are specific to the inline rating widget that was introduced with IBM WebSphere Portal Express Version 8.5. For information about the earlier widgets and their parameters, read the appropriate topics in the WebSphere Portal Express Version 8.0 product documentation.

com.ibm.wps.cp.rating.inline.customLabel
Use this property to specify a non-localized custom label to describe the displayed ratings. This property has no default.

com.ibm.wps.cp.rating.inline.numStars = (5)
Use this property to specify the number of stars or asterisks of which a rating consists. Specify a positive numeric value. The default value is `5`. Do not specify a value larger than the value specified for the property `com.ibm.wps.cp.rating.maxratingvalue` in the WP CP configuration service for tagging and rating. For more information about this property, read *General properties for tagging and rating*.

com.ibm.wps.cp.rating.inline.privateRatingEnabled = (false)
Use this parameter to enable private rating. To enable private rating, set this parameter to `true`. The default value is `false`.

com.ibm.wps.cp.rating.inline.ratingScope = (COMMUNITY_PERSONAL_PUBLIC)
Use this property to specify the scope of ratings that you want to show in this inline widget. Specify one of the following values:

```
COMMUNITY_PERSONAL_PUBLIC|PERSONAL_PUBLIC|PERSONAL_PRIVATE
```

If you do not specify a value, the property defaults to `COMMUNITY_PERSONAL_PUBLIC`.

com.ibm.wps.cp.rating.inline.ratingDesc
Use this property to specify the rating description that you want to show in this rating widget. By default, this property is not part of the rating widget. If you add this property to the rating widget, the default value is `ALL`. Specify one of the following values:

RATING_VALUE
With this value, the rating description includes only the numerical rating value.

TOTAL_NO_RATING
With this value, the rating description includes only the total number of ratings assigned.

ALL With this value, the rating description includes both the numerical rating value and the total number of ratings. This is the default value if you add the `com.ibm.wps.cp.rating.inline.ratingDesc` property to the rating widget.

NONE
If you do not specify a value, the rating description is not displayed at all.

Related concepts:

"The rating widget" on page 1315
Users can use the rating widget to view, apply, and update ratings that were applied to a resource.

IBM WebSphere Portal V 8 Product Documentation

Content Access Service:

Portlets can access content from remote systems that are located on the other side of a firewall by invoking the portal Content Access Service. If you configure properties of the Content Access Service, these settings applies only to the portlets that call this service.

In the WebSphere Integrated Solutions Console, the portal Content Access Service is listed as **WP ContentAccessService**.

You can configure the properties of the portal Content Access Service at either of the following locations:

- Under the **WP PortletServiceRegistryService** in the WebSphere Integrated Solutions Console.
- In the property file `PortletServiceRegistryService.properties` under the items beginning with `com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl`.

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.no.proxy.for =
Specifies host names for which ContentAccessServices does not use a proxy, even if a proxy is configured. Values must be separated by semicolon (`;`). Wildcards are not supported.

Example: `com.ibm.wps.pe.pc.legacy.service...no.proxy.for =localhost;127.0.0.1`

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.protocol.handlers =
Assigns additional URL protocol handlers that Java uses to handle connections to various URL protocols. Values must be separated by a vertical bar (`|`). The default is usually sufficient, as it supplies a handler for HTTPs URLs.

Example:
`com.ibm.wps.pe.pc.legacy.service...ServiceImpl.protocol.handlers = com.ibm.net.ssl.internal.www.protocol`

Proxy protocol and port properties

The following properties allow you to specify proxy protocol and port settings for different protocols. You must specify for each protocol the name and port number of the proxy servers that you use. The general format is as follows:

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.proxy.http.host = *hostname*
Specifies an HTTP proxy host for HTTP URLs.

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.proxy.http.port = *port number*
Specifies the port for the HTTP proxy. If this is not specified, 80 is used as the default value.

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.proxy.https.host
Specifies an HTTP proxy host for HTTPs URLs. The proxy must support CONNECT requests, otherwise known as 'tunneling' requests.

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.proxy.https.port
Specifies the port for the HTTP proxy. If this is not specified, 80 is used as the default value.

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.socks4.host
Specifies a SOCKS V4 proxy host for any URL.

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.socks4.port
Specifies the port. If this is not specified, 1080 is used as the default value.

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.socks5.host
Specifies a SOCKS V5 proxy host for any URL.

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.socks5.port
Specifies the port. If this is not specified, 1080 is used as the default value.

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.proxy.auth.enabled
Specifies whether authentication should be tried for proxied connections. This applies to the proxy server, not to the origin server from which the Content Access Service is fetching. Also, this only applies to HTTP proxy (with settings from proxy.http.* and proxy.https.*) and SOCKS proxy (with settings from proxy.socks4.* and proxy.socks5.*).

com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.proxy.auth.credentialslot
Specifies whether proxy authentication should be used for connections that use a proxy server. You must provide the user ID and password in a credential slot of the portal credential vault. You must also specify the name of this slot in the content access service configuration. The credential must have the type `UserPasswordPassive`. Proxy authentication applies to the proxy server, not to the origin server from which the ContentAccessService is fetching. Also, this only applies to HTTP proxy (with settings from proxy.http.* and proxy.https.*) and SOCKS proxy (with settings from proxy.socks4.* and proxy.socks5.*).

If no proxy host is set, WebSphere Portal Express tries to load all URLs directly. If no port is set, the default port for HTTP (80) is used. Alternatively, you can socksify the TCP/IP stack of your system. Examples:

The name of the HTTP proxy host:

```
com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.proxy.http.host = host.somewhere.ibm.com
```

The name of the HTTP proxy port:

```
com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.proxy.http.port = 80
```

The name of the tunneling HTTPs proxy host:

```
com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.proxy.https.host = securehost.somewhere.ibm.com
```

The name of the HTTPs proxy port:

```
com.ibm.wps.pe.pc.legacy.service.ContentAccessServiceImpl.proxy.https.port = 443
```

Data Store Service:

WebSphere Portal Express uses a database to store configuration data for pages, clients, markup, and all other resources. The Data Store Service is responsible for managing the data source of the portal as configured while installing WebSphere Portal Express.

In the WebSphere Integrated Solutions Console, the portal Data Store Service is listed as **WP DataStoreService**.

Under normal circumstances there should not be a need to modify any of the configuration properties in the Data Store service. The Data Store service properties are listed in the following:

scheduler.cleanup.enabled = (true)
Determines whether deletion of portal pages is performed later by the scheduled cleanup service, or immediately after the user completes the deletion task. This affects the deletion of portal pages and all their dependent resources, such as components and portlet instances. The default is `true`, which means that deletion of portal pages is delayed and performed by the cleanup service.

Note: Even if this property is set to `true` and delayed cleanup, deleted pages are no longer visible to users immediately after deletion.

For details about this property and how to schedule the cleanup service, see the topic about Delayed cleanup of deleted portal pages.

datasource.machineid
The value for this property is equivalent to the MAC address of the server. It consists of a string of 12 hexadecimal figures.

Note: Do not change the value for this property.

The following properties are domain specific properties. They are paired. The last three pairs are analog to the first pair. The possible valid values listed under the first property *xxx*`.datasource.dbms` of the first pair can also be specified for the first property of the following pairs.

Note: Do not assign the same schema name twice for database domains that reside in the same database instance. For example, if the release database domain resides in a database named `DB1` and uses the schema `SCHEMA1`, no other domain in the same database instance can use that same schema name `SCHEMA1`. This restriction applies to domains that are in the same database instance only. Using the same schema name more than once in different database instances of the same database management system is no problem.

rel.datasource.dbms = *your_DBMS*
Use this property to specify the database management system (DBMS) for the release database domain. The default value is . Valid values are listed in the following table. They are also valid for the property *xxx*.datasource.dbms properties in the following three property pairs.

*Table 34. Valid values for xxx.datasource.**dbms** properties*

DBMS used	DBMS value for *xxx*.datasource.dbms properties
IBM DB2 Universal Database for z/OS	DB2_ZOS
IBM DB2 Universal Database Enterprise Server Edition	DB2
IBM DB2 Universal Database for i	DB2_ISERIES
Oracle Enterprise Edition	ORACLE
Microsoft SQL Server Enterprise Edition	SQLSERVER2005

rel.datasource.schema = (*RELEASE*)
Use this property to specify the schema that is used for database objects in the release database domain.

cust.datasource.dbms = *your_DBMS*
Use this property to specify the database management system for the customization database domain. The default value is . For valid values see the property rel.datasource.dbms listed earlier.

cust.datasource.schema = (*CUSTOMIZATION*)
Use this property to specify the schema that is used for database objects in the customization database domain.

comm.datasource.dbms = *your_DBMS*
Use this property to specify the database management system for the community database domain. The default value is . For valid values see the property rel.datasource.dbms listed earlier.

comm.datasource.schema = (*COMMUNITY*)
Use this property to specify the schema that is used for database objects in the community database domain.

jcr.datasource.dbms = *your_DBMS*
Use this property to specify the database management system for the JCR database domain. The default value is . For valid values see the property rel.datasource.dbms listed earlier.

jcr.datasource.schema = (*JCR*)
Use this property to specify the schema that is used for database objects in the JCR database domain.

The following property specifies the **database domain tracking daemon** setting:

domain.tracker.wait = (1000)
Use this property to specify the time for which the domain tracking daemon waits for a response by the database domain until it polls again. The value is specified in milliseconds. The default value is 1000 (milliseconds), which is equivalent to 1 second.

Note: This daemon does not poll continuously, but only in case of errors. Therefore increasing this value will not reduce normal database traffic.

For further information about data sources and their configuration, see the WebSphere Application Server documentation.

Deployment Service:

The portal Deployment Service provides services for accessing the configuration properties that are required for the portlet deployment. The portlet deployment component is responsible for the integration of portlets into the portal. It handles the correct deployment of portlet applications and their WAR files into WebSphere Portal Express and WebSphere Application Server. It uses the WebSphere Application Server management services for the physical deployment and management of WAR files in the WebSphere Application Server. Management of WAR files includes installing, removing, redeploying, starting, and stopping portlet applications.

In the WebSphere Integrated Solutions Console, the portal Deployment Service is listed as **WP DeploymentService**.

Notes:

1. The WebSphere Portal Express configuration is separated into two types:
   - Deployed configuration. This type of configuration is read-only. The deployed configuration is always read from the file `portlet.xml`.
   - Administrative configuration. This type of configuration is read and write.

   The deployed configuration can be modified by administrative changes, for example, by using administrative portlets or the XML configuration interface. The administrative configuration is never overwritten by changes to the deployed configuration.
2. Portlet applications appear in the Enterprise Application list on the WebSphere Integrated Solutions Console. However, do not manage them from outside the portal. Instead, manage them by using the portal administration portlets or the XML configuration interface of the portal. You recognize web applications that comprise a portlet application by their administrative name, also called the display name. It is shown in the WebSphere Integrated Solutions Console. You can identify the name of such a portlet application by a portal-specific identifier prefix `PA_<name>`. This identifier is appended to the name. An example for such a name is `PA_WPS_Welcome`. The name in turn is derived from the name of the WAR file when the portlet application is installed. You can change this administrative name with an update of the portlet application.

In the following list of properties, the values that are given in parentheses are the default values.

was.admin.host = (*localhost*)
The WebSphere Application Server administrative host name. This property is used to adapt to the WebSphere Application Server bootstrap host name, if the default is not applicable.

use.admin.user = (true)
Use this key to select between two user authentication mechanisms for the portal Portlet Deployment Manager to authenticate with the WebSphere Application Server administrative services when portal security is enabled. Specify one of the following two possible values:

true
Use a single preset shared user ID for all portal administrative users who issue WAR deployment requests. This value is the default value. This user

ID is a separate user ID that is common for all users who have the access rights to install or manage applications. You must register this user ID with WebSphere Integrated Solutions Console User Administrator rights.

false
Use the actual user ID by which the administrator issues the WAR deployment request. Every portal user with portlet deployment rights must be added to the WebSphere Integrated Solutions Console User list with administrator rights. Alternatively, you can add the complete group of portal administrators to the WebSphere Integrated Solutions Console Group administrator rights.

was.notification.timeout = (900)
Use this property to specify the timeout value (in seconds). It specifies how many seconds the deployment tasks waits for an application server event during the management of WAR files. This value may have to be increased on large portal installations.

portletapp.starting.weight = (100)
Use this property to specify the value for the starting weight of the portlet applications (war files). To ensure the correct initialization sequence, this value must be higher than the starting weight of the portal itself.

portletapp.shared.library.list
This property defines a list of library references that are added to each deployed WAR file during deployment. You can specify multiple references by separating them with commas (**,**). The library references must already be defined in the application server, and the JAR files must already be deployed at the location that is assigned in the reference definition.

portletapp.reload.enabled = preserve
Use this property to define the value for the reload property of the deployed WAR file. This property can have the following values:

true
Specify this value to enable reloading mode for all WAR files. Use this value only for portlet development and portlet debugging purposes, but not for production environments.

false
Specify this value to disable reloading mode for all WAR files. This value is the default value.

preserve
When you specify this value, the setting from the file `ibm-web-ext.xmi` is applied, if available.

The default setting is `false`.

Note: Do not enable reloading in a production environment. Enable reloading only for portlet development and portlet debugging purposes.

discard.config.interval = (60)
This property defines the minimum time interval for which the configuration service workspace that is used during WAR file deployment is kept. After this time expires, the workspace is discarded when the portal runs the next deployment task. The unit of measure is minutes. Valid values are listed in the following, together with their meaning:

-1 Never discard the workspace.

0 Always discard the workspace immediately after the action that required the workspace was completed.

> 0 (numerical value greater than 0)
Time interval (in minutes) for which a workspace is retained before it is discarded. It is then rebuilt for the next deployment task.

Notes:

- When you set this property, use good judgment. The proper use of this setting must be a compromise between performance and workspace consumption for the following reasons:
  - Discarding the workspace frequently has a negative impact on deployment performance. The larger your portal installation is, the longer it takes to discard and rebuild the workspace to save the configuration changes during WAR file deployment.
  - However, retaining a workspace keeps the `wp_xxx` temporary directories in the WebSphere Application Server `wstemp` directory. Therefore, the temporary space that they occupy in the file system grows every time a WAR file is deployed and every time the portal is restarted.
- The configuration service workspace is not discarded immediately after expiry of the time interval that you set. The cleanup is done the next time that a deployment operation is called. It checks for expired changes and discards the workspace that they occupy. If further deployment operations occurred *after* the last time that the timer interval expired and the workspace was released, the changes in the last allocated workspace remain in the file system even on portal shutdown. Nevertheless, the previous cleanup reduces the volume of occupied disk space to only those temporary files that were processed after the last cleanup interval.

CF06 The following property protects deployment settings that users modified by using the WebSphere Integrated Solutions Console during WAR update through web module administration in the portal.

protect.deployment.attributes = (false)
Use this property to decide whether you want to have existing web module attributes of a deployed portlet WAR file overwritten with future portal updates or not. Portal deployment functions observe the values that are defined for this service during updates of a WAR file. However, a user can later modify the attributes of a deployed WAR by scripting or by using the WebSphere Integrated Solutions Console. For example, the user can modify the sequence by which class loaders are loaded for an individual WAR file. You can use this property to protect such modifications and prevent them from being overwritten by the portal web module deployment function. Valid values are as follows:

false
If you do not want to protect WAR file modifications, specify `false`. This value is the default value.

true
To protect modifications to WAR files, specify `true`.

File location definitions: The following values define file locations. All these settings have default values. Enable or modify them only if the defaults are not appropriate.

delete.temp.files = (true)
This property determines whether temporary files that were created during deployment in the directory *application.repository.dir.name*/temp are deleted or kept. The default is true, which means that the files are deleted. Change the value to false only for debugging purposes so that you can view the content of the temporarily expanded WAR files. When you complete debugging, change the value back to true and delete the directories manually. If you change the value to false, be aware that the hard disk drive space required by the temporary directory grows with each WAR file that you add or update.

shorten.deployment.names = (true)
Use this key to enforce shorter file names during deployment. Some platforms, such as Windows impose a limit to the length of a file path. File paths that are too long can cause deployment to fail if the resulting path is too long.

deployment.names.limit = (21)
This value is the threshold value for portlet application file and display names. Longer names are shortened if required.

The following setting is for debug purposes only. Enable it only when instructed to do so by support personnel.

deployment.debug.log.times = (false)
This setting is for debug purposes only. Enable it only when instructed to do so by support personnel.

HTTP Client Service:

Several components of the portal need to open HTTP or HTTPs connections to other resources. The portal HTTP Client Service provides a central point for configuration properties to these outbound connections. You can set global properties for the SSL configuration and proxy server usage.

In the WebSphere Integrated Solutions Console, the portal HTTP Client Service is listed as **WP HTTPClientService**.

Notes:

1. These properties do not currently replace all individual portlet proxy configuration properties. To set the proxy properties for specific portlets, consult the documentation for each portlet for how to modify their specific properties.
2. Some functional components of the portal can overwrite each of the settings if the component configuration differs from the global value. The following describes the global settings only; if a component allows you to set component specific properties, these are described in the respective component documentation.

global.ssl.configuration = (NodeDefaultSSLConfig)
Use this property to specify the name of an SSL configuration to be used for secure communication as defined in the WebSphere Application Server security configuration.

global.sso.domain = domain name
Use this property to specify the domain that starts with a dot, for example .a.com and denotes the range of hosts to which single-sign on cookies, such as LTPA, are forwarded from a client request. If the property is not set, single sign-on cookies are not forwarded to any remote host.

global.proxy.http.host = host name
Use this property to specify a proxy host for HTTP URLs. If no proxy host is set, the portal tries to load all HTTP URLs directly.

global.proxy.http.port = port number
Use this property to specify the port for the HTTP proxy. If no value is specified, 80 is used as the default value.

global.proxy.https.host = host name
Use this property to specify a proxy host for HTTPs URLs. If no proxy host is set, WebSphere Portal tries to load all HTTPs URLs directly.

global.proxy.https.port = port number
Use this property to specify the proxy port for HTTPs URLs. If no value is specified, 443 is used as the default value.

global.proxy.auth.credentialslot = slot name
Set this property if you want proxy authentication to be used for connections that use a proxy server. You must provide the user ID and password in a credential slot of the portal credential vault. You then specify the name of this credential slot in this property. The credential must have the type `UserPasswordPassive`. Proxy authentication applies to the proxy server only, not to the target server of the outbound connection.

global.proxy.excludehost = host name
Use this property to specify a particular host for which no proxy connection is used, even if a proxy is configured. You can set this property multiple times. Specify one setting for each host that is excluded from proxy connections.

Live Object Service:

You can use the Live Object configuration service to configure the behavior of the live object framework.

isLOFServiceRequired = true | false
Use this property to specify whether the theme loads the live object service code or not. It is up to the theme code to enforce this property. The portal default theme supports this property. The default value is `true` .

true The theme loads the live object framework service code. This is the default value.

false The theme does not load the live object framework service code.

isDynamicLoading = true | false
Use this property to specify whether the live object handlers are loaded dynamically or statically. The default value is `false` . The setting of this property influences the effect of the properties for specific handlers.

false If you set this property to `false` , the handlers are loaded statically. This means that the handler javascript code is loaded as part of the static file of the live object framework service at the time when the service is requested. This is the default. This setting increases the size of the initial download content, but reduces the number of requests if the live object framework is used on the page.

true If you set this property to `true` , the handlers are loaded dynamically if the appropriate microformat is part of the page. This means that handlers such as click-to-action (C2A) and Person Card are loaded by the semantic service, if DOM (document object model) nodes exist in the page that match the appropriate criteria. After you set this property to `true` , changing the properties for

specific handlers has no effect. For example, if you set this property to `true` and the property `isPersonCardHandlerRequired` is set to `false` , the semantic service loads the Person Card handler dynamically if a `vcard` node exists in the page markup. This setting reduces the size of downloaded content on first page access, but it might increase the number of requests required to render the page.

isPersonCardHandlerRequired = true|false
Use this property to specify whether the Person Card handler is included in static content. The default value is `true` .

Note: This property is only considered if the property `isDynamicLoading` is set to the value `false` .

true The Person Card handler is loaded.

false The Person Card handler is not loaded, and the Person Card does not show, even if `vcard` nodes are on the page.

isActionHandlerRequired
Use this property to specify whether the Person Card action handler is included in static content. The default value is `true` .

Note: This property is only considered if the property `isDynamicLoading` is set to the value `false` .

true The Person Card action handler is loaded.

false The Person Card action handler is not be loaded and `vcard` does not show extension menu actions, even if they are on the page.

isC2AHandlerRequired
Use this property to specify whether the click-to-action (C2A) handler is included in static content. The default value is `true` .

Note: This property is only considered if the property `isDynamicLoading` is set to the value `false` .

true The C2A handler is loaded.

false The C2A handler is not loaded and click-to-action does not work, even if C2A nodes are on the page.

Loader Service:

The portal Loader Service is responsible for dynamically loading class files. The service does so by looking up a given class name in different packages. Upon loading the respective class file, an instance of that class is returned.

In the WebSphere Integrated Solutions Console, the portal Loader Service is listed as **WP LoaderService**.

The Loader Service loads class files in four categories: commands, and supporting classes for screen templates, skin templates, and theme templates. To optimize the efficiency, the implementation of the service is free to cache loaded class files or instances and return a cached instance. That means that the implementation of such classes must be thread safe.

In cases where additional or alternative commands are required, the following configuration property can be modified:

command.path
Use this property to specify the package prefix or prefixes in which commands are searched.

Localizer Service:

The portal Localizer Service provides access to the configured default locale and the system default locale. It also provides a list of supported bidirectional languages. Giving the system default locale is necessary because `Locale.getDefault()` is set to the default.

In the WebSphere Integrated Solutions Console, the portal Localizer Service is listed as **WP LocalizerService**.

Although the locale is set during installation time, you can later change the locale by modifying the following properties in the Localizer Service:

locale.default.language
The language of the locale, for example, EN or PT.

locale.default.country
The country or region code of the locale, for example, US or BR.

locale.default.variant
The variant code of the locale.

The default language must be supported by WebSphere Portal Express. If you leave all three properties without a specified value, the system locale is used as the default locale.

All properties are case-insensitive. The ISO standard ISO-639 is used for the language codes of most languages. For Hebrew the old language code `iw` is used. The ISO standard ISO-3166 is used for the country/region codes.

Model WebDAV Service:

The WP Model WebDAV configuration service provides parameters that the portal uses during theme creation. Changing the values for these parameters only affects future theme instances, but leaves existing theme instances unchanged.

theme.resourceroot.default
This parameter specifies the resource root for the creation of theme folders.

theme.contextroot.default
This parameter specifies the context root for the creation of theme folders.

skin.resourceroot.default
This parameter specifies the resource root for the creation of skin folders.

skin.contextroot.default
This parameter specifies the context root for the creation of skin folders.

Navigator Service:

The portal Navigator Service allows you to specify a number of settings; among these are properties for cache scope and cache expiration. Depending on your configuration, you might be able improve your performance by modifying these properties.

In the WebSphere Integrated Solutions Console, the portal Navigator Service is listed as **WP NavigatorService**.

For more detailed information about page caching for improved performance, see the section about tuning the caching of your portal.

The following list gives properties that influence remote caching:

public.session
Use this property to specify whether an anonymous user always has a public session. This may be useful when a portlet requires a session for anonymous users. the default value is `false` . To enable public sessions for pages that anonymous users can view without logging in, set this property to `true`.

The setting of `public.session` influences the remote cache scope for public pages. If `public.session` is set to `true`, then the cache scope is set to non-shared (private). If `public.session` is set to `false`, then the cache scope is set to shared (public).

Note: Setting `public.session` to `true` might reduce performance.

public.expires
Use this property to specify the cache expiration time (in seconds) for caches outside of WebSphere Portal Express and for unauthenticated pages only. These caches must adhere to the HTTP 1.1 specification (RFC 2616). The `public.expires` key specifies the time after which HTTP caches should drop the response. You can further restrict this time by the `remote.cache.expiration` key.

This value is used as a maximum value for the cache expiration time and as a global default value for unauthenticated pages. If you also set the property `remote.cache.expiration` to a value greater than or equal to zero (`0`), the smaller one of the two values is used.

WebSphere Portal Express calculates and aggregates the remote cache information, that is the scope and expiration time, by a number of properties contributed by themes, pages, and portlets besides the properties described here. Therefore WebSphere Portal Express can do any of the following internally while processing a request:

- Reduce the cache lifetime
- Reduce the cache scope, for example, from public (shared) to private (non-shared)
- Switch off the overall cachability of pages.

Therefore this value might not be static for all responses resulting from requests to unauthenticated pages.

The response of WebSphere Portal Express sets the following header fields:

- The `Expires` header with the expiration time added to the system date and time.
- The `Cache-Control : max-age =` header with the expiration time as its parameter.

The default value specified for this property is `60` seconds. If no value is specified, WebSphere Portal Express defaults the value to `60` seconds.

remote.cache.expiration
This property specifies the maximum cache lifetime of a page, both public and private, in seconds. Use this property to specify a global value for the

expiration of pages in remote caches. Setting this value to zero (`0`) switches caching off in remote caches. If the legacy setting is not available, this property is used for authenticated and unauthenticated pages. If the legacy setting is available, then the smaller of the two values is used for unauthenticated pages only. In this case the `remote.cache.expiration` property is used for authenticated pages in general. If theme, composition, and portlets contribute remote cache information, then the global settings also contribute to the information. In this case the lowest of the values of all contributors is used, including the global settings.

The default value for this property is `60` seconds. If no value is specified, WebSphere Portal Express defaults the value to zero (`0` seconds).

`remoteCacheInfo.response.header.vary`
This property specifies the HTTP headers that force a proxy to cache different variants of the same URL. Use this property to specify a comma separated list of HTTP header fields to which WebSphere Portal Express should refer in its vary field of the generated HTTP response. This is required to ensure that proxy caches can invalidate entries in their cache if the specified header fields do not match from request to request. The default for this property is `User-Agent` .

`public.cache-control`
This property specifies the HTTP headers that force a proxy to cache different variants of the same URL. Use this property to specify a comma separated list of HTTP header fields to which WebSphere Portal Express should refer in its vary field of the generated HTTP response. This is required to ensure that proxy caches can invalidate entries in their cache if the specified header fields do not match from request to request. The default for this property is `no-cache` .

`private.cache-control`
This property specifies the value that is set for the `cache-control` HTTP header field when the portal generates a response in request for private pages. This header field controls the behavior of all caching mechanisms along the request-response chain. The default for this property is `no-cache` .

Portal Security Services:

WebSphere Portal Express provides several configuration services for authentication, Portal Access Control, and Portal User Management (PUMA).

"Authentication Service" on page 331
The portal Authentication Service contains the configuration properties for portal authentication. Authentication means that users identify themselves in order to gain access to the system. Usually they do this by a user ID and password.

"Credential Vault Service" on page 332
You can use the portal Credential Vault Service to configure Vault Adapter implementations that are used by the Credential Vault Service to store credential secrets.

"Portal Access Control Services" on page 333
WebSphere Portal Express provides several configuration services for Portal Access Control.

"Puma Store and Validation Services" on page 343
The following topics list and describe the configuration services for Portal User Management (PUMA): these are the Puma Store Service and the Puma Validation Service.

Authentication Service:

The portal Authentication Service contains the configuration properties for portal authentication. Authentication means that users identify themselves in order to gain access to the system. Usually they do this by a user ID and password.

In the WebSphere Integrated Solutions Console, the portal Authentication Service is listed as **WP AuthenticationService**.

authentication.execute.portal.jaas.login = (false)
Use this property to enable or disable the execution of the portal JAAS login:

false
Disables the execution of the portal JAAS login. This is the default. Disable this property only if you have no JAAS Login Modules defined for the portal application login configuration.

true
Enables the execution of the portal JAAS login. You can enable this property if you have JAAS Login Modules defined for the portal application login configuration.

This is related to performance.

authentication.isLoginUrlActive = (true)
Use this property to enable or disable the automatic login URL in Portal.

Note: This is a `java.lang.Boolean` property.

true
Enables the automatic login URL. This is the default.

false
Disables the automatic login URL

Use the following properties to define the custom filters in the various authentication filter chains in the portal. Each of these properties takes a list of the fully qualified class names of the custom filter implementations, separated by colons (**:**) or semicolons (**;**). For concept information about authentication filters, read the topic about *Configuring authentication filters*.

login.explicit.filterchain = <none>
Use this property to specify the custom filters for the filter chain that is triggered for an explicit login by user name and password. The classes listed in this property must implement the interface `com.ibm.portal.auth.ExplicitLoginFilter`.

login.implicit.filterchain = <none>
Use this property to specify the custom filters for the filter chain that is triggered for an implicit login, that is if the user is already authenticated to WebSphere Application Server but has no portal session yet. The classes listed in this property must implement the interface `com.ibm.portal.auth.ImplicitLoginFilter`.

logout.explicit.filterchain = <none>
Use this property to specify the custom filters for the filter chain that is triggered for an explicit logout. The classes listed in this property must implement the interface `com.ibm.portal.auth.ExplicitLogoutFilter`.

logout.implicit.filterchain = <none>
Use this property to specify the custom filters for the filter chain that is

triggered for an implicit logout, that is if the user got a session timeout. The classes listed in this property must implement the `interface com.ibm.portal.auth.ImplicitLogoutFilter`.

sessiontimeout.filterchain = <none>
Use this property to specify the custom filters for the filter chain that is triggered directly after an idle timeout of the session occurred. The classes listed in this property must implement the interface `com.ibm.portal.auth.SessionTimeoutFilter`.

sessionvalidation.filterchain = <none>
Use this property to specify the custom filters for the filter chain that is triggered for every request before the action handling and rendering is processed. The classes listed in this property must implement the interface `com.ibm.portal.auth.SessionValidationFilter`.

filterchain.properties = <none>
Use an arbitrary set of properties according to the previous pattern to specify properties for any of your custom filters. The property value is then available to the specified filter class in the `SecurityFilterConfig` object passed to its `init` method.

Related concepts:

"Configuring authentication filters" on page 265
The portal authentication filters are a set of plug-in points. You can use them to intercept or extend the portal login, logout, session timeout, and request processing by custom code, for example to redirect users to a specific URL.

Credential Vault Service:

You can use the portal Credential Vault Service to configure Vault Adapter implementations that are used by the Credential Vault Service to store credential secrets.

In the WebSphere Integrated Solutions Console, the portal Credential Vault Service is listed as **WP VaultService**.

General Credential Vault Service properties

You can set the following general configuration properties Credential Vault Service:

systemcred.dn
Specifies the Distinguished name (DN) of the vault administrative user. All system credentials are stored under the user's account. This property is set to the portal administrative user by default.

export.userDN
This is the user DN value of the XML Access user that is allowed to import/export secrets via the XML Configuration interface. This is usually the same user DN string as defined in the same configuration file under the property `systemcred.dn`. This user needs authority to use the XML Configuration interface and has to be used during the import/export. Otherwise an import/export of credential secrets is not possible.

export.cipher
The cipher used during export for encryption. This cipher has to be available via Java JCE in the WebSphere Portal Express system. The default value is AES.

export.keyLength
Number of bits used as key length for the cipher. The default value is 128 .

export.enforceSSL
This field controls whether credential import and export must be done via secured HTTP connection or not. If you set this property to `true` , credential import and export must be done via secured HTTP connection. If you set this property to `false` , it is allowed to import and export credentials also via an unsecured HTTP connection. The default value is `true` .

Vault Adapter specific properties

By default, two Vault Adapter implementations are available: `default-release` and `default-customization`. Those Vault Adapters store credential secrets in the portal server data store. For each implementation, define a unique string type, a class name, and a domain. Optionally, you can specify a configuration file, managing resources, and a read only flag.

You can define the following properties for each Vault Adapter Implementation Type. To be able to differentiate the properties for each type, the properties are in the format `vault.`*`type.key`* . Replace *type* by the Vault Adapter Implementation Type, and replace *key* by the key. The following list shows the properties that you can append:

class
Use this property to specify the Vault Adapter Implementation Class Name, but without the `.class` extension. This property is mandatory.

config
Use this property to specify the path of a configuration file that your adapter may need . This property is optional.

domain = (rel)
Use this property to specify the database domain where the segment and slot configuration data is stored. In the special case of the `DefaultVault`, this also specifies where the actual credentials are stored. This property is mandatory. Possible values are all available database domains as specified in the Data Store Service. The default value is `rel` ; this specifies the release domain.

manageresources = (false)
Use this property to specify whether the Vault Adapter should create and delete resources. This property is optional.

Note: If you set this property to `true`, the adapter must have internal support to manage resources. If you omit this property, it will default to `false` .

readonly = (true)
Use this property to specify whether the underlying vault for this adapter should be considered read only. This property is optional.

Note: If you set this property to `true`, the `manageresources` property is ignored. If you omit this property, it will default to `true` .

Portal Access Control Services:

WebSphere Portal Express provides several configuration services for Portal Access Control.

"Access Control Data Management Service" on page 334
The Access Control Data Management Service contains the configuration

properties for Portal Access Control. The domain short names have to correspond to the domain names that are defined for the portal Data Store Service.

"External Access Control Service" on page 336
The portal External Access Control Service is responsible for collecting authorization data from external security managers, such as Computer Associates eTrust SiteMinder or IBM Security Access Manager.

"Auditing Service" on page 340
With the Auditing Service, you can log a set of events in to a separate audit log file. All events are organized in groups. For example, the logging events **User created** and **User deleted** are grouped and must be turned on or off together.

Access Control Data Management Service:

The Access Control Data Management Service contains the configuration properties for Portal Access Control. The domain short names have to correspond to the domain names that are defined for the portal Data Store Service.

In the WebSphere Integrated Solutions Console, the portal Access Control Data Management Service is listed as **WP AccessControlDataManagementService**.

The following set of properties is mandatory for each database domain that contains resources that need to be protected by Portal Access Control:

accessControlDataManagement.domain.*domain_short_name*.adminuser = *full distinguished name of the administrative user for this domain*
Use this property to define the administrative user. As the value specify a full distinguished name that corresponds to a valid entry in the associated user repository. This property is mandatory.

accessControlDataManagement.domain.*domain_short_name*.admingroup = *full distinguished name of the administrative group for this domain*
Use this property to define the administrative group. As the value specify a full distinguished name that corresponds to a valid entry in the associated user repository. This property is mandatory.

accessControlDataManagement.domain.*domain_short_name*.virtualresource = *name of the virtual root resource of this domain*
This property specifies the virtual root resource. The value is the name of a virtual resource that actually exists in the domain and represents the root of the protected resource hierarchy in this domain. This property is meant for internal use only; do not change its value.

The administrative user and group are granted administrator roles on the full hierarchy of protected resources starting from the virtual root resource of the domain defined with the third setting. These roles are granted in addition to the portal roles of the user or group and therefore not displayed in the Access Control portlets. A valid set of values to these properties could for example look like the following:

```
accessControlDataManagement.domain.rel.adminuser=uid=Bob,o=Your Company
accessControlDataManagement.domain.rel.admingroup=cn=Admins,o=Your Company
accessControlDataManagement.domain.rel.virtualresource=PORTAL
accessControlDataManagement.domain.cust.adminuser=uid=Bob,o=Your Company
accessControlDataManagement.domain.cust.admingroup=cn=Admins,o=Your Company
accessControlDataManagement.domain.cust.virtualresource=PORTAL
accessControlDataManagement.domain.comm.adminuser=uid=Bob,o=Your Company
accessControlDataManagement.domain.comm.admingroup=cn=Admins,o=Your Company
accessControlDataManagement.domain.comm.virtualresource=PORTAL
```

```
accessControlDataManagement.domain.jcr.adminuser=uid=Bob,o=Your Company
accessControlDataManagement.domain.jcr.admingroup=cn=Admins,o=Your Company
accessControlDataManagement.domain.jcr.virtualresource=PORTAL
```

The following additional properties of the Access Control Data Management Service are optional:

accessControlDataManagement.enableNestedGroups = (true)
Use this setting to determine whether the group membership of groups is exploited at all by the Portal Access Control component. Supported values are: `true` and `false`. The default is `true`.

accessControlDataManagement.enableTargetResourceGroupInheritance = (false)
Use this setting to determine whether the group membership of groups is exploited by the Portal Access Control component for permission enforcement on users or groups. If you specify `false`, you can only get permissions on user groups via roles on the groups and on users via roles on the direct groups of which the user is a member. Supported values are: `true` and `false`. The default is `false`.

accessControlDataManagement.reorderRoleNames = (false)
Use this setting to determine whether the role name contains the unique name or the title of the resource on which the role was created. Specify `true` when you use an external authorization provider, such as IBM Security Access Manager, as this makes it easier to find the role names. Supported values are: `true` and `false`. The default is `false`.

accessControlDataManagement.externalizeAllRoles = (false)
This property is only applicable for externalization of resources through the user interface. the default value is `false`. If the property is set to `false` and a resource is externalized, then the following things happen:

1. The resource and all descendants of this resource that are not private and not externalized so far are externalized.
2. The roles and role mappings that exist on all resources that were identified in the previous step 1 are written into the external security manager object space.
3. For the root resource that was chosen to be externalized, a role mapping for the Administrator role for the executing user is created in the external security manager object space.

If this property is set to `true`, then in addition to the previous three steps, roles are created in the external security manager object space for all action sets for the root resource that have not already been created in steps 2 and 3.

accessControlDataManagement.createAdminMappingXMLAccess = (true)
This property is only applicable for externalization of resources through the XML Configuration Interface. If the property is set to false and a resource is externalized the following happens:

1. The resource will be externalized.
2. The roles and role mappings on the resource are written into the external security manager object space.

If the property is set to `true`, then in addition to the two previous steps, a role mapping for the Administrator role is created for the executing user in the external security manager object space.

Connecting to the user repository during startup

If you want the portal to wait and retry connecting to the underlying user repository, and if it is not available during portal startup, change the following two properties. This might be necessary in scenarios where the user repository is only available in a certain time frame after the initialization of the portal startup. As the domain administrative users and groups have to be resolved, the portal cannot start without connecting to the user repository. The service startup performs the specified number of attempts to connect to the user repository, each time waiting for the specified time interval before starting the next attempt. If none of the attempts is successful, the service startup quits with an exception.

accessControlDataManagement.ldapFailoverNumberOfAttempts = (1)
Use this property to specify how many times the service startup attempts to connect to the user repository. The default is 1 (once).

accessControlDataManagement.ldapFailoverInterval = (60)
Use this property to specify how long the service startup waits until it retries to connect to the user repository. This value is specified in seconds. The default is 60 seconds.

External Access Control Service:

The portal External Access Control Service is responsible for collecting authorization data from external security managers, such as Computer Associates eTrust SiteMinder or IBM Security Access Manager.

In the WebSphere Integrated Solutions Console, the portal External Access Control Service is listed as **WP ExternalAccessControlService**.

In the portal External Access Control Service, you can modify the configuration properties listed in the following. However, plan well ahead and apply special care when modifying these properties.

General properties of the External Access Control Service

These properties are used for general purposes of the External Access Control Service.

externalaccesscontrol.ready = (false)
This property indicates whether the configuration in this file has been configured to connect to the External Security Manager. The default value is false .

externalaccesscontrol.server = WebSphere_Portal
externalaccesscontrol.application = WPS
externalaccesscontrol.cell = cell
Role name representations are qualified with a context built by these three properties. For example, the **Administrator@External_Access_Control/xxx/xxx** is represented as follows:

Security Access Manager: Protected object space entry

```
/WPSv6/Administrator@External_Access_Control/xxx/xxx/WPS/WebSphere_Portal/cell
```

eTrust SiteMinder:

```
resource/subrealms under Domain: WebSphere Portal v8
/cell/WebSphere_Portal/WPS/Administrator@External_Access_Control/xxx/xxx
```

Access Manager configuration

Use the following properties to configure the connection between WebSphere Portal Express and your Tivoli Access Manager.

externalaccesscontrol.pdroot = (/WPSv6)
After you completed the `AMJRTE` and `SrvSslCfg` configuration tasks, the following directives are required to allow WebSphere Portal Express to use Tivoli Access Manager as an External Security Manager. Provide the root of your Protected Object Space for Portal Server entries.

externalaccesscontrol.pduser = *sec_master*
externalaccesscontrol.pdpw = *passw0rd*
Use these properties to provide an administrative user ID and password with adequate rights in Tivoli to create, delete, modify the objects in the Protected Object Space. You can use the WebSphere Application Server PropFilePasswordEncoder utility to mask the password. Using PropFilePasswordEncoder will remove any comments and uncommented properties. Therefore create a back up copy of this file for future reference. Example for IBM i Linux Windows:

```
AppServer_root/bin/PropFilePasswordEncoder
wp_profile_root/PortalServer/config/properties/ExternalAccessControlService.properties
        externalaccesscontrol.pdpw
```

Example for :

Note: This command should be typed *on one line* in a command line window.

externalaccesscontrol.pdurl=file:///${WAS_INSTALL_ROOT}/java/jre/PdPerm.properties
Use this property to specify the URL location of the Access Manager properties file for AMJRTE. This URL must be in the format `file:///` *directory_path_to_properties_file* . HTTP URLs are not supported.

externalaccesscontrol.createAcl = (true)
This property is optional. Use this property to specify whether Access Control Lists (ACLs) are created in Access Manager for roles that are stored externally. The default is `true`. If this property is set to `false`, the Access Manager administrator will be responsible for all ACL linkages between Security Access Manager and WebSphere Portal Express. Possible values for this property are:

true
A Security Access Manager ACL will be created for **every** WebSphere Portal Express resource. This is the default.

false
No ACLs will be created for portal objects.

externalaccesscontrol.pdactiongroup = ([WPS])
externalaccesscontrol.pdAction = (m)
These properties are optional. Use these properties to specify the action group and the customized actions to map to portal role membership. If these items do not exist, they will be created at startup. The values previously given are the default values.

Computer Associates eTrust SiteMinder policy server information

Use the following properties to configure the connection between WebSphere Portal Express and your Policy Server.

externalaccesscontrol.domainname = WebSphere Portal V 8
Use this property to specify the domain name that is to be created in the eTrust SiteMinder administrative GUI. All realms and sub-realms will be created under this domain. This domain will be created when starting WebSphere Portal Express.

externalaccesscontrol.scheme = (Basic)
Use this property to specify the scheme that is to be to associated with the realms. You must define this scheme in eTrust SiteMinder before starting WebSphere Portal Express. The default value is `Basic`.

externalaccesscontrol.agentname = *wpsagent*
externalaccesscontrol.agentsecret = *passw0rd*
Use these properties to specify the agent name and secret to establish a run time connection with eTrust SiteMinder. The agent should be a web agent with a static shared secret, so that Web Agents later than Version 4.6 of WebAgents should enable the property `supports 4.x agents` on the eTrust SiteMinder web agent. You can use the WebSphere Application Server PropFilePasswordEncoder utility to mask the password.

Note: Using PropFilePasswordEncoder removes all comments and all properties that are commented out. Therefore make sure you create a back up copy of this file for future reference *before* using the PropFilePasswordEncoder utility.

An example of masking the password is:

```
AppServer_root/bin/PropFilePasswordEncoder wp_profile_root/PortalServer/
config/properties/ExternalAccessControlService.properties
externalaccesscontrol.agentsecret
```

Note: Type this command *on one line* in a command line window.

externalaccesscontrol.admin = *siteminder*
externalaccesscontrol.password = *passw0rd*
Use these properties to specify the administrative user ID and password for a user who can create, delete, and modify eTrust SiteMinder objects that are used to represent WebSphere Portal Express roles. This user ID must have sufficient access to domain level objects in eTrust SiteMinder. You can use the WebSphere Application Server PropFilePasswordEncoder utility to mask the password.

Note: Using PropFilePasswordEncoder removes all comments and all properties that are commented out. Therefore make sure you create a back up copy of this file for future reference *before* using the PropFilePasswordEncoder utility.

An example of masking the password is:

```
AppServer_root/bin/PropFilePasswordEncoder wp_profile_root/PortalServer/
properties/ExternalAccessControlService.properties
externalaccesscontrol.password
```

externalaccesscontrol.userdir = (User Directory 1)
Use this property to specify the User Directory that is associated with the domain. You can configure the failover for user directories in the eTrust SiteMinder administrative GUI. The user directory must exist before you start WebSphere Portal Express.

externalaccesscontrol.failOver = (false)
Use this property to specify whether the ESM subsystem should switch to

another Policy Server if it cannot contact the current one. Possible values are `true` and `false`. You can specify this property as either `externalaccesscontrol.failOver` or as `externalaccesscontrol.failover` .

Note: It is important that this value and the number of Policy Server IP addresses that are specified by the `servers` property are carefully coordinated. If you specify multiple Policy Server addresses on the `servers` property, and this property is set to `false`, then the Computer Associate's Agent API will follow round-robin load balancing, by distributing or spraying requests between the configured Policy Servers. This may be appropriate for a TAI which is only doing `read` operations from the Policy Server(s), but not for `write` operations . If you have multiple servers defined in the `externalaccesscontrol.servers` property (following next), set `failOver` to `true` .

`externalaccesscontrol.servers = server1,server2, . . .`
Use this property to specify the IP addresses of all the Policy Servers. Multiple addresses need to separated by commas. An example is: `servers=10.0.0.1,10.0.0.2` .

Note: If you have multiple servers defined in the `externalaccesscontrol.servers` property, set the `failOver` property to `true` .

You can define the following properties for each server. In order to differentiate the properties for each server, specify the keys in the format `Server IP address.key=value` . The defaults are assumed for any keys that you omit. The available keys are as follows:

`accountingPort = (44441)`
The accounting port for the Policy Server. The default is 44441.

`authenticationPort = (44442)`
The authentication port for the Policy Server. The default is 44442.

`authorizationPort = (44443)`
The authorization port for the Policy Server. The default is 44442.

`connectionMax = (10)`
The maximum number of connections which the authorization service may make to this Policy Server. The default is 10.

`connectionMin = (1)`
The initial number of connections which the authorization service will establish with this Policy Server. The default is 1.

`connectionStep = (1)`
The number of connections that are to be allocated if the authorization service runs out of connections to the Policy Server. The default is 1.

`timeout = (20)`
The connection timeout in seconds. The default is 20.

An example for server 10.0.0.1 is as follows:

```
10.0.0.1.accountingPort=44441
10.0.0.1.authenticationPort=44442
10.0.0.1.authorizationPort=44443
10.0.0.1.connectionMax=30
10.0.0.1.connectionMin=10
10.0.0.1.connectionStep=5
10.0.0.1.timeout=60
```

Auditing Service:

With the Auditing Service, you can log a set of events in to a separate audit log file. All events are organized in groups. For example, the logging events **User created** and **User deleted** are grouped and must be turned on or off together.

In the WebSphere Integrated Solutions Console, the portal Auditing Service is listed as **WP AuditService**.

The section about available events lists and describes the events that are available for auditing.

The audit log output is written to the audit log file. No other log messages are written to this file. For an explanation of the contents of the audit log file, refer to the section about the audit log file.

Auditing service configuration

By default, the audit log service is disabled. Therefore, the service is loaded, but does not register any event listeners for audit logging. The auditing service configuration is controlled by the Auditing Service.

audit.service.enable = (false)
This parameter is the global switch. Set this parameter to `true` to turn on the service. Set this parameter to `false` to turn off the service. The default setting is false.

The actual log file access of the service can be configured by using the following property:

audit.logFileName = log/audit_*$create_time*.log
This property defines the location and the name of the audit log file. The placeholder *$create_time* is replaced by a time stamp during file name generation. A second placeholder *$APPSERVER_NAME* is used for a vertical cluster configuration to make the log file name unique. Example:

```
audit.logFileName = log/audit_$APPSERVER_NAME_$CREATE_TIME.log
```

With the auditing service, you can have the transaction ID written to the audit log file. The project ID can also be written to the audit log file. As these IDs can be long and might not be required in every environment, you can disable the inclusion of the IDs.

audit.showTransactionID.enable = (true)
Use this property to disable transaction IDs in the audit log. Change the value to `false`. The default value is `true`.

audit.projects.enable = (true)
Use this property to disable project IDs in the audit log. Change the value to `false`. The default value is `true`.

You determine the events that you want to be logged by enabling the appropriate properties as required. Set the events that you want to enable to the value `true`. The following groups of events are defined:

```
audit.groupEvents.enable
audit.userEvents.enable
audit.portletEvents.enable
audit.roleEvents.enable
audit.roleBlockEvents.enable
```

```
audit.ownerEvents.enable
audit.resourceEvents.enable
audit.externalizationEvents.enable
audit.userInGroupEvents.enable
audit.webModuleEvents.enable
audit.domainAdminDataEvents.enable
audit.designerDeployServiceEvents.enable
audit.impersonationEvents.enable
audit.taggingEvents.enable
audit.ratingEvents.enable
audit.projectPublishEvents.enable
audit.vanityURLEvents.enable
```

The default value for all of these properties is `false`. That means that no events are logged by default, even if you turned on the service by setting the property `audit.service.enable` to `true`.

To enable one or more groups of events, change the default value of the appropriate `audit.`*`eventGroup`*`.enable` property to `true`.

Available events

This list shows the events that you can log with the auditing service. They are listed by the groups in which they are available. If you enable one group, all events in that group are logged.

Table 35. Groups of events for the audit logging service

Audit logging group	Audit logging event	Meaning of the event
`audit.groupEvents`	Group created event	A new user group was created via portal UIs.
`audit.groupEvents`	Group modified event	A user group was modified via portal UIs.
`audit.groupEvents`	Group deleted event	A user group was deleted via portal UIs.
`audit.userEvents`	User created event	A new user was created via portal UIs.
`audit.userEvents`	User modified event	A user was modified via portal UIs.
`audit.userEvents`	User deleted event	A user was deleted via portal UIs.
`audit.portletEvents`	Portlet Application created event	A new web module or portlet application was created via portal UIs.
`audit.portletEvents`	Portlet Application modified event	A web module or portlet application was modified via portal UIs.
`audit.portletEvents`	Portlet Application deleted event	A web module or portlet application was deleted via portal UIs.
`audit.roleEvents`	Role assigned event	A portal role was assigned to a user. The user was given the specified type of access permission on all resources that are affected by this role. For example, it can be EDITOR on Page1.
`audit.roleEvents`	Role unassigned event	A portal role was unassigned from a user. The user no longer has the specified access rights on the resources that are affected by this role. For example, the user is no longer EDITOR on Page1.
`audit.roleBlockEvents`	Role block modified event	The portal role block information of a resource was changed. The event message contains a list of blocked and non-blocked roles on the resource. As roles can either be inherited or propagated, there are two separate lists for inheriting roles and propagating roles. If propagating role blocks was changed, the list for inheriting roles is empty and vice versa.
`audit.ownerEvents`	Resource owner modified event	The owner of a resource was changed.
`audit.resourceEvents`	Resource created event	A new resource was registered. This event is triggered when the resource is registered in Portal Access Control.

Table 35. Groups of events for the audit logging service (continued)

Audit logging group	Audit logging event	Meaning of the event
audit.resourceEvents	Resource modified event	A registered resource was modified. This event is triggered if the resource is modified in Portal Access Control.
audit.resourceEvents	Resource deleted event	A registered resource is no longer registered in Portal Access Control. This event usually happens when a resource is deleted.
audit.externalizationEvents	Resource externalized event	A resource was externalized. This event means that access permissions to this resource are no longer controlled by Portal Access Control, but by an external Access Manager. For example, it might be Security Access Manager.
audit.externalizationEvents	Resource internalized event	A resource was internalized. It is now controlled by Portal Access Control and no longer by an external Access Manager.
audit.userInGroupEvents	User added to group event	A user was added to a group. The user is now a member of this group and therefore inherits access rights from the group.
audit.userInGroupEvents	User who is removed from group event	A user was removed from a group. The user is no longer a member of that group and does no longer have the inherited access rights.
audit.webModuleEvents	Web Module started event	A new web module was started.
audit.webModuleEvents	Web Module stopped event	An installed web module was stopped.
audit.domainAdminDataEvents	Domain administration data initialized event	The administrative data for a domain, such as administrative user, administrative group, and virtual root resource, was initialized during the start of portal. For the lifetime of the current portal process, this user and group have administrative permissions on the domain resource hierarchy, starting from the virtual root resource. For more information, refer to the Access Control Data Management Service. This event is always thrown for each defined domain during the server start. Because the system causes this event, no user is logged.
audit.designerDeployServiceEvents	Component installed event	A portlet application was created by using IBM Lotus Component Designer.
audit.designerDeployServiceEvents	Component modified event	A portlet application that is created by using IBM Lotus Component Designer was modified.
audit.designerDeployServiceEvents	Component uninstalled event	A portlet application that is created by using IBM Lotus Component Designer was deleted.
audit.impersonationEvents	Impersonation started event	A user started impersonation with another user.
audit.impersonationEvents	Impersonation ended event	A user ended impersonation with another user.
audit.impersonationEvents	Impersonation attempted with no permission event	A user tried to impersonate another user but has no permission.
audit.vanityURLEvents	Vanity URL created	A user created a vanity URL.
audit.vanityURLEvents	Vanity URL modified	A user modified a Vanity URL.
audit.vanityURLEvents	A user deleted a Vanity URL	Vanity URL deleted A user deleted a Vanity URL.
audit.tagEvents	Tag created	A user created a tag.
audit.tagEvents	Tag deleted	A user deleted a tag.
audit.ratingEvents	Rating created	A user created a rating
audit.ratingEvents	Rating deleted	A user deleted a rating.
audit.projectPublishEvents	Project created	A user created a project.
audit.projectPublishEvents	Project published	A user published a project.
audit.projectPublishEvents	Project removed	A user removed a project.

Audit log file

The audit log file contains one audit log message per line. All log messages start with a time stamp, followed by the optional transaction ID, the message code, and the event message. Each event message contains the following information:

- The user ID of the user who triggered the audit event
- Additional information about the event itself.

Events for actions that run in a transaction are written to the log file when the transaction is committed. If the transaction is rolled back, no event messages are written to the log file.

Events for actions that do not run in a transaction are written to the log immediately. In such cases, it is not guaranteed that the related action was completed successfully.

Puma Store and Validation Services:

The following topics list and describe the configuration services for Portal User Management (PUMA): these are the Puma Store Service and the Puma Validation Service.

"Puma Store Service"
The portal Puma Store Service contains the configuration properties for the Portal User Management (PUMA).

"Puma Validation Service" on page 344
The portal PUMA Validation Service contains the configuration properties for the validation component of PUMA.

Puma Store Service:

The portal Puma Store Service contains the configuration properties for the Portal User Management (PUMA).

In the WebSphere Integrated Solutions Console, the portal Puma Store Service is listed as **WP PumaStoreService**.

Properties for both the Portal User Management and the PUMA SPI

The following properties configure both the Portal User Management and the PUMA SPI:

store.puma_default.user.fbadefault.filter =
Defines the default search attribute for users. Usually this is the same as the Relative Distinguished Name (RDN) attribute of the LDAP. Depending on your environment, it might be a different attribute. The value for this property should correspond to the value of one of the following properties in `wkplc.properties`, depending on your security configuration:

- **federated.ldap.loginProperties**
- **standalone.ldap.loginProperties**

store.puma_default.group.fbadefault.filter =
Defines the default search attribute for groups. Usually this is the same as the RDN attribute of the LDAP. Depending on your environment, it might be a different attribute. The value for this property should correspond to the value of one of the following properties in `wkplc.properties`, depending on your security configuration:

- **federated.ldap.loginProperties**
- **standalone.ldap.loginProperties**

store.puma_default.user.base.attributes =
Defines the attribute subset that portal loads during direct user lookups, for

example at Login. Attributes that are not defined in this list are loaded by a separate request to the backend user store.

store.puma_default.user.minimum.attributes =
Defines the attribute subset that portal loads during attribute searches for users. Attributes that are not defined in this list are loaded by a separate request to the backend user store.

store.puma_default.group.minimum.attributes =
Defines the attribute subset that portal loads during attribute searches for groups. Attributes that are not defined in this list are loaded by a separate request to the backend user store.

store.puma_default.userManagement.cacheMode = (true)
Defines whether Puma uses a cache or not. The default for this property is `true`.

store.puma_default.logDuplicateKeyExceptions = (true)
Use this property to determine whether the Data Store component writes DuplicateKeyException error messages out to the portal log or not. This does not influence the error handling: With either setting, the exceptions are handled without an error to the portal system.

true
This is the default. If this property is set to `true` or if the property is not set at all, the exception error messages are written to the log. The exceptions are handled without error to the portal.

false
If you set this property to `false`, the error messages are **not** written out to the log. The exceptions are handled without error to the portal.

Properties for the Portal User Management only, but not the PUMA SPI

The following properties configure only the Portal User Management, but not the PUMA SPI:

store.puma_default.puma.commonname = ({0} {1})
The **Registration / Edit My Profile** portlet can generate the common name (CN) of a user automatically. This property defines how the CN is generated. You can define dynamic and static parts. Dynamic parts are added by using {*X*}, where *X* stands as a reference number to the `puma.commonname.X` that defines the attribute that you want to place here. Dynamic parts can only be user attributes that are available and valid. The default is `{0} {1}`.

store.puma_default.puma.commonname.parts =
Defines the number of dynamic parts in the common name.

store.puma_default.puma.commonname.X =
The user attribute for dynamic part *X*. *X* must be between `0` and `puma.commonname.parts -1`. The default is `puma.commonname.0 = givenname` and `puma.commonname.1 = sn`.

Puma Validation Service:

The portal PUMA Validation Service contains the configuration properties for the validation component of PUMA.

In the WebSphere Integrated Solutions Console, the portal Puma Validation Service is listed as **WP ValidationService**.

Properties for user validation

user.YOURATTRIBUTE.min = (1)
Defines the minimum number of characters that is allowed for the defined *YOURATTRIBUTE*. The default is 1.

user.YOURATTRIBUTE.max = (60)
Defines the maximum number of characters that is allowed for the defined *YOURATTRIBUTE*. The default is 60.

user.YOURATTRIBUTE.charset = (ascii)
Defines the character set against which characters are validated. Supported values are ascii and unicode. The default is ascii.

user.YOURATTRIBUTE.extra_chars = (-._)
Defines extra special characters which are not in the supported character set, but should be treated as valid. By default, the dash, period, and underscore are valid: - . _

Note: The YOURATTRIBUTE portion of the property needs to be spelled in uppercase. The following sections show example sets of properties with attributes. They follow the same pattern as the set described in this section. The example properties are set to the default values.

Settings for the attribute user.fbadefault.filter defined in the Puma Store Service

The following example set of properties shows the settings for the attribute user.fbadefault.filter defined in the Puma Store Service:

user.UNIQUEID =
For this property, specify the value of the user.fbadefault.filter attribute that is defined in the Puma Store Service.

user.UNIQUEID.min = 1

user.UNIQUEID.max = 60

user.UNIQUEID.charset = ascii

user.UNIQUEID.extra_chars = -._

Properties for group validation

The following example set shows the settings for the attribute group.fbadefault.filter defined in the Puma Store Service:

group.RDN=
For this property specify the value of the group.fbadefault.filter attribute that is defined in the portal Puma Store Service. For more information see the topic about the portal Puma Store Service.

group.RDN.min = 1

group.RDN.max = 200

group.RDN.extra_chars = -,_

Properties for password validation

Unlike the properties listed earlier, the properties for password validation do not require any uppercase spelling.

password.min_characters = 5

password.max_characters = 60

password.charset = ascii

password.extra_chars = -._

Portlet Container Service:

The portal Portlet Container service provides properties for portlet filtering.

In the WebSphere Integrated Solutions Console, the portal Portlet Container Service is listed as **WP PortletContainerService**.

legacy.portlet.enable.filtering = (true)
This property determines whether or not portlet filtering is used.

Project Identification Service:

The Project Identification Service provides access to the identifier for a currently selected project in IBM Web Content Manager. Projects enable you to make changes to a set of items and publish those changes at the same time.

All changes to items occur either within the scope of a project or outside of a project. Changes made to item in the project result in draft items that do not affect the live content. Changes made outside of a project affect the live content.

A project's scope applies to each request, so that the request either completely executes within the scope of a particular project or completely outside the project's scope. For a given request, you cannot switch between projects during request processing.

Because a request is associated with a thread, the project identifier is also associated with the thread. The project service `com.ibm.portal.services.project.ProjectIdentificationService` returns this thread-specific project identifier. Note that the service does not define how to associate a project identifier with a thread; this is handled during URL generation.

Example:

```
InitialContext ctx = new InitialContext();
ProjectIdentificationService piService = (ProjectIdentificationService)
                                         ctx.lookup(ProjectIdentificationService.JNDI_NAME);
ObjectID projectID = piService.getProjectID();
```

Registry Service:

The portal Registry Service loads and caches a small number of objects that are regularly accessed in the engine. This improves performance. However the trade off is that the cached objects can be stale compared to their database counterparts. This applies particularly in a cluster environment.

If the age of those objects causes a problem, try reducing the refresh rate for the respective entities.

In the WebSphere Integrated Solutions Console, the portal Registry Service is listed as **WP RegistryService**.

The following list describes the Registry Service properties:

default.interval = (1800)
The default interval for refreshing a bucket. The amount is specified in seconds, for example `default.interval = 1800`.

bucket.<bucket-name>.class
The type of class that the bucket with the given name is caching.

bucket.<bucket-name>.reload [optional = true]
This property controls whether or not the bucket with the given name is reloaded in frequent intervals.

bucket.<bucket-name>.interval = (default.interval)
The length of the reload interval for the bucket with the given name. If no value is set, the default.interval setting is used.

bucket.<bucket-name>.sorted [optional = false]
This property controls whether or not the bucket with the given name needs to keep the cached objects in a sorted order. The sorting order is determined by the objects themselves.

The bucket names are described in the following:

theme
The theme bucket is used to cache the database representation of all themes stored in the database.

language
The language bucket is used to cache the database representation of all languages that are stored in the database.

skin
The skin bucket is used to cache the database representation of all skins stored in the database.

language
The language bucket is used to cache the database representation of all languages stored in the database.

client
The client bucket is used to cache the database representation of all clients stored in the database.

markup
The markup bucket is used to cache the database representation of all markups stored in the database.

State Manager Service:

The portal State Manager Service is the access point for managing the navigational state of the portal. The navigational state represents the current view of portal resources as displayed to a user.

In the WebSphere Integrated Solutions Console, the portal State Manager Service is listed as **WP StateManagerService**.

The portal State Manager Service holds the following properties:

preprocessors =
(com.ibm.wps.state.preprocessors.selection.StandardPortalSelectionImpl)
This property specifies a list of one or more preprocessors that are used. It can take multiple values.

Notes:

1. If you want to add your own custom preprocessors in the WebSphere Integrated Solutions Console, you must first enter the default values in the following sequence and then append your custom preprocessors to the end of the list. The reason is as follows:
   - If you specify a value for this parameter, that value overwrites the default value.
   - The default value is mandatory. Therefore, you cannot replace it by a different value.
   - The following preprocessors must be arranged in order, as for requests they are processed in that order.
2. The required syntax is (*classname* (, *classname*) *) 1 .

The default value is as follows:

```
preprocessors = com.ibm.wps.state.preprocessors.urlmapping.URLMappingPreProcessor,
                com.ibm.wps.resolver.friendly.preprocessors.FriendlyPreProcessor,
                com.ibm.wps.resolver.portal.ResolvedPreprocessor,
                com.ibm.wps.state.preprocessors.selection.StandardPortalSelectionImpl,
                com.ibm.wps.state.preprocessors.selection.FragmentSelectionImpl,
                com.ibm.wps.state.preprocessors.selection.ResourceSelectionImpl,
                com.ibm.wps.state.preprocessors.eclipse.ExtensionPreProcessor,
                com.ibm.wps.state.preprocessors.portlet.RequestParameterMerger
```

Of the default values given, the following two selection preprocessors are alternative options. They process the page that the user selected. All other preprocessors are for portal internal use only and must not be changed.

Note: Both of the following selection preprocessors are mutually exclusive. They cannot be used in combination with each other.

com.ibm.wps.state.preprocessors.selection.StandardPortalSelectionImpl
This value implements the standard portal selection behavior, which prefers displaying pages over displaying labels. Therefore, if a user selects a label, the portal displays a page under that label, rather than the label itself with the message that says that there is no content available. (In this case the page that is displayed is the last page that the user selected under this label, or if that page is not available, the first available page under the label.) This value is the default value.

com.ibm.wps.state.preprocessors.selection.SimpleSelectionImpl
This value implements a simple selection strategy; it always displays the element that the user selected, regardless of whether the user selects a label or a page. If the user selects a label, the portal displays that label with the message that there is no content available. You can replace this value for the previously listed default value.

To prevent loss of the language information of users' browser session, you can also add the following preprocessor to the list of preprocessors:

com.ibm.wps.state.preprocessors.locale.CookieSupportedLanguagePreProcessor
This preprocessor creates a backup copy of the locale information that is found in the navigational state of the portal page to a cookie. A users's choice of language is lost when the navigational state is cleared. For example, the language information is lost if users use bookmarks to friendly URLs for navigation or if the navigational state is cleared intentionally. You can use this preprocessor to preserve the user's language choice. The language is then persisted to the next page that the user selects. When then user selects a different language, the portal updates the

information in the cookie accordingly. You can also determine the maximum lifetime of the cookie that holds the language information. To do so, specify the following property in the State Manager Service:

com.ibm.wps.state.preprocessors.locale.CookieSupportedLanguagePreProcessor.cookie = (-1)

Specify an integer value. The value is interpreted as the number of seconds until the cookie is invalidated. A negative value, for example -1, means that the cookie is not deleted until the browser session is finished, for example by closing the web browser window. The default value for this property is -1, by which the cookie is not invalidated until the end of the browser session. Examples:

com.ibm.wps.state.preprocessors.locale .CookieSupportedLanguagePreProcessor.cookie.maxage=30

The cookie is active for 30 seconds after the last request.

com.ibm.wps.state.preprocessors.locale .CookieSupportedLanguagePreProcessor.cookie.maxage=-1

The cookie is active while the browser window remains open.

com.ibm.wps.state.preprocessors.selection.StandardPortalSelectionImpl.selection.fallback

Use this property to specify what happens if a user requests a page that does not exist, for example by selecting a bookmark for a page that was deleted. Specify one of the following values:

true

This value is the default value. With this value, the portal takes the user to the default fallback page, for example the home page.

false

With this value, the portal gives an HTTP 404 error.

Use this property together with the `state.decoding.fallback` property in the portal WP configuration service. Set the values for the two properties in a consistent way.

keymanager.lru.size = (*integer*)

Use this property to specify the history expiration limit of portal pages that users select. The number that you specify defines the minimum number of different pages that are selected by the user after which the portal can discard the render parameters of a page. (The decision whether the render parameters of the page are discarded depends on the expiration policy of the internal cache that stores the render parameters of those pages.) If the user returns to a page after the user selects the specified number of other pages *and* if the render parameters of that page expired, the portal displays that page in its default state.

You can specify by which circumstances the render parameters of a page are stored or discarded:

1 Each time that the user selects a different page, the render parameters of the portlets on the previously selected page can be discarded.

A positive integer

Specify the required number of pages. The render parameters of a page can be discarded after the user selected that number of other pages.

0 Render parameters are always stored in the portal session memory and never discarded.

Do not specify a value less than zero (0). Negative values are considered to be not valid.

"URL normalization for search of portal pages by external search engines"
You can configure the normalization of the URL of your portal. URL normalization is required to enable external search engines to crawl the content of your portal.

URL normalization for search of portal pages by external search engines:

You can configure the normalization of the URL of your portal. URL normalization is required to enable external search engines to crawl the content of your portal.

For this purpose, URL normalization runs the following actions:

- It removes all elements from a portal page URL that are used for portal internal purposes. For example, it removes actions that are coded into the URL and change the portal state.
- It reduces the portal page URL to those elements that are required for a crawler to read the URL and crawl the portal page.

You can use the following properties to configure the normalization of the URL of your portal.

com.ibm.wps.state.outputmediators.OutputMediatorFactory.normalization_xsl_file =

(UrlNormalization_MIN.xsl)
Use this property to specify the XSL style sheet file that defines the transformation that you want to use to normalize the portal URL. This property needs to be set all on one line and concatenated. The default value is `UrlNormalization_MIN.xsl`. The following two files are available to allow for a minimum or maximum transformation:

UrlNormalization_MIN.xsl
This XSL style sheet contains the states for `portlet-mode`, `window-state`, `renderparameters`, `selection`, and `locale` in the normalized URL. This transformation represents the minimum set of states that must be defined in the URL. All other states are removed from the URL. This value is the default.

UrlNormalization_MAX.xsl
This XSL style sheet contains the states for `portlet-mode`, `window-state`, `renderparameters`, `selection`, `solo`, `locale`, and `screen-template`. This maximum transformation represents the set of states that can be defined in a normalized URL for a web crawler. All other states are removed from the URL.

The meaning of the different states that are listed for the minimum and maximum normalization style sheets is as follows:

portlet-mode
Portlet modes allow a portlet to display a different user interface, depending on the task that the user performs with the portlet. A portlet has five modes of display: `view`, `help`, `edit`, `edit_defaults`, `config`.

window-state
Portlet states allow users to change how the portlet window is displayed within the portal. Users can choose from three different states: maximized, minimized, normal.

renderparameters
Parameters set to render a portal page.

selection
Defines the selected portal page.

solo
A portlet can also be displayed in solo state. Solo state hides the portal theme elements, such as a banner, page navigation, or toolbar.

locale
Defines the language in which the page is presented.

screen-template
Defines the screen that is used on the portal page.

theme-template
Defines the theme that is used on the portal page.

You can also set up your own URL normalization. You can implement a URL normalization that is different from the URL normalization that is provided by the two XSL style sheets that come with the portal. To do so, create your own XSL style sheet and set it as the value for the URL normalization parameter:

1. Here is an example for creating your own XSL style sheet:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
     <xsl:output method="xml" version="1.0" encoding="UTF-8" indent="yes"/>

     <xsl:template match="text()">
     </xsl:template>

     <!-- Traverse through the tree starting at the root element -->
     <xsl:template match="root">
          <xsl:copy>
               <xsl:copy-of select="@*"/>
     <!-- Search for the state node with the attribute type = navigational -->
               <xsl:apply-templates select="state[@type='navigational']"/>
          </xsl:copy>
     </xsl:template>

     <!-- Selection of all states which should stay coded in the URL -->
     <!-- Allowed States: portlet-mode, window-state, renderparameters (param, value, text),
        selection, solo, locale , screen-template -->
     <xsl:template match="state">
          <xsl:copy>
               <xsl:copy-of select="@*"/>
               <xsl:apply-templates select=" . . . "/>
. . .
          </xsl:copy>
     </xsl:template>

. . .
. . .
. . .

</xsl:stylesheet>
```

2. Set the name of the new XSL style sheet as the value for the URL normalization parameter:

```
com.ibm.wps.state.outputmediators.OutputMediatorFactory.normalization_xsl_file =
     UrlNormalization_Your_Own_Style_Sheet_File_Name.xsl
```

Virtual Portal Configuration Service:

The Virtual Portal configuration service (WP VirtualPortalConfigService) enables you to specify properties for the default virtual portal and for specific virtual portals.

Property syntax

There are several ways that you can define properties for virtual portals:

URL context for the virtual portal
Property format:
`context.`*`virtual_portal_context`*`.property.`*`property_name`*`.`*`property_value`*

Example: `context.vp1.property.property1.true`

Host name of the virtual portal
Property format:
`hostname.`*`virtual_portal_hostname`*`.property.`*`property_name`*`.`*`property_value`*

Example: `hostname.vp1.example.com.property.property1.true`

The default keyword
The default keyword is used to identify the default virtual portal. The default virtual portal has no dedicated URL context or host name.

Property format: `default.`*`property_name`*`.`*`property_value`*

Example: `default.property1.true`

The global keyword
The global keyword is used as a fallback property if there no more specific property defined for a virtual portal.

Property format: `global.`*`property_name`*`.`*`property_value`*

Example: `global.property1.true`

Replace the following variables when defining specific properties:

`property_name`
The name of the property that you are defining.

`property_value`
The value of the property that you are defining.

`virtual_portal_context`
The URL context of the target virtual portal.

`virtual_portal_hostname`
The host name of the target virtual portal.

Note: You can determine the URL context and the host name of the target virtual portal with the Manage Virtual Portals administration portlet.

Evaluation order

The portal evaluates properties for virtual portals in the following order and returns the appropriate value:

1. The portal checks for a specific property defined for a virtual portal by the **`context`**, **`hostname`**, or **`default`** keyword. The value of the property is returned.

Important: If you define conflicting values for a virtual portal with different properties, the results can be unpredictable. For example, this issue can occur if you define one value with the **context** keyword and a different value with the **hostname** keyword. To avoid problems, use only one value.

2. If no specific property is defined for a virtual portal, the portal checks for a property defined by the **global** keyword. The value of the property is returned.
3. If no global property is defined, the value `null` is returned.

Web Content Manager service configuration:

Configuration services for IBM Web Content Manager contain settings for the general operation of the web content system, including settings for messaging, pre-rendering, and searching.

Note: To view or change settings in these configuration services, the preferred method is to use the WebSphere Integrated Solutions Console.

"Web Content Manager configuration service"
The Web Content Manager configuration service (WCM WCMConfigService) defines common configuration settings for Web Content Manager.

"Web Content Manager messaging service" on page 357
The Web Content Manager messaging service (WCM MessagingService) defines settings for enabling the Java messaging services for web content.

"Web Content Manager pre-rendering service" on page 357
The Web Content Manager pre-rendering service (WCM PrerenderService) defines settings that affect how web sites are pre-rendered.

"Web Content Manager search service" on page 359
The Web Content Manager search service (WCM SearchService) defines settings that control how web content is crawled and indexed for searching.

"Personalization service" on page 360
The Web Content Manager Personalization service (WCM PersonalizationService) defines settings that control how web content is used by Personalization.

Web Content Manager configuration service:

The Web Content Manager configuration service (WCM WCMConfigService) defines common configuration settings for Web Content Manager.

api.use.dn
This property specifies whether calls to the Web Content Manager API accept or return the common name (cn) or distinguished name (dn) for user lookups. A value of `true` indicates that the distinguished name is used.

Default value: `false`

defaultLibrary
The name of the default library used for rendering and the API. This is used if the URL or context does not contain a library.

Default value: `Web Content`

default.SiteArea
The name of the default site area to use if the URL does not contain a site area.

Default value: `SiteArea`

connect.businesslogic.module
A list of the modules that are run as part of Web Content Manager on the

portal. Some modules are run as part of the content server itself, while others are only accessed through a URL command. The following modules can be defined:

- `web`: Core module for processing requests for web content. This module is required, so do not remove this module from the list.
- `default`: Core module for processing requests for web content. This module is required, so do not remove this module from the list.
- `ajpe`: Core module for processing requests for web content. This module is required, so do not remove this module from the list.
- `custom`: Core module used to enable custom workflow actions. This module is required, so do not remove this module from the list.
- `syndication`: Core module for managing syndication. This must be enabled on both the syndicator and subscriber servers.
- `itemdispatcher`: Core module used by syndication to send the requested item to a subscriber. This must be enabled on a syndicator server.
- `synd`: Core module for syndication. This must be enabled on a syndicator server.
- `subs`: Core module for subscribing to a syndicator. This must be enabled on a subscriber server.
- `mail`: Core module used for sending email from the email workflow action.
- `plutouploadfile`: Core module used by the authoring portlet to transfer files from the user's computer to the web content system.
- `plutodownloadfile`: Core module used by the authoring portlet to transfer files from the web content system to the user's computer.
- `refreshallitems`: Module to touch all items in a specified library. This will force all items to be saved. This module is accessed through a URL command.
- `unlocklibrary`: Module to unlock a specified library. This module is accessed through a URL command.
- `ajpecatselect`: Module used to update the profile information for the user making the request. This module is accessed through a URL command.
- `memberfixer`: Module to identify or change member IDs between environments with different LDAP topologies. This module is accessed through a URL command.
- `workflowenablement`: Module to enable workflow on content types that do not currently have workflow enabled. This module is accessed through a URL command.
- `clearversions`: Module to clear the version history of an item. This module is accessed through a URL command.
- `clearhistory`: Module to clear the history of an item. This module is accessed through a URL command.

Default value: `web, mail, default, ajpe, ajpecatselect, memberfixer, workflowenablement, itemdispatcher, plutouploadfile, plutodownloadfile, synd, subs, syndication, refreshallitems, unlocklibrary, custom, data, clearversions, clearhistory`

`connect.moduleconfig.syndication.inittasks`

Indicates whether automatic syndication is enabled. This property should be set the same on both the syndicator and the subscriber. If set to "false" , automatic syndication is not enabled. If set to "true", automatic syndication is enabled.

Default value: `true`

`cmpnt.htmlEncodeDefault`
Indicates whether HTML encoding occurs for text in components.

Default value: `true`

`active.content.filtering.enable`
Indicates whether active content filtering is enabled or disabled.

Default value: `true`

`nestedGroupLookup.disabled`
The **`accessControlDataManagement.enableNestedGroups`** setting does not apply to Web Content Manager. Web Content Manager continues to request a user's full hierarchical group membership and therefore prevents environments using Web Content Manager from completely disabling nested groups. This setting will control whether Web Content Manager will perform a nested group lookup with a value of true indicating to disable nested group lookups and a value of false indicating to perform nested group lookups.

Default value: `false`

`recentitems.size`
Specifies the maximum number of recent items to store, up to a maximum value of `100`.

Default value: `10`

`versioningStrategy.Default`
Specifies the default versioning behavior. Possible values include `always`, `never`, or `manual`.

Default value: `always`

`versioningStrategy.AuthoringTemplate`
Specifies the versioning behavior used for authoring templates. Possible values include `always`, `never`, or `manual`.

Default value: `always`

`versioningStrategy.Component`
Specifies the versioning behavior used for components. Possible values include `always`, `never`, or `manual`.

Default value: `always`

`versioningStrategy.Content`
Specifies the versioning behavior used for content items. Possible values include `always`, `never`, or `manual`.

Default value: `always`

`versioningStrategy.PresentationTemplate`
Specifies the versioning behavior used for presentation templates. Possible values include `always`, `never`, or `manual`.

Default value: `always`

`versioningStrategy.SiteArea`
Specifies the versioning behavior used for sites. Possible values include `always`, `never`, or `manual`.

Default value: `always`

versioningStrategy.Taxonomy
Specifies the versioning behavior used for taxonomy items. Possible values include `always`, `never`, or `manual`.

Default value: `always`

versioningStrategy.Workflow
Specifies the versioning behavior used for workflow items. Possible values include `always`, `never`, or `manual`.

Default value: `always`

resource.maxUploadSize
Specifies the maximum size in megabytes (MB) of individual files uploaded in file, image, rich text, and HTML components.

Default value: `16`

resourceserver.maxCacheObjectSize
Specifies the maximum size in kilobytes (KB) of resources to be cached by the resource server module.

Default value: `300`

resourceserver.cacheExpiryDate
Specifies the expiry date of resources cached by the resource server module.

Default value: `REL 1M`

user.cache.enable
Indicates whether the cache holds user object in the web content system.

Default value: `false`

admin.delete.error.percent.threshold
The error percent threshold for a given type when deleting a library. This value is specified as an integer from `0` to `100`. If the threshold level is reached for any type, the library deletion task is stopped.

Note: If the threshold is set to `100`, the task ignores the error rate. If the threshold is set to an unsupported value, such as a value less than `0` or greater than `100`, the threshold is set to the default value of `40` percent.

Default value: `40`

deployment.subscriberOnly
Indicates whether this instance of Web Content Manager will only be subscribed to by other servers and will never itself syndicate content to other servers. If this property is set to `true`, all item gatherers are deleted and the item changed task is not added to the scheduler. This improves performance and is recommended for production machines that are subscribe-only servers.

Default value: `false`

deployment.itemChangedTaskDelay
Specifies the number of seconds to use as the syndication interval, with a minimum of `0` seconds and a maximum of `65536` seconds. A value of `0` will prevent syndication from occurring. The shorter the interval, the sooner an update can be sent, but because frequent syndication can affect performance on servers with large amounts of content, a longer interval might be required.

Default value: `30`

wcm.transaction.timeout
Web Content Manager uses a default transaction timeout of 120 seconds even when the value is changed in the server.

Default value: 120

Web Content Manager messaging service:

The Web Content Manager messaging service (WCM MessagingService) defines settings for enabling the Java messaging services for web content.

topic.publishing.enabled
This must be set to true to enable message generation and delivery.

Default value: `false`

items.topic.publishing.enabled
Indicates whether item topics are published. This must be set to true to enable messages for item state changes.

Default value: `true`

syndication.topic.publishing.enabled
Indicates whether syndication topics are published. This must be set to true to enable messages for the status of syndication.

Default value: `true`

prerender.topic.publishing.enabled
Indicates whether pre-render topics are published. This must be set to true to enable messages for the status of pre-rendering.

Default value: `true`

items.topic.name
The JNDI name of the JMS topic for status changes.

Format for item state changes: jms/IWKTopics/Items

Format for syndication state changes: jms/IWKTopics/Syndication

Format for pre-rendering state changes: jms/IWKTopics/PreRender

Default value: None

topic.connection.secure

Set to true to enable secure topic connections. You must also set username and password.

Default value: `false`

topic.connection.secure.username

Username for secure topic connections.

topic.connection.secure.password

A clear text or encoded password for secure topic connections. The password can be encoded using the *PropFilePasswordEncoder* task.

Web Content Manager pre-rendering service:

The Web Content Manager pre-rendering service (WCM PrerenderService) defines settings that affect how web sites are pre-rendered.

prerender.extended.support.enabled
Indicates whether prererendering supports JSP and PZN requests.

Default value: `false`

prerender.authenticator.classname
Indicates the authenticator used to make a connection to the default login URL for the portal, when an external security manager is not installed.

Default value:
`com.aptrix.cacher.authentication.WCMDefaultPrerenderAutthenticator`

prerender.authenticator.credentials.classname
The credentials used by the authenticator specified by the `prerender.authenticator.classname` property.

Default value:
`com.aptrix.cacher.authentication.DefaultPrerenderPropertiesCredentials`

prerender.default.authenticator.credentials.username
Indicates the user name used by the DefaultPrerenderPropertiesCredentials authenticator. If you are using a custom credential provider, this property is not required.

Default value: *portal_admin_id*

prerender.default.authenticator.credentials.password
Indicates the password used by the DefaultPrerenderPropertiesCredentials authenticator. If you are using a custom credential provider, this property is not required. The password can be encoded using the PropFilePasswordEncoder utility provided with WebSphere Application Server.

Default value: *portal_admin_password*

prerender.default.isSecure
Indicates whether the server URLs should be formatted with secure HTTP (`https://...`) or unsecured HTTP (`http://...`).

Default value: `false`

prerender.default.hostName
The host name of the server performing prerendering. The value is typically represented as a WebSphere Application Server variable (for example, `${WCM_HOST}`).

Default value: `${WCM_HOST}`

prerender.default.hostPort
The port number for server performing prerendering. The value is typically represented as a WebSphere Application Server variable (for example, `${WCM_PORT}`).

Default value: `${WCM_PORT}`

prerender.default.portalContext
The context root for the Web Content Manager web application (for example, `/wps/wcm`). The value is typically represented as a WebSphere Application Server variable (for example, `${WCM_WPS_CONTEXT_ROOT}`).

Default value: `${WCM_WPS_CONTEXT_ROOT}`

prerender.default.portal.servlet.authenticatedContext
The authenticated context root for the portal (for example, `/myportal`). The value is typically represented as a WebSphere Application Server variable (for example, `${WCM_WPS_CONTEXT_ROOT}/${WCM_WPS_PERSONALIZED_HOME}`).

Default value: ${WCM_WPS_CONTEXT_ROOT}/${WCM_WPS_PERSONALIZED_HOME}

prerender.default.portal.servlet.unauthenticatedContext
The unauthenticated context root for the portal (for example, /portal). The value is typically represented as a WebSphere Application Server variable (for example, ${WCM_WPS_CONTEXT_ROOT}/${WCM_WPS_DEFAULT_HOME}).

Default value: ${WCM_WPS_CONTEXT_ROOT}/${WCM_WPS_DEFAULT_HOME}

prerender.default.wcm.servlet.authenticatedContext
The default secured path to the Web Content Manager servlet.

Default value: ${WCM_CONTEXT_ROOT}/myconnect

prerender.default.wcm.servlet.unauthenticatedContext
The default unsecured path to the Web Content Manager servlet.

Default value: ${WCM_CONTEXT_ROOT}/connect

Web Content Manager search service:

The Web Content Manager search service (WCM SearchService) defines settings that control how web content is crawled and indexed for searching.

SearchService.DateFormatString
Indicates the date format to use when entering dates in search forms and for displaying search results. Enter a supported Java date format string. If this property is not set, then the default format is MMM dd yyyy HH:mm:ss z.

Default value: None

SearchService.RecrawlInterval
Indicates the interval in hours between crawling of new web content search sources.

Default value: 4

SearchService.BrokenLinksExpirationAge
Indicates the expiration age in days for broken links in new web content search sources.

Default value: 1

SearchService.MetaFields
Specifies additional elements to crawl when searching for metadata. The format for this property is elementName,key1. To specify more than one metadata field maps, use the following format: elementName1,key1;elementName2,key2;elementName3,key3. For example: metaText,meta.

- elementName is the name of element you want to search for metadata. Any valid element with that name in a searchable site area or content item will be crawled.
- key is the "key" that is specified in an element tag used as part of a search element design. In the previous example, the key of meta has been used. To render the content of the metaText element in a search element design, you would use the following tag: <Element context="autoFill" type="content" key="meta"/>.

Notes:

- Only text elements and short text elements can be searched.
- Only site areas that have been configured to be searchable will be crawled.

Default value: None

SearchService.SearchSeed.ExcludeFileAttachments
Indicates whether resource component attachments are included in the search results. If this property is set to `false`, the files stored in file resource elements in content items can also be searched. Files stored in file resource elements in a site area can also be searched as long as a default content item has been selected.

Default value: `false`

SearchService.SearchSeed.excludeExtensions
Set this to a list of file name extensions that you want to exclude from search results. Separate each item in the list with a comma. Any file resource component attachments and file resource element attachments that have these extensions are excluded from search results. For example, `SearchService.SearchSeed.excludeExtensions=avi,mpeg,zip`.

Default value: None

SearchService.DefaultResultPageSize
Specifies the default number of items displayed per page for new web content search components.

Default value: `10`

SearchService.Siapi.IIOP_URL
The IIOP URL created for the default search service.

Default value: None

SearchService.Siapi.EJB
The EJB name for the JNDI associated with the default search service.

Default value: None

SearchService.Siapi.SOAP_URL
The SOAP URL created for the default search service.

Default value: None

SearchService.Siapi.PSE.Type
The type of search service used for the default search service.

Default value: None

SearchService.DefaultCollectionName
The default web content search collection created during installation.

Default value: `WebContentCollection`

SearchService.DefaultSeedPageSize
Specifies the number of items displayed per page for the Web Content Manager search seed servlet.

Default value: `200`

Personalization service:

The Web Content Manager Personalization service (WCM PersonalizationService) defines settings that control how web content is used by Personalization.

rulesEngine.user.nestedGroupLookup
The accessControlDataManagement.enableNestedGroups setting does not apply to Personalization. Personalization continues to request a users full hierarchical group membership and therefore prevents environments using

Personalization from completely disabling nested groups. This setting will control whether Personalization performs a nested group lookup with a value of true indicating to perform nested group lookups and a value of false indicating to disable nested group lookups.

Default value: `true`

Changing ports

You can change the IBM WebSphere Portal Express ports values after installation if there are port conflicts with other cells on the system.

Before you begin

WebSphere Portal Express is installed.

Note: The starting port parameter is required for a successful completion of the **`modify-ports-by-startport`** task. When you specify a start port, this port becomes the base for assigning port values. The code increments this value as each port is assigned, which means that the WebSphere Portal Express ports are assigned incrementally starting with the port defined with the **`modify-ports-by-startport`** task.

Procedure

1. Run the following task from the *wp_profile_root*`/ConfigEngine` directory to generate the `WebSphere_Portal_PortMatrix.txt` file:

   Note: The port file is in the *wp_profile_root*`/ConfigEngine/log` directory. It lists the WebSphere Portal Express (WebSphere_Portal) ports for your installation.

   - Linux : `./ConfigEngine.sh list-server-ports-by-name -DServerName=WebSphere_Portal -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat list-server-ports-by-name -DServerName=WebSphere_Portal -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh list-server-ports-by-name -DServerName=WebSphere_Portal -DWasPassword=`*`password`*
2. Stop the WebSphere_Portal server.
3. Run the following command to change the starting port number:
   - Linux : `./ConfigEngine.sh modify-ports-by-startport -DWasPassword=`*`password`* `-DModifyPortsServer=`*`WebSphere_Portal`* `-DStartPort=`*`starting port number`*
   - Windows: `ConfigEngine.bat modify-ports-by-startport -DWasPassword=`*`password`* `-DModifyPortsServer=`*`WebSphere_Portal`* `-DStartPort=`*`starting port number`*
   - IBM i: `ConfigEngine.sh modify-ports-by-startport -DWasPassword=`*`password`* `-DModifyPortsServer=`*`WebSphere_Portal`* `-DStartPort=`*`starting port number`*
4. Run the following command to change ports by using the port file:

   Note: Sample port files are available on the Setup disc. The following information is an example of a port file although the port values are different based on your environment:

   ```
   BOOTSTRAP_ADDRESS=10035
   SOAP_CONNECTOR_ADDRESS=10025
   ORB_LISTENER_ADDRESS=10034
   SAS_SSL_SERVERAUTH_LISTENER_ADDRESS=10041
   CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS=10036

- Windows: `ConfigEngine.bat modify-ports-by-portsfile -DWasPassword=`*`password`* `-DModifyPortsServer=`*`WebSphere_Portal`* `-DPortsFile=`*`full path to ports file`*
- IBM i: `ConfigEngine.sh modify-ports-by-portsfile -DWasPassword=`*`password`* `-DModifyPortsServer=`*`WebSphere_Portal`* `-DPortsFile=`*`full path to ports file`*

5. Restart the WebSphere_Portal server.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Completing the portal URI change started during installation

If you changed the context root on the **Configuration for IBM WebSphere Portal: Profile configuration details: Advanced** pane during installation, there are more steps to take to complete the change.

About this task

IBM WebSphere Portal Express and Web Services for Remote Portlets are installed with a default URI. You can change this URI after installation to better suit the requirements of your organization.

Notes:

- To change the WebSphere Portal Express URI: When you specify the context root, do not specify a value that is the same as a directory that exists in a portlet WAR directory. For example, you set the WebSphere Portal Express context root to `/images`. There is a portlet with the directory structure `/myPortlet.ear/myPortlet.war/images`. This issue might cause a conflict if the portlet encodes URI references to resources in its own `/images` directory. In this situation, the portlet would be unable to display images. WebSphere Portal Express looks for the image resources according to its own context root path instead of the directory path that is specified by the portlet WAR file.
- For changing the URI of a WSRP Producer portal: Changing the WSRP Producer context root does not require that you redeploy all portlets. Run the **`modify-servlet-path`** configuration task only.

Important: With Version 8, the URI of the context root for the WSRP Producer is `/wps/wsrp`. Before Version 8, this context root was `/wsrp`. If you migrated from an earlier version, you still might have WSRP Consumers that attempt to access the WSRP Producer with the previous context root (`/wsrp`). You can correct this issue in one of the following ways:

- Modify the context root for the WSRP Producer to `/wsrp`. This change enables the Consumers to access the Producer without requiring further changes to the Consumers.
- Update the configuration of the WSRP Consumers to use the new context root (`/wps/wsrp`).

- If you use IBM Web Content Manager Syndication, the Syndicators and Subscribers servers that refer to this Portal instance must be updated with the modified URI. Log on to the WebSphere Portal Express syndicating to this instance. Click the **Administration menu** icon. Then, click **Portal Content** > **Syndicators**. Click the edit icon of the Syndicator you want to edit. Update the URL with the new context root information. Then, log on to the WebSphere Portal Express subscribing to this instance. Click the **Administration menu** icon. Then, click **Portal Content** > **Subscribers**. Click the edit icon of the subscriber you want to edit. Update the URL with the new context root information.

Procedure

1. If necessary, start the WebSphere_Portal server in a stand-alone environment or the deployment manager and node agent in a clustered environment.
2. For combined cumulative fix 7 or earlier: Complete the following steps on the Deployment Manager server:
   a. Log on to the Deployment Manager WebSphere Integrated Solutions Console.
   b. Go to **Security** > **Global security**.
   c. Click **Trust association** in the Web and SIP security section.
   d. Click **Interceptors** in the Additional Properties section.
   e. Click **com.ibm.portal.auth.tai.HTTPBasicAuthTAI**.
   f. Edit the **urlBlackList** and **urlWhiteList** parameters with the new context path, for example:
      - **urlBlackList**: */wpsmodified*/myportalmodified*
      - **urlWhiteList**: */wpsmodified*/mycontenthandler*
   g. Click **Apply**.
   h. Save all changes.
   i. Log out of the Deployment Manager WebSphere Integrated Solutions Console.
3. Complete the following steps if you are using an external web server, such as an HTTP Server:
   a. Choose one of the following options that are based on your WebSphere Portal Express environment:

Table 36. `configurewebservername` command options

WebSphere Portal Express environment	Steps
Stand-alone configuration	Complete the following steps in a stand-alone configuration: 1. Copy the following script from the `plugin_root/bin` directory of the web server to the *wp_profile_root*`/bin` directory on your WebSphere Portal Express server: • Linux : `./configure`*`webservername`*`.sh` • Windows: `configure`*`webservername`*`.bat` • IBM i: `configure`*`webservername`*`.sh` where *webservername* is the web server definition name you defined previously when you configured the HTTP Server for WebSphere Portal Express, for example: `configurewebserver1.bat`. 2. Run the following command, from the *wp_profile_root*`/bin` directory: • Linux : `./configure`*`webservername`*`.sh` • Windows: `configure`*`webservername`*`.bat` • IBM i: `configure`*`webservername`*`.sh`
Idle standby configuration	Complete the following steps in a idle standby configuration: 1. Copy the following script from the `plugin_root/bin` directory of the web server to the `dmgr_profile/bin` directory on your Deployment Manager server: • Linux : `./configure`*`webservername`*`.sh` • Windows: `configure`*`webservername`*`.bat` • IBM i: `configure`*`webservername`*`.sh` where *webservername* is the web server definition name you defined previously when you configured the HTTP Server for WebSphere Portal Express, for example: `configurewebserver1.bat`. 2. Run the following command on the Deployment Manager server: • Linux : `./configure`*`webservername`*`.sh` • Windows: `configure`*`webservername`*`.bat` • IBM i: `configure`*`webservername`*`.sh`

b. Regenerate the web server plug-in in WebSphere Application Server. If you are using a remote web server, copy the generated `plugin-cfg.xml` file to the remote server.

   Important: Do not complete these steps if you are changing only the WSRP Producer URI.

c. Restart the web server.

d. Restart the WebSphere_Portal server.

4. For combined cumulative fix 7 or earlier: Complete the following steps to update the registered Application URI entries in the JCR.ICMSTJCRNODEREGISTER table:

   Cluster note: In a clustered environment, complete these steps on the primary node only.

   a. Stop the WebSphere_Portal server.
   b. Back up the database.
   c. Prior to CF04, start the WebSphere_Portal server. CF04 Starting with CF04, do not restart the WebSphere_Portal server.
   d. Complete the following steps to unregister the node types:
      - Open the `ibmcontentwcm.registernodetypes` file, which is in the `/WebSphere/PortalServer/wcm/prereq.wcm/config/nodetypes/` directory.
      - Change `<registerAction action="register"/>` to `<registerAction action="deregister"/>`.
      - Save your changes.
      - Run the following task:
        - Linux : `./ConfigEngine.sh action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
        - Windows: `ConfigEngine.bat action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
        - IBM i: `ConfigEngine.sh action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
   e. Complete the following steps to register the node types:
      - Open the `ibmcontentwcm.registernodetypes` file, which is in the `/WebSphere/PortalServer/wcm/prereq.wcm/config/nodetypes/` directory.
      - Change `<registerAction action="deregister"/>` to `<registerAction action="register"/>`.
      - Update all lines that contain the `<ApplicationURI name="wps/mypoc/?view=auth&uri=wcm:oid:"/>` content.

        Change the name of the attribute value to reflect the new **`WpsContextRoot`** value that is found in the `wkplc.properties` file. For example, if the original value for **`WpsContextRoot`** was `wps` and the new value is `wp8`, change the lines to `<ApplicationURI name="wp8/mypoc/?view=auth&uri=wcm:oid:"/>`.
      - Run the following task:
        - Linux : `./ConfigEngine.sh action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
        - Windows: `ConfigEngine.bat action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
        - IBM i: `ConfigEngine.sh action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
   f. Run the following SQL query to verify that the entries in the table now show the new URI:

      ```
      select * from JCR.ICMSTJCRNODEREGISTER
      ```

   g. Restart the WebSphere_Portal server.

5. Required if you use IBM Web Content Manager: Complete the following steps to manually change the JSP components in the Web Resources v70 Library:

Cluster note: In a clustered environment, complete these steps on the primary node only.

a. Log on to WebSphere Portal Express.
b. Go to **Applications** > **Content** > **Web Content Authoring**.
c. Under **Preferences**, select **Edit Shared Settings**.
d. Under **Library Selection**, add **Web Resources v70** to the **Selected Libraries** list.
e. Click **OK**.
f. Under **Item Views**, select **All Items** > **All** > **Components** > **JSP**.
g. Select every **JSP component** from the Web Resources v70 library and then click **Edit**.
h. Update the **Path** field for every JSP component with the new context root path.

   The JSP path includes two parts, which are separated by a semi-colon. The first part is the context path to the IBM Web Content Manager extensions web application and then the second part is the path to the JSP. Update the path to the web application.

   For example, the other path might be: `/wcmextension;/jsp/html/general/UpdateItem.jsp`. If you changed the context root to `mynewcontext`, change the old path to `/mynewcontext/wcmextension;/jsp/html/general/UpdateItem.jsp`.

6. Complete the following steps to edit the context root for every search collection:

   Attention: Edit the context root for each existing search collection.

   a. Log on to WebSphere Portal Express as the administrator.
   b. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   c. Click **Search Collections**.
   d. Click the search collection that you want to update. For example: **Default Search Collection**.
   e. Click the **Edit Content Source** icon for the first content source in the list.
   f. Edit the URL listed in the **Collect documents link from the URL** with the new context root.
   g. Click **Save**.
   h. Edit the URL in each remaining content source and then save your changes.
   i. Start the WebSphere Portal Express crawler content source for each collection:
      - If the documents are not stored in the search collection but a schedule is defined for the crawler, the crawler automatically runs at the scheduled time. You can also start the crawler manually.
      - If the documents are already collected, select **Regather documents** to update the documents with the new context root information.
   j. Click **Collections from All Services** in the breadcrumb trail and select the next search collection to modify.

7. For combined cumulative fix 7 or earlier: Complete the following steps to change the context root for the **Seedlist_Servlet**:

   a. Log in to the WebSphere Integrated Solutions Console.

b. Go to **Applications** > **Application Types** > **WebSphere enterprise applications**.
c. Click the **Seedlist_Servlet** application link.
d. Click **Context Root For Web Modules**.
e. Change the context root and then click **OK**.
f. Save your changes.

8. Idle standby only: Resynchronize the nodes and restart the cluster.

Table 37. Steps to resynchronize the nodes and restart the cluster.

Cluster type	Steps
Idle standby	Complete the following steps if you have an idle standby environment: 1. Open the deployment manager WebSphere Integrated Solutions Console. 2. Click **System Administration** > **Nodes**, select the primary node from the list, and click **Full Resynchronize**. 3. Click **Servers** > **Clusters**. 4. Select the cluster and click **Stop**. 5. After the cluster stops, restart it by selecting the cluster. Then, click **Start**.

9. For combined cumulative fix 7 or earlier: Complete the following steps on the stand-alone server or on each node within your cluster to create the WebSphere environment variables that IBM Web Content Manager needs:
   a. Locate the `wkplc.properties` and `wkplc_comp.properties` files in the *wp_profile_root*`/ConfigEngine/properties` directory and create backup copies before you change any values.
   b. Use a text editor to open the `wkplc.properties` file and enter the appropriate value for your environment in the **`WpsContextRoot`** property.
   c. Save and close the file.
   d. Use a text editor to open the `wkplc_comp.properties` file and enter the appropriate value for your environment in the following properties:
      - **`WsrpContextRoot`**
      - **`WpsPersonalizedHome`**
      - **`WpsDefaultHome`**

      Attention: Do not enter the same value for **`WpsPersonalizedHome`** and **`WpsDefaultHome`**.
   e. Save and close the file.
   f. Run the following task to create the WebSphere environment variables for Web Content Manager:
      - Linux : `./ConfigEngine.sh create-wcm-servletpath-variables -DServerName=`*`your_application_server_name`* `-DWasPassword=`*`password`*
      - Windows: `ConfigEngine.bat create-wcm-servletpath-variables -DServerName=`*`your_application_server_name`* `-DWasPassword=`*`password`*
      - IBM i: `ConfigEngine.sh create-wcm-servletpath-variables -DServerName=`*`your_application_server_name`* `-DWasPassword=`*`password`*

Note: Check the output for any error messages before you proceed with the next task. If any of the configuration tasks fail, verify the values in the `wkplc.properties` and `wkplc_comp.properties` files.

10. Resynchronize the nodes and restart the cluster.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Changing the portal URI after an installation

You can change the default portal Uniform Resource Identifier (URI) any time after you install IBM WebSphere Portal Express. Some applications have a fixed context root that cannot be changed.

About this task

IBM WebSphere Portal Express and Web Services for Remote Portlets are installed with a default URI. You can change this URI after installation to better suit the requirements of your organization.

Notes:

- To change the WebSphere Portal Express URI: When you specify the context root, do not specify a value that is the same as a directory that exists in a portlet WAR directory. For example, you set the WebSphere Portal Express context root to `/images`. There is a portlet with the directory structure `/myPortlet.ear/myPortlet.war/images`. This issue might cause a conflict if the portlet encodes URI references to resources in its own `/images` directory. In this situation, the portlet would be unable to display images. WebSphere Portal Express looks for the image resources according to its own context root path instead of the directory path that is specified by the portlet WAR file.
- For changing the URI of a WSRP Producer portal: Changing the WSRP Producer context root does not require that you redeploy all portlets. Run the **`modify-servlet-path`** configuration task only.

  Important: With Version 8, the URI of the context root for the WSRP Producer is `/wps/wsrp`. Before Version 8, this context root was `/wsrp`. If you migrated from an earlier version, you still might have WSRP Consumers that attempt to access the WSRP Producer with the previous context root (`/wsrp`). You can correct this issue in one of the following ways:
  - Modify the context root for the WSRP Producer to `/wsrp`. This change enables the Consumers to access the Producer without requiring further changes to the Consumers.
  - Update the configuration of the WSRP Consumers to use the new context root (`/wps/wsrp`).
- If you use IBM Web Content Manager Syndication, the Syndicators and Subscribers servers that refer to this Portal instance must be updated with the modified URI. Log on to the WebSphere Portal Express syndicating to this instance. Click the **Administration menu** icon. Then, click **Portal Content** > **Syndicators**. Click the edit icon of the Syndicator you want to edit. Update the URL with the new context root information. Then, log on to the WebSphere Portal Express subscribing to this instance. Click the **Administration menu** icon.

Then, click **Portal Content** > **Subscribers**. Click the edit icon of the subscriber you want to edit. Update the URL with the new context root information.

Cluster note: If you modify the URI in a clustered environment, complete the steps that are described here on the primary node only, except where specified differently. Also, verify that **AutoSynch** is set to a frequency of 1 minute.

Procedure

1. Complete the following steps to manually modify the WebSphere Portal Express context root:
   a. Stop the WebSphere_Portal server.
   b. Locate the `wkplc.properties` and `wkplc_comp.properties` files in the *wp_profile_root*`/ConfigEngine/properties` directory and create backup copies before you change any values.
   c. Use a text editor to open the `wkplc.properties` file and enter the appropriate value for your environment in the **WpsContextRoot** property.
   d. Save and close the file.
   e. Use a text editor to open the `wkplc_comp.properties` file and enter the appropriate value for your environment in the following properties:
      - **WsrpContextRoot**
      - **WpsPersonalizedHome**
      - **WpsDefaultHome**

      Attention: Do not enter the same value for **WpsPersonalizedHome** and **WpsDefaultHome**.
   f. Save and close the file.
   g. Start the WebSphere_Portal server in a stand-alone environment or the deployment manager and node agent in a clustered environment.
   h. Open a command prompt and change to the *wp_profile_root*`/ConfigEngine` directory.
   i. Complete the following steps to change the WebSphere Portal Express URI:
      1) To change the context root for the values that you entered in the **WpsContextRoot**, **WsrpContextRoot**, **WpsPersonalizedHome**, and or **WpsDefaultHome** properties, run the following task:
         - Linux :`./ConfigEngine.sh modify-servlet-path -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
         - Windows: `ConfigEngine.bat modify-servlet-path -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
         - IBM i: `ConfigEngine.sh modify-servlet-path -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

         Note: Check the output for any error messages before you proceed with the next task. If any of the configuration tasks fail, verify the values in the `wkplc.properties` and `wkplc_comp.properties` files.
      2) Restart the WebSphere_Portal server.
   j. Run the following task to change the context root for the portlets:
      - Linux : `./ConfigEngine.sh modify-servlet-path-portlets -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
      - Windows: `ConfigEngine.bat modify-servlet-path-portlets -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

- IBM i: `ConfigEngine.sh modify-servlet-path-portlets -DPortalAdminPwd=password -DWasPassword=password`

Note: Check the output for any error messages before you proceed with the next task. If any of the configuration tasks fail, verify the values in the `wkplc.properties` and `wkplc_comp.properties` files.

2. For combined cumulative fix 7 or earlier: Complete the following steps on the Deployment Manager server:
   a. Log on to the Deployment Manager WebSphere Integrated Solutions Console.
   b. Go to **Security** > **Global security**.
   c. Click **Trust association** in the Web and SIP security section.
   d. Click **Interceptors** in the Additional Properties section.
   e. Click **com.ibm.portal.auth.tai.HTTPBasicAuthTAI**.
   f. Edit the **urlBlackList** and **urlWhiteList** parameters with the new context path, for example:
      - **urlBlackList**: */wpsmodified*/myportalmodified*
      - **urlWhiteList**: */wpsmodified*/mycontenthandler*
   g. Click **Apply**.
   h. Save all changes.
   i. Log out of the Deployment Manager WebSphere Integrated Solutions Console.
3. If necessary, start the WebSphere_Portal server in a stand-alone environment or the deployment manager and node agent in a clustered environment.
4. Complete the following steps if you are using an external web server, such as an HTTP Server:
   a. Choose one of the following options that are based on your WebSphere Portal Express environment:

Table 38. `configurewebservername` command options

WebSphere Portal Express environment	Steps
Stand-alone configuration	Complete the following steps in a stand-alone configuration: 1. Copy the following script from the `plugin_root/bin` directory of the web server to the *wp_profile_root*`/bin` directory on your WebSphere Portal Express server: • Linux : `./configure`*`webservername`*`.sh` • Windows: `configure`*`webservername`*`.bat` • IBM i: `configure`*`webservername`*`.sh` where *webservername* is the web server definition name you defined previously when you configured the HTTP Server for WebSphere Portal Express, for example: `configurewebserver1.bat`. 2. Run the following command, from the *wp_profile_root*`/bin` directory: • Linux : `./configure`*`webservername`*`.sh` • Windows: `configure`*`webservername`*`.bat` • IBM i: `configure`*`webservername`*`.sh`
Idle standby configuration	Complete the following steps in a idle standby configuration: 1. Copy the following script from the `plugin_root/bin` directory of the web server to the `dmgr_profile/bin` directory on your Deployment Manager server: • Linux : `./configure`*`webservername`*`.sh` • Windows: `configure`*`webservername`*`.bat` • IBM i: `configure`*`webservername`*`.sh` where *webservername* is the web server definition name you defined previously when you configured the HTTP Server for WebSphere Portal Express, for example: `configurewebserver1.bat`. 2. Run the following command on the Deployment Manager server: • Linux : `./configure`*`webservername`*`.sh` • Windows: `configure`*`webservername`*`.bat` • IBM i: `configure`*`webservername`*`.sh`

b. Regenerate the web server plug-in in WebSphere Application Server. If you are using a remote web server, copy the generated `plugin-cfg.xml` file to the remote server.

   Important: Do not complete these steps if you are changing only the WSRP Producer URI.

c. Restart the web server.

d. Restart the WebSphere_Portal server.

5. For combined cumulative fix 7 or earlier: Complete the following steps to update the registered Application URI entries in the JCR.ICMSTJCRNODEREGISTER table:

   Cluster note: In a clustered environment, complete these steps on the primary node only.

   a. Stop the WebSphere_Portal server.

   b. Back up the database.

   c. Prior to CF04, start the WebSphere_Portal server. CF04 Starting with CF04, do not restart the WebSphere_Portal server.

   d. Complete the following steps to unregister the node types:
      - Open the `ibmcontentwcm.registernodetypes` file, which is in the `/WebSphere/PortalServer/wcm/prereq.wcm/config/nodetypes/` directory.
      - Change `<registerAction action="register"/>` to `<registerAction action="deregister"/>`.
      - Save your changes.
      - Run the following task:
        - Linux : `./ConfigEngine.sh action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
        - Windows: `ConfigEngine.bat action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
        - IBM i: `ConfigEngine.sh action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*

   e. Complete the following steps to register the node types:
      - Open the `ibmcontentwcm.registernodetypes` file, which is in the `/WebSphere/PortalServer/wcm/prereq.wcm/config/nodetypes/` directory.
      - Change `<registerAction action="deregister"/>` to `<registerAction action="register"/>`.
      - Update all lines that contain the `<ApplicationURI name="wps/mypoc/?view=auth&uri=wcm:oid:"/>` content.

        Change the name of the attribute value to reflect the new **`WpsContextRoot`** value that is found in the `wkplc.properties` file. For example, if the original value for **`WpsContextRoot`** was `wps` and the new value is `wp8`, change the lines to `<ApplicationURI name="wp8/mypoc/?view=auth&uri=wcm:oid:"/>`.
      - Run the following task:
        - Linux : `./ConfigEngine.sh action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
        - Windows: `ConfigEngine.bat action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
        - IBM i: `ConfigEngine.sh action-register-wcm-nodetypes -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*

   f. Run the following SQL query to verify that the entries in the table now show the new URI:

      ```
      select * from JCR.ICMSTJCRNODEREGISTER
      ```

   g. Restart the WebSphere_Portal server.

6. Required if you use IBM Web Content Manager: Complete the following steps to manually change the JSP components in the Web Resources v70 Library:

Cluster note: In a clustered environment, complete these steps on the primary node only.

a. Log on to WebSphere Portal Express.
b. Go to **Applications** > **Content** > **Web Content Authoring**.
c. Under **Preferences**, select **Edit Shared Settings**.
d. Under **Library Selection**, add **Web Resources v70** to the **Selected Libraries** list.
e. Click **OK**.
f. Under **Item Views**, select **All Items** > **All** > **Components** > **JSP**.
g. Select every **JSP component** from the Web Resources v70 library and then click **Edit**.
h. Update the **Path** field for every JSP component with the new context root path.

   The JSP path includes two parts, which are separated by a semi-colon. The first part is the context path to the IBM Web Content Manager extensions web application and then the second part is the path to the JSP. Update the path to the web application.

   For example, the other path might be: `/wcmextension;/jsp/html/general/UpdateItem.jsp`. If you changed the context root to `mynewcontext`, change the old path to `/mynewcontext/wcmextension;/jsp/html/general/UpdateItem.jsp`.

7. Optional: Update your custom themes to reference the correct Dojo context root.

   The default Dojo context root in WebSphere Portal Express is `/wps/portal_dojo`. After you run the **`modify-servlet-path`** and **`modify-servlet-path-portlets`** tasks, the Dojo context root is changed to include the new value in the **`WpsContextRoot`** parameter as the prefix. For instance, if the new **`WpsContextRoot`** value is `myco`, then the new Dojo context root becomes `/myco/portal_dojo`. If your theme includes hardcoded references to `"/wps/portal_dojo"`, update those references to the new context root. If you migrated a custom theme, you might find that it has references to `/portal_dojo` without the `/wps` prefix. Look for these references in both the WAR file and in the WebDAV storage for your theme.

   Cluster note: In a clustered environment, complete these steps on the primary node only.

8. Complete the following steps to edit the context root for every search collection:

   Attention: Edit the context root for each existing search collection.

   a. Log on to WebSphere Portal Express as the administrator.
   b. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   c. Click **Search Collections**.
   d. Click the search collection that you want to update. For example: **Default Search Collection**.
   e. Click the **Edit Content Source** icon for the first content source in the list.
   f. Edit the URL listed in the **Collect documents link from the URL** with the new context root.
   g. Click **Save**.

h. Edit the URL in each remaining content source and then save your changes.
i. Start the WebSphere Portal Express crawler content source for each collection:
   - If the documents are not stored in the search collection but a schedule is defined for the crawler, the crawler automatically runs at the scheduled time. You can also start the crawler manually.
   - If the documents are already collected, select **Regather documents** to update the documents with the new context root information.
j. Click **Collections from All Services** in the breadcrumb trail and select the next search collection to modify.

9. For combined cumulative fix 7 or earlier: Complete the following steps if you changed the context root and you have existing search scopes:
   a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**. Then, click **Search Scopes**.
   b. Delete the following search scopes:
      - **All Sources**
      - **Managed Web Content**
   c. Restart the portal server to re-create the search scopes with the correct context.
10. For combined cumulative fix 7 or earlier: Complete the following steps to change the context root for the **Seedlist_Servlet**:
    a. Log in to the WebSphere Integrated Solutions Console.
    b. Go to **Applications** > **Application Types** > **WebSphere enterprise applications**.
    c. Click the **Seedlist_Servlet** application link.
    d. Click **Context Root For Web Modules**.
    e. Change the context root and then click **OK**.
    f. Save your changes.
11. Idle standby only: Resynchronize the nodes and restart the cluster.

Table 39. Steps to resynchronize the nodes and restart the cluster.

Cluster type	Steps
Idle standby	Complete the following steps if you have an idle standby environment: 1. Open the deployment manager WebSphere Integrated Solutions Console. 2. Click **System Administration** > **Nodes**, select the primary node from the list, and click **Full Resynchronize**. 3. Click **Servers** > **Clusters**. 4. Select the cluster and click **Stop**. 5. After the cluster stops, restart it by selecting the cluster. Then, click **Start**.

12. For combined cumulative fix 7 or earlier: Complete the following steps on the stand-alone server or on each node within your cluster to create the WebSphere environment variables that IBM Web Content Manager needs:

a. Locate the `wkplc.properties` and `wkplc_comp.properties` files in the *wp_profile_root*`/ConfigEngine/properties` directory and create backup copies before you change any values.
b. Use a text editor to open the `wkplc.properties` file and enter the appropriate value for your environment in the **`WpsContextRoot`** property.
c. Save and close the file.
d. Use a text editor to open the `wkplc_comp.properties` file and enter the appropriate value for your environment in the following properties:
   - **`WsrpContextRoot`**
   - **`WpsPersonalizedHome`**
   - **`WpsDefaultHome`**

   Attention: Do not enter the same value for **`WpsPersonalizedHome`** and **`WpsDefaultHome`**.
e. Save and close the file.
f. Run the following task to create the WebSphere environment variables for Web Content Manager:
   - Linux : `./ConfigEngine.sh create-wcm-servletpath-variables -DServerName=`*`your_application_server_name`* `-DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat create-wcm-servletpath-variables -DServerName=`*`your_application_server_name`* `-DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh create-wcm-servletpath-variables -DServerName=`*`your_application_server_name`* `-DWasPassword=`*`password`*

   Note: Check the output for any error messages before you proceed with the next task. If any of the configuration tasks fail, verify the values in the `wkplc.properties` and `wkplc_comp.properties` files.

13. Resynchronize the nodes and restart the cluster.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Configuring managed pages

When you create a new installation of IBM WebSphere Portal Express 8.5, managed pages are enabled by default. However, you can also manually disable and enable the feature as needed.

About this task

Migration note: If you migrate from a previous version, managed pages are disabled by default, but you can enable the feature after migration.

"Enabling managed pages"
By default, support for managed pages is enabled for the default virtual portal. However, you can also manually enable this support if managed pages are disabled.

"Disabling managed pages" on page 379
Disable support for managed pages by running the `disable-managed-pages` configuration task.

"Transferring content associations to the Portal Site library" on page 380
When you enable manage pages, any web content pages that you have are converted to managed pages and added to the Portal Site library. However, the content that is associated with the web content pages remains in the original libraries. You can transfer this associated content to the Portal Site library with the `internalize-content-mappings` task.

"Enabling managed pages"
By default, support for managed pages is enabled for the default virtual portal. However, you can also manually enable this support if managed pages are disabled.

"Disabling managed pages" on page 379
Disable support for managed pages by running the `disable-managed-pages` configuration task.

When you enable manage pages, any web content pages that you have are converted to managed pages and added to the Portal Site library. However, the content that is associated with the web content pages remains in the original libraries. You can transfer this associated content to the Portal Site library with the `internalize-content-mappings` task.

Related concepts:

"Vanity URLs" on page 2094
You can associate vanity URLs with portal pages and labels. Vanity URLs are short URLs that people can easily remember. They are shorter than full WebSphere Portal Express URLs. They are sometimes also called marketing URLs. You can publish vanity URLs for marketing campaigns through different channels, such as email or print. This way, you can use vanity URLs to direct customers to a specific portal page or content item. Interested site visitors who want to view your campaign can then remember or copy the short vanity URL and type it into the browser address field.

Enabling managed pages

By default, support for managed pages is enabled for the default virtual portal. However, you can also manually enable this support if managed pages are disabled.

About this task

Important: Do not attempt to enable managed pages on a server where managed pages are already enabled. If you previously disabled managed pages and want to re-enable the feature, you must ensure that the Portal Site library is empty first. If you fail to remove the page artifacts from the previous configuration, the resulting portal might not work properly.

When supported, managed pages is enabled for a virtual portal, all pages in the virtual portal are copied into the Portal Site library in IBM Web Content Manager. However, the following pages are not treated as managed pages and are not copied:

- Administration pages, as identified by the label `ibm.portal.Administration` and its child pages
- Private pages

Each virtual portal has its own Portal Site library.

Note: To take advantage of the features available to managed pages in the user interface, your pages must use the Portal 8.5 theme.

Cluster consideration: In a cluster, you need to apply this procedure only to the primary node.

Attention: If you lost your JCR workspace and the backup was create before you created the virtual portal, restoring the workspace creates an inconsistency between the database domains. The **create-virtual-portal-site-nodes** task fails because the JCR workspace is missing. Run the **action-migrate-vps** task to correct the inconsistency with the database domains and to restore the JCR workspace.

Procedure

1. Start the portal server.
2. To enable support for managed pages, run the **enable-managed-pages** task from the *wp_profile_root*`/ConfigEngine` directory.

   Windows
   ```
   ConfigEngine.bat enable-managed-pages -DPortalAdminPwd=password
   -DWasPassword=password
   ```

   Linux
   ```
   ./ConfigEngine.sh enable-managed-pages -DPortalAdminPwd=password
   -DWasPassword=password
   ```

   IBM i
   ```
   ConfigEngine.sh enable-managed-pages -DPortalAdminPwd=password
   -DWasPassword=password
   ```

   After you run the **enable-managed-pages** task for the first time, the property **managed.pages** is created in the portal WP Configuration Service. The value of the property is set to `true`.
3. Restart the portal server.
4. To populate web content libraries with information about virtual portals in the system, run the **create-virtual-portal-site-nodes** task from the *wp_profile_root*`/ConfigEngine` directory. For each virtual portal, this task creates a library and a site area that is called `lost-found` for resources that cannot be properly located. If the library or site area exist, the task exits. By default, the task runs on all virtual portals in the system.

   Windows
   ```
   ConfigEngine.bat create-virtual-portal-site-nodes
   -DPortalAdminPwd=password -DWasPassword=password
   ```

   Linux
   ```
   ./ConfigEngine.sh create-virtual-portal-site-nodes
   -DPortalAdminPwd=password -DWasPassword=password
   ```

   IBM i
   ```
   ConfigEngine.sh create-virtual-portal-site-nodes
   -DPortalAdminPwd=password -DWasPassword=password
   ```
5. To populate web content libraries with information about the portal pages in the system, run the **create-page-nodes** task from the *wp_profile_root*`/ConfigEngine` directory.

This task can also be used when portal pages and managed pages artifacts in Web Content Manager are not synchronized. In this case, the task attempts to resynchronize the portal artifacts and web content artifacts, giving precedence to the portal artifacts.

Performance note: Depending on the amount of information in the system, the **create-page-nodes** task can take a long time to run. Because of the database load of the task, do not run the task frequently. The initial run of the task requires the most time, while subsequent runs typically require less time.

Note: If you have many pages, then it might be necessary to increase the soap client timeout. Edit the *wp_profile_root*/properties/soap.client.props file to change the **com.ibm.SOAP.requestTimeout** to 60000.
Attention: If your virtual portals have different administrative accounts, you cannot run the **create-page-nodes** task directly. You must run the task for every virtual portal, including the base virtual portal. Use the **VirtualPortalHost** or **VirtualPortalContext** parameter with the **create-page-nodes** task. Run the **list-all-virtual-portals** task to get a list of all your virtual portals. When you run the create-page-nodes task on the base virtual portal, set the **VirtualPortalContext** value to __NO__VP__ID__.

Windows
```
ConfigEngine.bat create-page-nodes -DPortalAdminPwd=password
-DWasPassword=password
```

Linux
```
./ConfigEngine.sh create-page-nodes -DPortalAdminPwd=password
-DWasPassword=password
```

IBM i
```
ConfigEngine.sh create-page-nodes -DPortalAdminPwd=password
-DWasPassword=password
```

By default, this task is run on all pages in all virtual portals. To limit this task to a specific virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix -D on the command line.

VirtualPortalHost
Specify the host name of the virtual portal. For example, vp.example.com.

Important: If the host name of the virtual portal is the same as the host name of the default virtual portal, you must also specify the **VirtualPortalContext** property. You can specify the **VirtualPortalHost** property by itself only if the host name is unique.

VirtualPortalContext
Specify the virtual portal context that identifies the virtual portal. For example, vp1.

You can customize the task with the following optional parameters on the command line. Each parameter requires the prefix -D on the command line.

RunParallel
Indicate whether you want the task to run with multiple threads. A value of false indicates a single thread and is the default setting.

A value of true indicates multiple threads, as specified by the work manager **wpsJcrSyncWorkManager** in the WebSphere Integrated Solutions Console. Each thread requires a database connection. For optimal performance, ensure that your database connection pool supports at least as many connections as there are threads in the pool.

Excluded

Specify a list of unique names of page nodes to exclude from the creation process. Excluding a page also excludes its child pages. By default, the portal administration pages (`ibm.portal.Administration`) are excluded.

6. Optional: If you used web content pages before you enabled managed pages, you can transfer the content for those pages to the Portal Site library. If you plan to use the default page templates and store your web content in the Portal Site library, transfer the content for the template pages to the Portal Site library. For more information, go to *Transferring content associations to the Portal Site library*.
7. Optional: Ensure that users have appropriate access to the Web Content Manager REST virtual resource so they can use **Edit mode**. For example, they have `user` access.

Related concepts:

"Page templates" on page 1786
Content authors use the page templates to quickly create pages that are consistent with your site design. They do not have to waste time to configure settings that are probably consistent across your site, such as theme selection, page layout, and more.

Related tasks:

"Transferring content associations to the Portal Site library" on page 380
When you enable manage pages, any web content pages that you have are converted to managed pages and added to the Portal Site library. However, the content that is associated with the web content pages remains in the original libraries. You can transfer this associated content to the Portal Site library with the `internalize-content-mappings` task.

Disabling managed pages

Disable support for managed pages by running the `disable-managed-pages` configuration task.

About this task

Disabling managed pages has the following effects:

- By default, each virtual portal has its own specific workspace where content is stored. When you disable managed pages, only a single workspace for the default virtual portal is available. The workspaces of other virtual portals are still there, but you can no longer access them. Any system associations between pages in those virtual portals and their respective Portal Site libraries no longer work.

  Important: To preserve content in the other virtual portals, you must import or syndicate the libraries into the default virtual portal before disabling managed pages.
- You can still access the Portal Site library for the default virtual portal, but the library is no longer automatically synchronized with the page structure.
- Pages are no longer managed in IBM Web Content Manager, with the following implications:
  - No page drafts can be created.
  - No new versions of pages can be created.
  - Pages are no longer syndicated.

  - Access control changes that you perform in the portal interface are no longer applied to the portal page site area.
  - If you delete a page from the portal interface, the corresponding portal page site area is not deleted.
- If you create a page with either the **Basic** or **Articles** page template, the page has no web content association. This missing association can cause errors if you attempt to add content from the **Create Content** tab of the site toolbar. To use the sample web content items when managed pages are disabled, create a web content association on the page before attempting to add content.
- Having managed pages enabled is a mandatory requirement to have vanity URLs enabled. Therefore, if you have vanity URLs enabled and disable managed pages, vanity URLs are also disabled.

Procedure

1. Run the **disable-managed-pages** task from the *wp_profile_root*/ConfigEngine directory.

   Linux `./ConfigEngine.sh disable-managed-pages -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

   IBM i `ConfigEngine.sh disable-managed-pages -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

   Windows
   `ConfigEngine.bat disable-managed-pages -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

   After running the **disable-managed-pages** task for the first time, the property **managed.pages** is created in the **WP WPConfigService** configuration service. The value of the property is set to `false`.
2. Restart the portal server.

Transferring content associations to the Portal Site library

When you enable manage pages, any web content pages that you have are converted to managed pages and added to the Portal Site library. However, the content that is associated with the web content pages remains in the original libraries. You can transfer this associated content to the Portal Site library with the `internalize-content-mappings` task.

About this task

Note: Administration pages are not intended to be managed pages and so are not included when you enable managed pages.

When you transfer the content association for a page to the Portal Site library, several things happen:

- The content that is referenced by the default content association for the page is copied to the portal page site area for the page. Only the default content association is affected; other content associations for the page are ignored.

  Note: Nested pages are not copied. Nested site areas are not copied in the following cases:
  - The nested site area is referenced by the default association of another page.
  - The nested site area has the same name as an existing site area for the same page.

- Template mappings and content elements that exist in the associated site area are copied over into the portal page. If the template mapping or element exists for the page, the copy is not performed.
- The default content setting for the portal page is modified to reference the copied content.
- The configuration of any web content viewers on the page is updated to reference the content that is stored in the portal page site area. However, viewer configurations that use content paths are not affected.

Procedure

To transfer content associations, run the `internalize-content-mappings` task from the *wp_profile_root*`/ConfigEngine` directory.

Windows
```
ConfigEngine.bat internalize-content-mappings
-DPortalPage=target_page -DIncludeDescendants=true_or_false
-DSynchronous=true_or_false -DPortalAdminPwd=password
-DWasPassword=password
```

Linux
```
./ConfigEngine.sh internalize-content-mappings
-DPortalPage=target_page -DIncludeDescendants=true_or_false
-DSynchronous=true_or_false -DPortalAdminPwd=password
-DWasPassword=password
```

IBM i
```
ConfigEngine.sh internalize-content-mappings
-DPortalPage=target_page -DIncludeDescendants=true_or_false
-DSynchronous=true_or_false -DPortalAdminPwd=password
-DWasPassword=password
```

The following properties must be specified either on the command line or in the `wkplc.properties` file.

PortalPage
The object ID or the unique page name of the page for which you want to transfer content. If the target page is contained in a virtual portal, you must identify the virtual portal by specifying either the **`VirtualPortalContext`** parameter or **`VirtualPortalHost`** parameter.

IncludeDescendants
Specify `true` to transfer content for the target page and any child pages. To transfer content only for the target page, specify `false`. If not specified, the default value is `true`.

Synchronous
Specify `true` to perform the transfer synchronously. To perform the transfer asynchronously, specify `false`. If not specified, the default value is `true`.

Verbose
Specify `true` to output additional information to the log. To generate basic log information, specify `false`. If not specified, the default value is `false`.

CollisionHandling
When you copy content to a page, specify the action to take if the content item exists. By default, that content item is not copied. If you set **`CollisionHandling`** to `replace`, the content item on the page is replaced with the content item to be copied to the page.

VirtualPortalContext
Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

VirtualPortalHost
Specify the host name of the virtual portal. For example, `vp.example.com`.

Important: If the host name of the virtual portal is the same as the host name of the default virtual portal, you must also specify the **`VirtualPortalContext`** property. You can specify the **`VirtualPortalHost`** property by itself only if the host name is unique.

PortalAdminPwd
The administrator password for WebSphere Portal Express.

WasPassword
The administrator password for WebSphere Application Server.

Example commands:

- Windows: `ConfigEngine.bat internalize-content-mappings -DPortalPage=example.page -DIncludeDescendants=true -DSynchronous=true -DPortalAdminPwd=password -DWasPassword=password`
- Linux : `./ConfigEngine.sh internalize-content-mappings -DPortalPage=example.page -DIncludeDescendants=true -DSynchronous=true -DPortalAdminPwd=password -DWasPassword=password`
- IBM i: `ConfigEngine.sh internalize-content-mappings -DPortalPage=example.page -DIncludeDescendants=true -DSynchronous=true -DPortalAdminPwd=password -DWasPassword=password`

Create a WebSphere Portal profile

During the installation process, the IBM Installation Manager creates the WebSphere Portal Express profile. If you are on WebSphere Portal Express Version 8.5 without a combined cumulative fix applied, then you can use this option in the Configuration Wizard to create an additional profile.

Configuration Wizard

On the Configuration Wizard home page, click **More Options** to find **Create a WebSphere Portal Profile**.

Important: You cannot complete this configuration option, if you have CF01 or a later combined cumulative fix applied.

Managing your WebSphere Portal Express environment

After you install IBM WebSphere Portal Express, you can use the IBM Installation Manager function to manage your environment. The Installation Manager function consists of updating and modifying the environment. You can also uninstall or roll back the modifications you made to your environment.

About this task

Choose the appropriate topic to manage your WebSphere Portal Express environment:

CAUTION:
The information in these files is basic instructions. Before you make any changes to your system, review all readme files that are included with your fixes for complete instructions. Also, review the *Backup and Restore* **topic for instructions on backup and recovery of data files and databases.**

"Using the Installation Manager to install fixes"
Periodically fix packs are released to integrate product code fixes. Between fix pack releases, interim fixes may be recommended or required to ensure product reliability and stability. The Recommended fixes page provides links to fix pack and interim fix downloads, information about what is recommended and what is required, and links to recommended related product fixes. To find the most current service update information, see the Recommended fixes link.

"Using the Installation Manager to modify your environment" on page 387
You can use the Installation Manager function to add or remove the IBM WebSphere Portal Express profile. You can also use the Configuration Wizard to create and add, or remove a profile from your environment. See Create a WebSphere Portal profile and Remove a WebSphere Portal profile for information about using the Configuration Wizard to modify your environment.

"Using the Installation Manager to uninstall interim fixes" on page 388
After upgrading to an interim fix, you can use the IBM Installation Manager function to uninstall it.

"Using the Installation Manager to rollback fixes" on page 388
After upgrading to a fix pack or a cumulative fix, you can use the IBM Installation Manager function to rollback to the original installation.

Related concepts:

Chapter 8, "Backup and restore," on page 771
Backup and recovery of data files and databases is an essential operation for any business system, particularly for data and applications that run in production environments. Create and follow a plan for backing up and recovering data on all tiers of your IBM WebSphere Portal Express deployment. IBM Installation Manager must also be included in backup and recovery planning. If you back up the WebSphere Portal Express file structure and then install a fix pack, the WebSphere Portal Express and IBM Installation Manager become out of sync after you restore the WebSphere Portal Express file system. This condition is not recoverable.

Using the Installation Manager to install fixes

Periodically fix packs are released to integrate product code fixes. Between fix pack releases, interim fixes may be recommended or required to ensure product reliability and stability. The Recommended fixes page provides links to fix pack and interim fix downloads, information about what is recommended and what is required, and links to recommended related product fixes. To find the most current service update information, see the Recommended fixes link.

About this task

Use the IBM Installation Manager update function to update the product files, and then run the ConfigEngine command to update the profile. Complete the following steps to install fixes:

CAUTION:
The information in these files are basic instructions. Before making any changes to your system, review all readme files that are included with your fixes for complete instructions.

Note: A fix is considered an interim fix, a cumulative fix, or a fix pack.

Attention: During the installation, several temporary IBM WebSphere Application Server fixes are installed. When you install your first fix, a warning displays to uninstall the temporary fixes. Uninstall the temporary fixes and then install your fixes.

Procedure

1. Launch the Installation Manager.
2. Add the repository containing the fix.
3. Test the repository connection and provide authentication credentials, if necessary, to access the directory where the repositories are stored.
4. Select **Update** to install the fix.
5. Select or enter the fix level.
6. After accepting the license agreement and reviewing the summary information, run the process to install the fix.
7. When you have installed the fix, you must run the **APPLY-FIX** task from the *wp_profile_root*/ConfigEngine directory to update your profile.

   Note: If you have more than one profile, you must run the ConfigEngine command for each profile.

   Linux
   ```
   ./ConfigEngine.sh APPLY-FIX -DWasPassword=password
   -DPortalAdminPwd=password
   ```

   IBM i
   ```
   ConfigEngine.sh APPLY-FIX -DWasPassword=password
   -DPortalAdminPwd=password
   ```

   Windows
   ```
   ConfigEngine.bat APPLY-FIX -DWasPassword=password
   -DPortalAdminPwd=password
   ```

Recommended fixes and updates for WebSphere Portal and Web Content Management

Using the Installation Manager to modify your environment

You can use the Installation Manager function to add or remove the IBM WebSphere Portal Express profile. You can also use the Configuration Wizard to create and add, or remove a profile from your environment. See Create a WebSphere Portal profile and Remove a WebSphere Portal profile for information about using the Configuration Wizard to modify your environment.

About this task

You can use the Installation Manager to remove only profiles that are created with the Installation Manager. If you use the Configuration Wizard to create and add a profile, you must you use the Configuration Wizard to remove that profile.

Complete the following steps to modify your environment using the Installation Manager:

Procedure

1. Launch the Installation Manager.
2. Select **Modify** to add or remove the portal profile.
3. Select the profile that you want to add or remove.
4. Review the summary information and then run the process to add or remove the profile.

Related concepts:

"Create a WebSphere Portal profile" on page 382
During the installation process, the IBM Installation Manager creates the WebSphere Portal Express profile. If you are on WebSphere Portal Express Version 8.5 without a combined cumulative fix applied, then you can use this option in the Configuration Wizard to create an additional profile.

"Remove a WebSphere Portal profile" on page 384
Use the Configuration Wizard to remove a portal profile.

Using the Installation Manager to uninstall interim fixes

After upgrading to an interim fix, you can use the IBM Installation Manager function to uninstall it.

About this task

Complete the following steps if you want to uninstall an interim fix from your environment:

CAUTION:
The information in these files are basic instructions. Before making any changes to your system, review all readme files that are included with your fixes for complete instructions.

Procedure

1. Launch the Installation Manager.
2. Select **Uninstall** to remove the interim fix.

   Note: Ensure that you select the fix level to uninstall and not the product.
3. Select or enter the interim fix level to which you want to return.
4. Clear the interim fix level from the WebSphere Portal Express product build.
5. Review the summary information, and then run the process to uninstall the interim fix.

Using the Installation Manager to rollback fixes

After upgrading to a fix pack or a cumulative fix, you can use the IBM Installation Manager function to rollback to the original installation.

About this task

Use the IBM Installation Manager rollback function to rollback the product files, and then run the ConfigEngine command to update the profile. Complete the following steps to install fixes:

CAUTION:
The information in these files are basic instructions. Before making any changes to your system, review all readme files that are included with your fixes for complete instructions.

Procedure

1. Launch the Installation Manager.
2. Select **Rollback** to remove the fix pack.
3. Select or enter the fix pack level to which you want to return.
4. Review the summary information and then run the process to remove the fix pack or cumulative fix.
5. When you have removed the fix, you must run the **PRE-ROLLBACK-FIX** task from the *wp_profile_root*/ConfigEngine directory to prepare your profile for rollback.

   Note: If you have more than one profile, you must run the ConfigEngine command for each profile.

   Linux
   ```
   ./ConfigEngine.sh PRE-ROLLBACK-FIX -DWasPassword=password
   -DPortalAdminPwd=password
   ```

   IBM i
   ```
   ConfigEngine.sh PRE-ROLLBACK-FIX -DWasPassword=password
   -DPortalAdminPwd=password
   ```

   Windows
   ```
   ConfigEngine.bat PRE-ROLLBACK-FIX -DWasPassword=password
   -DPortalAdminPwd=password
   ```
6. Run the **ROLLBACK-FIX** task from the *wp_profile_root*/ConfigEngine directory to rollback your profile.

   Note: If you have more than one profile, you must run the ConfigEngine command for each profile.

   Linux
   ```
   ./ConfigEngine.sh ROLLBACK-FIX -DWasPassword=password
   -DPortalAdminPwd=password
   ```

   IBM i
   ```
   ConfigEngine.sh ROLLBACK-FIX -DWasPassword=password
   -DPortalAdminPwd=password
   ```

   Windows
   ```
   ConfigEngine.bat ROLLBACK-FIX -DWasPassword=password
   -DPortalAdminPwd=password
   ```

Configuring the IBM License Metric Tool

IBM License Metric Tool monitors license compliance. It recognizes and monitors what product offerings and their versions, releases, and fix packs are installed and used on the system. It measures the processor value units (PVU) available to and used by these assets. The tool ensures compliance with IBM subcapacity licensing requirements and to demonstrate good IT governance. Information about installed software is collected from monitored computers by an agent that can be deployed

on a range of operating systems. It is stored on a central server in a DB2 database and can be accessed through pre-configured reports that are available from a web user interface.

Before you begin

Install and configure WebSphere Portal Express before you configure the IBM License Metric Tool.

Procedure

1. Download the IBM License Metric Tool agent and install it on each server that has IBM WebSphere Portal Express installed. Read Passport Advantage® for instructions on downloading the IBM License Metric Tool agent, prerequisites, and licensing process.
2. Complete the following steps to provide credentials to IBM License Metric Tool:
   a. Open a shell window.
   b. Change to the IBM License Metric Tool installation directory: *agent_home*/wasagent.
   c. Run the following task to start the WebSphere agent:
      - Linux : ./WASAgentClient.sh
      - IBM i: WASAgentClient.sh
      - Windows: WASAgentClient.bat
   d. Enter servers to list the WebSphere server IDs and locations.
   e. Enter credentials *id userid password* to provide credentials for the servers. Where *id* is the server ID and *userid* and *password* correspond to the WebSphere Application Server administrator user ID and password.

      Note: Whenever the IBM Tivoli® License Compliance Manager agent is stopped, rerun the WASAgentClient task and then reissue the credentials.
   f. Complete any additional configuration tasks after installation. Read the following topic for instructions: Configuring IBM License Metric Tool.
3. Follow the IBM License Metric Tool instructions that are provided with your customer agreement to complete the IBM License Metric Tool licensing configuration for WebSphere Portal Express and IBM Web Content Manager.
4. Ensure that the appropriate inventory signature file exists in the *PortalServer_root*/properties/version directory path. The file that is present depends on your license agreement and has a general format of IBM_*offering_nameversion_number*.swtag.

   Tip: Only one *filename*.swtag signature file can exist per product offering. Refer to the following table to determine the correct signature file.

   Note: If the wrong file is found, the wrong offering might be installed. You must uninstall that offering and install the correct offering. If necessary, contact IBM Support for assistance with this process.

Table 40. Product signature files

Product offering / Component name	IBM Tivoli License Manager signature file	Signature file's directory path
IBM WebSphere Portal Express Extend Version 8.5	IBM_WebSphere_Portal_Extend.8.5.0.swtag	The default path of the *PortalServer_root*/properties/version directory

Table 40. Product signature files (continued)

Product offering / Component name	IBM Tivoli License Manager signature file	Signature file's directory path
IBM WebSphere Portal Express Enable Version 8.5	IBM_WebSphere_Portal_Enable.8.5.0.swidtag	The UserData path of the *PortalServer_root*/properties/version directory
IBM WebSphere Portal Express Server Version 8.5	IBM_WebSphere_Portal_Server.8.5.0.swidtag	The UserData path of the *PortalServer_root*/properties/version directory
IBM Web Content Manager Version 8.5	IBM_Web_Content_Manager.8.5.0.swidtag	The UserData path of the *PortalServer_root*/properties/version directory
IBM Web Content Manager Standard Edition Version 8.5	IBM_Web_Content_Manager.8.5.0.swidtag	The UserData path of the *PortalServer_root*/properties/version directory
IBM WebSphere Portal Express Version 8.5	IBM_WebSphere_Portal_Express.8.5.0.swidtag	The UserData path of the *PortalServer_root*/properties/version directory

5. Verify that the `itlm.product` file exists in the *PortalServer_root*/version directory.

Upgrading your existing product offering

After your initial WebSphere Portal Express installation, you can purchase a license for an upgraded product offering.

About this task

Cluster note: In a clustered environment, run these steps on all the nodes.

Response file note: You can record and run a response file to upgrade your existing product offering. Read Use response files to install for information. Use the following steps when you record your response file. Ensure that you exit from the IBM Installation Manager program to finish your recording.

IBM i response file note: Run the sample response file to upgrade your existing product offering. Read Use response files to install for information. For IBM i, edit the appropriate sample response file that is in the `setup_root/responsefiles/iseries` directory. You cannot record the response file from your IBM i operating system. You can record a response file on another operating system. Use the following steps when you record your response file. Ensure that you exit from the IBM Installation Manager program to finish your recording. You must edit the response file that you recorded to add your IBM i specific parameters.

Procedure

1. Stop all the application servers.
2. Open the IBM Installation Manager and complete the following steps to add the content repository:
   a. Go to **File** > **Preferences** > **Repositories**.
   b. Select **Add Repositories**.
   c. Select **Browse** and go to the *offering-install-eimage*/Setup directory.
   d. Select the `repository.config` file.

e. Click **OK**.
f. Ensure that all necessary repositories are checked.
g. Ensure that the content repository is after the Server repository in the list.
h. Click **Test Connections** to ensure that the IBM Installation Manager can successfully access the directory where the repository is stored.
i. Select **Apply**.
j. Select **OK**.

3. On the main IBM Installation Manager panel, select **Install** to begin the installation process.
4. On the Install Package: Select packages to install panel, check the box for the additional package that you purchased. Then, click **Next**.
5. Accept the license agreement and then click **Next**.
6. On the **Location** panel, select **Use the existing package group**. Select the **IBM WebSphere Portal V85** package group name and then click **Next**.
7. On the Features panel, check the box for the additional feature that you purchased. Then, click **Next**.
8. Confirm the Summary panel information and then click **Install**.

What to do next

New profiles are enabled with the upgraded offering. Existing profiles are only updated if they were created with the IBM Installation Manager.

Removing the upgrade package: You can remove any new features and return to your previous installation offering. Start the IBM Installation Manager. On the main IBM Installation Manager panel, select **Uninstall**. Remove the upgrade package that you installed.

Web Content Manager

Set up a content server by installing IBM Web Content Manager in various deployments to provide robust and flexible environments for web content development and delivery. After you install the content server, more configuration steps must be completed according to the role that the server plays in your web content environment.

About this task

Configuration for Web Content Manager is managed through services that are defined as resource environment providers in IBM WebSphere Application Server. For each service, you can edit existing properties and add new properties through the WebSphere Integrated Solutions Console.

"Configuring a web content authoring environment" on page 393
Set up the authoring environment by installing the authoring portlet and enabling other features that are required to support the authoring environment.

"How to configure a web content staging environment" on page 411
Configure the staging environment to emulate the web content delivery environment and allow for testing before deployment.

"Configuring a web content delivery environment" on page 411
Set up your delivery environment by installing web content viewers and enabling any other required features.

"Reserved authoring portlet" on page 430
When you use the web content viewer or web content pages, some scenarios involve web content authoring tasks that are accomplished with authoring tools components. Authoring tasks are run through a special instance of the authoring portlet that is reserved specifically for these tasks and is installed on page that is hidden from the page navigation available to typical users.

"Further configuration options" on page 432
These configuration options are available to address installation requirements for other deployment scenarios.

"Configuring managed pages" on page 375
When you create a new installation of IBM WebSphere Portal Express 8.5, managed pages are enabled by default. However, you can also manually disable and enable the feature as needed.

"Managing tagging and rating for web content" on page 443
When you use tagging and rating with web content, the web content viewer provides extra scope options for the filtering of tagging and rating results. Because changes in the web content system can affect the accuracy of the tagging and rating information that is used by the portal, it is important to keep the scope information up to date by synchronizing the scopes regularly.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Configuring a web content authoring environment

Set up the authoring environment by installing the authoring portlet and enabling other features that are required to support the authoring environment.

"How to install the authoring portlet" on page 394
Pages that include the Web Content Manager authoring portlet and the local rendering portlet are created when you install WebSphere Portal. You run the authoring portlet configuration task only if you have previously uninstalled your authoring or local rendering portlets. The authoring portlet configuration task automatically creates Web Content Manager pages and installs the authoring portlet and local rendering portlets.

"Further authoring portlet configuration options" on page 395
Further authoring portlet configuration options can be specified by using the portlet administration view.

"Web content authoring options" on page 396
You can tailor the authoring behavior of your web content environment by changing configuration settings such as workflow, profiling, and version control.

"EditLive! editor toolbar configuration options" on page 401
Run these configuration tasks to change the configuration of the EditLive! editor toolbar.

"How to configure authoring portlet search" on page 402
You can change the configuration of the authoring portlet to change how search works.

"Increase timeouts to prevent save errors" on page 403
If users are experiencing timeout errors when they try to save items, you can increase the `total transaction lifetime timeout` setting of your WebSphere Portal Express server.

"Configuring remote server access for links" on page 404
Before you can add links to files and documents that are stored in remote content management systems into web content elements, you must configure your server with information about the remote system and the settings that are used to handle communication with the system.

"Setting up support for federated documents" on page 405
Before you can access metadata from federated documents, you need to configure access to the remote servers that contain the documents and specify information about the feeds or service documents that are used to retrieve the documents. You can also tune the cache settings that are used with the federated documents feature.

How to install the authoring portlet

Pages that include the Web Content Manager authoring portlet and the local rendering portlet are created when you install WebSphere Portal. You run the authoring portlet configuration task only if you have previously uninstalled your authoring or local rendering portlets. The authoring portlet configuration task automatically creates Web Content Manager pages and installs the authoring portlet and local rendering portlets.

1. Open a command prompt.
2. Run the `configure-wcm-authoring` task from the *wp_profile_root*`/ConfigEngine` directory.

   Linux
   ```
   ./ConfigEngine.sh configure-wcm-authoring
   -DPortalAdminPwd=password -DWasUserid=username
   -DWasPassword=password
   ```

   IBM i
   ```
   ConfigEngine.sh configure-wcm-authoring -DPortalAdminPwd=password
   -DWasUserid=username -DWasPassword=password
   ```

   Windows
   ```
   ConfigEngine.bat configure-wcm-authoring
   -DPortalAdminPwd=password -DWasUserid=username
   -DWasPassword=password
   ```
3. Log out of the portal and log back in.
4. Select **Web Content** from the product banner to access the authoring portlet.

Locale consistency

The language that is displayed in the authoring portlet is determined by the region or locale of the user. There are, however, some elements of the authoring portlet that use WebSphere Portal Express functions, such as date selection fields. They are displayed with the locale of the WebSphere Portal Express server. For this reason, the language and locales of the site being created, the client and server should be consistent.

If your site contains content in different languages, then a separate Web Content Manager authoring applications should be set up for each language on different WebSphere Portal Express Servers. These can then be combined into one site using a staging server.

Note: If a user changes their locale, any currently opened Web Content Manager dialogs will be closed. A user also must start a new session before it is displayed using the new locale. It is best practice to have the client's correct locale set before using Web Content Manager.

Further authoring portlet configuration options

Further authoring portlet configuration options can be specified by using the portlet administration view.

To add further authoring portlet configuration parameters:

- Log in to the portal as an administrator.
- Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
- Search for the **Web Content Authoring portlet**.
- Open the configuration view.

You can add any of the following optional configuration parameters:

Table 41. Further authoring portlet configuration parameters

Parameter	Details
htmlfield.rows	Defines the number of rows to display in an HTML field that is used in an element design or presentation template. If not specified, the default setting of 15 rows is used.
htmlfield.columns	Defines the width of an HTML field that is used in an element design or presentation template. The width is defined as the number of characters to display per row. If not specified, the default setting of 85 characters is used.
htmlfield.embedded.rows	Defines the number of rows to display in an HTML field that is used in an element design or presentation template, but not an HTML component. If not specified, the number of rows that are defined by using *htmlfield.rows* is used.
htmlfield.embedded.columns	Defines the width of an HTML field that is used in an element design or presentation template, but not an HTML component. The width is defined as the number of characters to display per row. If not specified, the number of characters that are defined by using *htmlfield.columns* is used.
htmlfield.htmlcomponent.rows	Defines the number of rows to display in the HTML field that is used in an HTML component. If not specified, the number of rows that are defined by using *htmlfield.rows* is used.
htmlfield.htmlcomponent.columns	Defines the width of the HTML field that is used in an HTML component. The width is defined as the number of characters to display per row. If not specified, the number of characters that are defined by using *htmlfield.columns* is used.
htmlfield.presentation.rows	Defines the number of rows to display in the HTML field that is used in a presentation template. If not specified, the number of rows that are defined by using *htmlfield.rows* is used.

Table 41. Further authoring portlet configuration parameters (continued)

Parameter	Details
htmlfield.presentation.columns	Defines the width of the HTML field that is used in a presentation template. The width is defined as the number of characters to display per row. If not specified, the number of characters that are defined by using *htmlfield.columns* is used.
edit_live_custom_licence	Use this parameter to enter a custom license key to use in place of the OEM license for Ephox EditLive with this format:`Account ID,Domain,Expiration,License Key,Licensee,Product,Release`

Note: All users need to log off and login before any configuration changes appear in the authoring portlet.

Web content authoring options

You can tailor the authoring behavior of your web content environment by changing configuration settings such as workflow, profiling, and version control.

You define and manage authoring options in the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console.

Enabling workflows

As default, the IBM Web Content Manager application will workflow content items only. You can update the `WCM WCMConfigService` service to enable workflows for different items.

To enable workflows, create a new property for the item type to which you want to apply workflow, and specify a value of `com.aptrix.pluto.workflow.WorkflowControl` for the property. You can enable workflow for the following item types:

- Content items (`control.Content`)
- Presentation templates (`control.Style`)
- Authoring templates (`control.Template`)
- Taxonomy items (`control.Taxonomy`)
- Categories (`control.Category`)
- Site area items (`control.SiteArea`)
- Library components (`control.Cmpnt`)

For example to enable workflow for authoring templates, you would add the following property:

- Property name: `control.Template`
- Value: `com.aptrix.pluto.workflow.WorkflowControl`

To disable workflow for an item type, you set the property to "false". For example, to disable workflow for authoring templates, you would do the following:

- Property name: `control.Template`
- Value: `false`

Note: If workflows are enabled for the following items, a workflow view is not available in the item views navigator.

- Site areas.
- Taxonomies and categories.
- Workflows, workflow stages, or workflow actions.

Individual items can still be moved through workflow stages by accessing them through the normal item views and approving them.

Note: Only content items can be moved through a workflow by using the web content API. If you enable workflows for other item types, you cannot approve or reject these items by using the API.

Enabling profiling

As default, the Web Content Manager application profiles content items only. You can update the `WCM WCMConfigService` service to enable profiling for different items.

To enable profiling, create a new property for the item type to which you want to apply profiling, and specify a value of `com.aptrix.pluto.taxonomy.ProfileControl` for the property. You can enable workflow for the following item types:

- Content items (`control.Content`)
- Presentation templates (`control.Style`)
- Authoring templates (`control.Template`)
- Taxonomy items (`control.Taxonomy`)
- Categories (`control.Category`)
- Site area items (`control.SiteArea`)
- Library components (`control.Cmpnt`)

For example to enable profiling for components, you would add the following property:

- Property name: `control.Cmpnt`
- Value: `com.aptrix.pluto.taxonomy.ProfileControl`

To disable profiling for an item type, you set the property to "false". For example, to disable profiling on components, you would do the following:

- Property name: `control.Cmpnt`
- Value: `false`

Version control options

By default version control is enabled with the following properties:

- `versioningStrategy.AuthoringTemplate`
- `versioningStrategy.Component`
- `versioningStrategy.Content`
- `versioningStrategy.PresentationTemplate`
- `versioningStrategy.Taxonomy`
- `versioningStrategy.Workflow`
- `versioningStrategy.Default`

You can use the following values to specify version control settings:

always
A version is saved every time a non-workflowed item is saved, or every time a workflowed item is published.

manual
Versions are saved when a user with at least editor access chooses to save a version. This setting causes the following changes in the interface:

- The **Save Version** button is available in the read mode of non-workflowed items and in workflowed items in the published state.
- The **Save and Version** button is available in the edit mode of non-workflowed items and in workflowed items in the published state.

never Disable version control for an item type.

If a version control strategy is not defined for an item type, then the version control strategy that is specified in by the `versioningStrategy.Default` property is used.

Inheritance options

By default, inheritance is automatically propagated down to each item. You can disable automatic inheritance by specifying the following property:

- Property name: `default.inherit.permissions.enabled`
- Value: `false`

When this setting is specified, it is applied only to new items. The inheritance on existing items remain unchanged.

Hierarchical item locking options

When a content item is being edited, it is locked. Other users are prevented from editing the content item until it is unlocked. Locking of site areas, taxonomies, and categories are configurable and is not enabled by default. To enable locking for hierarchical item types, specify the following properties: change the following parameters to "true":

Property name	Value
`wcm.authoringui.lock.taxonomies`	`true`
`wcm.authoringui.lock.categories`	`true`
`wcm.authoringui.lock.siteareas`	`true`
`wcm.authoringui.lock.projects`	`true`

When locking is enabled for site areas, you cannot create any children within the locked site area. For example, if a site area is locked, you cannot create any new site areas or content items within that site area until it is unlocked. This applies only to direct children of the locked parent. Items that are descendants of the children of a locked parent are not affected.

Defining valid mime types for the image element

You define the mime types of files that are allowed to be uploaded into the image element by using the `imageresourcecmpnt.allowedmimetypes` property and a list of mime types for the value. For example:

- Property name: `imageresourcecmpnt.allowedmimetypes`

- Value: `image/gif,image/jpeg`

This will prevent users uploading non-image files into the image element.

Active content filtering

Active content filtering provides the ability to strip specified HTML fragments from HTML entered in elements. This includes rich text and HTML elements. Active content filtering is configured using the `active.content.filtering.enable` property. By default, active content filtering is enabled. If enabled, this will prevent a user from introducing malicious code into a website such as cross site scripting.

For example, if a user entered this code into an HTML element:

```
Welcome
<a href="javascript:window.alert("boo!")">my link</a>
<script language="javascript">window.alert("boo 2!")</script>
Click the link for a surprise.
```

It would be changed to this when saved:

```
Welcome
<a href="<"- active content removed -->">my link</a>
<"- active content removed -->
Click the link for a surprise.
```

Setting the default child placement position

You can set the parameter **wcm.authoringui.childPlacementDefault** to specify the default placement of new content items.

Property value	Description
`start`	This setting will, by default, place a new content item as the first content item within a site area.
`end`	This setting will, by default, place a new content item as the last content item within a site area.

- If this parameter is not set, the default child position is "end".
- The default placement position that is specified in an authoring template overrides this setting for content items that are created with that authoring template.

Setting the size of the breadcrumb library dropdown

You can set the parameter **wcm.authoringui.breadcrumbLibrariesMaximum** to specify the number of libraries that are shown in the authoring interface breadcrumb. For example, `wcm.authoringui.breadcrumbLibrariesMaximum=16`

- If this parameter is not set, only the first 10 libraries are displayed.
- The value of this parameter must be an integer between 5 and 50.
- It is recommended that its value should be between 10 and 20.
- If more than this number of libraries exist, the remaining libraries are accessible by using the **Select from all libraries** option.

Expired items

By default, expired items are displayed alongside published and draft items.

To determine if expired items are listed in views, you can specify the `wcm.authoringui.showexpireditems` property in the `WCM` `WCMConfigService` service by using the WebSphere Integrated Solutions Console:

- If set to `true`, expired items are displayed alongside published and draft items.
- If set to `false`, only published and draft items are displayed.
- If not specified, this setting defaults to `true`.

Default inplace editing mode

These parameters are used to define the default inplace editing mode for text fields and rich text fields:

- `inplaceEdit.defaultModeForRichText`
- `inplaceEdit.defaultModeForText`

Use these values to specify the editing mode for text and rich text fields:

- Specify `inplace` to enable inplace editing of an element. Not all fields support inplace mode. If an element does not support inplace mode, dialog mode is used instead.
- Specify `embed` to enable embedded editing of an element. Not all fields support embed mode. If an element does not support embed mode, dialog mode is used instead.
- Specify `dialog` to enable editing in a dialog. This is useful for larger elements such as rich text elements that may not be suitable for inplace editing. All fields support dialog mode.

If this setting is not specified, inplace editing mode is used by text fields by default, and dialog editing mode is used by rich text fields by default.

CF03 CF03 From version 8.5.0 CF3, if this setting is not specified, embed mode is used by text fields and rich text fields by default.

The default inplace editing mode can be overridden in EditableElement tags using the *mode* parameter.

Note: The default rich text editor is always used when the modes 'inplace' or 'embed' are used. When the 'dialog' mode is used, the rich text editor selected in the authoring portlet settings, or in the content template for content items, is used.

Default css styles for inplace editable fields

The default css class used for inplace editable fields is **wcm-default-inplace-editable**.

This class can be overridden by adding the following setting:
`inplaceEdit.defaultClasses=class1 class2`

As many classes as required are added to this setting, separated by spaces.

You should base your custom classes on the default style sheet located at *AppServer_root*`\installedApps\nodename\wcm.ear\wcm-inplaceEdit.war\css\default-style.css`.

Note: Any classes specified on the EditableElement or EditableProperty tag will take precedence over this value.

If you need to use the default css class as well, add it to the list of classes. For example: `inplaceEdit.defaultClasses=wcm-default-inplace-editable class1 class2`

Restrict users ability to apply authoring templates

By default, only managers have access to the **Apply Template** button. To allow all users to apply a new authoring template to content items they have edit access to, change this setting to false:

- `wcm.authoringui.onlyShowApplyTemplateButtonForManagers=false`

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

EditLive! editor toolbar configuration options

Run these configuration tasks to change the configuration of the EditLive! editor toolbar.

Note: In a clustered environment, these tasks are only run on the primary server.

Reverting to the EditLive! editor version 7 toolbar

1. Open a command prompt.
2. Run the following command from the *wp_profile_root*/ConfigEngine directory:

   Windows

   ```
   ConfigEngine.bat configure-wcm-ephox-editor-v7-configuration
   -DWasPassword=password -DPortalAdminId=username
   -DPortalAdminPwd=password
   ```

   Linux

   ```
   ./ConfigEngine.sh configure-wcm-ephox-editor-v7-configuration
   -DWasPassword=password -DPortalAdminId=username
   -DPortalAdminPwd=password
   ```

   IBM i

   ```
   ConfigEngine.sh configure-wcm-ephox-editor-v7-configuration
   -DWasPassword=password -DPortalAdminId=username
   -DPortalAdminPwd=password
   ```

   Note: An administrator user name and password is not required if you already specified the portal administrator user name and password with the **PortalAdminId** and **PortalAdminPwd** settings in the wkplc.properties file.
3. Restart the server.

Note: To revert to the default editor toolbar, run the task that is named **remove-wcm-ephox-editor-v7-configuration** on the primary node only.

Using a custom EditLive! editor toolbar

1. The EditLive! editor uses a custom configuration file that is named config.xml.jsp to set custom parameters for the toolbar. Copy your custom configuration file to *wp_profile_root*\PortalServer\wcm\shared\app\config\ephox.

   Note: Sample configurations can be found in *PortalServer_root*\wcm\prereq.wcm\wcm\config\templates\shared\app\config\ephox

2. Open a command prompt.
3. Run the following command from the *wp_profile_root*/ConfigEngine directory:

   Windows

   ```
   ConfigEngine.bat configure-wcm-ephox-editor-custom-configuration
   -DWasPassword=password -DPortalAdminId=username
   -DPortalAdminPwd=password
   ```

   Linux

   ```
   ./ConfigEngine.sh configure-wcm-ephox-editor-custom-configuration
   -DWasPassword=password -DPortalAdminId=username
   -DPortalAdminPwd=password
   ```

   IBM i

   ```
   ConfigEngine.sh configure-wcm-ephox-editor-custom-configuration
   -DWasPassword=password -DPortalAdminId=username
   -DPortalAdminPwd=password
   ```

   Note: An administrator user name and password is not required if you already specified the portal administrator user name and password with the **PortalAdminId** and **PortalAdminPwd** settings in the wkplc.properties file.
4. Restart the server.

Note: To revert to the default editor toolbar, run the task that is named **remove-wcm-ephox-editor-custom-configuration** on the primary node only.

How to configure authoring portlet search

You can change the configuration of the authoring portlet to change how search works.

You define and manage authoring portlet search options in the WCM WCMConfigService service by using the WebSphere Integrated Solutions Console.

You can specify the following properties:

wcm.authoringui.advancedsearch.searchonselection

- Possible values are true or false.
- If set to true, when you click **Advanced Search**, an advanced search is automatically run based on any text that is entered in the basic search. If nothing is entered in the basic search, advanced search is not automatically run.
- If set to false, advanced search is not automatically run if there is existing text in the basic search field.
- If the property is not specified, this setting defaults to the false behavior.

wcm.authoringui.simplesearch.addstar

- Possible values are true or false.
- If set to true, a wildcard character is added to the end of text that is entered in the basic search. For example, searching for Span automatically searches for Span* and displays search results that have a title, description or keywords that begin with the word Span such as Spanish.
- If set to false, only exact matches to the text entered in the basic search field are searched for.
- If the property is not specified, this setting defaults to the false behavior.

wcm.authoringui.advancedsearch.addstar

- Possible values are `true` or `false`.
- If set to `true`, a wildcard character is added to the end of text that is entered in the advanced search. For example, searching for `Span` automatically searches for `Span*` and displays search results that have a title, description or keywords that begin with the word `Span` such as `Spanish`.
- If set to `false`, only exact matches to the text entered in the advanced search field are searched for.
- If the property is not specified, this setting defaults to the `false` behavior.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Increase timeouts to prevent save errors

If users are experiencing timeout errors when they try to save items, you can increase the `total transaction lifetime timeout` setting of your WebSphere Portal Express server.

The `total transaction lifetime timeout` setting is changed by using the WebSphere Integrated Solutions Console.

Go to **Servers** > **Server Types** > **WebSphere application servers** > *portal_server* > **Container Services** > **Transaction Service**.

The `total transaction lifetime timeout` setting must be changed to the same amount on all the servers in your web content system.

Alternatives to increasing server timeouts

Increasing the `total transaction lifetime timeout` setting might not always be the best solution to server timeouts. Increasing this setting too much might cause a drop in performance. Timeout errors that are generated when saving items occur when the current transaction finishes before the item is saved. If the item you are saving contains large amounts of data, it might be better to redesign the item rather than change the `total transaction lifetime timeout` setting:

Table 42. Alternatives to increasing server timeouts

Option	Details
Authoring Templates	If many elements are added to an authoring template, you might experience a timeout error when an item is saved. Instead of using a single authoring template, create multiple authoring templates that contain only those elements that are required for a specific task.
Presentation templates and components	You might receive timeout errors when you try to save presentation templates or components that contain large amounts of HTML or rich text in their designs. You can instead create multiple HTML or rich text components and then reference these components in the presentation templates or component designs.

Table 42. Alternatives to increasing server timeouts (continued)

Option	Details
Site areas and content items	You can receive timeout errors when you try to save site areas and content items that contain elements that use large amounts of HTML. You can instead create multiple HTML or rich text components and then reference these components in element designs. If many elements are added to a site area or content item, you can also experience a timeout error when you try to save the item. In this case, you can reduce the number of elements that are stored in the site area or content item.
Downloadable files	Another alternative to creating web content with large amounts of HTML or rich text is to provide information on your website in the form of downloadable files. These files can be stored as file resource elements.

Configuring remote server access for links

Before you can add links to files and documents that are stored in remote content management systems into web content elements, you must configure your server with information about the remote system and the settings that are used to handle communication with the system.

About this task

To prevent linking to unsafe servers, you need to specify a list of allowed domains that your portal can access by using the portal's AJAX proxy component. You can use the global AJAX proxy configuration to customize the outgoing HTTP traffic, such as applying specific HTTP timeout values or configuring an outbound HTTP proxy server. To do this, map the URL patterns for the Enterprise Content Manager server to the `federated_documents_policy` dynamic policy using the `WP ConfigService` configuration service.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP ConfigService**.
4. Under **Additional Properties**, click **Custom Properties**.
5. Click **New**, and enter the property name `wp.proxy.config.urlreplacement.federated_documents_policy.`*`suffix`*, and set the string value to the URL pattern of the Enterprise Content Manager server.

   For example, to enable the server to access information from the Enterprise Content Manager server `ecm.example.com` on port 10038 over HTTP, you would add the following property:

```
wp.proxy.config.urlreplacement.federated_documents_policy.1=http://ecm.example.com:10038/*
```

   Note: The value of the property key *`suffix`* can be any value as long as it is unique within the set of keys mapping to the `federated_documents_policy`.
6. Create additional properties as needed for any other Enterprise Content Manager servers that you need to access through the server.
7. Save your changes, and restart the portal server.

What to do next

If a user tries to access a server (for example, `www.example.com`) that has not been added to the list of allowed domains, the following message is displayed:

```
Access to remote server www.example.com has not been granted.
Please contact your system administrator.
```

AJAX proxy configuration

Setting up support for federated documents

Before you can access metadata from federated documents, you need to configure access to the remote servers that contain the documents and specify information about the feeds or service documents that are used to retrieve the documents. You can also tune the cache settings that are used with the federated documents feature.

Before you begin

Authentication requirement: Before you can use the federated documents feature, you must complete one of the following steps:

- Enable single sign-on (SSO) in IBM WebSphere Application Server between the portal server and the content management system.
- Use a content management system that supports HTTP basic authentication, and enable a credential vault slot that stores the credentials to authenticate with the remote server.

  "Configuring access to remote systems for federated documents" on page 406
  To retrieve metadata information for documents on remote content management systems, configure the federated documents feature with information about the remote system and the settings that are used to handle communication with the system.

  "Configuring the federated documents feature" on page 407
  Configure the federated documents feature to specify information about the source servers for the documents that are available to users.

  "Cache tuning for federated documents" on page 410
  The federated documents feature uses the document list cache, the document data cache, and the feed type cache to manage information about the list of documents, the document data, and the types of feeds a server provides.

Configuring access to remote systems for federated documents:

To retrieve metadata information for documents on remote content management systems, configure the federated documents feature with information about the remote system and the settings that are used to handle communication with the system.

About this task

Because the federated documents feature uses the AJAX proxy component to access the remote content management system, you can use the global AJAX proxy configuration to customize the outgoing HTTP traffic, such as applying specific HTTP timeout values or configuring an outbound HTTP proxy server. You must list the individual content management servers to be accessed through the federated documents feature as allowed request targets in the AJAX proxy configuration, and enable LTPA cookie forwarding for those requests. To do this, map the URL patterns for the content management server to the `federated_documents_policy` dynamic policy using the `WP ConfigService` configuration service.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP ConfigService**.
4. Under **Additional Properties**, click **Custom Properties**.
5. Click **New**, and enter the property name `wp.proxy.config.urlreplacement.federated_documents_policy.`*`suffix`*, and set the string value to the URL pattern of the content management server.

   For example, to enable the federated documents feature to access information from the content management server `ecm.example.com` on port 10038 over HTTP, you would add the following property:

```
wp.proxy.config.urlreplacement.federated_documents_policy.1=http://ecm.example.com:10038/*
```

   Note: The value of the property key *`suffix`* can be any value as long as it is unique within the set of keys mapping to the `federated_documents_policy` dynamic policy.
6. Create additional properties as needed for any other content management servers that you need to access through the federated documents feature.
7. Optional: The federated documents feature can also consume arbitrary ATOM feeds. To enable this, you can map the URL prefix of the ATOM feed to the `default_policy` dynamic policy.
   a. Click **New**, and enter the property name `wp.proxy.config.urlreplacement.default_policy.`*`suffix`*, and set the string value to the URL pattern of the server providing the ATOM feed.

      For example, to enable the federated documents feature to access ATOM feeds from the server `www.example.com`, you would add the following property:

      ```
      wp.proxy.config.urlreplacement.default_policy.1=http://www.example.com/*
      ```

      The value of the property key *`suffix`* can be any value as long as it is unique within the set of keys mapping to the `default_policy` dynamic policy.

Important: To prevent security token forwarding to untrusted servers, be sure that you do not use the `federated_documents_policy` dynamic policy for those servers.

b. Create additional properties as needed for any other ATOM feed servers that you need to access through the federated documents feature.

8. Save your changes, and restart the portal server.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Configuring the federated documents feature:

Configure the federated documents feature to specify information about the source servers for the documents that are available to users.

About this task

When the portal retrieves documents from a remote server, authentication might be required to access the documents on the remote server. You can use several types of authentication:

- Single sign-on (SSO) between the portal and the remote server
- User name and password information in the user interface. Only HTTP basic authentication is supported for CMIS servers.
- Credential vault slots that handle HTTP authentication

In addition to enabling or disabling credential vault slots for authentication, you can identify the servers that provide documents. For each server, you can define characteristics such as the type of document that the server returns and the title that is used to identify the server.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP FederatedDocumentsService**.
4. Under **Additional Properties**, click **Custom Properties**.
5. Specify whether credential vaults slots are used for authentication with remote servers.

   Because you can access federated documents through either the personalization editor or the rich text editor that is provided with Web Content Manager, you can configure credential vault slots for each method independently.

   a. If you are accessing federated documents through the personalization editor, click **wp.federated.documents.pzn.vaultselection.enabled**. To enable credential vaults slots, set the value to `true`, or, to disable credential vault slots, set the value to `false`. By default, the value is `true`.

   b. If you are accessing federated documents through the rich text editor in Web Content Manager, click **wp.federated.documents.wcm.vaultselection.enabled**. To enable credential

vaults slots, set the value to `true`, or, to disable credential vault slots, set the value to `false`. By default, the value is `true`.

If you enable credential vault slots, users can select a credential vault slot in the user interface. You can also use the property **wp.federated.documents.*suffix*.vault.slot** to specify a default credential slot to be used with a given remote server.

6. Specify whether users can enter their own servers when they access remote content or can use only predefined servers that you configure.
   a. Click **wp.federated.documents.custom.server.enabled**.
   b. To allow users to enter their own servers, set the value to `true`. To prevent users from entering custom servers, set the value to `false`. When set to `false`, the user interface does not display the entry field for custom servers. By default, the value is `true`.
7. Specify whether documents from servers that support Document Services remote interfaces can be retrieved by the portal. Examples of products that support Document Services remote interfaces include IBM Content Manager, and IBM FileNet Content Manager.
   a. Click **wp.federated.documents.document.services.enabled**.
   b. To enable access to Document Services feeds, set the value to `true`. To disable access to Document Services feeds, set the value to `false`. If set to `false`, users can still access servers that support CMIS or Atom feeds, but connections to Document Services servers are not supported. `CF06` Prior to CF06, this value is set to `true` by default. In CF06 or higher, this value is set to `false` by default.
8. For each remote server that contains documents you want to access from the portal, configure the server URL, feed type, and extra optional properties.

   The value of the *`suffix`* portion of the property key is used to group related properties for each server. Use the same *`suffix`* value for properties that are related to the same server. The *`suffix`* can be any value when it is unique across the property keys.

   For each property, click **New** and enter the name and value:

   wp.federated.documents.*suffix*.url
   Value: The URL for an Atom feed or CMIS service document for the remote server. This property is required.

   wp.federated.documents.*suffix*.type
   Value:
   - The value `CMIS` indicates that the remote server provides a CMIS service document.
   - The value `DocumentServices` indicates that the remote server supports Document Services remote interfaces.
   - The value `ATOM` indicates that the remote server provides a generic Atom feed.

   If no value is specified, a default value of `CMIS` is used.

   wp.federated.documents.*suffix*.title.default
   Value: The title that is used to identify this source server in the user interface, when there is no resource bundle that is defined to provide title text. If no default title and no resource bundle are defined, the value of the wp.federated.documents.*suffix*.url property is used in the user interface.

wp.federated.documents.*suffix*.nls.resources
Value: The name of the resource bundle that contains the translated title and description that is used to identify this source server in the user interface. If this property is not defined, the default title is used. If no default title and no resource bundle are defined, the value of the wp.federated.documents.*suffix*.url property is used in the user interface.

wp.federated.documents.*suffix*.vault.slot
Value: The name of the credential vault slot that stores the credentials that are used for authentication with the remote server. Credential vault slots are set up and managed by the portal administrator. This property defines the default credential vault slot that is predefined in the user interface, although the user can also select a different slot if one is available. If this property is not defined, the user interface does not display a default credential vault slot, but you can still select a slot from the available list. This property is optional.

Note: The credential vault slot must contain the credentials that are required for authentication with the remote server.

wp.federated.documents.*suffix*.override.authentication.enabled
Value: `true` or `false`. When set to `true`, the user can change the authentication method for the server in the user interface. When set to `false`, the user interface does not display the field to change the authentication method. The default value is `true`.

9. Optional: Configure the amount of data that is returned for the summary metadata attribute of the document.
   a. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
   b. Click **WCM WCMConfigService**.
   c. Under **Additional Properties**, click **Custom Properties**.
   d. Click **wcm.pzn.ecm.max.field.length**, and enter the number of characters to be returned. If no value is specified, the default value is 128 characters.
10. Optional: Configure whether property changes are automatically loaded.
    By default, the Federated Documents service automatically reloads properties at a specified interval, without requiring you to restart the portal. You can change the automatic reloading behavior or modify the reloading interval.
    a. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
    b. Click **WP FederatedDocumentsService**.
    c. Under **Additional Properties**, click **Custom Properties**.
    d. Click **wp.federated.documents.document.service.reload.disabled**, and specify a value of `true` to disable automatic reloading of properties. The default value is `false`.
    e. Click **wp.federated.documents.document.service.reload.interval**, and specify the interval in seconds for reloading properties. The default value is 3 seconds.
11. Save your changes. The Federated Documents service automatically reloads any updated properties. If you disabled automatic reloading, restart the portal server.
12. If you enable credential vault slots, grant access to credential vault slots for all authenticated users.

a. Log in to the portal as an administrator.
b. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**.
c. From the list of resource types, go to **Virtual Resources**.
d. For the **ADMIN_SLOTS** resource, click the **Assign Access** icon.
e. Edit the **User** role, and add the **All Authenticated Portal Users** group to the role.

Cache tuning for federated documents:

The federated documents feature uses the document list cache, the document data cache, and the feed type cache to manage information about the list of documents, the document data, and the types of feeds a server provides.

- The *document list cache* contains the list of document identifiers that are contained in the rule selection result of a specific user and a specific selection rule. The cache is activated by default with a default cache entry lifetime of 10 minutes.
- The *document data cache* contains the metadata of a specific document. The cache is activated by default with a default cache entry lifetime of 10 minutes.
- The *feed type cache* contains the type of feed for a feed URL. The feed type can be Document Services, CMIS, or ATOM. The cache is activated by default with a default cache entry lifetime of 24 hours.

To tune these caches, you can configure the Cache Manager Service (`WP CacheManagerService`) in the WebSphere Integrated Solutions Console by using the following properties:

- Document list cache: `cacheinstance.com.ibm.pzn.wcm.ecm.DocumentListCache`
- Document data cache: `cacheinstance.com.ibm.pzn.wcm.ecm.DocumentMetaDataCache`
- Feed type cache: `cacheinstance.com.ibm.pzn.wcm.ecm.FeedTypeServerCache`

Updates occurring on the remote content management system might not immediately be reflected on the portal side if there is a corresponding entry in the cache. The individual cache life time values determine the maximum time lag for corresponding updates.

Note:

- The time lag for new documents to be visible and deleted documents to be removed depends on the lifetime value for the configured document list cache.
- The time lag for updates in the metadata in a document (for example, changes to the document title) depends on the configured lifetime value for the document list cache.

The user-specific document list cache is explicitly invalidated each time the user logs in, so that the most current list of available document identifiers is available upon login.

Configuring a web content delivery environment

Set up your delivery environment by installing web content viewers and enabling any other required features.

"Setting up site analysis for the Web Content Viewer"
To track usage data for the Web Content Viewer, you can configure the portal for site analysis logging for the Web Content Viewer.

"XML configuration interface parameters for the Web Content Viewer" on page 415
As with other portlets in your portal, you can use the XML configuration interface (**xmlaccess** command) to deploy and configure the Web Content Viewer. To simplify the configuration of the portlet with the XML configuration interface, the portlet parameters you can specify accept path values in addition to the standard IDs.

"Caching options" on page 418
Both IBM Web Content Manager generated web pages and content from external data sources can be cached by the Web Content Manager application. If used correctly, Web Content Manager caching can dramatically increase the performance of a site.

"Pre-rendering options" on page 425
You can enable pre-rendering so that content can be viewed either through a IBM Web Content Manager application or as a stand-alone site that is accessed through a web server.

Setting up site analysis for the Web Content Viewer

To track usage data for the Web Content Viewer, you can configure the portal for site analysis logging for the Web Content Viewer.

"Enabling the Web Content Viewer logger" on page 412
To take advantage of the site analysis logging available for the Web Content Viewer, you need to configure the **WP SiteAnalyzerLogService** service and activate the `SiteAnalyzerJSRPortletLogger` service.

"Site analysis example for the Web Content Viewer"
The site analysis log uses the NCSA Combined log format, which is a combination of NCSA Common log format and three extra fields: the referrer field, the user_agent field, and the cookie field. This example describes typical site analysis logging information for the Web Content Viewer.

Related tasks:

"Analyzing portal usage data" on page 1687
You can collect data about the usage of your portal and analyze them.

"Instrumenting web content for Active Site Analytics" on page 3399
You can collect information from web content for Active Site Analytics.

Enabling the Web Content Viewer logger:

To take advantage of the site analysis logging available for the Web Content Viewer, you need to configure the **WP SiteAnalyzerLogService** service and activate the `SiteAnalyzerJSRPortletLogger` service.

Before you begin

Before you activate the `SiteAnalyzerJSRPortletLogger` logger, you must ensure that site analysis is enabled for the portal in general, as described in Logging and analyzing server side site data.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP SiteAnalyzerLogService**.
4. Activate the `SiteAnalyzerJSRPortletLogger` logger through the **WP SiteAnalyzerLogService** by defining the parameter `SiteAnalyzerJSRPortletLogger.isLogging` and by setting the parameter value to `true`.
5. Save your changes, and restart the portal.

Site analysis example for the Web Content Viewer:

The site analysis log uses the NCSA Combined log format, which is a combination of NCSA Common log format and three extra fields: the referrer field, the user_agent field, and the cookie field. This example describes typical site analysis logging information for the Web Content Viewer.

The IBM WebSphere Portal Express site analysis log is:
wp_profile_root`/logs/WebSphere_Portal/sa_`*date_time*`.log`

where *date_time* is the date and time the file was created. The current (active) log file is named *sa.log*.

Note: The WP SiteAnalyzerService might be configured to use different file names.

The following example displays a sample entry in the site analysis log as it is written by the Web Content Viewer if the SiteAnalyzerJSRPortletLogger is enabled.

```
9.37.3.88 - jdoe [22/Nov/2008:22:11:27 +0100] "GET /Portlet/

1"
```

The table describes each field of the log format:

Table 43. Explanation of each field in the log format

Field in the Example	Log Field Name and Explanation
9.37.3.88	**host** The IP address of the HTTP client that sent the request. **Important:** If there is a reverse proxy server between the client and the portal, the IP address that is logged is that of the reverse proxy server rather than the HTTP client. To log the IP address of the HTTP client, you must remove the reverse proxy server from the environment.
-	**rcf931** The identifier that is used to identify the client making the request. If the client identifier is not known, the field is set to the hyphen character (-).
jdoe	**username** The user ID for the client. If the user ID is not known, the field is set to the hyphen character (-).
[22/Nov/2008:22:11:27 +0100]	**date:time timezone** The date and time of the HTTP request.

Table 43. Explanation of each field in the log format (continued)

Field in the Example	Log Field Name and Explanation
`"GET /Portlet/[...] HTTP/1.1"`	**request** The HTTP method, the URI of the requested resource, and the version of HTTP used by the client. The URI is composed of the following elements: • The identifier `Portlet`. • The ID of the Web Content Viewer instance that is requested. • The administrative name of the Web Content Viewer (Note: This name is always the same unless the portlet has been cloned.). • The context path of the rendered Web Content Manager item encoded in UTF-8. • A query string containing the following parameters: **PortletPID** The ID of the Web Content Viewer instance that is requested. **PortletMode** The mode in which the portlet is rendered. Note that the Web Content Viewer writes log entries only in its view mode. **PortletState** The portlet window state. **RequestType** The request type (note that the Web Content Viewer writes log entries only for render requests). This is followed by a list of all request parameters that are available to the Web Content Viewer instance as UTF-8 encoded key-value-pairs.
`200`	**statuscode** The HTTP status code for the request.
`-1`	**bytes** The number of bytes of data that is transferred from the client as part of the request. A value of -1 indicates that the number of bytes is unknown.

Table 43. Explanation of each field in the log format (continued)

Field in the Example	Log Field Name and Explanation
"http://myserver.company.com/Page/6_8000CB1A00UR402F0JC25U1O25/MyPage"	**referrer** The referrer in case of portlet site analysis log entries identifies the portal page on which the Web Content Viewer instance is rendered.
"Mozilla/5.0 [...]"	**user_agent** The type of web browser that is used by the client.
"JSESSIONID=0000JwIm04xm7btVLwzCj9Qo-uj:-1"	**cookies** The name and value of a cookie that was sent to the client browser as part of the request. If multiple cookies were sent, the list is delimited by the semicolon character.

Understanding the site analysis log

XML configuration interface parameters for the Web Content Viewer

As with other portlets in your portal, you can use the XML configuration interface (**xmlaccess** command) to deploy and configure the Web Content Viewer. To simplify the configuration of the portlet with the XML configuration interface, the portlet parameters you can specify accept path values in addition to the standard IDs.

By default, the Web Content Viewer is configured with unique IDs. This has the advantage that the configuration does not break if an item is renamed of moved. However, when you are configuring a portlet with the XML configuration interface, it can be difficult to determine the unique ID of an item. When you are configuring the Web Content Viewer, you can reference web content items by their path, as well as by their IDs, by using the following parameters:

AUTHORINGTEMPLATE_OVERRIDE
Specifies the authoring templates of the profile section. The parameter can contain multiple values, which are separated by commas. The list can contain both ID and path values.

CATEGORY_OVERRIDE
Specifies the categories of the profile section. To list multiple categories, separate the categories by commas. You can use both ID values and path values.

SITEAREA_OVERRIDE
Specifies the site areas of the profile section. To list multiple site areas, separate the site areas by commas. You can use both ID values and path values.

WCM_BROADCASTS_TO
Specifies the link broadcasting setting for the Web Content Viewer. Values include:

- WCM_LINKING_DYNAMIC: Information about the web content item that is displayed in the Web Content Viewer is used to dynamically determine to which page the context is broadcast.
- WCM_LINKING_SELF: The context of the current Web Content Viewer is broadcast to other Web Content Viewers on the same portal page.
- WCM_LINKING_OTHER: The context of the current Web Content Viewer is broadcast to other Web Content Viewers on another portal page, as specified by the WCM_PORTAL_PAGE_ID parameter.
- WCM_LINKING_NONE: The context of the current Web Content Viewer is not broadcast to other Web Content Viewers.

WCM_COMPONENT_IDR
Specifies a library component and is only used if content type **Component** is selected.

WCM_CONTENT_COMPONENT
Specifies the name of the element to be displayed, when the WCM_CONTENT_TYPE parameter has the value CONTENT_COMPONENT.

WCM_CONTENT_CONTEXT_IDR
Specifies the content render context. It can be a content item or site area, as specified by the WCM_CONTENT_CONTEXT_TYPE parameter.

WCM_CONTENT_CONTEXT_TYPE
Specifies the type of the configured content context. Values include:
- CONTENT: Indicates that the content context is a content item.
- PARENT: Indicates that the content context is a site area.

WCM_CONTENT_TYPE
Specifies the item to be displayed. Values include:
- CONTENT: Indicates that the item to be displayed is a content item.
- COMPONENT: Indicates that the item to be displayed is a component.
- CONTENT_COMPONENT: Indicates that the item to be displayed is an element.
- SUMMARY: Indicates that the item is to be rendered with the summary presentation template. A summary presentation template can be specified in the item's content template.
- ALTERNATE: Indicates that the item is to be rendered with the alternative presentation template, as specified by the parameter WCM_DESIGN_IDR.

WCM_DESIGN_IDR
Specifies an alternative presentation template.

WCM_LISTENS_TO
Specifies how the Web Content Viewer is configured to receive links that are broadcast from other Web Content Viewers. Values include:
- WCM_LINKING_OTHER: Information is received from any Web Content Viewer broadcasting links.
- WCM_LINKING_SELF: Information is received only from this Web Content Viewer.
- WCM_LINKING_NONE: No information from other Web Content Viewers is received.

WCM_PAGE_TITLE
Used with the WCM_PAGE_TITLE_TYPE parameter, this parameter specifies the page title for the Web Content Viewer. Values include:

- The user-defined title for the page, if the WCM_PAGE_TITLE_TYPE parameter has a value of WCM_PAGE_TITLE_TYPE_GENERAL.
- The name of the resource bundle containing the title for the page, if the WCM_PAGE_TITLE_TYPE parameter has a value of WCM_PAGE_TITLE_TYPE_RESBUN.

WCM_PAGE_TITLE_TYPE

Specifies how the page title is displayed for the Web Content Viewer. Values include:

- WCM_PAGE_TITLE_TYPE_DEFAULT: The default title that is defined in the portal's administration interface is used.
- WCM_PAGE_TITLE_TYPE_GENERAL: A user-defined title is used, as specified by WCM_PAGE_TITLE parameter.
- WCM_PAGE_TITLE_TYPE_RESBUN: The title is defined in a resource bundle, as specified by WCM_PAGE_TITLE parameter.
- WCM_PAGE_TITLE_TYPE_DYN: The title is defined by the value of the **Display title** field for the content item that is displayed in the Web Content Viewer.
- WCM_PAGE_TITLE_TYPE_DYN_CONTENT_CMPNT: The title is defined by the value of an element of the content item that is displayed in the Web Content Viewer. You must also specify the element name using the **WCM_PAGE_TITLE** parameter.

WCM_PORTAL_PAGE_ID

Specifies the unique name or object ID of the page, which is the target for link broadcasts when the WCM_BROADCASTS_TO parameter is set to WCM_LINKING_OTHER.

WCM_PORTLET_TITLE

Used with the WCM_PORTLET_TITLE_TYPE parameter, this parameter specifies the portlet title for the Web Content Viewer. Values include:

- The user-defined title for the portlet, if the WCM_PORTLET_TITLE_TYPE parameter has a value of WCM_PORTLET_TITLE_TYPE_GENERAL.
- The name of the resource bundle containing the title for the portlet, if the WCM_PORTLET_TITLE_TYPE parameter has a value of WCM_PORTLET_TITLE_TYPE_RESBUN.

WCM_PORTLET_TITLE_TYPE

Specifies how the portlet title is displayed for the Web Content Viewer. Values include:

- WCM_PORTLET_TITLE_TYPE_DEFAULT: The default title that is defined in the portal's administration interface is used.
- WCM_PORTLET_TITLE_TYPE_GENERAL: A user-defined title is used, as specified by WCM_PORTLET_TITLE parameter.
- WCM_PORTLET_TITLE_TYPE_RESBUN: The title is defined in a resource bundle, as specified by WCM_PORTLET_TITLE parameter.
- WCM_PORTLET_TITLE_TYPE_DYN: The title is defined by the value of the **Display title** field for the content item that is displayed in the Web Content Viewer.
- WCM_PORTLET_TITLE_TYPE_DYN_CONTENT_CMPNT: The title is defined by the value of an element of the content item that is displayed in the Web Content Viewer. You must also specify the element name using the WCM_PORTLET_TITLE parameter.

When specifying a content path, you must begin with the forward slash character (/) followed by the library name, as indicated in the following examples of valid content paths:

```
/mylib/myfolder/mysitearea/mycontent
```

or

```
/mylib/mypresentationtemplate
```

Note: If you configure an item by its path rather than by its ID, the portlet configuration can become invalid if the item is renamed or moved. If an item has been configured by its path, the Web Content Viewer displays a small path icon after the item when you are in the **Edit Shared Settings** or **Configure** mode.

Important: When configuring an item by its path, you cannot build the path from the **Display title** fields of the items in the path. You must use the **Name** fields of the items when specifying the path.

Caching options

Both IBM Web Content Manager generated web pages and content from external data sources can be cached by the Web Content Manager application. If used correctly, Web Content Manager caching can dramatically increase the performance of a site.

"Web content cache types"
Learn about the types of caching used by IBM Web Content Manager, basic web content caching, and advanced web content caching.

"Caching versus pre-rendering" on page 420
Content that is displayed in rendering portlets and through IBM Web Content Manager can be cached. An alternative to caching is the use of the pre-rendering feature. View the differences between each strategy.

"Strategies for expiring content" on page 421
Like caching strategies, a server's default expiration strategies can be set in the `WCM WCMConfigService` service by using the WebSphere Integrated Solutions Console. Custom expiring parameters can also be set in connect tags and URL requests to override a server's default expiration strategies.

"Web content cache configuration" on page 422
You can tailor the caching behavior of your web content environment by changing configuration settings such as the default cache type and expire settings.

"Data cache configuration" on page 425
Data caching is used to cache data that is retrieved by the IBM Web Content Manager application from external sources that use connect tags or by requests that are made through URLs.

Web content cache types:

Learn about the types of caching used by IBM Web Content Manager, basic web content caching, and advanced web content caching.

Basic web content caching

This option is the simplest caching option. The first time a web page is rendered by the Web Content Manager application, it is stored in a cache. Users then access this page from the cache until it expires. Only then is the web page rendered afresh. The main benefit of this scenario is improved performance. Basic caching is used only on static content that does not require "real-time" access.

Advanced web content caching

There are two major differences between basic caching and advanced caching:

- Advanced caching can cache pages based on different user profiles.
- Cache parameters in connect tags and URL requests can be used to override your server's default advanced web content caching settings that allow you to set custom cache settings for individual web pages or components.

Table 44. Advanced caching types

Advanced caching type	**Details**
Site caching	This type is the same as the basic web content cache except that cache parameters in connect tags and URL requests can be used to override your server's default advanced web content caching settings.
Session caching	When session caching is enabled, a copy of each web page a user visits is stored in the session cache. The User accesses the cached version of a web page until they start a new session, or until the cached web page is expired from the cache.
User caching	When user caching is enabled, a copy of each web page a user visits is stored in the user cache. The user accesses the cached version of a web page until the cached web page is expired from the cache.
Secured caching	Secured caching is used on sites where the item security features are used to grant different users access to different web pages and components based on the groups they belong to.
Personalized caching	Personalized caching is used to cache web pages of users who have the same "personalization profile". This means that users who have selected the same personalization categories and keywords, and who belong to the same group, share a single cache.

Default web content caching versus custom caching

Cache parameters in connect tags and URL requests can be used to override your server's default advanced web content caching settings allowing you to set custom cache settings for individual web pages or components.

In most cases, basic, site and session caching would only be used as your server's default web content cache. User, secured and personalized caching would mostly be used when using custom caching in connect tags and URL requests.

Note: If basic caching is used as your default web content cache, custom caching cannot be used.

Cache comparisons

Table 45. Basic caching versus advanced caching

Function	Basic caching	Advanced caching
Memory usage per item:	Medium	High
Performance improvement:	Very High	High
Custom caching available:	No	Yes
Connect tag processing:	No	Yes
Web Content Viewer Portlet:	No	Yes

Caching Personalization components:

Web content caching can sometimes be used with Personalization components but will depend on the conditions set in the personalization rule, or the resources used to determine the rule results. Cache testing will be required to determine if the content returned by your personalization component can be cached using web content caching.

Caching versus pre-rendering:

Content that is displayed in rendering portlets and through IBM Web Content Manager can be cached. An alternative to caching is the use of the pre-rendering feature. View the differences between each strategy.

A pre-rendered site can be viewed in two ways:

Using a web server
Viewing a pre-rendered site through a web server is similar to using basic caching because the displayed content is static and custom caching cannot be used.

Using Web Content Manager
Viewing a pre-rendered site through Web Content Manager is similar to using advanced caching because content can be dynamic and custom caching can be used.

Basic caching versus a pre-rendered site delivered with a web server

At first glance, the pre-rendering feature and basic caching do the same thing. There are some differences that determine which feature is the best for you.

The main difference between the two features is that the pre-rendering feature takes a snapshot of the entire site each time it is run. Basic caching caches only on a page-by-page basis. If performance is your main issue, then pre-rendering might be the answer. If not, then basic caching might be a better option.

Table 46. Basic caching versus a pre-rendered site delivered with a web server

Function	Basic caching	Pre-rendered site that is delivered with a web server
Performance:	Very fast	Extremely fast
Connect tag processing:	Yes	No
Custom caching:	Yes	No

Table 46. Basic caching versus a pre-rendered site delivered with a web server (continued)

Function	Basic caching	Pre-rendered site that is delivered with a web server
Memory requirements:	Low to Medium	Memory requirements depend on the web server that is being used.
Disk requirements:	Low to Medium	Potentially very high as the entire site must be able to fit on disk.
Unexpected broken links:	Yes As some pages can be cached at different times, there is a small chance that not all the links on a cached page are currently valid.	No The site is pre-rendered in a single batch, greatly reducing the chances of inconsistencies in the site.

Advanced caching versus a pre-rendered site delivered by using Web Content Manager

These options are similar. You might need to test both strategies before you which is best for your site.

Table 47. Advanced caching versus a pre-rendered site delivered by using Web Content Manager

Function	Advanced caching	Pre-rendered site that is delivered through Web Content Manager
Performance:	Fast when cached, but slower if the requested page has expired from the cache. (As tag processing has a cost, this depends on how many connect tags a page contains.)	Fast, but as tag processing has a cost, this depends on how many connect tags a page contains.
Connect tag processing:	Yes	No
Custom caching:	Yes	No
Memory requirements:	Medium to high.	Medium to high.
Disk requirements:	Medium to high.	Medium to high.
Unexpected broken links:	Yes As some pages may be cached at different times, there is a small chance that not all the links on a cached page will be currently valid.	No The site is pre-rendered in a single batch, greatly reducing the chances of inconsistencies in the site.

Strategies for expiring content:

Like caching strategies, a server's default expiration strategies can be set in the `WCM WCMConfigService` service by using the WebSphere Integrated Solutions Console. Custom expiring parameters can also be set in connect tags and URL requests to override a server's default expiration strategies.

Note: If basic caching is used as your default web content cache, custom expiration cannot be used.

In most cases the expiry schedule is based around how often the source content is updated. So, if the source content is updated hourly, then each cache would be expired hourly. If the source content is updated daily, then each cache would be expired daily.

Beyond these examples, a different expiry schedule would be used. If your web pages were only updated weekly, or monthly, you would still schedule your caches to expire daily. Otherwise, when your source content was updated, it might take up to a week for it to appear on your site.

Caching expiries versus workflow expiries

The expiration parameter in a workflow is not related to the `Expires` parameter in IBM Web Content Manager caching. A page that is set to expire at midnight as part of a workflow will only do so if it has not already been saved in a cache. The page remains in the cache until expired by the Web Content Manager application regardless of the `Expires` setting in a workflow.

Related concepts:

"Cache expire parameters" on page 1842
You use the "expires" parameter in IBM Web Content Manager tags and URLs to specify how long to maintain data in the cache before it is expired. When data expires from a cache, the next request for the data will be retrieved from the original server. The **`expires`** parameter is not mandatory.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Web content cache configuration:

You can tailor the caching behavior of your web content environment by changing configuration settings such as the default cache type and expire settings.

You define and manage web content cache options in the `WCM WCMConfigService` service by using the WebSphere Integrated Solutions Console.

Go to **Resources** > **Resource Environment** > **Resource Environment Providers** > **WCM WCMConfigService** > **Custom Properties**.

Setting the default web content cache type

The default web content caching environment for your web content server is specified by the following properties:

- `connect.businesslogic.defaultcache`
- `connect.moduleconfig.ajpe.contentcache.defaultcontentcache`

Table 48. Caching parameters

Parameter	**`defaultcache`** value	**`defaultcontentcache`** value
No caching:	`false`	`None`

Table 48. Caching parameters (continued)

Parameter	defaultcache value	defaultcontentcache value
Basic cache:	true	Not specified
Site caching:	false	Site
Session caching:	false	Session
User caching:	false	User
Secured caching:	false	Secured
Personalized caching:	false	Personalized

Further default web content cache parameters

Web content cache configuration settings are specified by the following properties in the WCM WCMConfigService service.

Table 49. Cache properties per cache type

Cache Type	Properties
Basic cache:	connect.businesslogic.defaultcacheexpires connect.businesslogic.defaultcache
Advanced cache: All	connect.moduleconfig.ajpe.contentcache.defaultcontentcache connect.moduleconfig.ajpe.contentcache.contentcacheexpires
Advanced cache: Session cache only	connect.sessioncacheconfig.memcachesize

Table 50. Cache properties details

Cache Property	Details
contentcacheexpires	This property sets the default expiry for all advanced caches. It can be either a relative period or an absolute date and time.
defaultcache	If true, basic caching is enabled. If false or missing, advanced caching is enabled.
defaultcacheexpires	This property sets the default expiry for the basic cache. It can be either a relative period or an absolute date and time.
defaultcontentcache	If the advanced cache is enabled, the default advanced cache is set here.
resourceserver.browserCacheMaxAge	This property is used to define the maximum time that an item is stored in a web browser cache.
resourceserver.maxCacheObjectSize	This property is used to define the maximum size of objects that can be cached in kilobytes. By default this property is set to 300.

Additional Cache Keys

These additional cache keys are used to customize and optimize both basic and advanced caching.

Table 51. Additional Keys

Key	Purpose	Prerequisites
locale	Enable caching based on browser locale.	8.5
portalcontext	Enable caching based on portal context.	8.5 CF02 (PI20951)
portalmapping	Enable caching based on portal mapping.	8.5 CF02 (PI20951)
portletcontext	Enable caching based on portlet context.	8.5 CF02 (PI20951)
deviceclass	Enable caching based on device type.	8.5 CF04 (PI27550)

To configure these additional cache keys, add the required caching keys to the value of the property, using commas to separate each value:

Basic Caching:
connect.businesslogic.cache.additionalcachekeys.requestattributes

Advanced Caching:
connect.moduleconfig.ajpe.contentcache.additionalcachekeys.requestattributes

Cache expire time formats

When you use the cache expire settings that are listed in Table 3, you can specify either a relative time, or absolute time:

- REL {integer-value}{units}
- ABS {date-format-string}

{units} =

- d|D for days
- m|M for months
- s|S for seconds
- h|H for hours

{date-format-string} =

- Mon, 06 Nov 2000 09:00:00 GMT
- Monday, 06-Nov-00 09:00:00 GMT
- Mon Nov 6 09:00:00 2000
- 6 Nov 2000 9:00 AM

Note: The last two formats assume GMT.

Examples:

- `contentcacheexpires="REL 300S"`
- `contentcacheexpires="ABS Mon, 06 Nov 2000 09:00:00 GMT"`

Data cache configuration:

Data caching is used to cache data that is retrieved by the IBM Web Content Manager application from external sources that use connect tags or by requests that are made through URLs.

You define and manage data cache options in the `WCM WCMConfigService` service by using the WebSphere Integrated Solutions Console.

Specify the following properties for data cache options:

`connect.connector.httpconnector.defaultcache`
Used when no cache is specified in a request for data. Possible values are `true` or `false`. If `true`, the data is stored in the site cache.

`connect.connector.httpconnector.defaultcacheexpires`
The expiry date/time for items added to a cache (site or session) if the expiry date/time is not specified in the request.

`connect.connector.sqlconnector.defaultcache`
Determines whether to cache data by default or not. Possible values are `true` or `false`.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Pre-rendering options

You can enable pre-rendering so that content can be viewed either through a IBM Web Content Manager application or as a stand-alone site that is accessed through a web server.

You define and manage pre-rendering options in the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console.

Pre-rendering automatically

Although you can manually pre-render a website through the URL interface, you can also configure pre-rendering to run automatically when the server starts.

1. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
2. Click **WCM WCMConfigService**.
3. Under **Additional Properties**, click **Custom Properties**.
4. Edit the **`connect.businesslogic.module`** property, and append `cacher` to the value. For example:

   ```
   web,mail,default,ajpe,federatedproxy,ajpecatselect,memberfixer,workflowenablement,
   itemdispatcher,plutouploadfile,plutodownloadfile,synd,subs,syndication,
   refreshallitems,unlocklibrary,custom,data,clearversions,clearhistory,
   reseteventlog,cacher
   ```

5. Ensure that **`connect.businesslogic.module.cacher.autoload`** is set to true.
6. Save your changes and restart the server.

Enable pre-rendering for sites viewed by using Web Content Manager

This option is used when you are accessing the pre-rendered site through Web Content Manager. This increases performance as static content is accessed from the pre-rendered site, but dynamic content is still rendered through Web Content Manager.

To enable users to access the pre-rendered site through a Web Content Manager application, specify the **connect.businesslogic.module.default.class** property in the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console.

- Property name: **connect.businesslogic.module.default.class**
- Value: `com.aptrix.cacher.CacherModule`

Note: You cannot use the local rendering portlet (Web Content Viewer) when pre-rendering is set as the default module.

Enable pre-rendering for stand-alone sites

This option is used when you are using Web Content Manager to generate a pre-rendered site, but are not using Web Content Manager to view the pre-rendered site. You need to use a web server to view the pre-rendered site.

Specify the **connect.businesslogic.module.cacher.class** property in the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console.

- Property name: **connect.businesslogic.module.cacher.class**
- Value: `com.aptrix.cacher.CacherModule`

Specify the following properties to configure caching. Default values are listed, although you can tailor these values as needed. Unless you explicitly set a value for a property, the default value is used.

connect.moduleconfig.cacher.destdir
Value: `${USER_INSTALL_ROOT}/PortalServer/wcm/ilwwcm/cacher`

Base directory under which each site cache is created. There is one subdirectory created for each site.

Important: If the prerenderer is run with the **connect.moduleconfig.cacher.overwritecache** property set to `true`, any files in the **connect.moduleconfig.cacher.destdir** path that were not written in the last run of the pre-renderer is deleted. For this reason, ensure that the **connect.moduleconfig.cacher.destdir** path is only used for storing rendered content and that it does not contain any other data that cannot be re-created.

connect.moduleconfig.cacher.tempdir
Value: `${USER_INSTALL_ROOT}/PortalServer/wcm/ilwwcm/cacher/temp`

The temporary directory that is required to build the site cache before moving the data over to the base directory specified by the `connect.moduleconfig.cacher.destdir` property.

connect.moduleconfig.cacher.delay
Example value: 1

This property is used to set the time, in seconds, between requesting a page while caching.

connect.moduleconfig.cacher.busydelay
Example value: 5

This property is used to set the time, in seconds, of the busy delay setting. This is used if running within the busy start to busy end period. Otherwise the delay setting is used.

connect.moduleconfig.cacher.busystart/connect.moduleconfig.cacher.busyend
Example value: 9:00 am/5:00 pm

These settings determine the times between which the busy delay setting is used. Enter an absolute time as shown.

connect.moduleconfig.cacher.overwritecache

true The pre-renderer overwrites files in the destdir cache directory (then delete unneeded files). This results in a progressive change in site content as seen by the user. This is the default value.

false The first time a site is pre-rendered, the cached site files are added to the destination directory. As changes are made to the site through the authoring portlet, the new version of the site is gradually cached in the temporary directory and the old site remains in the destination directory. After the cacher has finished caching the site completely, the contents of the temporary directory are moved to the destination directory that will then contain both old and new versions of the cached site.

Note: A value of false should not be used if a web server is used to display the pre-rendered data because some web servers lock the data directories.

connect.moduleconfig.cacher.rendereruser
Example value: Anonymous.

This determines the user to be used to render the Web Content Manager content. Either type Anonymous or Administrator or a specific user or group name.

The site is pre-rendered based on this user's security rights. If the user specified here does not have access to a particular component, it is not pre-rendered.

connect.moduleconfig.cacher.task.cacherurl
Example value: http://${WCM_HOST}:${WCM_PORT}/${WCM_CONTEXT_ROOT}/connect/

The full URL to be used as the replacement for the connect servlet in pre-rendered pages. The URL ends with the string specified in **connect.moduleconfig.cacher.task.servletpath** property if it is not blank. The context of cacherurl is used when generating a URL with pre-rendering. This property is not used when a page belongs to a site that has not already been pre-rendered at a site level by the scheduled task or through a SRV=cacheSite request.

connect.moduleconfig.cacher.task.servletpath
Example value: /connect

The path of the substituted connect servlet that is defined in the **connect.moduleconfig.cacher.task.cacherurl** property. This property can remain blank if the cacherurl context should be used unchanged.

connect.moduleconfig.cacher.defaultcontentname
Example value: `index.html`

This sets the name of the default or home file that is used when accessing the pre-rendered site. This normally would be `index.html`.

connect.moduleconfig.cacher.task.siteareas
Example value: `LibraryA/SiteAreaA,LibraryB/SiteAreaB,SiteAreaC`

The site areas within a Web Content Manager environment to cache are entered here, separated by commas. This property provides the option of specifying the library in addition to the site area. If the library is specified, the pre-renderer looks for the site area in that library. If no library is specified, the default library is used, as specified in the `defaultLibrary` property.

Note: If any of your site area names contain commas, you must create separate parameters for each site area using this format: `connect.moduleconfig.cacher.task.siteareas.N`

N represents a different integer for each parameter. For example, if you want to pre-render a site area named "SiteArea,Red" and a site named "Site,Yellow", you would need to create the following parameters:

```
connect.moduleconfig.cacher.task.siteareas.1=MyLib/SiteArea,Red
connect.moduleconfig.cacher.task.siteareas.2=Site,Yellow
```

connect.moduleconfig.cacher.task.interval.recurrence
connect.moduleconfig.cacher.task.interval.startdelay
The CacherModule can be set to run after a recurring number of minutes.

recurrence:
Example value: `10`.

The recurring period in minutes for a recurring task.

startdelay:
Example value: `1`

The delay in minutes prior to starting the first recurring task.

Note: If you do not configure pre-rendering to start automatically when the server starts, pre-rendering at intervals does not work until you manually trigger the cacher module.

connect.moduleconfig.cacher.task.scheduled.times
Example value: `3:00 am`

Alternately, the CacherModule can be set to run at certain times. Enter a series of absolute times, separated by commas.

Important: When specifying time values, be sure you conform to the format `H:MM am|pm`, including the use of the colon (`:`) character and the space. Incorrectly specified values prevent pre-rendering from functioning properly.

Note: If you do not configure pre-rendering to start automatically when the server starts, pre-rendering at scheduled times does not work until you manually trigger the cacher module.

Pre-rendering resources

connect.moduleconfig.cacher.useTieredResourceFolders

Value: `false`

All resources, such as images and file resources, are stored under the following folder:

`CACHER_DIR\LIBRARY\SITEAREA\resources`

By default, each individual resource is saved under its own folder. For example, a resource with the ID of "7961d78049717f29bc57fee5670e9d7b" will be stored under this folder:

`CACHER_DIR\LIBRARY\SITEAREA\resources\`**`7961d78049717f29bc57fee5670e9d7b`**

You can change this behavior so that resources are stored under a tiered set of sub-folders based on the first two characters of the resource ID by changing the value of **connect.moduleconfig.cacher.useTieredResourceFolders** to `true`. For example, a resource with the ID of "7961d78049717f29bc57fee5670e9d7b" will be stored under this folder:

`CACHER_DIR\LIBRARY\SITEAREA\resources\7\9\`

All other resources that whose IDs begin with "79" will also be stored under this folder. This is done to reduce the number of sub-folders under the "resources" folders.

Minimum configuration settings

You can pre-render sites either manually, or to a schedule, or at intervals. These are the minimum settings required for each type of pre-rendering.

Manual:

- `connect.moduleconfig.cacher.rendereruser`
- `connect.businesslogic.module.cacher.class`

Scheduled:

- `connect.moduleconfig.cacher.rendereruser`
- `connect.businesslogic.module.cacher.class`
- `connect.businesslogic.module.cacher.autoload`
- `connect.moduleconfig.cacher.task.siteareas`
- `connect.moduleconfig.cacher.task.scheduled.times`
- `connect.businesslogic.module`

At intervals:

- `connect.moduleconfig.cacher.rendereruser`
- `connect.businesslogic.module.cacher.class`
- `connect.businesslogic.module.cacher.autoload`
- `connect.moduleconfig.cacher.task.siteareas`
- `connect.moduleconfig.cacher.task.interval.recurrence`
- `connect.businesslogic.module`

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some

of these services.

Reserved authoring portlet

When you use the web content viewer or web content pages, some scenarios involve web content authoring tasks that are accomplished with authoring tools components. Authoring tasks are run through a special instance of the authoring portlet that is reserved specifically for these tasks and is installed on page that is hidden from the page navigation available to typical users.

The following tasks use the reserved authoring portlet:

- Selecting a web content folder when you create or edit the properties of a web content page.
- Configuring the web content viewer, such as selecting the content item to display.
- Using inline editing or authoring tools components that are rendered in the web content viewer.

Authoring tasks are run in a separate window that opens from the current page, but you can configure the behavior of authoring tools components to redirect users to the hidden page that contain the reserved authoring portlet.

Ensuring the availability of the reserved authoring portlet

If either the authoring portlet instance or the hidden portal page is not available or if the user lacks the permission to access either of them, the authoring tasks that require the reserved authoring portlet fail, causing web content pages and the web content viewer to be unusable. For this reason, you must be careful when you administer the reserved authoring portlet and the hidden portal page.

The following conditions are essential for the proper function of the reserved authoring portlet:

- Users must have the User role on the hidden portal page.
- Users must have the User role on the reserved authoring portlet.
- The reserved authoring portlet must be the only portlet that is on the hidden portal page.
- The unique name of the hidden portal page must be `com.ibm.wps.hiddenpage.wcm.Authoring_Portlet`.
- The unique name of the portlet window of the authoring portlet instance on the hidden portal page must be `com.ibm.wps.hiddenpage.wcm.control.Authoring_Portlet`.

Availability problems that are related to the reserved authoring portlet or the hidden portal page are identified by the following symptoms:

- The `SystemOut.log` file for the portal server contains error messages that are referenced by the authoring portlet or hidden page. For example:

```
EJPDB0124E: The specified string
[com.ibm.wps.hiddenpage.wcm.Authoring_Portlet] can neither be
deserialized as an object ID nor resolved as a unique name.
EJPDB0124E: The specified string
[com.ibm.wps.hiddenpage.wcm.control.Authoring_Portlet] can neither be
deserialized as an object ID nor resolved as a unique name.
```

- When a separate window is opened from the current page to run the authoring task, the new window displays the following message:

  `Error 400: EJPPH0006E: The resolution of a URI failed. Refer to the stack trace for more detailed information.`
- When a separate window is opened from the current page to run the authoring task, the new window is empty.
- When the user is redirected to another portal page to run the authoring task, the user is redirected to the default portal page instead of the page that contains the reserved portlet.
- When the user is redirected to another portal page to run the authoring task, the user is redirected to an empty page.

If any of these problems occur, verify that the conditions for proper operation of the reserved authoring portlet and hidden portlet page are fully implemented.

Note: If the reserved authoring portlet or the hidden portlet page are removed inadvertently, you can deploy them again using the `action-install-wcm-hidden-authoring` configuration task.

"Configuring the reserved authoring portlet"
The reserved authoring portlet is essential to the proper operation of web content pages and the web content viewer, so it is important that the configuration of the reserved authoring portlet is similar to the configuration of other instances of the authoring portlet.

Configuring the reserved authoring portlet

The reserved authoring portlet is essential to the proper operation of web content pages and the web content viewer, so it is important that the configuration of the reserved authoring portlet is similar to the configuration of other instances of the authoring portlet.

Procedure

1. Log in to the portal as an administrator.
2. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
3. Search for the page with the unique name of `com.ibm.wps.hiddenpage.wcm.Authoring_Portlet`.
4. Click the **Edit Page Layout** icon for the page.
5. Select **Edit shared settings** from the portlet menu, and specify any settings for the reserved authoring portlet. The available settings and the process for updating them is the same for the reserved authoring portlet as it is for any other instance of the authoring portlet.

   Note: Changes made to the reserved authoring portlet with the **Edit shared settings** mode affect only the reserved authoring portlet and no other instances of the authoring portlet. To ensure a consistent authoring experience, you can make the same changes to other authoring portlet instances by using the **Edit shared settings** mode for each instance. Alternatively, you can make the same changes to every instance of the authoring portlet by using the **Configure** mode from a single instance. Changes that you make in the **Configure** mode also affect the reserved authoring portlet.
6. Save your changes.

Further configuration options

These configuration options are available to address installation requirements for other deployment scenarios.

"Web content substitution variables"
IBM Web Content Manager uses several substitution variables that are defined in the configuration for IBM WebSphere Application Server.

"Setting scoped configuration settings for virtual portals" on page 433
Web Content Manager configuration settings can be scoped for individual virtual portals.

"Disabling Workflow Actions" on page 434
Disable workflow action on servers that do not require workflows to be processed, such as a subscriber. This strategy can improve performance and reduce the number of versions that are created for each item.

"Enabling connect tags" on page 435
Enable connect tags to reference web content components and apply customized caching to the components.

"Enabling email" on page 435
To use the email workflow action, you must configure Web Content Manager to use your SMTP server.

"Defining alternative administrators for multi-realm configurations" on page 436
Web Content Manager requires a user to run various system tasks such as initialization, and background tasks such as syndication. By default, this system user is the configured JCR domain administrator. In scenarios where the configured user realm does not contain the domain administrator then an alternative user must be provided.

Web content substitution variables

IBM Web Content Manager uses several substitution variables that are defined in the configuration for IBM WebSphere Application Server.

If you need to modify these variables, use the WebSphere Integrated Solutions Console for the application server. If you are working with a managed cell or cluster, use the WebSphere Integrated Solutions Console for the deployment manager.

Table 52. Web content substitution variables

Variable	Description
`WCM_CONTEXT_ROOT`	The context root for the enterprise application for Web Content Manager. Example: `wps/wcm`
`WCM_HOST`	The fully qualified host name of the server. Example: `www.example.com`
`WCM_ILWWCM_HOME`	This variable is the directory where the Web Content Manager application is installed Example: *`PortalServer_root`*`/wcm`
`WCM_PORT`	The port number that is used to access the portal. Example: `10038`

Table 52. Web content substitution variables (continued)

Variable	Description
WCM_SCHEMA	The database schema name of the JCR domain that is configured for use with IBM WebSphere Portal Express. Example: jcr
WCM_SEARCHSEED_CONTEXT_ROOT	The context root for the Search Seed portlet. Example: wps/wcmsearchseed
WCM_WEB_APP_HOME	The directory path where the ilwwcm.war file is located.
WCM_WPS_CONTEXT_ROOT	The context root or base URI for the portal. All URLs beginning with this path is reserved for the portal. Example: wps http://hostname.example.com:10038/wps/portal
WCM_WPS_DEFAULT_HOME	The default portal page. This page is the page for users who are not logged in. Example: portal http://hostname.example.com:10038/wps/portal
WCM_WPS_PERSONALIZED_HOME	The portal page for users who are already logged in to the portal. This page cannot be accessed by anonymous users. Example: myportal http://hostname.example.com:10038/wps/myportal

Setting scoped configuration settings for virtual portals

Web Content Manager configuration settings can be scoped for individual virtual portals.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **WCM WCMConfigService** > **Custom properties**.

   Cluster note: If you are using this web content server as part of a cluster, ensure that you use the WebSphere Integrated Solutions Console for the deployment manager when you edit configuration properties.
3. Add a configuration setting for each virtual portal that requires unique configuration settings. You can set this setting for either the host name or context path:

   Host name:

   vp.*uniquename*.hostname=*ExistingVPHost*

   Context path:

   vp.*uniquename*.context=*ExistingVPContext*

4. To add a scoped configuration setting for a virtual portal, use this format:
   PropertyKey.vp.*uniquename=override_value*

   This setting overrides the *property key* in the virtual portal that is specified in the *unique name*.
5. Restart the server or cluster.

Example

If your virtual portal was named "yellowportal", you might create a scoped configuration for it using this format.

```
vp.yellow.context=yellowportal
```

The default value for the deployment subscriber is "false":
`deployment.subscriberOnly=false`

You can override this value for the "yellowportal" virtual portal and change it to "true" by using this configuration parameter:
`deployment.subscriberOnly.vp.yellow=true`

If the base configuration for a setting is different from all the virtual portals, it is more efficient to use a base override setting. To do this, add this setting:
`enable.base.portal.overrides=true`

To add a setting just for the base portal, add "`.base`" to the end of the parameter name.

For example, if you use the default setting `deployment.subscriberOnly=true`, you can add another setting that is named `deployment.subscriberOnly.base=false` that is applied to the base portal only. All the virtual portals use the default value of `deployment.subscriberOnly=true`.

Disabling Workflow Actions

Disable workflow action on servers that do not require workflows to be processed, such as a subscriber. This strategy can improve performance and reduce the number of versions that are created for each item.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **WCM WCMConfigService** > **Custom properties**.

   Cluster note: If you are using this web content server as part of a cluster, ensure that you use the WebSphere Integrated Solutions Console for the deployment manager when you edit configuration properties.
3. Add a configuration setting named `disableWorkflowAction`.
   a. Use a comma to separate the workflow action names that you want to disable. For example:
      `disableWorkflowAction=ScheduledMoveAction1,ScheduledMoveAction2`

      Note: Workflow action names are case-sensitive.
   b. To disable all workflow actions on the server, use this setting:
      `disableWorkflowAction=*`
4. Restart the server or cluster.

Enabling connect tags

Enable connect tags to reference web content components and apply customized caching to the components.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **WCM WCMConfigService** > **Custom properties**.

   Cluster note: If you are using this web content server as part of a cluster, ensure that you use the WebSphere Integrated Solutions Console for the deployment manager when you edit configuration properties.
3. Specify `connect.businesslogic` properties to process connect tags from any host or from specific hosts.

   Process connect tags from any host

   Add the following property:

   - Property name: `connect.businesslogic.processunknownhosts`
   - Value: `true`

   Process connect tags from specific hosts

   Add the following property:

   - Property name: `connect.businesslogic.processunknownhosts`
   - Value: `false`

   For each host for which you want to enable processing, add a property:

   - Property name: `connect.businesslogic.hosts.`*`hostname`*
   - Value: `true`
4. Restart the server or cluster.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Enabling email

To use the email workflow action, you must configure Web Content Manager to use your SMTP server.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **WCM WCMConfigService** > **Custom properties**.

   Cluster note: If you are using this web content server as part of a cluster, ensure that you use the WebSphere Integrated Solutions Console for the deployment manager when you edit configuration properties.
3. Specify `connect.connector.mailconnect` properties to use your SMTP server. Add the following properties:

   Default SMTP server

   - Property name: `connect.connector.mailconnector.defaultsmtpserver`

- Value: *mail.yourmailserver.com*

Default SMTP port

- Property name: `connect.connector.mailconnector.defaultsmtpport`
- Value: *yourport*

Default email address for "from" field

- Property name: `connect.connector.mailconnector.defaultfromaddress`
- Value: *admin@yourmailserver.com*

Default email address for "reply-to" field

- Property name: `connect.connector.mailconnector.defaultreplytoaddress`
- Value: *admin@yourmailserver.com*

4. If you use a secured SMTP server, you need to specify a user name and password to access the SMTP server: Add the following properties:

   Default user name

   - Property name: `connect.connector.mailconnector.defaultusername`
   - Value: *username*

   Default password

   - Property name: `connect.connector.mailconnector.defaultpassword`
   - Value: *password*

5. Save your changes.
6. Restart the portal for the new settings to take effect.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Defining alternative administrators for multi-realm configurations

Web Content Manager requires a user to run various system tasks such as initialization, and background tasks such as syndication. By default, this system user is the configured JCR domain administrator. In scenarios where the configured user realm does not contain the domain administrator then an alternative user must be provided.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **WCM WCMConfigService** > **Custom properties**.

   Cluster note: If you are using this web content server as part of a cluster, ensure that you use the WebSphere Integrated Solutions Console for the deployment manager when you edit configuration properties.
3. The settings are different for the base portal and any virtual portals.

   The base portal

   - Property name: `wcm.admin.user.dn`
   - Value: The distinguished name of the alternative admin.

For example: `wcm.admin.user.dn=uid=myadmin,o=myRealm`

You can use a base override setting for this property. See "Setting scoped configuration settings for virtual portals" on page 433 for further information about setting a base override setting for your base portal.

Virtual portals
Use scoped configuration settings to apply different settings for specific virtual portals. See "Setting scoped configuration settings for virtual portals" on page 433 for further information.

4. Save your changes.
5. Restart the portal for the new settings to take effect.

Configuring managed pages

When you create a new installation of IBM WebSphere Portal Express 8.5, managed pages are enabled by default. However, you can also manually disable and enable the feature as needed.

About this task

Migration note: If you migrate from a previous version, managed pages are disabled by default, but you can enable the feature after migration.

"Enabling managed pages" on page 376
By default, support for managed pages is enabled for the default virtual portal. However, you can also manually enable this support if managed pages are disabled.

"Disabling managed pages" on page 379
Disable support for managed pages by running the `disable-managed-pages` configuration task.

"Transferring content associations to the Portal Site library" on page 380
When you enable manage pages, any web content pages that you have are converted to managed pages and added to the Portal Site library. However, the content that is associated with the web content pages remains in the original libraries. You can transfer this associated content to the Portal Site library with the `internalize-content-mappings` task.

"Enabling managed pages" on page 376
By default, support for managed pages is enabled for the default virtual portal. However, you can also manually enable this support if managed pages are disabled.

"Disabling managed pages" on page 379
Disable support for managed pages by running the `disable-managed-pages` configuration task.

"Transferring content associations to the Portal Site library" on page 380
When you enable manage pages, any web content pages that you have are converted to managed pages and added to the Portal Site library. However, the content that is associated with the web content pages remains in the original libraries. You can transfer this associated content to the Portal Site library with the `internalize-content-mappings` task.

Related concepts:

"Vanity URLs" on page 2094
You can associate vanity URLs with portal pages and labels. Vanity URLs are short URLs that people can easily remember. They are shorter than full WebSphere Portal Express URLs. They are sometimes also called marketing URLs. You can publish vanity URLs for marketing campaigns through different channels, such as email or print. This way, you can use vanity URLs to direct customers to a specific portal page or content item. Interested site visitors who want to view your campaign can then remember or copy the short vanity URL and type it into the browser address field.

Enabling managed pages

By default, support for managed pages is enabled for the default virtual portal. However, you can also manually enable this support if managed pages are disabled.

About this task

Important: Do not attempt to enable managed pages on a server where managed pages are already enabled. If you previously disabled managed pages and want to re-enable the feature, you must ensure that the Portal Site library is empty first. If you fail to remove the page artifacts from the previous configuration, the resulting portal might not work properly.

When supported, managed pages is enabled for a virtual portal, all pages in the virtual portal are copied into the Portal Site library in IBM Web Content Manager. However, the following pages are not treated as managed pages and are not copied:

- Administration pages, as identified by the label `ibm.portal.Administration` and its child pages
- Private pages

Each virtual portal has its own Portal Site library.

Note: To take advantage of the features available to managed pages in the user interface, your pages must use the Portal 8.5 theme.

Cluster consideration: In a cluster, you need to apply this procedure only to the primary node.

Attention: If you lost your JCR workspace and the backup was create before you created the virtual portal, restoring the workspace creates an inconsistency between the database domains. The **create-virtual-portal-site-nodes** task fails because the JCR workspace is missing. Run the **action-migrate-vps** task to correct the inconsistency with the database domains and to restore the JCR workspace.

Procedure

1. Start the portal server.
2. To enable support for managed pages, run the **enable-managed-pages** task from the *wp_profile_root*`/ConfigEngine` directory.

   Windows

   ```
   ConfigEngine.bat enable-managed-pages -DPortalAdminPwd=password
   -DWasPassword=password
   ```

   Linux

   ```
   ./ConfigEngine.sh enable-managed-pages -DPortalAdminPwd=password
   -DWasPassword=password
   ```

IBM i `ConfigEngine.sh enable-managed-pages -DPortalAdminPwd=`*`password`*
`-DWasPassword=`*`password`*

After you run the **enable-managed-pages** task for the first time, the property **managed.pages** is created in the portal WP Configuration Service. The value of the property is set to `true`.

3. Restart the portal server.
4. To populate web content libraries with information about virtual portals in the system, run the **create-virtual-portal-site-nodes** task from the *wp_profile_root*`/ConfigEngine` directory. For each virtual portal, this task creates a library and a site area that is called `lost-found` for resources that cannot be properly located. If the library or site area exist, the task exits. By default, the task runs on all virtual portals in the system.

   Windows
   `ConfigEngine.bat create-virtual-portal-site-nodes`
   `-DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*

   Linux `./ConfigEngine.sh create-virtual-portal-site-nodes`
   `-DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*

   IBM i `ConfigEngine.sh create-virtual-portal-site-nodes`
   `-DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
5. To populate web content libraries with information about the portal pages in the system, run the **create-page-nodes** task from the *wp_profile_root*`/ConfigEngine` directory.

   This task can also be used when portal pages and managed pages artifacts in Web Content Manager are not synchronized. In this case, the task attempts to resynchronize the portal artifacts and web content artifacts, giving precedence to the portal artifacts.

   Performance note: Depending on the amount of information in the system, the **create-page-nodes** task can take a long time to run. Because of the database load of the task, do not run the task frequently. The initial run of the task requires the most time, while subsequent runs typically require less time.

   Note: If you have many pages, then it might be necessary to increase the soap client timeout. Edit the *wp_profile_root*`/properties/soap.client.props` file to change the **com.ibm.SOAP.requestTimeout** to `60000`.
   Attention: If your virtual portals have different administrative accounts, you cannot run the **create-page-nodes** task directly. You must run the task for every virtual portal, including the base virtual portal. Use the **VirtualPortalHost** or **VirtualPortalContext** parameter with the **create-page-nodes** task. Run the **list-all-virtual-portals** task to get a list of all your virtual portals. When you run the create-page-nodes task on the base virtual portal, set the **VirtualPortalContext** value to `__NO__VP__ID__`.

   Windows
   `ConfigEngine.bat create-page-nodes -DPortalAdminPwd=`*`password`*
   `-DWasPassword=`*`password`*

   Linux `./ConfigEngine.sh create-page-nodes -DPortalAdminPwd=`*`password`*
   `-DWasPassword=`*`password`*

   IBM i `ConfigEngine.sh create-page-nodes -DPortalAdminPwd=`*`password`*
   `-DWasPassword=`*`password`*

By default, this task is run on all pages in all virtual portals. To limit this task to a specific virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix `-D` on the command line.

VirtualPortalHost
Specify the host name of the virtual portal. For example, `vp.example.com`.

Important: If the host name of the virtual portal is the same as the host name of the default virtual portal, you must also specify the **`VirtualPortalContext`** property. You can specify the **`VirtualPortalHost`** property by itself only if the host name is unique.

VirtualPortalContext
Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

You can customize the task with the following optional parameters on the command line. Each parameter requires the prefix `-D` on the command line.

`RunParallel`
Indicate whether you want the task to run with multiple threads. A value of `false` indicates a single thread and is the default setting.

A value of `true` indicates multiple threads, as specified by the work manager **wpsJcrSyncWorkManager** in the WebSphere Integrated Solutions Console. Each thread requires a database connection. For optimal performance, ensure that your database connection pool supports at least as many connections as there are threads in the pool.

`Excluded`
Specify a list of unique names of page nodes to exclude from the creation process. Excluding a page also excludes its child pages. By default, the portal administration pages (`ibm.portal.Administration`) are excluded.

6. Optional: If you used web content pages before you enabled managed pages, you can transfer the content for those pages to the Portal Site library. If you plan to use the default page templates and store your web content in the Portal Site library, transfer the content for the template pages to the Portal Site library. For more information, go to *Transferring content associations to the Portal Site library*.
7. Optional: Ensure that users have appropriate access to the Web Content Manager REST virtual resource so they can use **Edit mode**. For example, they have `user` access.

Related concepts:

"Page templates" on page 1786
Content authors use the page templates to quickly create pages that are consistent with your site design. They do not have to waste time to configure settings that are probably consistent across your site, such as theme selection, page layout, and more.

Related tasks:

"Transferring content associations to the Portal Site library" on page 380
When you enable manage pages, any web content pages that you have are converted to managed pages and added to the Portal Site library. However, the content that is associated with the web content pages remains in the original libraries. You can transfer this associated content to the Portal Site library with the `internalize-content-mappings` task.

Disabling managed pages

Disable support for managed pages by running the `disable-managed-pages` configuration task.

About this task

Disabling managed pages has the following effects:

- By default, each virtual portal has its own specific workspace where content is stored. When you disable managed pages, only a single workspace for the default virtual portal is available. The workspaces of other virtual portals are still there, but you can no longer access them. Any system associations between pages in those virtual portals and their respective Portal Site libraries no longer work.

  Important: To preserve content in the other virtual portals, you must import or syndicate the libraries into the default virtual portal before disabling managed pages.
- You can still access the Portal Site library for the default virtual portal, but the library is no longer automatically synchronized with the page structure.
- Pages are no longer managed in IBM Web Content Manager, with the following implications:
  - No page drafts can be created.
  - No new versions of pages can be created.
  - Pages are no longer syndicated.
  - Access control changes that you perform in the portal interface are no longer applied to the portal page site area.
  - If you delete a page from the portal interface, the corresponding portal page site area is not deleted.
- If you create a page with either the **Basic** or **Articles** page template, the page has no web content association. This missing association can cause errors if you attempt to add content from the **Create Content** tab of the site toolbar. To use the sample web content items when managed pages are disabled, create a web content association on the page before attempting to add content.
- Having managed pages enabled is a mandatory requirement to have vanity URLs enabled. Therefore, if you have vanity URLs enabled and disable managed pages, vanity URLs are also disabled.

Procedure

1. Run the **disable-managed-pages** task from the *wp_profile_root*/ConfigEngine directory.

   Linux `./ConfigEngine.sh disable-managed-pages -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

   IBM i `ConfigEngine.sh disable-managed-pages -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

   Windows
   `ConfigEngine.bat disable-managed-pages -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

   After running the **disable-managed-pages** task for the first time, the property **managed.pages** is created in the **WP WPConfigService** configuration service. The value of the property is set to `false`.
2. Restart the portal server.

Transferring content associations to the Portal Site library

When you enable manage pages, any web content pages that you have are converted to managed pages and added to the Portal Site library. However, the content that is associated with the web content pages remains in the original libraries. You can transfer this associated content to the Portal Site library with the `internalize-content-mappings` task.

About this task

Note: Administration pages are not intended to be managed pages and so are not included when you enable managed pages.

When you transfer the content association for a page to the Portal Site library, several things happen:

- The content that is referenced by the default content association for the page is copied to the portal page site area for the page. Only the default content association is affected; other content associations for the page are ignored.

  Note: Nested pages are not copied. Nested site areas are not copied in the following cases:
  - The nested site area is referenced by the default association of another page.
  - The nested site area has the same name as an existing site area for the same page.
- Template mappings and content elements that exist in the associated site area are copied over into the portal page. If the template mapping or element exists for the page, the copy is not performed.
- The default content setting for the portal page is modified to reference the copied content.
- The configuration of any web content viewers on the page is updated to reference the content that is stored in the portal page site area. However, viewer configurations that use content paths are not affected.

Procedure

To transfer content associations, run the `internalize-content-mappings` task from the *wp_profile_root*`/ConfigEngine` directory.

Windows

```
ConfigEngine.bat internalize-content-mappings
-DPortalPage=target_page -DIncludeDescendants=true_or_false
-DSynchronous=true_or_false -DPortalAdminPwd=password
-DWasPassword=password
```

Linux

```
./ConfigEngine.sh internalize-content-mappings
-DPortalPage=target_page -DIncludeDescendants=true_or_false
-DSynchronous=true_or_false -DPortalAdminPwd=password
-DWasPassword=password
```

IBM i

```
ConfigEngine.sh internalize-content-mappings
-DPortalPage=target_page -DIncludeDescendants=true_or_false
-DSynchronous=true_or_false -DPortalAdminPwd=password
-DWasPassword=password
```

The following properties must be specified either on the command line or in the `wkplc.properties` file.

PortalPage
The object ID or the unique page name of the page for which you want to transfer content. If the target page is contained in a virtual portal, you must identify the virtual portal by specifying either the **VirtualPortalContext** parameter or **VirtualPortalHost** parameter.

IncludeDescendants
Specify `true` to transfer content for the target page and any child pages. To transfer content only for the target page, specify `false`. If not specified, the default value is `true`.

Synchronous
Specify `true` to perform the transfer synchronously. To perform the transfer asynchronously, specify `false`. If not specified, the default value is `true`.

Verbose
Specify `true` to output additional information to the log. To generate basic log information, specify `false`. If not specified, the default value is `false`.

CollisionHandling
When you copy content to a page, specify the action to take if the content item exists. By default, that content item is not copied. If you set **CollisionHandling** to `replace`, the content item on the page is replaced with the content item to be copied to the page.

VirtualPortalContext
Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

VirtualPortalHost
Specify the host name of the virtual portal. For example, `vp.example.com`.

Important: If the host name of the virtual portal is the same as the host name of the default virtual portal, you must also specify the **VirtualPortalContext** property. You can specify the **VirtualPortalHost** property by itself only if the host name is unique.

PortalAdminPwd
The administrator password for WebSphere Portal Express.

WasPassword
The administrator password for WebSphere Application Server.

Example commands:

- Windows: `ConfigEngine.bat internalize-content-mappings -DPortalPage=example.page -DIncludeDescendants=true -DSynchronous=true -DPortalAdminPwd=password -DWasPassword=password`
- Linux : `./ConfigEngine.sh internalize-content-mappings -DPortalPage=example.page -DIncludeDescendants=true -DSynchronous=true -DPortalAdminPwd=password -DWasPassword=password`
- IBM i: `ConfigEngine.sh internalize-content-mappings -DPortalPage=example.page -DIncludeDescendants=true -DSynchronous=true -DPortalAdminPwd=password -DWasPassword=password`

Managing tagging and rating for web content

When you use tagging and rating with web content, the web content viewer provides extra scope options for the filtering of tagging and rating results. Because changes in the web content system can affect the accuracy of the tagging and

rating information that is used by the portal, it is important to keep the scope information up to date by synchronizing the scopes regularly.

"Applying tagging and rating scopes to web content"
Scoping is typically used to filter the tag cloud or ratings overview according to hierarchical metadata attached to the resources that are being tagged. When you apply tagging and rating to web content, you can scope these display components according to authoring template, category, or content item parent.

"Synchronizing scopes for web content"
When users are tagging or rating web content, the web content viewer provides the tagging or rating information to the portal, where it is stored. If information in the web content system changes, this change can cause the tagging and rating information that is stored in the portal to be out of sync. This issue can happen, for example, if content items are moved or category information changes. To ensure that the tagging and rating information is current, synchronize the scopes that are used for web content. You can set up automatic synchronization according to different conditions or run a manual synchronization as needed.

Applying tagging and rating scopes to web content

Scoping is typically used to filter the tag cloud or ratings overview according to hierarchical metadata attached to the resources that are being tagged. When you apply tagging and rating to web content, you can scope these display components according to authoring template, category, or content item parent.

About this task

You can configure the advanced settings of the web content viewer to limit results to show only tags or ratings that are associated with one or more of the following scopes:

- The parent of the content item that is being displayed (for example, a site area).
- The authoring template that is used to generate the content item or site area that is being displayed.
- The categories that are used to profile the content item that is being displayed. In this way, you can manage scopes from within your web content system by defining taxonomies for your content items.

Synchronizing scopes when items change:

To automatically run scope synchronization whenever an item changes in the web content system, specify the `tagging.syndication.enableItemModificationSynchronization` property in the Web Content Manager configuration service.

About this task

Note: This type of synchronization works only for individual item changes. For example, this type of synchronization is not automatically run when an entire site area or folder is moved. To synchronize scopes after such a change, you can run synchronization manually.

Procedure

1. Log in to the WebSphere Integrated Solutions Console (`http://`*`hostname.example.com`*`:10027/ibm/console`).
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WCM WCMConfigService**.
4. Under **Additional Properties**, click **Custom Properties**.
5. Add the `tagging.syndication.enableItemModificationSynchronization` property.
   a. Click **New**, and enter the property name `tagging.syndication.enableItemModificationSynchronization`.
   b. Set the string value to `true`.
6. Click **OK**, and save the changes to the master configuration.
7. Restart the portal.

Related tasks:

Scheduling scope synchronization:

You can schedule scope synchronization to be run at specific times by defining the schedule with the XML configuration interface.

Procedure

1. Verify whether any scheduled synchronizations are defined for the portal.
   a. Create an export file that you can use with the **xmlaccess** command. Here is an example of a request you can use to query the current configuration:

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="export" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd" >
  <portal action="locate">
    <task action="export" name="com.ibm.portal.cp.SynchronizationTask"/>
  </portal>
</request>
```

   b. Run the **xmlaccess** command, specifying the export file. The resulting output file contains any scheduled synchronization times that are defined in the portal.
2. Set the synchronization schedule.

a. To set a time for a scheduled synchronization, create an XML request document. For example, to schedule a synchronization to occur at 15:36 hours every day, you would use a request like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
  <portal action="locate">
    <task action="create" name="com.ibm.portal.cp.SynchronizationTask">
      <startTime>15:36</startTime>
    </task>
  </portal>
</request>
```

For each scheduled synchronization, create a separate `task` element and specify the time with a `startTime` element.

b. Run the **xmlaccess** command, specifying the file that contains the scheduling request. Scope information for the web content system is then synchronized automatically according to the schedule you defined.

3. Optional: If you want to set a minimum time before subsequent synchronizations are run, specify the `tagging.syndication.minimumTagSynchronizationTimeInterval` property in the Web Content Manager configuration service.
   a. Log in to the WebSphere Integrated Solutions Console (`http://`*`hostname.example.com`*`:10027/ibm/console`).
   b. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
   c. Click **WP ConfigService**.
   d. Under **Additional Properties**, click **Custom Properties**.
   e. Click **New**, and enter the property name `tagging.syndication.minimumTagSynchronizationTimeInterval`.
   f. Set the string value to the number of seconds between synchronizations.
   g. Click **OK**, and save the changes to the master configuration.
   h. Restart the portal.

Synchronizing scopes manually:

If automatic synchronization is not enabled for the scopes that are used for web content, or if you want to run synchronization outside of a scheduled synchronization period, you can manually start the synchronization process.

Procedure

To manually run synchronization, run the `cp-sync` configuration task or submit an XML request to the portal by using the XML configuration interface.

- To run synchronization with a configuration task, run the following task from the *wp_profile_root*`/ConfigEngine` directory:
  - Windows: `ConfigEngine.bat cp-sync -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
  - Linux: `./ConfigEngine.sh cp-sync -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
  - IBM i: `ConfigEngine.sh cp-sync -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`*
- Create an XML request file and submit it using the **`xmlaccess`** command. Here is an example of a request you can use to start synchronization:

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
  <portal action="locate">
    <task action="create" name="com.ibm.portal.cp.SynchronizationTask"/>
  </portal>
</request>
```

Syndication

Use syndication to replicate web content library data from one server to another server. Syndication is based on a syndicator and subscriber relationship. The syndicator has the current data. The subscriber received the current data from the syndicator.

"Syndication relationships" on page 449
Syndication is the method that is used by IBM Web Content Manager to replicate data from a web content library on one server to a web content library on another server.

"Syndication properties" on page 454
You can tailor the syndication behavior of your web content environment by changing configuration settings such as the syndication interval and automatic syndication.

"Syndication tuning" on page 456
While syndication is a vital part of keeping your web content current, the same syndication strategy is not appropriate for every environment. Depending on how you deploy IBM Web Content Manager, you can use different syndication strategies to balance the currency of your content with the performance your environment requires.

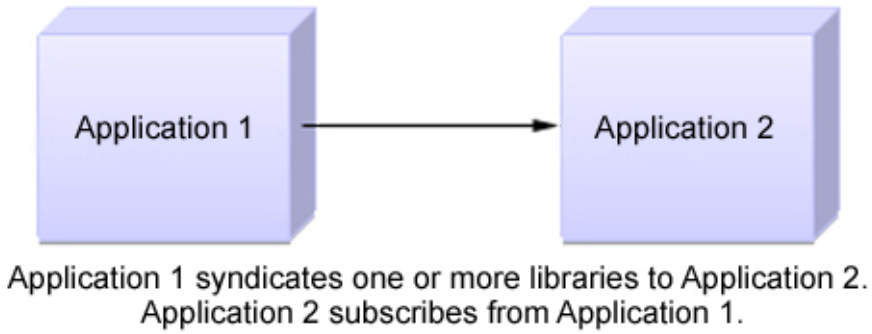
Syndication relationships

Syndication is the method that is used by IBM Web Content Manager to replicate data from a web content library on one server to a web content library on another server.

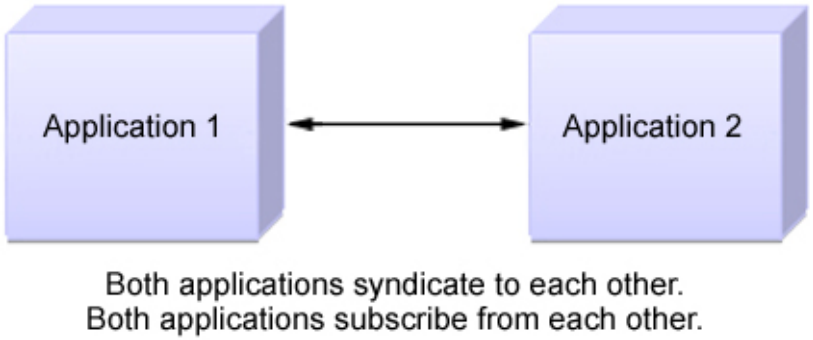
The relationship between a syndicator and a subscriber can be either a one-way or two-way relationship.

One-way syndication

Application 1 syndicates one or more libraries to Application 2, and Application 2 subscribes from Application 1.



Two-way syndication

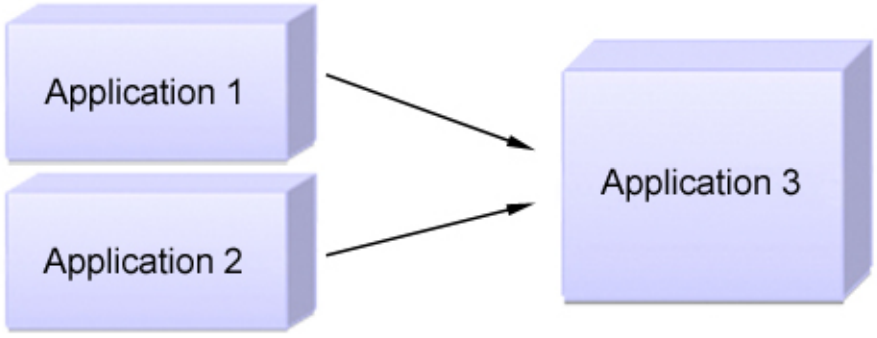


Note:

- When two-way syndication is enabled, you must first establish the syndication relationship from Application 1 to Application 2. After the libraries are replicated to Application 2, you can set up the syndication relationship between Application 2 and Application 1.
- When two-way syndication is used, all-item syndication must be enabled for each library that exists on both servers.
- Although it is possible to set up more than one syndication relationship between the same two applications, there is no reason to do so. The additional syndication relationships are not required because when a syndication relationship is established between two applications, no further relationships are established.

Multiple syndication relationships

Syndicators can syndicate libraries to multiple subscribers, and subscribers can subscribe to libraries from multiple syndicators.



Both Application 1 and 2 syndicate to Application 3.
Application 3 subscribes from both Application 1 and 2.

Syndication methods

There are three syndication methods available when a syndication relationship is configured:

Live items:

Live item syndication is mostly used when you syndicate to a staging or delivery server. The following items are syndicated:

- Published
- Expired

Draft items, projects, and items in a project are not syndicated.

Live and projects:

The advantage of using "Live and projects" syndication is to gradually syndicate projects to a staging or delivery server rather that waiting to syndicate all the items in a project after they all achieve a published state. The following items are syndicated:

- Published
- Expired

- Projects
- Draft items in a project

Draft items outside of projects are not syndicated.

All items:
All item syndication is mostly used when you syndicate between servers within an authoring environment. The following items are syndicated:

- Published
- Expired
- Projects
- Draft items in a project
- Other draft items
- Versions
- Deleted items

Switching from "all item" syndication to "live item" syndication: When you switch from "all item" syndication to "live and projects" syndication or "live item" syndication, any drafts previously syndicated to the subscriber are not removed.

Moving draft items between libraries: If you move a draft item from a library that uses "all item" syndication to a library that uses "live item" syndication, the draft item is also moved on the subscriber because the action occurred on the library that uses "all item" syndication. This behavior allows for some draft items to be included in a subscriber library even though "live item" syndication is being used.

CF05
Syndication modes

Each syndication relationship can be configured with a different syndication mode. This determines how syndication is scheduled.

CF05 **mode="*modetype*"**

- **Configured**: This uses the mode that is configured in the WCM WCMConfigService service.
- **Automatic**: Syndication is scheduled automatically based on the configured syndication interval set on the syndicator.
- **Manual**: Syndication occurs only when requested by using the administration portlet.

CF07
Manual syndication types

You can manually syndicate by using the following methods:

Update
This method syndicates items that are newer than the previous syndication. Items that are newer than the last syndication on the syndicator are sent to the subscriber. Items that are newer on the subscriber are not updated. Items that are created on the subscriber that do not exist on the syndicator are not removed from the subscriber.

Rebuild
This method syndicates all items that are newer on the syndicator. All items that are newer on the syndicator are sent to the subscriber. Items that

are newer on the subscriber are not updated. Items that are created on the subscriber that do not exist on the syndicator are not removed from the subscriber.

Rebuild with mirror

If you select the mirror option, all items on the subscriber are reset to mirror the syndicator. All items that are newer on the syndicator are sent to the subscriber. Items that are newer on the subscriber are overwritten with the older version from the syndicator. Items that are created on the subscriber that do not exist on the syndicator are removed from the subscriber. Version history is not syndicated.

Restriction: The **Rebuild with mirror** option can only be used when syndicating between servers that use CF07 or higher.

Restriction: The **Rebuild with mirror** option must not be used with two-way syndication.

Restriction: The **Rebuild with mirror** option can be used only on a syndicator.

Note: The **Rebuild with mirror** option will not automatically cascade through all subscribers downstream of the syndicator. You might need to repeat the **Rebuild with mirror** action on subscribers further down the syndication chain to synchronize all servers.

Cross version syndication

Cross-version syndication is supported between the following releases.

- WebSphere Portal version 7.0.0.2 with CF26 or higher.
- WebSphere Portal 8.0.0.1 with CF09 or higher.
- WebSphere Portal 8.5 or higher.

Syndicating from a newer software level to an older software level is only supported between different fix-pack levels of the same release. When syndicating between releases, only older to newer is supported.

See “Cross version syndication” on page 806 for further information.

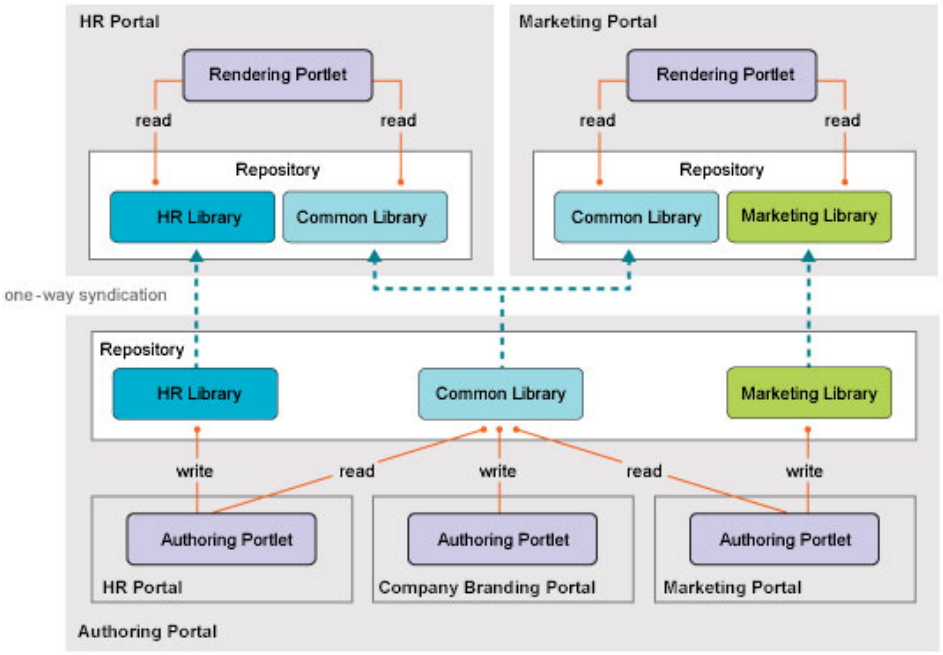
Web content libraries and syndication relationships

All the items that you work with as part of your Web Content Manager authoring environment are stored in web content libraries. When you syndicate data between applications, you do so on a library by library basis. As part of the definition of a syndicator or subscriber, you specify which web content libraries are to be included during syndication.

Because syndication is run on a library by library basis, it is important to consider how to organize your content between libraries to support your Web Content Manager environment. For example, suppose that you are using a single authoring server to develop content for two delivery servers, an intranet site that provides Human Resources information that is intended for internal employees of a company and an external Internet site that provides marketing material that is intended for customers and others outside the company. A basic approach to

support this environment would be to use two web content libraries, one for content specific to each site. You would then set up two syndication relationships with each going from the authoring server to the appropriate delivery server.

For easier management, you might divide your content further into three libraries, where one library contains data common to both the intranet and Internet sites and the other two libraries contain site-specific content. The following example demonstrates this configuration, with the addition of two other authoring portlets so that the content of each library is maintained by a different authoring portlet.



In this case you might set up several syndication relationships between the authoring server and the delivery servers:

- The Common Library syndicates to the intranet site (Human Resources Portal).
- The Common Library syndicates to the Internet site (Marketing Portal).
- The HR Library syndicates to the intranet site (Human Resources Portal).
- The Marketing Library syndicates to the Internet site (Marketing Portal).

Note: Web Content Manager provides flexibility in how you set up your syndication relationships. If you need to syndicate multiple libraries from one server to another, you can choose to use one syndication relationship that includes all the libraries, or you can choose to use separate syndication relationships for each library, or even a combination of both approaches, depending on how many libraries you are syndicating. The best approach for your situation depends not only on how many libraries are involved but also on how the libraries are related to one another. For example, you use a single syndication relationship for libraries that reference each other, as when one library contains design items like templates that are used by content in the other library. However, if the libraries are independent of one another and you think you might want to suspend syndication of one library but not the other, separate syndication relationships for each library can provide that.

Important:

- First-time syndication to an existing library is not supported. If you attempt to syndicate a library to a subscriber that already has a library with the same name, an error results.
- Some information about a Library is only syndicated the first time syndication occurs and not on subsequent updates and rebuilds. If you change the user access to a library, you must manually make the same changes to any subscriber libraries if you want the same settings on all your syndicated libraries.
- If content from one library (Library A) uses an item from another library (Library B), you must include both libraries in the syndicator to ensure that all items are syndicated successfully. If you include only Library A in the syndicator, any items in Library A that reference items in Library B are not syndicated, and syndication errors are generated.
- If you add a library to a syndicator after the initial syndication, you click `Update` to force the new library to be syndicated immediately.

Access control and syndication

Although syndication can be used to keep data current between libraries on different servers, access control settings for the libraries are not included as part of syndication. Depending on how your environment is set up and what policies you have in place for library access, there are extra considerations for access control when syndicating.

User consistency
: For user level access to remain consistent between the syndicator and subscriber, both servers must be configured to use the same user repository. If different user repositories are used, syndication occurs but there are errors in the subscriber log indicating missing users. If access controls are determined by using only virtual users and groups, such as "All authenticated" and "Anonymous Users", then there is no need to use the same user repository on the syndicator and subscriber.

First time syndication on a new library
: Because library access control settings are not syndicated, you must manually set access permissions on the subscriber's library when you syndicate for the first time. If the library does not exist on the subscriber, it is created during syndication. By default, no access control settings are specified on the new library, so you must set them manually before users can access content in the new library. The settings on the subscriber library do not have to match those on the syndicator library. This allows you to specify different levels of access for users and groups on the subscriber.

Syndication properties

You can tailor the syndication behavior of your web content environment by changing configuration settings such as the syndication interval and automatic syndication.

You define and manage syndication options in the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console.

Changing the syndication interval

Although the frequency of syndication is set by default during installation, you can change the syndication interval to better suit the needs of your environment.

For example, you might shorten the interval in an active authoring environment where users must collaborate heavily and rely on timely replication. Similarly, you might lengthen the interval to avoid excessive replication of data that does not change often.

Note: The syndication interval applies to all syndication operations and cannot be specified separately for different syndicator-subscriber pairs.

To change the syndication interval, modify the **deployment.itemChangedTaskDelay** property. By default, the syndication interval is set to 30 seconds. Specify the number of seconds to use as the syndication interval, with a minimum of `0` seconds and a maximum of `65536` seconds. A value of `0` prevents syndication from occurring. If you set the value to so short an interval that syndication cannot complete before the interval expires, syndication begins again when the previous syndication completes.

Syndication scheduling mode

Syndication can be set to either happen automatically, or manually:

Automatic
: Syndication is scheduled automatically based on the configured syndication interval.

Manual
: Syndication occurs only when requested by using the administration portlet.

Automatic syndication is enabled by default. To disable automatic syndication, specify the following property:
connect.moduleconfig.syndication.inittasks=false

Configuring a subscriber-only server

A syndicator server uses several processes to gather and queue content for syndication. These processes can sometimes affect server performance when run. However, a subscriber-only server does not require these processes, so you can improve performance on the subscriber-only server by disabling the processes.

To do this, ensure that `deployment.subscriberOnly` property is set to `true`.

Enabling secure syndication by using SSL

To enable and use SSL for syndication, the following properties must be changed in the `WCM WCMConfigService` to use the "https" protocol and the appropriate port.

- **deployment.itemDispatcherUrl=http://${WCM_HOST}:${WCM_PORT}/ ${WCM_CONTEXT_ROOT}/connect/?MOD=ItemDispatcher**
- **deployment.syndicatorUrl=http://${WCM_HOST}:${WCM_PORT}/ ${WCM_CONTEXT_ROOT}/connect/?MOD=Synd**
- **deployment.subscriberUrl=http://${WCM_HOST}:${WCM_PORT}/ ${WCM_CONTEXT_ROOT}/connect/?MOD=Subs**

For example, to enable SSL for syndication where the server is configured to provide SSL on port 10080, change **deployment.syndicatorUrl** from `http://${WCM_HOST}:${WCM_PORT}/${WCM_CONTEXT_ROOT}/connect/?MOD=Synd` to `https://${WCM_HOST}:10080/${WCM_CONTEXT_ROOT}/connect/?MOD=Synd`.

If self-signed certificates are used, extra steps maybe necessary to ensure the certificates that are exchanged are trusted on both servers. See the "SSL Configurations" topic in the WebSphere Application Server documentation.

Related tasks:

“Setting service configuration properties” on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Syndication tuning

While syndication is a vital part of keeping your web content current, the same syndication strategy is not appropriate for every environment. Depending on how you deploy IBM Web Content Manager, you can use different syndication strategies to balance the currency of your content with the performance your environment requires.

There are several different means to manage how and when content is replicated to other servers. It is important to note that, as with any process, syndication entails a performance cost. You must account for this when you set not only the frequency of syndication, but also the number of syndication relationships for a server.

Syndication interval

The syndication interval controls the frequency of syndication while automatic syndication is enabled and can be used by administrators to put an upper limit how often syndication occurs. Because up-to-date information is important to any web content environment, automatic syndication is enabled by default when IBM WebSphere Portal Express is installed. While the default setting for the syndication interval ensures maximum currency, you can choose to adjust the value if the currency demands of your environment do not call for the shortest interval.

Here are some general guidelines for setting the syndication interval.

Table 53. Syndication interval

Interval setting	Recommended environments
10 minutes – 2 hours	Staging servers to delivery servers.
30 seconds – 10 minutes	Any environment that requires frequent replication, such as an authoring server to a staging server, a test server, or distributed authoring server. When you increase the syndication interval for environments where authoring servers are involved, be mindful that timely replication is often essential, particularly in collaborative authoring environments where multiple authors on different servers might be working on the same content.

Syndication types

Live items:

Live item syndication is mostly used when you syndicate to a staging or delivery server. The following items are syndicated:

- Published
- Expired

Draft items, projects, and items in a project are not syndicated.

Live and projects:
The advantage of using "Live and projects" syndication is to gradually syndicate projects to a staging or delivery server rather that waiting to syndicate all the items in a project after they all achieve a published state. The following items are syndicated:

- Published
- Expired
- Projects
- Draft items in a project

Draft items outside of projects are not syndicated.

All items:
All item syndication is mostly used when you syndicate between servers within an authoring environment. The following items are syndicated:

- Published
- Expired
- Projects
- Draft items in a project
- Other draft items
- Versions
- Deleted items

Manual syndication

It is not necessary to wait for the syndication interval to elapse to run syndication. Manual syndication can be used at any time to cause syndication to occur immediately. There are different ways to take advantage of manual syndication:

- You can use manual syndication along with the syndication interval to provide flexibility. For example, if you are using an increased syndication interval to optimize performance between servers, you can still run manual syndication when you need to update content without waiting for the next syndication.
- If you require complete control of when syndication occurs, you can use manual syndication only. For this approach, you must disable automatic syndication so that the syndication interval setting is ignored.

CF07 You can manually syndicate by using the following methods:

Update
This method syndicates items that are newer than the previous syndication. Items that are newer than the last syndication on the syndicator are sent to the subscriber. Items that are newer on the subscriber are not updated. Items that are created on the subscriber that do not exist on the syndicator are not removed from the subscriber.

Rebuild
This method syndicates all items that are newer on the syndicator. All items that are newer on the syndicator are sent to the subscriber. Items that

are newer on the subscriber are not updated. Items that are created on the subscriber that do not exist on the syndicator are not removed from the subscriber.

Rebuild with mirror

If you select the mirror option, all items on the subscriber are reset to mirror the syndicator. All items that are newer on the syndicator are sent to the subscriber. Items that are newer on the subscriber are overwritten with the older version from the syndicator. Items that are created on the subscriber that do not exist on the syndicator are removed from the subscriber. Version history is not syndicated.

Restriction: The **Rebuild with mirror** option can only be used when syndicating between servers that use CF07 or higher.

Restriction: The **Rebuild with mirror** option must not be used with two-way syndication.

Restriction: The **Rebuild with mirror** option can be used only on a syndicator.

Note: The **Rebuild with mirror** option will not automatically cascade through all subscribers downstream of the syndicator. You might need to repeat the **Rebuild with mirror** action on subscribers further down the syndication chain to synchronize all servers.

CF05

Syndication modes

Each syndication relationship can be configured with a different syndication mode. This determines how syndication is scheduled.

CF05 **mode="***modetype***"**

- **Configured**: This uses the mode that is configured in the WCM WCMConfigService service.
- **Automatic**: Syndication is scheduled automatically based on the configured syndication interval.
- **Manual**: Syndication occurs only when requested by using the administration portlet.

Publish and expire dates

Because the syndication interval is not based on a scheduled time of the day, it is not suitable for setting up syndication to run during off-peak times. The publish date and expire date are the preferred methods for doing this.

The publish date for each content item specifies the date and time when the content is published to a website. After a content item is approved and the publish date is reached, the content item is queued for syndication according to the next syndication interval. By using the publish date, you can delay the publishing of content, effectively delaying its syndication. For example, if you are using a short syndication interval to ensure timely replication of most content, you can delay the syndication of less urgent content through the publish date for that content.

The expire date specifies the date and time when the content item is removed from a website. As with the publish date, you can use the expire date to cause the syndication activity that is associated with removing the content to occur at a time when other syndication activity is less intensive.

For more information on the publish and expire dates in the workflow process, refer to “Item status” on page 1929.

Syndicating large libraries

When you syndicate large libraries, you might also need to adjust these timeout settings:

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Servers** > **Server Types** > **WebSphere application servers** > *portal_server* > **Container Services** > **Transaction Service**.
3. Change the **total transaction lifetime timeout** and the **maximum transaction timeout** settings to 2000 seconds.

Syndication troubleshooting

If you encounter issues when syndicating, there are some common methods available to troubleshoot these issues.

Common issues

Table 54. Common issues

Issue	Solution
Unable to reach host	This is a common reason why syndication does not work. The URL for the syndicator or the subscriber might not be valid. You might need to use the IP address rather than the domain name.
Syndicator becomes unresponsive during syndication	Syndication can require a large amount of resources to run successfully. Consequently, if your server is performing other tasks at the same time as syndication, the process of syndication might slow or stop altogether. You must schedule your syndication to occur at times when the server load is at its lowest.
Syndicator status hangs on "Pending", or "Pending, Active"	If you are attempting to update or rebuild a syndicated library that contains large number of items, the syndicator status might hang on "Pending", or "Pending, Active". This can occur because the syndicator keeps retrying to syndicate when some items fail to syndicate to the subscriber, or when a system timeout occurs on the subscriber when saving data. Improving the performance of your database can help avoid these situations. For example, two of the database attributes that DB2 relies upon to perform optimally are the database catalog statistics and the physical organization of the data in the tables. Catalog statistics must be recomputed periodically during the life of the database, particularly after periods of heavy data modifications (inserts, updates, and deletes) such as a population phase. To fix this, you must run "Runstats" on the JCR database before and after syndication. The DB2 runstats command is used to count and record the statistical details about tables, indexes, and columns. See database performance for information on using the "Runstats" task. Due to the heavy load of computing these statistics, it is recommend that this maintenance occurs during off hours, periods of low demand, or when the portal is offline.

Table 54. Common issues (continued)

Issue	Solution
Time-outs during syndication	Time-outs during syndication are often caused by the failure of large items to be saved. Increasing the `total transaction lifetime timeout` setting of your IBM WebSphere Portal Express server can address this issue. The `total transaction lifetime timeout` setting of your subscriber must be at least the same as the syndicator. The `total transaction lifetime timeout` setting is changed by using the WebSphere Integrated Solutions Console. Go to **Servers > Server Types > WebSphere application servers** > ***portal_server*->Container Services** > **Transaction Service**. See the WebSphere Application Server information center for more information.
Subscriber becomes unresponsive during syndication	If you are attempting to syndicate a library that contains more than 10000 items, the subscriber machine might become unresponsive during the syndication operation. This action can occur due to an insufficient Java heap size setting on the subscriber. To update the maximum Java heap size that is used by the portal application server on the subscriber machine, complete the following steps: 1. In the WebSphere Integrated Solutions Console, click **System administration** > **Deployment manager** > **Java and Process Management** > **Process Definition** > **Java Virtual Machine**. 2. Update the value in the **Maximum Heap Size** field. A value of at least 1024 MB is recommended. 3. Click **OK**, and then save your changes. In addition, ensure that you have at least as much swap space allocated on the subscriber machine as you have physical memory.
500 errors on ext2 and ext3 versions of Linux	If you receive 500 errors on ext2 and ext3 versions of Linux, you exceeded the number of children that a parent folder can hold. You cannot store more than 32768 children under one folder on ext2 and ext3 versions of Linux. Move some content items out of the affected site area to another site area. So that none of your site areas contain more than 32768 children under one folder and then try syndicating again. You can move the content items back to the correct site areas after syndication is complete.

Table 54. Common issues (continued)

Issue	Solution
Subscriber is successful but syndicator is pending with no updates or failed items	Verify that the subscriber URL is correct. For example, the subscriber URL might be one of the following URLs: • `http://myportalhostname.ibm.com:port/wps/wcm/connect?MOD=Synd`, where *myportalhostname* is the name of your portal host • `http://mywebserverhostname.ibm.com:port/wps/wcm/connect?MOD=Synd`, where *mywebserverhostname* is the name of your web server host **Note:** In some configurations, TAM automatically appends itself to the subscriber URL, as in the following example: • `http://TAMmyportalhostname.ibm.com:port/wps/wcm/connect?MOD=Synd` 1. Click the **Administration menu** icon. Then, click **Portal Content** > **Syndicators**. 2. Click the **Edit Syndicator** icon for your idle syndicator. 3. Verify that the subscriber URL begins with either your portal host name or your web server host name. If it does not, update the URL so that it matches the examples of the subscriber URLs.

Other solutions

Table 55. Other solutions

Option	Details
Resetting the web content event log.	To assist in the troubleshooting process, you can reset the web content event log. For more information, see *Resetting the web content event log* in the related links.
Enabling the "deployment.enableReport" setting on the subscriber.	You can update the `WCM WCMConfigService` service and specify the `deployment.enableReport` property with a value of `true`. This update enables high level reporting of syndication to the SystemOut log on the subscriber server. It provides a summary of items that were processed, and which items failed syndication to help you troubleshoot syndication issues.

Working with failed items

From time to time items fail to syndicate. You use the failed items view to review a list of failed items and then run syndication again after you fix the issue.

1. Log on to your syndicator as an administrator.
2. Click the **Administration menu** icon. Then, click **Portal Content** > **Syndicators**.
3. The number of failed items for a syndicator are displayed in the Failed Items column. Click the number of failed items to open the Failed Items view.
   - Each failed item for the selected syndicator is displayed in the **Failed Items** view. Information is displayed about each failed item, including information about how the appropriate action required to fix the issue.
   - The Root and Impact columns are used to find the root cause of a syndication failure, and what secondary items are impacted by the root cause. By finding and fixing the root cause of the syndication failure, you also potentially fix the syndication failures of the items that are impacted by the root cause.

- The Important Items tab can also be used to narrow down which items are the most crucial to fix.

4. After you identified and fixed the issues, you can click **Retry** to initiate syndication for individual items, or use the **Retry All** in the Important Items tab to try to syndicate all failed items. You can also choose to update or rebuild a syndication relationship.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

"Resetting the web content event log" on page 1195
From time to time, you might need to reset the web content event log. The event log can be reset only on a syndicator server. Any changes that are made by resetting the event log are then syndicated to its corresponding subscribers. In most cases, you reset the event log on the server you imported or migrated data onto, or on a syndicator to troubleshoot syndication problems in a syndication relationship.

Creating a syndication relationship from the command line

You can set up syndication relationships by using the Administration Portlets or the command line. To set up a syndication relationship from the command line, use the XML configuration interface (XML access) and the ConfigEngine command to configure the subscriber.

Before you begin

Make sure that you have the appropriate configuration setup before you enable syndication.

Disk space

Before you use syndication, you must ensure that your subscriber has sufficient memory to receive the data that is syndicated from the syndicator. For example, if you are going to syndicate all libraries, then you need at least as much space on your subscriber as the database used by your syndicator.

Swap space

Ensure that you have at least as much swap space allocated on the subscriber server as you have physical memory.

Cross version syndication

Cross-version syndication is supported between the following releases. Syndication from a newer release to an older release is not supported:

- WebSphere Portal version 7.0.0.2 with CF26 or higher.
- WebSphere Portal 8.0.0.1 with CF09 or higher.
- WebSphere Portal 8.5 or higher.

Library already exists on the subscriber

First-time syndication to an existing library is not supported. If you attempt to syndicate a library to a subscriber that already has a library with the same name, an error results.

Large library with more that 10000 items

To syndicate a library that contains more than 10000 items, update the maximum Java heap size that is used by the portal application server on the subscriber server:

1. In the WebSphere Integrated Solutions Console, browse to the Java virtual machine settings.

   Stand-alone server:

   Servers > **Server Types** > **WebSphere application servers** > **WebSphere_Portal** > **Java and Process Management** > **Process definition** > **Java Virtual Machine**

   Clustered server:

   System administration > **Deployment manager** > **Java and Process Management** > **Process Definition** > **Java Virtual Machine**
2. Update the value in the **Maximum Heap Size** field. A value of at least 1024 MB is recommended.
3. Click **OK**, and then save your changes.

About this task

To set up syndication between web content libraries on two IBM Web Content Manager applications, establish a relationship between a syndicator and a subscriber. The syndicating server contains the data to be replicated, and the subscribing server receives the replicated data.

What can and cannot be syndicated:

- Information about a web content library is only syndicated the first time syndication occurs and not on subsequent updates and rebuilds. If a library is renamed or library user access is changed, this information is not syndicated to the Subscriber.
- If you change the name of a library or change user access to a library, these changes are not syndicated. If you want the same settings on all your syndicated libraries, you must manually make the same changes to any subscriber libraries.
- If content from one library (Library A) uses an item from another library (Library B), you must include both libraries in the syndicator. Including both libraries ensures that all items are syndicated successfully.
- If you include only Library A in the syndicator, any items in Library A that reference items in Library B are not syndicated. Syndication errors are also generated.
- If you add a library to a syndicator after the initial syndication, you must click **Rebuild** to force the new library to be syndicated immediately.
- If you are creating a two-way syndication relationship, you must use a consistent syndication strategy. For example, if you syndicate "All items", then both syndication relationships must be syndicating "All items".

Procedure

1. Ensure both the subscriber and syndicator are running and that they can access each other over a network.
2. On the subscriber server, create a shared credential vault slot with the XML configuration interface.
   a. Create the `CreateVaultSlot.xml` file using a text editor.

This sample file uses the following values that you can change to reflect your environment:

syndication-slot
The name of the shared credential vault slot.

wpsadmin
The user ID for the portal administrator.

passw0rd
The password for the portal administrator.

```
<?xml version="1.0" encoding="UTF-8"?>
<request
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    type="update" create-oids="true">

    <!-- Sample for creating a new credential vault slot. This script creates a     -->
    <!-- credential vault resource and a shared slot in the Default Admin Segment   -->
    <portal action="locate">
         <credential-segment action="locate" adapter-type="default" name="DefaultAdminSegment"
             user-mapped="false">
             <description>Default Admin Segment</description>
             <credential-slot action="update" active="false" name="syndication-slot"
                 resource="syndication-resource" secrettype="userid-password" system="true">
                 <localedata locale="en">
                     <description>used for syndicator and subscriber pair</description>
                 </localedata>
                 <password-secret action="create" external-id="wpsadmin"
                     user="uid=wpsadmin,o=defaultWIMFileBasedRealm">passw0rd</password-secret>
             </credential-slot>
         </credential-segment>
    </portal>
</request>
```

b. Run the **xmlaccess** command with the CreateVaultSlot.xml file.

Linux `./xmlaccess.sh -in CreateVaultSlot.xml -out slot-out.xml -url http://localhost:10039/wps/config -user wpsadmin -password passw0rd`

IBM i `xmlaccess.sh -in CreateVaultSlot.xml -out slot-out.xml -url http://localhost:10039/wps/config -user wpsadmin -password passw0rd`

Windows
`xmlaccess.bat -in CreateVaultSlot.xml -out slot-out.xml -url http://localhost:10039/wps/config -user wpsadmin -password passw0rd`

3. On the subscriber server, create a virtual portal on the subscriber with the create-virtual-portal task.

   This example creates a virtual portal called *sample*, although you can change this value to reflect your environment.

Linux `./ConfigEngine.sh create-virtual-portal -DPortalAdminPwd=passw0rd -DWasPassword=passw0rd -DVirtualPortalTitle=sample -DVirtualPortalContext=sample`

IBM i `ConfigEngine.sh create-virtual-portal -DPortalAdminPwd=passw0rd -DWasPassword=passw0rd -DVirtualPortalTitle=sample -DVirtualPortalContext=sample`

Windows
`ConfigEngine.bat create-virtual-portal -DPortalAdminPwd=passw0rd -DWasPassword=passw0rd -DVirtualPortalTitle=sample -DVirtualPortalContext=sample`

4. On the subscriber server, set up the syndication relationship with the **run-wcm-admin-task-subscribe-now** task.

   This sample command uses the following additional values that you can change to reflect your environment:

syndicator-hostname
The host name of the syndicator server.

syndicator1
This name is used for the syndicator item that is created on the syndicator server. Enter a name that helps identify the syndication relationship you are creating. This name must be unique and cannot be the same as an existing syndicator name.

Note: To reuse syndicator names of previously deleted syndication relationships on a subscriber, you must also delete the same relationship on the syndicator.

subscriber1
This name is used for the subscriber item that is created on the subscriber server. Enter a name that helps identify the syndication relationship you are creating. This name must be unique and cannot be the same as an existing subscriber name.

updateAfterCreation
If set to `true`, a syndication update is run as soon as the syndication pair is successfully created. If not specified, the default setting is `true`. This is a one-off syndication event not related to any automatic configuration settings.

In addition, use the following properties to identify the libraries to which you are subscribing and the type of syndication that you want to perform. For each syndication relationship, you can specify only one type of syndication. Separate multiple libraries with commas.

liveItems="*library_name_1*,*library_name_2*"
Live item syndication is mostly used when you syndicate to a staging or delivery server. The following items are syndicated:

- Published
- Expired

Draft items, projects, and items in a project are not syndicated.

liveProjectsItems="*library_name_1*,*library_name_2*"
Use "Live and projects" syndication to gradually syndicate projects to a staging or delivery server, rather than waiting until all items in a project achieve a published state. The following items are syndicated:

- Published
- Expired
- Projects
- Draft items in a project

Draft items outside of projects are not syndicated.

allItems="*library_name_1*,*library_name_2*"
All item syndication is mostly used when you syndicate between servers within an authoring environment. The following items are syndicated:

- Published
- Expired
- Projects
- Draft items in a project
- Other draft items

- Versions
- Deleted items

CF05 **mode="*modetype*"**

- **Configured**: This uses the mode configured in the WCM WCMConfigService service.
- **Automatic**: Syndication will be scheduled automatically based on the configured syndication interval.
- **Manual**: Syndication will occur only when requested using the administration portlet.

Example commands:

Linux
```
./ConfigEngine.sh run-wcm-admin-task-subscribe-now
-Dsyndicator=http://syndicator-hostname:10039/wps/wcm
-DvaultSlotName=syndication-slot -DsyndicatorName=syndicator1
-DsubscriberName=subscriber1 -DVirtualPortalContext=sample
-DliveItems="Web Content,Portal Site" -DPortalAdminPwd=passw0rd
-DWasPassword=passw0rd
```

IBM i
```
ConfigEngine.sh run-wcm-admin-task-subscribe-now
-Dsyndicator=http://syndicator-hostname:10039/wps/wcm
-DvaultSlotName=syndication-slot -DsyndicatorName=syndicator1
-DsubscriberName=subscriber1 -DVirtualPortalContext=sample
-DliveItems="Web Content,Portal Site" -DPortalAdminPwd=passw0rd
-DWasPassword=passw0rd
```

Windows
```
ConfigEngine.bat run-wcm-admin-task-subscribe-now
-Dsyndicator=http://syndicator-hostname:10039/wps/wcm
-DvaultSlotName=syndication-slot -DsyndicatorName=syndicator1
-DsubscriberName=subscriber1 -DVirtualPortalContext=sample
-DliveItems="Web Content,Portal Site" -DPortalAdminPwd=passw0rd
-DWasPassword=passw0rd
```

Database Management Systems

Configure the connection between IBM WebSphere Portal Express and your database management system. The **Database Transfer** configuration option in the Configuration Wizard assigns users and permissions, creates databases, obtains support for database collation, and transfers your database.

"DB2: Database transfer" on page 467
Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

"IBM DB2 for i: Database transfer" on page 476
Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

"DB2 for z/OS: Database transfer" on page 480
Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme

development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

"SQL Server: Database transfer" on page 487
Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

"Oracle: Database transfer" on page 495
Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

"Manual Steps: Database Transfer option in the Configuration Wizard" on page 504
The database transfer option in the Configuration Wizard includes manual steps. Some manual steps include scripts for you or your database administrator to run. For reference only, you can see the manual steps in this section of the product documentation. Use the Configuration Wizard to complete the deployment configuration. The wizard generates specific instructions and scripts based on your unique input.

"Oracle: Creating JCR table spaces (Automatic Storage Management)" on page 554
If you configured your database with Automatic Storage Management, you might need to perform additional manual instructions to create JCR table spaces when you use the Database Transfer option in the Configuration Wizard . If you select the option to let the wizard create your database schemas and assign permissions, you must perform the steps in this topic after you run the setup database script.

"Assigning custom table spaces" on page 555
You cannot use the **Database Transfer** option in the configuration wizard to assign custom table spaces on your database server. You can perform manual steps to assign custom table spaces.

"DB2: Enabling support for high availability recovery and rollforward recovery " on page 560
Optional: To prevent data loss on DB2, modify the JCR schema to support High Availability Disaster Recovery and rollforward recovery.

"Connecting to existing database domains" on page 561
View the steps to share a database domain between two separate WebSphere Portal Express instances (*instance1* and *instance2*), where *instance2* is connected to an *instance1* database domain.

DB2: Database transfer

Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

Configuration Wizard

The primary Configuration Wizard options are based on your target configuration topology, such as a stand-alone server or a cluster. The database transfer option is included with both **Set Up a Stand-alone Server** and **Set Up a Cluster**. For the stand-alone server topology, run the database transfer option before you run the federated security option. For the cluster option, run the database transfer before you create your deployment manager profile.

Validation

Prevent a possible database transfer failure by validating your entries in the wizard. When you chose to validate settings for the Database Transfer option, field syntax and database connection validations are performed to prevent a possible failure before you run the configuration.

Syntax validation checks that you:

- Enter a valid port number in the range of 1 - 65535.
- Use the correct format for your host name.

The database connection validation checks that a connection can be made to your database server. The wizard can connect to your database server to validate the host name and port number values that you enter.

On the Database Settings panel, you can choose to turn validation on or off by selecting **Yes** or **No** to the **Connect to database server to validate settings** option. Select **No**, if you know that your parameters are correct and your database server is unavailable at the time of creating your instructions.

"DB2: DB2 worksheet: Transfer to a single database" on page 471
When you use the database transfer option, you can select the condition to create a single database in the Configuration Wizard. This worksheet highlights the fields and properties that you see in the Configuration Wizard when you select the single database condition.

"DB2: DB2 worksheet: Transfer to multiple databases" on page 472
When you use the database transfer option, you can use the condition to create multiple databases in the Configuration Wizard. This condition is selected by default. This worksheet highlights the fields and properties that you see in the Configuration Wizard when you use the multiple databases condition.

Transferring data to a different database server

Depending on your environment, the wizard generates a configuration process. The following steps reflect all possible steps in the configuration process. The steps do not represent a literal configuration. The steps are provided as a reference.

About this task

If you click **View Step Command**, you can see the task and properties associated with each step in the wizard.

Procedure

1. Back up the properties files that the wizard uses during the configuration.

   Condition

   None

ConfigEngine task
backup-property-files-for-dbxfer

2. Manual Step: Create the database users and groups.

   Condition
   None

   ConfigEngine task
   None

3. Create your databases.

   Condition
   None

   ConfigEngine task
   create-database

4. Manual Step: Download the script and run it on the database server to create your database.

   Condition
   Select to manually create your database.

   ConfigEngine task
   None

5. Set up your database.

   Condition
   None

   ConfigEngine task
   setup-database

6. Manual Step: Download the script and run it on the database server to set up your database.

   Condition
   Select to manually assign users permissions.

   ConfigEngine task
   None

7. Manual Step: Set up JCR collation for correct language locale order.

   Condition
   Select to have advanced database collation support.

   ConfigEngine task
   None

8. Manual Step: Restart the DB2 server.

   Condition
   None

   ConfigEngine task
   None

9. Validate the database connection and environment.

   Condition
   None

   ConfigEngine task
   validate-database validate-database-environment

10. Stop the portal server.

Condition
collation support

ConfigEngine task
stop-portal-server

11. Transfer the database.

    Condition
    None

    ConfigEngine task
    database-transfer enable-profiles-check-managed package-profiles

12. Grant privileges to the database runtime users.

    Condition
    None

    ConfigEngine task
    grant-runtime-db-user-privileges

13. Manual Step: Download the script and run it on the database server to grant privileges to the runtime user.

    Condition
    Select to manually create users and assign them permissions.

    ConfigEngine task
    None

14. Configure the JCR domain to support large files.

    Condition
    None

    ConfigEngine task
    datasource-enable-fully-materialize-lob-data

15. Start the portal server.

    Condition
    None

    ConfigEngine task
    start-portal-server

What to do next

You transferred your data from Apache Derby to your preferred database.

One quick way to test your database configuration is to log in and explore the site to validate the site is working as you expected.

Go to http://*host_name*:*port*/*context_root*/*default_portal_home*. For example, go to http://*host_name:10039*/*wps*/*portal*.

Next, you can use other options to configure your environment more.

If you are setting up a stand-alone server environment, you can use the Enable Federated Security option to add an LDAP user registry.

If you are setting up a cluster environment, you can use the Create a Deployment Manager option to create a deployment manager profile that is augmented with WebSphere Portal Express resources.

DB2: DB2 worksheet: Transfer to a single database

When you use the database transfer option, you can select the condition to create a single database in the Configuration Wizard. This worksheet highlights the fields and properties that you see in the Configuration Wizard when you select the single database condition.

Typical fields

When you use the database transfer option, you answer questions about your environment. Some fields are required. Other fields are required or removed based on your selections for environment conditions.

The following table lists the typical fields that display when you select the option to transfer your data to a single database. To see additional fields that apply to an advanced configuration, click **Advanced**.

Values that you enter for some typical fields apply across domains. Rather than entering a value multiple times, this value is copied to fields in the Advanced view and applied across the database domains.

Table 56. Transfer to a single database..

You might not see all of the fields listed in this table. Use the Conditions column in this table to find out what selections are required to see the fields. If you do not see conditions listed for a field, the field always appears. A selection might result in multiple fields displaying in the wizard. For this type of selection, a selection listed in the Conditions column spans multiple field label rows.

Field Label	Property	Condition	Your Value
Database name	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbName` properties.		
Data source	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DataSourceName` properties.		
Database URL	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbUrl` properties.		
Configuration user ID	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbUser` properties.		
Configuration password	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbPassword` properties.		
Database administrator ID	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DBA.DbUser` properties.		
Database administrator password	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DBA.DbPassword` properties.		

Table 56. Transfer to a single database. (continued).

You might not see all of the fields listed in this table. Use the Conditions column in this table to find out what selections are required to see the fields. If you do not see conditions listed for a field, the field always appears. A selection might result in multiple fields displaying in the wizard. For this type of selection, a selection listed in the Conditions column spans multiple field label rows.

Field Label	Property	Condition	Your Value
Runtime user	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbRuntimeUser` properties.	To see this field, continue to use the default selection of **Yes** for needing a runtime database user for day-to-day operations.	
Runtime password	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbRuntimeDbRuntimePassword` properties.		
IBM DB2 library	`Db2.DbLibrary`		

Field used for the database collation condition

Database collation is an optional condition available to you.

Table 57. Database collation

Field Label	Property	Conditions	Your Value
Temporary directory to be used for collation		To see this field, you must select the **Yes** option for advanced database collation support. The default selection is **No**.	

DB2: DB2 worksheet: Transfer to multiple databases

When you use the database transfer option, you can use the condition to create multiple databases in the Configuration Wizard. This condition is selected by default. This worksheet highlights the fields and properties that you see in the Configuration Wizard when you use the multiple databases condition.

Typical fields

When you use the database transfer option, you answer questions about your environment. Some fields are required. Other fields are required or removed based on your selections for environment conditions.

The following table lists the typical fields that display when you select the condition to transfer your data to multiple databases. To see additional fields that apply to an advanced configuration, click **Advanced**.

Depending on the conditions that you select, values that you enter for some typical fields might apply across domains. Rather than entering a value multiple times, this value is copied to fields in the Advanced view and applied across the database domains.

Table 58. Transfer to multiple database. You might not see all of the fields listed in this table. Use the Conditions column in this table to find out what selections are required to see the fields. If you do not see conditions listed for a field, the field always appears. A selection might result in multiple fields displaying in the wizard. For this type of selection, a selection listed in the Conditions column spans multiple field label rows.

Field Label	Property	Conditions	Your Value
Release database name	`release.DbName`		
Release data source	`release.DataSourceName`		
Release database URL	`release.DbUrl`		
Community database name	`community.DbName`		
Community data source	`community.DataSourceName`		
Community database URL	`community.DbUrl`		
Customization database name	`customization.DbName`		
Customization Data source	`customization.DataSourceName`		
Customization database URL	`customization.DbUrl`		
JCR database URL	`JCR.DbName`		
JCR database name	`JCR.DataSourceName`		
JCR data source	`JCR.DbUrl`		
Feedback database name	`feedback.DbName`

Field used for the database collation condition

Database collation is an optional condition available to you.

Table 59. Database collation

Field Label	Property	Conditions	Your Value
Temporary directory to be used for collation		To see this field, you must select the **Yes** option for advanced database collation support. The default selection is **No**.	

IBM DB2 for i: Database transfer

Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme

development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

Configuration Wizard

The primary Configuration Wizard options are based on your target configuration topology, such as a stand-alone server or a cluster. The database transfer option is included with both **Set Up a Stand-alone Server** and **Set Up a Cluster**. For the stand-alone server topology, run the database transfer option before you run the federated security option. For the cluster option, run the database transfer before you create your deployment manager profile.

"IBM DB2 for i: IBM DB2 for i worksheet: Transfer your database" on page 478
This worksheet highlights the fields and properties that you see in the Configuration Wizard when you use the transfer database option.

Transferring data to a different database server

Depending on your environment, the wizard generates a configuration process. The following steps reflect all possible steps in the configuration process. The steps do not represent a literal configuration. The steps are provided as a reference.

About this task

If you click **View Step Command**, you can see the task and properties associated with each step in the wizard.

Procedure

1. Back up the properties files that the wizard uses during the configuration.

   Condition
   None

   ConfigEngine task
   backup-property-files-for-dbxfer
2. Manual Step: Create the database user profile on IBM DB2 for i.

   Condition
   None

   ConfigEngine task
   None
3. Manual Step: Create the database runtime users and groups.

   Condition
   None

   ConfigEngine task
   None
4. Create your databases.

   Condition
   None

   ConfigEngine task
   create-database
5. Validate the database connection and environment.

Condition
None

ConfigEngine task
validate-database validate-database-environment

6. Stop the portal server.

   Condition
   collation support

   ConfigEngine task
   stop-portal-server

7. Transfer the database.

   Condition
   None

   ConfigEngine task
   database-transfer enable-profiles-check-managed package-profiles

8. Grant privileges to the database runtime users.

   Condition
   None

   ConfigEngine task
   grant-runtime-db-user-privileges

9. Start the portal server.

   Condition
   None

   ConfigEngine task
   start-portal-server

What to do next

You transferred your data from Apache Derby to your preferred database.

One quick way to test your database configuration is to log in and explore the site to validate the site is working as you expected.

Go to http://*host_name*:*port*/*context_root*/*default_portal_home*. For example, go to http://*host_name:10039*/*wps*/*portal*.

Next, you can use other options to configure your environment more.

If you are setting up a stand-alone server environment, you can use the Enable Federated Security option to add an LDAP user registry.

If you are setting up a cluster environment, you can use the Create a Deployment Manager option to create a deployment manager profile that is augmented with WebSphere Portal Express resources.

IBM DB2 for i: IBM DB2 for i worksheet: Transfer your database

This worksheet highlights the fields and properties that you see in the Configuration Wizard when you use the transfer database option.

Typical fields

When you use the database transfer option, you answer questions about your environment. Some fields are required. Other fields are required or removed based on your selections for environment conditions.

The following table lists the typical fields that display when you select the database transfer option. To see additional fields that apply to an advanced configuration, click **Advanced**.

Table 60. Transfer database..

You might not see all of the fields listed in this table. Use the Conditions column in this table to find out what selections are required to see the fields. If you do not see conditions listed for a field, the field always appears. A selection might result in multiple fields displaying in the wizard. For this type of selection, a selection listed in the Conditions column spans multiple field label rows.

Field Label	Property	Condition	Your Value
Database name	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbName` properties.		
Data source	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DataSourceName` properties.		
Database URL	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbUrl` properties.		
Configuration user ID	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbUser` properties.		
Configuration password	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbPassword` properties.		
Database administrator ID	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DBA.DbUser` properties.		
Database administrator password	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DBA.DbPassword` properties.		
Runtime user	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbRuntimeUser` properties.	To see this field, continue to use the default selection of **Yes** for needing a runtime database user for day-to-day operations.	
Runtime password	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbRuntimeDbRuntimePassword` properties.		
IBM for DB2i connection type	`db2_iseries.DbDriverType`		

Table 60. Transfer database. (continued).

You might not see all of the fields listed in this table. Use the Conditions column in this table to find out what selections are required to see the fields. If you do not see conditions listed for a field, the field always appears. A selection might result in multiple fields displaying in the wizard. For this type of selection, a selection listed in the Conditions column spans multiple field label rows.

Field Label	Property	Condition	Your Value
IBM for DB2i library	**db2_iseries.DbLibrary**		

DB2 for z/OS: Database transfer

Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

Configuration Wizard

The primary Configuration Wizard options are based on your target configuration topology, such as a stand-alone server or a cluster. The database transfer option is included with both **Set Up a Stand-alone Server** and **Set Up a Cluster**. For the stand-alone server topology, run the database transfer option before you run the federated security option. For the cluster option, run the database transfer before you create your deployment manager profile.

Validation

Prevent a possible database transfer failure by validating your entries in the wizard. When you chose to validate settings for the Database Transfer option, field syntax and database connection validations are performed to prevent a possible failure before you run the configuration.

Syntax validation checks that you:

- Enter a valid port number in the range of 1 - 65535.
- Use the correct format for your host name.

The database connection validation checks that a connection can be made to your database server. The wizard can connect to your database server to validate the host name and port number values that you enter.

On the Database Settings panel, you can choose to turn validation on or off by selecting **Yes** or **No** to the **Connect to database server to validate settings** option. Select **No**, if you know that your parameters are correct and your database server is unavailable at the time of creating your instructions.

SQL Server: Database transfer

Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

Configuration Wizard

The primary Configuration Wizard options are based on your target configuration topology, such as a stand-alone server or a cluster. The database transfer option is included with both **Set Up a Stand-alone Server** and **Set Up a Cluster**. For the stand-alone server topology, run the database transfer option before you run the federated security option. For the cluster option, run the database transfer before you create your deployment manager profile.

Validation

Prevent a possible database transfer failure by validating your entries in the wizard. When you chose to validate settings for the Database Transfer option, field syntax and database connection validations are performed to prevent a possible failure before you run the configuration.

Syntax validation checks that you:

- Enter a valid port number in the range of 1 - 65535.
- Use the correct format for your host name.

The database connection validation checks that a connection can be made to your database server. The wizard can connect to your database server to validate the host name and port number values that you enter.

On the Database Settings panel, you can choose to turn validation on or off by selecting **Yes** or **No** to the **Connect to database server to validate settings** option. Select **No**, if you know that your parameters are correct and your database server is unavailable at the time of creating your instructions.

"SQL Server: SQL Server worksheet: Transfer to a single database" on page 490
When you use the database transfer option, you can select the condition to create a single database in the Configuration Wizard. This worksheet highlights the fields and properties that you see in the Configuration Wizard when you select the single database condition.

"SQL Server: SQL Server worksheet: Transfer to multiple databases" on page 491
When you use the database transfer option, you can use the condition to create multiple databases in the Configuration Wizard. This condition is selected by default. This worksheet highlights the fields and properties that you see in the Configuration Wizard when you use the multiple databases condition.

Transferring data to a different database server

Depending on your environment, the wizard generates a configuration process. The following steps reflect all possible steps in the configuration process. The steps do not represent a literal configuration. The steps are provided as a reference.

About this task

If you click **View Step Command**, you can see the task and properties associated with each step in the wizard.

Procedure

1. Back up the properties files that the wizard uses during the configuration.

   Condition
   None

   ConfigEngine task
   backup-property-files-for-dbxfer

2. Create your databases.

   Condition
   None

   ConfigEngine task
   create-database

3. Manual Step: Download the script and run it on the database server to create your database.

   Condition
   Select to manually create your database.

   ConfigEngine task
   None

4. Set up your database.

   Condition
   None

   ConfigEngine task
   `setup-database`

5. Manual Step: Download the script and run it on the database server to set up your database.

   Condition
   Select to manually create users and assign them permissions.

   ConfigEngine task
   None

6. Validate the database connection and environment.

   Condition
   None

   ConfigEngine task
   `validate-database validate-database-environment`

7. Stop the portal server.

   Condition
   collation support

   ConfigEngine task
   `stop-portal-server`

8. Transfer the database.

   Condition
   None

   ConfigEngine task
   `database-transfer enable-profiles-check-managed package-profiles`

9. Grant privileges to the database runtime users.

   Condition
   None

   ConfigEngine task
   `grant-runtime-db-user-privileges`

10. Manual Step: Download the script and run it on the database server to grant privileges to database runtime users.

    Condition
    Select to manually create users and assign them permissions.

    ConfigEngine task
    None

11. Start the portal server.

    Condition
    None

    ConfigEngine task
    `start-portal-server`

What to do next

You transferred your data from Apache Derby to your preferred database.

One quick way to test your database configuration is to log in and explore the site to validate the site is working as you expected.

Go to http://*host_name*:*port*/*context_root*/*default_portal_home*. For example, go to http://*host_name:10039*/*wps*/*portal*.

Next, you can use other options to configure your environment more.

If you are setting up a stand-alone server environment, you can use the Enable Federated Security option to add an LDAP user registry.

If you are setting up a cluster environment, you can use the Create a Deployment Manager option to create a deployment manager profile that is augmented with WebSphere Portal Express resources.

SQL Server: SQL Server worksheet: Transfer to a single database

When you use the database transfer option, you can select the condition to create a single database in the Configuration Wizard. This worksheet highlights the fields and properties that you see in the Configuration Wizard when you select the single database condition.

Typical fields

When you use the database transfer option, you answer questions about your environment. Some fields are required. Other fields are required or removed based on your selections for environment conditions.

The following table lists the typical fields that display when you select the option to transfer your data to a single database. To see additional fields that apply to an advanced configuration, click **Advanced**.

Table 62. Transfer to a single database..

You might not see all of the fields listed in this table. Use the Conditions column in this table to find out what selections are required to see the fields. If you do not see conditions listed for a field, the field always appears. A selection might result in multiple fields displaying in the wizard. For this type of selection, a selection listed in the Conditions column spans multiple field label rows.

Field Label	Property	Condition	Your Value
Database name	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbName` properties.		
Data source	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DataSourceName` properties.		
Database URL	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbUrl` properties.		
Database home directory			
Configuration user ID	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbUser` properties.		

Table 62. Transfer to a single database. (continued).

You might not see all of the fields listed in this table. Use the Conditions column in this table to find out what selections are required to see the fields. If you do not see conditions listed for a field, the field always appears. A selection might result in multiple fields displaying in the wizard. For this type of selection, a selection listed in the Conditions column spans multiple field label rows.

Field Label	Property	Condition	Your Value
Configuration password	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbPassword` properties.		
Database administrator ID	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DBA.DbUser` properties.		
Database administrator password	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DBA.DbPassword` properties.		
Runtime user	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbRuntimeUser` properties.	To see this field, continue to use the default selection of **Yes** for needing a runtime database user for day-to-day operations.	
Runtime password	The value that you enter is copied to fields in the Advanced view for the *dbdomain*`.DbRuntimeDbRuntimePassword` properties.

SQL Server: SQL Server worksheet: Transfer to multiple databases

When you use the database transfer option, you can use the condition to create multiple databases in the Configuration Wizard. This condition is selected by default. This worksheet highlights the fields and properties that you see in the Configuration Wizard when you use the multiple databases condition.

Typical fields

When you use the database transfer option, you answer questions about your environment. Some fields are required. Other fields are required or removed based on your selections for environment conditions.

The following table lists the typical fields that display when you select the condition to transfer your data to multiple databases. To see additional fields that apply to an advanced configuration, click **Advanced**.

Table 63. Transfer to a multiple database.

You might not see all of the fields listed in this table. Use the Conditions column in this table to find out what selections are required to see the fields. If you do not see conditions listed for a field, the field always appears. A selection might result in multiple fields displaying in the wizard. For this type of selection, a selection listed in the Conditions column spans multiple field label rows.

Field Label	Property	Conditions	Your Value
Release database name	**release.DbName**		
Release data source	**release.DataSourceName**		
Release database URL	**release.DbUrl**		
Release Admin URL	**release.AdminUrl**		
Release database home directory	**release.DbHome**		
Community database name	**community.DbName**		
Community data source	**community.DataSourceName**		
Community database URL	**community.DbUrl**		
Community Admin URL	**community.AdminDbUrl**		
Community database home directory	**community.DbHome**		
Customization database name	**customization.DbName**		
Customization data source	**customization.DataSourceName**		
Customization database URL	**customization.DbUrl**		
Customization Admin URL	**customization.AdminUrl**		
Customization database home directory	**customization.DbHome**		
JCR database name	**JCR.DbName**		
JCR data source	**JCR.DataSourceName**		
JCR database URL	**JCR.DbUrl**		
JCR Admin URL	**JCR.AdminUrl**		
JCR database home directory	**JCR.DbHome**

Oracle: Database transfer

Your portal is installed with an Apache Derby database. The database that is immediately available for use is good for demonstration and portlet and theme development environments. Otherwise, you must configure portal to use a production-level database. Use the Configuration Wizard to transfer the data and configure a new database server.

Configuration Wizard

The primary Configuration Wizard options are based on your target configuration topology, such as a stand-alone server or a cluster. The database transfer option is included with both **Set Up a Stand-alone Server** and **Set Up a Cluster**. For the stand-alone server topology, run the database transfer option before you run the

federated security option. For the cluster option, run the database transfer before you create your deployment manager profile.

For the **Do you want to transfer to one database or multiple databases or schemas** option, select **Single database** to configure one database with a single database user and a single data source. Select **Multiple databases or schemas** to configure multiple databases with different data sources and different users per schema. You can also use the multiple database option to configure a single database with different data sources and different users.

Validation

Prevent a possible database transfer failure by validating your entries in the wizard. When you chose to validate settings for the Database Transfer option, field syntax and database connection validations are performed to prevent a possible failure before you run the configuration.

Syntax validation checks that you:

- Enter a valid port number in the range of 1 - 65535.
- Use the correct format for your host name.
- Enter a valid context root value

The database connection validation checks that a connection can be made to your database server. The wizard can connect to your database server to validate the host name and port number values that you enter.

On the Database Settings panel, you can choose to turn validation on or off by selecting **Yes** or **No** to the **Connect to database server to validate settings** option. Select **No**, if you know that your parameters are correct and your database server is unavailable at the time of creating your instructions.

"Oracle: Oracle worksheet: Transfer your database" on page 498
This worksheet highlights the fields and properties that you see in the Configuration Wizard when you use the transfer database option.

"Oracle: Oracle worksheet: Transfer to multiple databases" on page 500
When you use the database transfer option, you can use the condition to create multiple databases in the Configuration Wizard. This condition is selected by default. This worksheet highlights the fields and properties that you see in the Configuration Wizard when you use the multiple databases condition.

Transferring data to a different database server

Depending on your environment, the wizard generates a configuration process. The following steps reflect all possible steps in the configuration process. The steps do not represent a literal configuration. The steps are provided as a reference.

About this task

If you click **View Step Command**, you can see the task and properties associated with each step in the wizard.

Procedure

1. Back up the properties files that the wizard uses during the configuration.

   Condition
   None

ConfigEngine task
backup-property-files-for-dbxfer

2. Manual Step: Create your Oracle database.

   Condition
   None

   ConfigEngine task
   None

3. Manual Step: Create the data directory, `data`, and the index directory, `index`, on your database server.

   Condition
   Select to manually create users and assign them permissions.

   ConfigEngine task
   None

4. Set up your database.

   (Automatic Storage Management Users only): If you have configured your database with Automatic Storage Management, you must perform additional manual instructions after you perform this step. Run the setup database script to create database schemas and users and grant privileges to database users . Then, go to "Oracle: Creating JCR table spaces (Automatic Storage Management)" on page 554 to perform additional manual instructions.

   Condition
   None

   ConfigEngine task
   setup-database

5. Manual Step: Download the script and run it on the database server to set up your database.

   (Automatic Storage Management Users only): If you have configured your database with Automatic Storage Management, you must edit the script that you download for your environment before you run it on the database server.

   Condition
   Select to manually create users and assign them permissions.

   ConfigEngine task
   None

6. Validate the database connection and environment.

   Condition
   None

   ConfigEngine task
   validate-database validate-database-environment

7. Stop the portal server.

   Condition
   collation support

   ConfigEngine task
   stop-portal-server

8. Transfer the database.

   Condition
   None

ConfigEngine task
database-transfer enable-profiles-check-managed package-profiles

9. Grant privileges to the database runtime users.

   Condition
   None

   ConfigEngine task
   grant-runtime-db-user-privileges

10. Manual Step: Download the script and run it to grant the database runtime user the appropriate privileges to work with database tables.

    Condition
    Select to manually create users and assign them permissions.

    ConfigEngine task
    None

11. Manual Step: Improve database response time for your database that contains the JCR domain.

    Condition
    None

    ConfigEngine task
    None

12. Start the portal server.

    Condition
    None

    ConfigEngine task
    start-portal-server

What to do next

You transferred your data from Apache Derby to your preferred database.

One quick way to test your database configuration is to log in and explore the site to validate the site is working as you expected.

Go to http://*host_name*:*port*/*context_root*/*default_portal_home*. For example, go to http://*host_name:10039*/*wps*/*portal*.

Next, you can use other options to configure your environment more.

If you are setting up a stand-alone server environment, you can use the Enable Federated Security option to add an LDAP user registry.

If you are setting up a cluster environment, you can use the Create a Deployment Manager option to create a deployment manager profile that is augmented with WebSphere Portal Express resources.

Oracle: Oracle worksheet: Transfer your database

This worksheet highlights the fields and properties that you see in the Configuration Wizard when you use the transfer database option.

Typical fields

When you use the database transfer option, you answer questions about your environment. Some fields are required. Other fields are required or removed based on your selections for environment conditions.

The following table lists the required fields that display when you select the database transfer option. To see additional fields that apply to an advanced configuration, click **Advanced**.

Important: To successfully complete the database transfer, the Oracle Thin Type-4 JDBC is required for Linux.

Table 64. Transfer database.

You might not see all of the fields listed in this table. Use the Conditions column in this table to find out what selections are required to see the fields. If you do not see conditions listed for a field, the field always appears. A selection might result in multiple fields displaying in the wizard. For this type of selection, a selection listed in the Conditions column spans multiple field label rows.

Field Label	Property	Condition	Your Value
Database name	This field corresponds to the *dbdomain*`.DbName` properties in the `wkplc_dbdomain.properties` file.		
Data source	This field corresponds to the *dbdomain*`.DataSourceName` properties in the `wkplc_dbdomain`.properties file.		
Database URL	This field corresponds to the *dbdomain*`.DbUrl` properties in the `wkplc_dbdomain.properties` file.		
Database home directory			
Configuration user ID	This field corresponds to the *dbdomain*`.DbUser` properties in the `wkplc_dbdomain.properties` file.		
Configuration password	This field corresponds to the *dbdomain*`.DbPassword` properties in the `wkplc_dbdomain.properties` file.		
Database administrator ID	This field corresponds to the *dbdomain*`.DBA.DbUser` properties in the `wkplc_dbdomain.properties` file.		
Database administrator password	This field corresponds to the *dbdomain*`.DBA.DbPassword` properties in the `wkplc_dbdomain.properties` file.		

Table 64. Transfer database (continued).

You might not see all of the fields listed in this table. Use the Conditions column in this table to find out what selections are required to see the fields. If you do not see conditions listed for a field, the field always appears. A selection might result in multiple fields displaying in the wizard. For this type of selection, a selection listed in the Conditions column spans multiple field label rows.

Field Label	Property	Condition	Your Value
Runtime user	This field corresponds to the *dbdomain*`.DbRuntimeUser` properties in the `wkplc_dbdomain.properties` file.	To see this field, continue to use the default selection of **Yes** for needing a runtime database user for day-to-day operations.	
Runtime password	This field corresponds to the *dbdomain*`.DbRuntimeDbRuntimePassword` properties in the `wkplc_dbtype.properties` file.

Manual Steps: Database Transfer option in the Configuration Wizard

The database transfer option in the Configuration Wizard includes manual steps. Some manual steps include scripts for you or your database administrator to run. For reference only, you can see the manual steps in this section of the product documentation. Use the Configuration Wizard to complete the deployment configuration. The wizard generates specific instructions and scripts based on your unique input.

"Database transfer: Create database users and groups" on page 511
Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the

wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

"Database transfer: Create database runtime users and groups" on page 512
Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

"Database transfer: Create database users and groups for DB2 for i" on page 512
Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

"Database Transfer: Granting privileges to database users for DB2 for i" on page 514
Configuration and runtime database users are granted a different set of privileges, depending on whether these users are schema owners or not. You can create a copy of the SQL scripts and edit this copy to manually grant permissions to configuration and runtime database users.

"Database transfer: Create database configuration users and groups for DB2 for z/OS" on page 517
Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

"Database transfer: Download the script and view instructions to delete existing databases for DB2 for z/OS" on page 518
Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

"Database transfer: Download the script and create the database on DB2 for z/OS server" on page 519
Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

"Database transfer: Download the script and reset the check pending status on portal table spaces for DB2 for z/OS" on page 521

migrating your server, installing add-ons, and more.

"Updating DB2 self-tuning memory manager (STMM) settings" on page 895
With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Database transfer: Create database users and groups

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

User and group names must comply with both the database management system software requirements and WebSphere Portal Express requirements.

The procedure is repeated for each portal database domain: release, community customization, jcr, feedback, and likeminds. The variable *dbdomain* represents the actual portal database domain name. You must also create group for each role. Configuration

Procedure

1. Create the database configuration users for the database domains on the operating system.
2. Create the *dbdomain* database configuration user. Use *dbdomain*.DbUser as the user ID when you create this user.
3. Create the database configuration groups for the database domains on the operating system where your database is installed. See your operating system instructions for details on creating groups.
4. Create the *dbdomain* database configuration group. Use *dbdomain*.DbConfigRoleName as the group name on your operating system.
5. Assign your database configuration users to the database configuration groups that you created. See your operating system instructions for details on adding users to groups.
6. Assign *dbdomain*.DbUser to the *dbdomain*.DbConfigRoleName.

Database Transfer: Granting privileges to database users for DB2 for i

Configuration and runtime database users are granted a different set of privileges, depending on whether these users are schema owners or not. You can create a copy of the SQL scripts and edit this copy to manually grant permissions to configuration and runtime database users.

Note: The wizard refers to the database user profile as the database configuration user.

Required privileges of the configuration database user

When a configuration database user (database user profile) is a schema owner, the **domain.DbUser** property is assigned the same value as the **domain.DbSchema** property, and a role is created for a configuration user in each database domain. This role is created and assigned automatically when you create your database using the configuration wizard or when you run the `create-database` configuration task.

To learn more about the specific permissions granted to the configuration database user, navigate to the SQL script templates in the installation directory of IBM WebSphere Portal Express. These read-only templates should not be modified. To grant these privileges, you can create a copy of the SQL scripts and use this copy to grant permissions manually.

Refer to the following locations of the SQL script templates to learn more about the specific permissions granted to the schema-owning configuration database user:

Table 66. Location of SQL script templates by database domain for information about specific permissions granted to schema-owning configuration database users

Database domain	Location of template
Release	*PortalServer_root*/base/wp.db.impl/config/templates/setupdb/db2_iseries/release/createConfigRoleForSameSchema.sql
Community	*PortalServer_root*/base/wp.db.impl/config/templates/setupdb/db2_iseries/community/createConfigRoleForSameSchema.sql
Customization	*PortalServer_root*/base/wp.db.impl/config/templates/setupdb/db2_iseries/customization/createConfigRoleForSameSchema.sql
JCR	*PortalServer_root*/base/wp.db.impl/config/templates/setupdb/db2_iseries/jcr/createConfigRoleForSameSchema.sql
Feedback	*PortalServer_root*/pzn/prereq.pzn/config/templates/setupdb/db2_iseries/feedback/createConfigRoleForSameSchema.sql
Likeminds	*PortalServer_root*/pzn/prereq.pzn/config/templates/setupdb/db2_iseries/likeminds/createConfigRoleForSameSchema.sql

Refer to the following locations of the SQL script templates for non-schema-owning configuration database user:

Table 67. Location of SQL script templates by database domain for information about specific permissions granted to non-schema-owning configuration database users

Database domain	Location of template
Release	*PortalServer_root*/base/wp.db.impl/config/templates/setupdb/db2_iseries/release/createConfigRoleForDifferentSchema.sql
Community	*PortalServer_root*/base/wp.db.impl/config/templates/setupdb/db2_iseries/community/createConfigRoleForDifferentSchema.sql
Customization	*PortalServer_root*/base/wp.db.impl/config/templates/setupdb/db2_iseries/customization/createConfigRoleForDifferentSchema.sql
JCR	*PortalServer_root*/base/wp.db.impl/config/templates/setupdb/db2_iseries/jcr/createConfigRoleForDifferentSchema.sql
Feedback	*PortalServer_root*/pzn/prereq.pzn/config/templates/setupdb/db2_iseries/feedback/createConfigRoleForDifferentSchema.sql
Likeminds	*PortalServer_root*/pzn/prereq.pzn/config/templates/setupdb/db2_iseries/likeminds/createConfigRoleForDifferentSchema.sql

Required privileges for the runtime database user

When the runtime database user is a schema owner, the **domain.DbUser** property is assigned the same value as the properties **domain.DbRuntimeUser** and **domain.DbSchema**. The runtime database user typically does not create tables used to query and manipulate data and does not by default have access to these tables. To grant minimum privileges to a runtime database user to work with these tables, access needs to be provided for the objects individually. A role is created for runtime database users in each database domain. These roles are created and assigned automatically when you run the following configuration tasks:

```
create-database
grant-runtime-db-user-privileges
```

Before you run these configuration tasks, the runtime database user can only access the database to validate configurations. To learn more about the specific permissions granted to the runtime database user, navigate to the SQL script

templates in the installation directory of WebSphere Portal Express. These read-only templates should not be modified. To grant these privileges, you can create a copy of the SQL scripts and use this copy to grant permissions manually.

Refer to the following locations of the SQL script templates to learn more about the specific permissions granted to the schema-owning configuration database user:

Table 68. Location of SQL script templates by database domain for information about specific permissions granted to schema-owning configuration runtime database users

Database domain	Location of template

Related concepts:

"Database users" on page 121
There are two types of database users: database configuration users and database runtime users. Become familiar with the privileges required for each user type to work with the database domains of IBM WebSphere Portal Express and the commands for creating database configuration users and granting privileges.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

"Updating DB2 self-tuning memory manager (STMM) settings" on page 895
With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Database transfer: Create database configuration users and groups for DB2 for z/OS

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

Procedure

1. Download the script. This script is contained in a compressed file. Extract the file.
2. Review the RACF commands that are contained in this script with your RACF administrator. Edit these commands as needed. For example, the RACF administrator might need to remove the ADDUSER commands if you already have database user IDs that are defined in your RACF.
3. If you have a security product other than RACF, you must change the syntax in the RACF commands into the appropriate syntax for your security product.
4. Run the RACF commands on z/OS in the order that is listed in the script.

   Example of the script that the Configuration Wizard generates.

```
//*  RACF setup for database user IDs and schemas:
ADDGROUP WPBASRT;
ADDGROUP WPJCRRT;
ADDGROUP WPPZNRT;
ADDUSER runtime_ID DFLTGRP(WPBASRT) NAME('WAS DB2 ACCESS USER')
PW USER(runtime_ID) NOINTERVAL
ALU runtime_ID PASSWORD(runtime_pwd) NOEXPIRED
CONNECT runtime_ID GROUP(WPJCRRT)
CONNECT runtime_ID GROUP(WPPZNRT)
ADDGROUP jcr SUPGROUP(group)
CONNECT dbconfig_ID GROUP(jcr)
CONNECT runtime_ID GROUP(jcr)
```

Database transfer: Download the script and view instructions to delete existing databases for DB2 for z/OS

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

Procedure

1. Copy the downloaded script to the database server and extract it.
2. Use your preferred SQL processor, such as SPUFI, to run the script on the database server. Run the DB2 commands on z/OS in the order that is listed in the script.

   Note: When you run this script when no other database exists, you might receive a message that this script is unsuccessful. You can ignore this message.

   Example of the script that the Configuration Wizard generates.

```
SET CURRENT SQLID = 'dbadmin';
REVOKE CREATEIN, DROPIN ON SCHEMA jcr
FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSTABLESPACE FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSVIEWS FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSDUMMY1 FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSTRIGGERS FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSINDEXPART FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSINDEXES FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSSYNONYMS FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSDATABASE FROM dbconfig_ID;
COMMIT;
DROP TABLESPACE WPFDBK.fdbkdbts;
COMMIT;
DROP TABLESPACE WPLM.lmdbts;
COMMIT;
DROP DATABASE WPREL;
COMMIT;
DROP DATABASE WPCOMM;
COMMIT;
DROP DATABASE WPCUST;
COMMIT;
DROP DATABASE WPJCR;
```

```
COMMIT;
DROP DATABASE WPFDBK;
COMMIT;
DROP DATABASE WPLM;
COMMIT;
DROP STOGROUP WPSSG;
COMMIT;
REVOKE SELECT ON SYSIBM.SYSCOLUMNS FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSTABLES FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSRELS FROM dbconfig_ID;
REVOKE SELECT ON SYSIBM.SYSFOREIGNKEYS FROM dbconfig_ID;
COMMIT;
REVOKE USE OF BUFFERPOOL BP2 FROM dbconfig_ID;
COMMIT;
REVOKE USE OF BUFFERPOOL BP32K1 FROM dbconfig_ID;
COMMIT;
REVOKE USE OF BUFFERPOOL BP3 FROM dbconfig_ID;
COMMIT;
```

Database transfer: Download the script and reset the check pending status on portal table spaces for DB2 for z/OS

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

Procedure

1. Copy the downloaded script to the database server and extract it.
2. Review the DB2 utilities that are contained in this script with your database administrator. Edit these utilities as needed.
3. Run the DB2 utilities that are listed in this script.
4. Use the SQL SELECT query that is created after you run the CHECK DATA commands to confirm that all of the CHECK PENDING states are resolved.

Database transfer: Create DB2 database

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

Before you begin

Ensure your DB2 server is already installed and running.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

Procedure

Instructions for AIX, HP-UX, Linux, and Solaris

1. Copy the JDBC Driver JAR files from your database server to your portal server.

   Example location:

   `/opt/ibm/db2/V10.5/java/db2jcc4.jar`

   `/opt/ibm/db2/V10.5/java/db2jcc_license_cu.jar`

   Place the files on the portal server in the directory that you specified for database library files.

   db2.DbLibrary

2. Log in as a DB2 system administrator with the required database privileges (SYSADM or at a minimum SYSCTRL).

   `su - domain.DBA.DbUser`

3. Copy the script that you downloaded for this step to the database server, and extract the file.
4. Rename the file that you downloaded to include a `.sh` extension.
5. Run the shell file on your database server.

   /your_database_server_file_location/`CreateDB2Database.sh`

   Example of the script that the Configuration Wizard generates.

```
db2set DB2COMM=TCPIP
db2set DB2_EVALUNCOMMITTED=YES
db2set DB2_INLIST_TO_NLJN=YES
db2 "UPDATE DBM CFG USING sheapthres 0"

db2 "CREATE DB WPSDB using codeset UTF-8 territory us PAGESIZE 8192"
db2 "UPDATE DB CFG FOR WPSDB USING locktimeout 30"

db2 "CONNECT TO WPSDB USER dba_ID USING dba_pwd"
db2 "CREATE BUFFERPOOL ICMLSFREQBP4 SIZE 1000 AUTOMATIC PAGESIZE 4K"
db2 "CREATE BUFFERPOOL ICMLSVOLATILEBP4 SIZE 16000 AUTOMATIC PAGESIZE 4K"
db2 "CREATE BUFFERPOOL ICMLSMAINBP32 SIZE 16000 AUTOMATIC PAGESIZE 32K"
db2 "CREATE BUFFERPOOL CMBMAIN4 SIZE 1000 AUTOMATIC PAGESIZE 4K"
db2 "CREATE REGULAR TABLESPACE ICMLFQ32 PAGESIZE 32K BUFFERPOOL ICMLSMAINBP32"
db2 "CREATE REGULAR TABLESPACE ICMLNF32 PAGESIZE 32K BUFFERPOOL ICMLSMAINBP32"
db2 "CREATE REGULAR TABLESPACE ICMVFQ04 PAGESIZE 4K BUFFERPOOL ICMLSVOLATILEBP4"
db2 "CREATE REGULAR TABLESPACE ICMSFQ04 PAGESIZE 4K BUFFERPOOL ICMLSFREQBP4"
db2 "CREATE REGULAR TABLESPACE CMBINV04 PAGESIZE 4K BUFFERPOOL CMBMAIN4"
db2 "CREATE SYSTEM TEMPORARY TABLESPACE ICMLSSYSTSPACE32 PAGESIZE 32K BUFFERPOOL ICMLSMAINBP32"
db2 "CREATE SYSTEM TEMPORARY TABLESPACE ICMLSSYSTSPACE4 PAGESIZE 4K BUFFERPOOL ICMLSVOLATILEBP4"
db2 "CREATE USER TEMPORARY TABLESPACE ICMLSUSRTSPACE4 PAGESIZE 4K BUFFERPOOL ICMLSVOLATILEBP4"
db2 "DISCONNECT WPSDB"
db2 "TERMINATE"
db2 "UPDATE DB CFG FOR WPSDB USING logfilsiz 16000"
db2 "UPDATE DB CFG FOR WPSDB USING logprimary 20"
db2 "UPDATE DB CFG FOR WPSDB USING logsecond 50"
db2 "UPDATE DB CFG FOR WPSDB USING logbufsz 500"
db2 "UPDATE DB CFG FOR WPSDB USING DFT_QUERYOPT 5"
```

Instructions for Windows

6. Copy the JDBC Driver JAR files from your database server to your portal server.

   Example location:

   `C:\\Program Files\\IBM\\SQLLIB\\java\\db2jcc4.jar`

   `C:\\Program Files\\IBM\\SQLLIB\\java\\db2jcc_license_cu.jar`

Place the files on the portal server in the directory that you specified for database library files.

db2.DbLibrary

7. Log in as a DB2 system administrator. This DB2 system administrator must have the required database privileges (SYSADM or at a minimum SYSCTRL) to create your database. This user is typically a member of both the Administrators and DB2ADMNS groups.
8. Copy the script that you downloaded for this step to the database server, and extract the file.
9. Rename the file that you downloaded to include a `.bat` extension.
10. Run the batch file on your database server.

    ```
    db2cmdadmin.exe -w C:\\your_database_server_file_location\\
    CreateDB2Database.bat
    ```

    Example of the script is not available for Windows.

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

"Updating DB2 self-tuning memory manager (STMM) settings" on page 895
With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Database transfer: Enable the DB2 pureScale load balancing feature

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

This step applies only to DB2 pureScale.

For multithreaded Java applications, set enableSysplexWLB to true in the connection string to use the transaction level workload balancing feature for DB2 pureScale. As more members are started, clients automatically route to the new member without any interruption of service. Members can be stopped without the application knowing.

Procedure

1. Access the WebSphere Integrated Solutions Console. Go to `http://`*`host_name`*`:`*`your_server_admin_port`*`/ibm/console/`. For example, go to `http://`*`host_name`*`:10038/ibm/console/`.
2. Click **Resources** > **JDBC** > **Data Sources**.
3. Click **Data sources** > **data source name** > **Custom properties**.

4. Search for enableSysplexWLB.
5. Click **enableSysplexWLB**, and enter `true` in the **Value** field.
6. Click **OK**.

With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Database transfer: Download a script and create your MS SQL database

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

Procedure

1. Copy the downloaded script to the database server and extract it.
2. Run the SQL statements that are listed in this script in your SQL processor.

   Example of the script that is created by the Configuration Wizard

```
CREATE DATABASE WPSDB ON (NAME=RELDB_DATA, FILENAME='C:\\Microsoft SQL Server\\instance\\MSSQL/Data/WPSDB_Data.MDF', SIZE=10MB, MAXSIZE=U
LOG ON (NAME=DB_LOG, FILENAME='C:\\Microsoft SQL Server\\instance\\MSSQL/Data/WPSDB_Log.LDF', SIZE=100MB, MAXSIZE=30000MB, FILEGROWTH=100
collate SQL_Latin1_General_CP1_CS_AS
;
ALTER DATABASE WPSDB SET READ_COMMITTED_SNAPSHOT ON;
```

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

"Updating DB2 self-tuning memory manager (STMM) settings" on page 895
With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Database transfer: Create Oracle database

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

Procedure

1. See the Oracle product documentation for instructions on creating databases.
2. All databases must be created using Unicode Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
3. It is recommended that all databases to be used with WebSphere Portal Express are configured in Dedicated Server Mode.
4. If you are using Oracle 11g databases, you must configure database transfer and runtime with only the `ojdbc6.jar`.
5. If you are using Oracle 12c databases, you must configure database transfer and runtime with the `ojdbc7.jar` and `xdb6.jar`.
6. You must set the buffer pools allocated to the Oracle database in order for WebSphere Portal Express to communicate with the Java Content Repository database. Refer to the Oracle product documentation for information on how to set the buffer pools. Use these recommended buffer pool values as a guide for setting your values:

   ```
   db_block_size = 8192 bytes
   db_cache_size = 1 gigabyte
   db_files = 1024 files
   log_buffer = 65536 bytes
   open_cursors = 1500 cursors
   pga_aggregate_target = 200 megabytes
   pre_page_sga = true
   processes = 300 processes
   shared_pool_size = 200 megabytes
   ```
7. If you are using Java Content Repository, the open_cursors value might need to be increased based on the table count in the Java Content Repository schema.
8. Raise the number of parallel servers as appropriate. For example, if you have more than 875 parallel servers, you should set the parallel_max_servers to 1200.
9. The Oracle parameter CURSOR_SHARING allows similar SQL Statements to be shared when possible, which prevents parsing and establishing a new execution plan. The execution plan is used by Oracle to gather the data that is needed to satisfy a request. There are two options for CURSOR_SHARING. WebSphere Portal Express supports both options. Regardless of the option that is selected, portlet applications should not be affected. Contact your database administrator for further assistance on these options.

   FORCE
   When you select this option, Oracle uses the same execution plan for all SQLs that are similar in value even if the values are different. When you use this option, the execution plan may not provide optimum performance. For example, similar SQLs with different values may behave differently when executed running the same plan.

   EXACT
   When you select this option, Oracle only shares the same execution plan for SQLs that are identical and use the same values. This option removes the risk of a SQL statement being executed when optimum performance conditions do not exist.

Database transfer: Download the script and setup your Oracle database

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

Procedure

1. Copy the downloaded script to the database server and extract it.
2. Run the SQL statements that are listed in this script in your SQL processor.

   Example of the script that the Configuration Wizard generates

```

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

"Updating DB2 self-tuning memory manager (STMM) settings" on page 895
With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Database transfer: Download the script and grant permissions for the Oracle database users

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

Procedure

1. Copy the downloaded script to the database server and extract it.
2. Run the SQL statements that are listed in this script in your SQL processor.

Example of the script that is generated by the Configuration Wizard.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

"Updating DB2 self-tuning memory manager (STMM) settings" on page 895
With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Database transfer: Set up the data and index directory for JCR collation

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

Create the data directory, `data`, and the index directory, `index`, on your database server

Procedure

1. Create the `data` directory in the following location:
   &*dbpath*/**jcr.DbName**/data/
2. Create the `index` directory in the following location:
   &*dbpath*/**jcr.DbName**/index/

The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

Procedure

1. Stop the WebSphere Portal Express server.
2. Copy files from the WebSphere Portal Express server to a temporary directory on the DB2 server.
   - `${WpsInstallLocation}/jcr/wp.content.repository.install/lib/wp.content.repository.install.jar`
   - `${WasUserHome}/PortalServer/jcr/config/registerCollationUDFTemplate.sql`

Set up collation on the database where the JCR domain is located.

3. Change to this directory:

   db2_instance_owner_home`/sqllib/function`
4. Enter this command:

   ```
   db2home/sqllib/java/jdk/bin/jar -xvf ${wf.ejp.collationTempDir}/
   wp.content.repository.install.jar icm/CollationUDF.class
   ```
5. Change to the temporary directory where you copied the files in a previous step. For example, you can use this temporary directory on the DB2 server:

   `${wf.ejp.collationTempDir}`
6. Open the file `registerCollationUDFTemplate.sql`, and change the multiple `<`*`SCHEMA`*`>` references to the JCR schema; for example, JCR. The value set for `<`*`SCHEMA`*`>` should match the value set for the jcr.DbSchema property. You specify jcr.DbSchema in the configuration file `wkplc_dbdomain.properties` when you modify database properties.
7. Connect to the JCR database.

   ```
   db2 connect to ${jcr.DbName} user ${jcr.DBA.DbUser} using
   ${jcr.DBA.DbPassword}
   ```
8. Enter this command to run the script:

   ```
   db2 -tvf ${wf.ejp.collationTempDir}/registerCollationUDFTemplate.sql
   ```
9. Disconnect from the JCR database.
10. Restart the DB2 instance.

Verify that the UDF is registered properly.

11. Log in as `${jcr.DbUser}`.
12. Open a DB2 terminal window.
13. Connect to the database that contains JCR domain:

    ```
    db2 connect to ${jcr.DbName} user ${jcr.DbUser} using ${jcr.DbPassword}
    ```
14. When you have connected to the JCR database, verify that the UDF is registered properly. To verify the UDF registration, run this command:

    ```
    db2 values ${jcr.DbSchema}.sortkeyj('abc','en')
    ```
15. Disconnect from DB2 terminal window:

    ```
    db2 disconnect all
    db2 terminate
    ```
16. Start the WebSphere Portal Express server.

Update the collation configuration options.

17. Log in to WebSphere Integrated Solutions Console.
18. Go to **Resources** > **Resource Environment** > **Resource Environment Providers** > **JCR ConfigService PortalContent** > **Custom properties**.
19. Add or update the following properties as necessary:

Enable/Disable collation support for all DB2 platforms(LUW, Z, I), this is disabled (false) by default

Name: jcr.query.collation.db2.enabled

Value: true

Type: java.lang.String

Name: jcr.query.collation.en

Value: en

Type: java.lang.String

20. To apply your settings, stop WebSphere Portal Express, and then restart WebSphere Portal Express.

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

"Updating DB2 self-tuning memory manager (STMM) settings" on page 895
With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Related reference:

"JCR search service configuration parameters" on page 680
The following search service configuration parameters can be modified to enable and configure searching for content that is stored in the JCR database. These JCR search service configuration parameters can be modified by accessing the **JCR ConfigService PortalContent** resource environment provider.

Database transfer: Improve database response time for your database domains

Manual steps from the Configuration Wizard are included in IBM Knowledge Center for reference and for advanced users. The procedure includes variables and steps for different databases. When you use the wizard to configure your deployment, it replaces the variable with information that you provided in the wizard. It also shows only the steps that are specific to your environment. The instructions that the wizard generates are specific to your environment.

About this task

Attention: All steps for all database environments are included without consideration for your environment. Use the Configuration Wizard to generate custom instructions for your environment.

After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response.

Run the following commands for your JCR domain. You might also want to run the following commands on all of your database domains, if there are large amounts of data. To run the commands on domains other than JCR, you must replace the *jcr*`.DbName` and *jcr*`.DbUser` with the specific domain for which you plan to run the commands. For example, *release*`.DbName` or *feedback*`.DbName`.

Note: *jcr.DbUser* in the following command refers to the schema owner of the JCR database objects.

Procedure

Run the following commands. Start SQL*Plus and log in to the **jcr.DbName** database as the **jcr.DbUser** user SQL> execute dbms_stats.gather_schema_stats(ownname=> '**jcr.DbUser**', cascade=> TRUE); SQL > commit; Exit sqlplus

Oracle: Creating JCR table spaces (Automatic Storage Management)

If you configured your database with Automatic Storage Management, you might need to perform additional manual instructions to create JCR table spaces when you use the Database Transfer option in the Configuration Wizard . If you select the option to let the wizard create your database schemas and assign permissions, you must perform the steps in this topic after you run the setup database script.

Procedure

1. Create table spaces using the following commands as examples:

   Note:

   - If you plan on customizing your table space names, you must ensure that the customized table space names are used during database transfer. Custom table spaces must exist prior to performing database transfer.
   - *ASM_disk_group_name* is the disk group name that you used to configure your Automatic Storage Management environment.
   - Ensure that the '.' is included in the variables when you substitute the values of your environment with these variables.

   create tablespace *ICMLFQ32* **datafile** '*+ASM_disk_group_name*' **size** *300M* **reuse** *autoextend on next 10M* **maxsize** *UNLIMITED* **extent management** local *autoallocate*;

   create tablespace *ICMLNF32* **datafile** '*+ASM_disk_group_name*' **size** *25M* **reuse** *autoextend on next 10M* **maxsize** *UNLIMITED* **extent management** local *autoallocate*;

   create tablespace *ICMVFQ04* **datafile** '*+ASM_disk_group_name*' **size** *25M* **reuse** *autoextend on next 10M* **maxsize** *UNLIMITED* **extent management** local *autoallocate*;

   create tablespace *ICMSFQ04* **datafile** '*+ASM_disk_group_name*' **size** *150M* **reuse** *autoextend on next 10M* **maxsize** *UNLIMITED* **extent management** local *autoallocate*;

create tablespace *ICMLSNDX* **datafile** '*+ASM_disk_group_name*' **size** *10M* **reuse** *autoextend on next 10M* **maxsize** *UNLIMITED* **extent management** local *autoallocate*;

a. Set the **size**, **autoextend**, and **maxsize** values according to your environment. For example, you may want to change the **maxsize** to a set value rather than *UNLIMITED*.
b. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.
c. Refer to the Oracle command reference for more information about using the **create tablespaces** command.

2. Ensure the database is registered with the Oracle listener. Use the tnsnames.ora file to describe this database and recycle the listener.

Assigning custom table spaces

You cannot use the **Database Transfer** option in the configuration wizard to assign custom table spaces on your database server. You can perform manual steps to assign custom table spaces.

"DB2: Assigning custom table spaces"
The repository of WebSphere Portal Express consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

"Oracle: Assigning custom table spaces" on page 556
The repository of WebSphere Portal Express consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

"SQL Server: Assigning custom table spaces" on page 558
The repository of WebSphere Portal Express consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

"DB2 for z/os: Assigning custom table spaces" on page 559
The repository of WebSphere Portal Express consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

DB2: Assigning custom table spaces

The repository of WebSphere Portal Express consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the *wp_profile_root*/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- The page size of table spaces used by WebSphere Portal must be 8192 bytes.
- For details on creating table spaces refer to the documentation for the database.

About this task

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

Procedure

1. Determine the names of your custom table spaces.
2. Open the mapping file *wp_profile_root* `/PortalServer/config/tablespaces/` *`dbdomain`*`.space_mapping.properties` that specifies the table space and index space property pairs for each database table:

   dbdomain.table_name.tablespace

   dbdomain.table_name.index_name.indexspace

   For the file name and each table space and index space property pair, *dbdomain* can be any one of the following values:

   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

   Note: For jcr, you need to open an additional maping file: *wp_profile_root*`/PortalServer/jcr/config/jcr.space_mapping.properties`. This mapping file contains additional table space and index space property pairs for each jcr.table_name.tablespace database table.
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword `IN` and a space. For example: `community.COMP_INST.tablespace=IN COMM8KSPACE`
   Repeat this step for each domain that you are transferring.
4. Save and close *`dbdomain`*`.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,

   Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`

   Linux: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

   IBM i: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

Oracle: Assigning custom table spaces

The repository of WebSphere Portal Express consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the *wp_profile_root*/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

About this task

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

Procedure

1. Determine the names of your custom table spaces.
2. Open the mapping file *wp_profile_root* /PortalServer/config/tablespaces/*dbdomain*.space_mapping.properties that specifies the table space and index space property pairs for each database table:

   dbdomain.table_name.tablespace

   dbdomain.table_name.index_name.indexspace

   For the file name and each table space and index space property pair, *dbdomain* can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

   Note: For jcr, you need to open an additional maping file: *wp_profile_root*/PortalServer/jcr/config/jcr.space_mapping.properties. This mapping file contains additional table space and index space property pairs for each jcr.table_name.tablespace database table.
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword TABLESPACE and a space. For example: community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close *dbdomain*.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,

   Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true

   Linux: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

IBM i: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

SQL Server: Assigning custom table spaces

The repository of WebSphere Portal Express consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

Before you begin

Before you begin:

- The custom filegroups must exist prior to the execution of the database transfer.
- To see which table spaces can be customized in each domain, refer to the *wp_profile_root*`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties` file.
- For details on creating filegroups refer to the documentation for the database.

About this task

If custom filegroups are assigned, each must be assigned explicitly. The default filegroups can be used to contain database objects; however the name of the default file group must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom filegroups:

Procedure

1. Determine the names of your custom filegroups.
2. Open the mapping file *wp_profile_root* `/PortalServer/config/tablespaces` that specifies the table space and index space for each property pairs for each database table:

   dbdomain.table_name.tablespace

   dbdomain.table_name.indexspace.indexspace

   For the file name and each table space and index space property pair, *dbdomain* can be any one of the following values:

   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

   Note: For jcr, you need to open an additional maping file: *wp_profile_root*`/PortalServer/jcr/config/jcr.space_mapping.properties`. This mapping file contains additional table space and index space property pairs for each jcr.table_name.tablespace database table.
3. Assign a filespace to each entry in the mapping file. The filegroup name must be prepended by the keyword `ON` and a space. For example:
   `community.COMP_INST.tablespace=ON COMM8KSPACE`
   Repeat this step for each domain that you are transferring.
4. Save and close *`dbdomain`*`.space_mapping.properties`.

5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,

   Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`

   Linux: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

   IBM i: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

DB2 for z/os: Assigning custom table spaces

The repository of WebSphere Portal Express consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the *wp_profile_root*`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties` file.
- For details on creating table spaces refer to the documentation for the database.
- When using IBM DB2 Universal Database for z/OS as a data store, WebSphere Portal Express requires that its indexes are not padded. Therefore, you must set the DSNZPARM parameters to **RETVLCFK**=*NO* or **PADIX**=*NO*, or both.

About this task

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

Procedure

1. Determine the names of your custom table spaces.
2. Open the mapping file *wp_profile_root* `/PortalServer/config/tablespaces/`*`dbdomain`*`.space_mapping.properties` that specifies the table space and index space property pairs for each database table:

   dbdomain.table_name.tablespace

   dbdomain.table_name.index_name.indexspace

   For the file name and each table space and index space property pair, *dbdomain* can be any one of the following values:

   - release
   - community
   - customization
   - jcr
   - feedback

- likeminds

  Note: For jcr, you need to open an additional maping file: *wp_profile_root*/PortalServer/jcr/config/jcr.space_mapping.properties. This mapping file contains additional table space and index space property pairs for each jcr.table_name.tablespace database table.

3. Assign a table space to each .tablespace entry in the mapping file. Assignments to .indexspace entries are ignored. The table space name must be qualified by the database name and prepended by the keyword IN and a space. For example: community.COMP_INST.tablespace=IN COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close *dbdomain*.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,

   Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true

   Linux: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

   IBM i: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

DB2: Enabling support for high availability recovery and rollforward recovery

Optional: To prevent data loss on DB2, modify the JCR schema to support High Availability Disaster Recovery and rollforward recovery.

Before you begin

Before you run the configuration task in this topic, use the **Database Transfer** option in the Configuration Wizard to transfer your data from Apache Derby to DB2

About this task

Procedure

1. Stop the portal server. Depending on your environment, you might have multiple portal servers to stop.
2. Back up the JCR database. This task permanently changes the JCR schema.
3. Run a configuration task from the *wp_profile_root*\ConfigEngine directory to convert columns in ICMUTMWIDE0 table from NOT LOGGED BLOG TO LOGGED BLOG.

   Note: For clustered environments, run this task only from one node.

   - Linux : ./ConfigEngine.sh reconfigure-jcr-for-hadr -DTransferDomainList=jcr -DWasPassword=*password*
   - Windows: ConfigEngine.bat reconfigure-jcr-for-hadr -DTransferDomainList=jcr -DWasPassword=*password*
4. Start the portal server.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Connecting to existing database domains

View the steps to share a database domain between two separate WebSphere Portal Express instances (*instance1* and *instance2*), where *instance2* is connected to an *instance1* database domain.

Before you begin

A WebSphere Portal Express instance can be either a single server or WebSphere Portal Express cluster.

Notes:

- Release data cannot be shared between separate WebSphere Portal Express instances. Also, if Web Content Manager is installed, the JCR domain cannot be shared.
- You can share only the WebSphere Portal Express Version 8.5 data.
- The entire set of database properties that are specified in the file *wp_profile_root*`/ConfigEngine/properties/wkplc_dbomain.properties` must be valid for the current configuration of all database domains. If you plan to connect or transfer a single database domain, you must modify only the database properties for that domain before you run the **`connect-database`** or **`database-transfer`** tasks.

Note: The **`connect-database`** configuration task does not preserve customizations to the data sources for the WebSphere Portal Express databases. If you previously tuned your data sources for the WebSphere Portal Express databases, make a note of the settings, run **`connect-database`**, and reapply the tuning after you run the configuration task.

About this task

Both WebSphere Portal Express instances must be installed and operational.

Procedure

1. Verify that both WebSphere Portal Express instances are operational.
2. Ensure that the database client software is installed on *instance2* with the same settings as *instance1* and that you can connect to the remote database.
3. The *instance2* data sources must be made to point to the database used by *instance1*. The `wkplc_dbtype.properties` and `wkplc_dbdomain.properties` files must be updated to specify what remote database is used. This information must match the database information that is used for the *instance1* installation.

   Remember: Do not use the same data source names for the domains that are used in the previous version of the product. Use a different data source so that the **`connect-database`** command drops the old data source and create the new one with the new connection information.
4. Reconfigure *instance2* to use one or more remote database domains of *instance1* by running the following command from the directory *wp_profile_root*`/ConfigEngine`:

- Windows: `ConfigEngine.bat connect-database -DTransferDomainList=domain1,domain2,domain3 -DWasPassword=password`
- Linux: `./ConfigEngine.sh connect-database -DTransferDomainList=domain1,domain2,domain3 -DWasPassword=password`
- IBM i From the UserData directory:
  - `ConfigEngine.sh connect-database -DTransferDomainList=domain1,domain2,domain3 -DWasPassword=password`

5. Restart *instance2*.

User registry

User information is stored in your user registry. You can enable LDAP referrals, configure IBM WebSphere Portal Express to use dynamic groups, update your user registry, or delete your user registry configurations.

"Enable federated security" on page 563
You can use the Configuration Wizard to configure WebSphere Portal to use a federated LDAP for security. Use the following information to get familiar with the information you must provide in the wizard and the configuration procedure that it generates.

"Adding more attributes to VMM" on page 568
After you install IBM WebSphere Portal Express and configuring your LDAP user registries, you must adapt the attribute configuration to match the configured LDAP servers and your business needs. However, do not complete these steps if you configured only a database user registry or the default federated file-based repository for out-of-box installations.

"Enabling application groups" on page 577
You can define user groups within the database user registry with members (users or groups) contained in the federated LDAP user registry you configured with application groups. The benefit of application groups is that you can create groups that are only used in IBM WebSphere Portal Express.

"Advanced group configurations" on page 578
It is possible to use IBM WebSphere Portal Express ConfigEngine helper tasks to set up advanced Virtual Member Manager (VMM) group configurations. Specifically, it is possible to configure VMM to understand and use the "Group membership attribute" that many directories support.

"Adding realm support" on page 582
A realm is a group of users from one or more user registries that form a coherent group within IBM WebSphere Portal Express. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When you configure realm support, complete these steps for each base entry that exists in your LDAP and database user registry to create multiple realm support.

"Updating your user registry" on page 585
After you deploy IBM WebSphere Portal Express, you can adjustment your federated user repository configurations. You can update these configurations to achieve the correct user registry configuration.

"Deleting your user registry configurations" on page 602
After you deploy IBM WebSphere Portal Express, you might not require some of the LDAP entity types, realms, realm base entries, or repositories that you created. You can delete these configurations to achieve the correct user registry configuration.

Enable federated security

You can use the Configuration Wizard to configure WebSphere Portal to use a federated LDAP for security. Use the following information to get familiar with the information you must provide in the wizard and the configuration procedure that it generates.

Configuration Wizard

The primary Configuration Wizard options are based on your target configuration topology, such as a stand-alone server or a cluster. The federated security option is included with both **Set Up a Stand-alone Server** and **Set Up a Cluster**. For the stand-alone server topology, run the federated security option after database transfer. For the cluster topology, run the federated security option after you create the cluster, but before you add more nodes.

Validation

For this configuration option, the wizard can connect to your LDAP directory and validate the information that you enter in the wizard. By default, validation is enabled. On the Security Settings panel, you can choose to turn validation on or off by selecting **Yes** or **No** to the **Validate LDAP user registry entries** option. Select **No** if you know that your parameters are correct and that your LDAP server is unavailable at the time of creating your instructions.

Two types of validation are performed when you select to validate settings including field syntax and LDAP connection validations. The syntax validation, for example, checks that you entered a valid port number in the range of 1 - 65535. The connection validation, for example, checks that a connection can be made to your LDAP server.

Enabling validation is recommended because it can prevent a possible failure by validating your entries in the wizard before you run the configuration. The LDAP settings including the **Repository ID**, **Host name**, **Port**, **Bind DN**, **Bind password**, **Base DN**, **Administrator group DN**, **Administrator DN**, and **Administrator password** are all validated before the wizard creates your instructions to run the configuration. Review the following worksheet section to see which fields are required based on your selections in the wizard.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

"Updating DB2 self-tuning memory manager (STMM) settings" on page 895
With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Worksheet

When you set up the federated security, you answer questions about your wanted configuration. Some fields apply to all federated security configurations. Some fields are required based on your environment. The remaining fields are advanced and do not apply to most configurations.

Minimal required fields

The following table lists the fields that are unique to the LDAP configuration. You might be prompted for additional information about system or user IDs and passwords that you defined during the portal installation process.

Attention: The Enable Federated Security option modifies the `wimconfig.xml` file. Make a backup copy of this file before you run any of the configuration tasks.
wp_profile_root/config/cells/*CellName*/wim/config/wimconfig.xml

Table 70. Minimal required fields

Field Label	Property	Your Value
LDAP Repository ID	**federated.ldap.id**	
LDAP host name	**federated.ldap.host**	
LDAP port	**federated.ldap.port**	
Bind DN **Restriction:** The following parameters must be unique to your environment: • **PortalAdminId**: this parameter is the user ID that you enter in the **Administrator user ID** field during the installation • **Bind DN** • **Administrator DN from LDAP**	**federated.ldap.bindDN**	
Bind password	**federated.ldap.bindPassword**	

Table 71. Optional fields

Field Label	Property	Your Value
Base DN **Note:** This field is optional. However, it is recommended that you enter a Base DN that matches your LDAP settings. If you are using a Domino LDAP, and you do not have a Base DN defined, then you can leave this field blank.	**federated.ldap.baseDN**	

Use an administrator from your LDAP

If you select to use an administrator from your LDAP server, then you must provide additional information about the LDAP group and ID.

Table 72. Use an administrator and administrator group in your LDAP

Field Label	Property	Your Value
Administrator group DN from LDAP	**newAdminGroupId**	

Table 72. Use an administrator and administrator group in your LDAP (continued)

Field Label	Property	Your Value
Administrator DN from LDAP **Restriction:** The following parameters must be unique to your environment: • **PortalAdminId**: this parameter is the user ID that you enter in the **Administrator user ID** field during the installation • **Bind DN** • **Administrator DN from LDAP**	**newAdminId**	
Administrator password from LDAP	**newAdminPw**	
Default parent for group	**groupParent**	
Default parent for PersonAccount	**personAccountParent**	

Advanced fields

Click **Advanced** on the Customize Values page to see the advanced properties. Default values are provided for advanced fields that are required.

Table 73. Advanced files

Field Label	Property	Your Value
LDAP group objectclasses	**federated.ldap.et.group.objectClass**	
LDAP group objectclasses for creating groups	**federated.ldap.et.group.objectClassForCreate**	
LDAP group search bases	**federated.ldap.et.group.searchBases**	
LDAP PersonAccount objectclasses	**federated.ldap.et.personaccount.objectClasses**	
LDAP PersonAccount objectclasses for creating users	**federated.ldap.et.personaccount.objectClassesForCreate**	
LDAP search bases for the PersonAccount	**federated.ldap.gm.personaccount.searchBases**	
Group dummy member	**federated.ldap.gm.dummyMember**	
Group member attribute	**federated.ldap.gm.groupMemberName**	
Group object class	**federated.ldap.gm.objectClas**	
GM member attribute scope	**federated.ldap.gm.scope**	
Membership attribute name	**federated.ldap.gc.name**	
GC member attribute scope	**federated.ldap.gc.scope**	
Certificate filter	**federated.ldap.certificateFilter**	
Certificate map mode	**federated.ldap.certificatMapMode**	
Group RDN attribute	**groupRdnProperties**	
PersonAccount RDN attribute	**personAccoutnRdnProperties**	
Application server SSL configuration	**federated.ldap.sslConfiguration**	

Nested or dynamic group support

If you need nested group support, then the wizard provides default values for some of the advanced fields. The default values are based on your LDAP server selection. You must click **Advanced** to see the fields if you want to verify the defaults. Nested or dynamic group support fields include **Group member**

attribute, **Membership attribute name**, **LDAP group objectclasses**, and **GC member attribute scope**.

Enabling federated security

After you answer questions and provide information about your LDAP, the wizard generates a custom configuration procedure.

About this task

Depending on your environment, the wizard generates a configuration process. The following steps reflect all possible steps in the configuration process. The steps do not represent a literal configuration. The steps are provided as a reference.

If you click **View Step Command**, you can see the task and properties that are associated with each step in the wizard.

Procedure

1. Manual Step: Retrieve the SSL certificate from the SSL port.

   Condition
   Select to configure SSL enabled LDAP.

   ConfigEngine task
   None

2. CF07 Create a backup of the WebSphere Portal Express profile before modifying cell security.

   Note: The backup is created in `/opt/IBM/WebSphere/AppServer/profiles/cw_profile/`.

   Condition
   None

   ConfigEngine task
   None

3. Validate your LDAP server settings.

   Condition
   None

   ConfigEngine task
   validate-federated-ldap

4. Add an LDAP user registry to the default federated repository.

   Condition
   None

   ConfigEngine task
   wp-create-ldap

   recycle-dmgr-if-cluster

5. Register the WebSphere Application Server scheduler tasks.

   Condition
   None

   ConfigEngine task
   stop-portal-server

   start-portal-server

reregister-scheduler-tasks

6. Replace the file-based WebSphere Portal and WebSphere Application Server users and groups with users and groups from your LDAP server.

   Condition
   Select to use an administrator and administrator group that is stored in your LDAP.

   ConfigEngine task
   wp-change-portal-admin-user

   wp-change-was-admin-user

7. Update the user registry where new users and groups are stored.

   Condition
   None

   ConfigEngine task
   wp-set-entitytypes

8. Recycle the servers after a security change.

   Condition
   None

   ConfigEngine task
   recyle-servers-after-security-change

9. Update the search administration user.

   Condition
   Select to use an administrator and administrator group that is stored in your LDAP.

   ConfigEngine task
   start-portal-server

   action-fixup-after-security-change-portal-wp.search.webscanner

10. After you change the security model, the servers need to be restarted. Restart the portal server.

    Condition
    None

    ConfigEngine task
    recycle-servers-after-security-change

    start-portal-server

11. Verify that all defined attributes are available in the configured LDAP user registry.

    Condition
    None

    ConfigEngine task
    wp-validate-federated-ldap-attribute-config

12. Manual Step: Update the appropriate `MemberFixerModule.properties` file with the values for your LDAP users.

    Condition
    Select to use an administrator and administrator group that is stored in your LDAP.

    ConfigEngine task
    None

13. Run the member fixer tool.

    Condition
    Select to use an administrator and administrator group that is stored in your LDAP.

    ConfigEngine task
    `run-wcm-admin-task-member-fixer`

14. Restart the WebSphere Portal Server.

    Condition
    None

    ConfigEngine task
    `stop-portal-server`

    `start-portal-server`

15. Manual Step: Map attributes to ensure proper communication between WebSphere Portal and the LDAP server.

    Condition
    None

    ConfigEngine task
    None

What to do next

If you are setting up a stand-alone server environment, you can now explore your site.

You can also use the **Create an Additional Cluster Node** option to add more nodes to your cluster. Your security updates to the primary node are applied to the nodes that you add to your cluster.

Adding more attributes to VMM

After you install IBM WebSphere Portal Express and configuring your LDAP user registries, you must adapt the attribute configuration to match the configured LDAP servers and your business needs. However, do not complete these steps if you configured only a database user registry or the default federated file-based repository for out-of-box installations.

About this task

After installation, IBM WebSphere Portal Express has a predefined set of attributes for users and groups. Your LDAP server might have a different set of predefined user and group attributes. To ensure communication between WebSphere Portal Express and your LDAP server, you can configure extra attributes. Flag the attributes as required or unsupported on a per repository basis or for all configure repositories.

LDAP servers can handle only attributes that are explicitly defined in their schema. The LDAP schema is different from the WebSphere Portal Express schema. The two schemas are required to match for communication between WebSphere Portal Express and the LDAP server. The task to add the LDAP user registry does some basic attribute configurations that depend on the LDAP server. You might still have to adapt the WebSphere Portal Express configuration to match the LDAP schema.

If an attribute is in WebSphere Portal Express but not in the LDAP server, complete one of the following tasks to resolve this mismatch:

- Flag the attribute as unsupported for the LDAP server
- Introduce an attribute mapping that maps the WebSphere Portal Express attribute to an attribute defined in the LDAP schema

Use the following tasks to adapt the attribute configuration to match the configured LDAP servers and your business needs:

1. "Querying the defined attributes"
   After you install IBM WebSphere Portal Express and configure your LDAP user registries, query the defined attributes. The task defines a list of attributes that are flagged as unsupported or mapped to a different LDAP attribute.
2. "Adding attributes"
   The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. Add attributes to extend the VMM attribute schema and then map them between IBM WebSphere Portal Express and your user registry.
3. "Mapping attributes" on page 573
   Map the attributes between IBM WebSphere Portal Express and your LDAP user registries.
4. "Removing attributes" on page 575
   The Virtual Member Manager (VMM) has a limitation. There is no task to update an attribute.

Related reference:

"People Finder" on page 928
The **People Finder** portlet provides both quick search and advanced search options for locating people and information about people. Once found, a person is visible to other users as a person link that indicates online presence and displays a menu of instant messaging and other options.

Querying the defined attributes

After you install IBM WebSphere Portal Express and configure your LDAP user registries, query the defined attributes. The task defines a list of attributes that are flagged as unsupported or mapped to a different LDAP attribute.

Procedure

1. Open a command prompt.
2. Change to the *wp_profile_root*`/ConfigEngine` directory.
3. Run the following task:
   - Linux : `./ConfigEngine.sh wp-query-attribute-config -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh wp-query-attribute-config -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat wp-query-attribute-config -DWasPassword=`*`password`*

   Note: This task does not validate the existence of attributes in the LDAP schema.

Adding attributes

The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. Add attributes to extend the VMM attribute schema and then map them between IBM WebSphere Portal Express and your user registry.

About this task

You can add multiple attributes at one time by creating an XML file that includes the properties and attributes for each property. The XML file is referred to as a *deployment file*. Create the XML file before you start this procedure.

The following sample is an XML deployment file that is used to add three properties.

```
<wplc-add-property>
 <resource propertyName="attribute_name_1" dataType="Int" entityTypes="Group" multiValued="true" />
 <resource propertyName="attribute_name_2" dataType="String" entityTypes="PersonAccount" multiValue
 <resource propertyName="attribute_name_3" dataType="Base64Binary" entityTypes="Group,PersonAccount
</wplc-add-property>
```

The resource tag includes attributes that are specific for the property: **propertyName**, **dataType**, **entityType**, and **multiValued**.

Procedure

1. This task requires server connections.
   - In a stand-alone environment, ensure that the WebSphere_Portal server is running.
   - In a clustered environment, stop all application servers on the system. Ensure that the WebSphere_Portal server is stopped. Then, start the node agent and deployment manager servers.
2. Install the enterprise archive (`.ear`) file on WebSphere Application Server:
   a. Open a command line.
   b. Change to the *wp_profile_root*`/ConfigEngine` directory.
   c. Run the following task:

Table 74. Stand-alone and cluster tasks to install the enterprise archive (EAR) file. Use the **wp-la-install-ear** task to install the EAR.

Environment	Task
Stand-alone environment	• Linux : `./ConfigEngine.sh wp-la-install-ear -DWasPassword=`*password* • IBM i: `ConfigEngine.sh wp-la-install-ear -DWasPassword=`*password* • Windows: `ConfigEngine.bat wp-la-install-ear -DWasPassword=`*password*

Table 74. Stand-alone and cluster tasks to install the enterprise archive (EAR) file (continued). Use the **wp-la-install-ear** task to install the EAR.

Environment	Task
Clustered environment	• Linux : `./ConfigEngine.sh wp-la-install-ear -DWasPassword=`*`dmgr_password`* `-DServerName=`*`dmgr_server_name`* `-DNodeName=`*`node_name`* • IBM i: `ConfigEngine.sh wp-la-install-ear -DWasPassword=`*`dmgr_password`* `-DServerName=`*`dmgr_server_name`* `-DNodeName=`*`node_name`* • Windows: `ConfigEngine.bat wp-la-install-ear -DWasPassword=`*`dmgr_password`* `-DServerName=`*`dmgr_server_name`* `-DNodeName=`*`node_name`* Where the default value for *`dmgr_server_name`* is `dmgr`. You can find the *`dmgr_server_name`* value in the WebSphere Integrated Solutions Console. Go to **System administrator** > **Deployment Manager** > **Configuration tab** > **General Properties** > **Name**. Where *`node_name`* is the name of the node where the deployment manager is located. You can find the *`node_name`* value in the WebSphere Integrated Solutions Console. Go to **System administrator** > **Deployment Manager** > **Runtime tab** > **General Properties** > **Node Name**.

3. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
4. Use a text editor to open the `wkplc.properties` file in the *wp_profile_root*`/ConfigEngine/properties` directory.
5. Find the *VMM Property Extension Properties* heading. You can either add a single attribute or multiple attributes.
   - To add a single attribute, update the following properties with information about the property to add.

     `la.providerURL`

     Description

     The remote endpoint where your portal server or deployment manager installation is available. Check the value for hostname:port. The port points to the BOOTSTRAP_ADDRESS port of either the WebSphere_Portal server or the deployment manager. The deployment manager is used in a clustered environment.

     `la.propertyName`

Description
The name of the property that you are adding.

la.entityTypes

Description
This value is a list of entity types that the new property is applicable to. If you need to enter multiple values, use a comma to separate each value, for example "value1,value2".

Valid values
Group

PersonAccount

la.dataType

Description

Defines the type of data that is stored in the attribute that is being created. If this attribute is mapped to LDAP, this data type must match the corresponding attribute type in LDAP. Consult your LDAP administrator if you are unsure of the data types in LDAP. If this attribute is stored in the VMM property extension database, the data type must match the corresponding attribute type as defined in VMM's database.

While it is possible to add attributes of different types to VMM, the Registration/Edit My Profile Portlet is only capable of working with attributes of type String and Int. If you need UI support for other types, you would need your own custom form or portlet that can process those types. Portal does not have a UI that reads or updates group attributes. The one exception is the UI that is used to create a group.

Valid values
String

Int

DateTime

Base64Binary

IdentifierType

Boolean

Long

Double

Short

la.multiValued

Description
Defines if the property can contain multiple values or not.

- To add multiple attributes, update the following properties:

la.providerURL

Description
The remote endpoint where your portal server or deployment manager installation is available. Check the

value for hostname:port. The port points to the BOOTSTRAP_ADDRESS port of either the WebSphere_Portal server or the deployment manager. The deployment manager is used in a clustered environment.

la.deployfile

Description

Use this property when you want to create multiple properties by using a single ConfigEngine operation. Specify the path and name of the XML file that contains the properties that you want to add. You can specify a path that is relative to the ConfigEngine directory or the fully qualified file system path. If you specify a value for this property, do not specify a value for la.propertyName, la.dataType, or la.Multivalued.

The following is a sample of an XML deploy file that is used to add three properties.

```
<wplc-add-property>
   <resource propertyName="attribute_name_1" dataType="Int" entityType
   <resource propertyName="attribute_name_2" dataType="String" entityT
   <resource propertyName="attribute_name_3" dataType="Base64Binary" e
</wplc-add-property>
```

The resource tag includes attributes that are specific for the property: propertyName, dataType, entityType, and multiValued.

6. Save your changes to the `wkplc.properties` file.
7. Run the **wp-add-property** task to add a property that maps to an attribute in your user registry. If you are defining a new property to store in the property extension database, run **wp-add-la-property**.

   Note: This task calls an EJB that must authenticate against WebSphere Application Server. Depending on the configuration in the `sas.client.props` file, you might receive a prompt that asks for your user ID and password. Enter the WebSphere Application Server user ID and password.

   - Linux : `./ConfigEngine.sh wp-add-property -DWasPassword=`*password*
   - IBM i: `ConfigEngine.sh wp-add-property -DWasPassword=`*password*
   - Windows: `ConfigEngine.bat wp-add-property -DWasPassword=`*password*
8. Stop and restart the appropriate servers to propagate the changes.

Mapping attributes

Map the attributes between IBM WebSphere Portal Express and your LDAP user registries.

Procedure

1. Use a text editor to open the `wkplc.properties` file in the *wp_profile_root*`/ConfigEngine/properties` directory.
2. Enter values for the following set of parameters to identify your LDAP server:

   The following parameters are found in the VMM Federated repository properties heading:

   Note: Go to the properties file for specific information about the parameters.

   federated.ldap.id

federated.ldap.host

federated.ldap.port

federated.ldap.sslEnabled

federated.ldap.bindDN

federated.ldap.bindPassword

federated.ldap.baseDN

Note: Make sure you use the same values that you used to configure your LDAP server.

3. Run the following task to check that all defined attributes that are available in the configured LDAP user registry:
   - Linux : `./ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat wp-validate-federated-ldap-attribute-config -DWasPassword=`*`password`*
4. Open the `ConfigTrace.log` file, in the *wp_profile_root*`\log` directory. Review the following output for the **PersonAccount** and **Group** entity type:

   The following attributes are defined in WebSphere Portal Express but not in the LDAP server

   This list contains all attributes that are defined in WebSphere Portal Express but not available in the LDAP. Flag attributes that you do not plan to use in WebSphere Portal Express as unsupported. Map the attributes that you plan to use to the attributes that exist in the LDAP; you must also map the `uid`, `cn`, `firstName`, `sn`, `preferredLanguage`, and `ibm-primaryEmail` attributes if they are contained in the list.

   The following attributes are flagged as required in the LDAP server but not in WebSphere Portal Express

   This list contains all attributes that are defined as "must" in the LDAP server but not as required in WebSphere Portal Express. Flag these attributes as required within WebSphere Portal Express; go to the next step to flag an attribute as either unsupported or required.

   The following attributes have a different type in WebSphere Portal Express and in the LDAP server

   This list contains all attributes that WebSphere Portal Express might ignore because the data type within WebSphere Portal Express and within the LDAP server do not match.
5. Use a text editor to open the `wkplc.properties` file
6. Enter a value for the following set of parameters in the `wkplc.properties` file to correct any issues that are found in the configuration trace file:

   The following parameters are found in the VMM Federated repository properties heading:

   federated.ldap.attributes.nonSupported

   federated.ldap.attributes.nonSupported.delete

   federated.ldap.attributes.mapping.ldapName

   federated.ldap.attributes.mapping.portalName

   federated.ldap.attributes.mapping.entityTypes

The following values flag `certificate` and `members` as unsupported attributes and maps `ibm-primaryEmail` to `mail` and `ibm-jobTitle` to `title` for the `PersonAccount` **`entityTypes`**:

```
federated.ldap.attributes.nonSupported=certificate, members
federated.ldap.attributes.nonSupported.delete=

federated.ldap.attributes.mapping.ldapName=mail, title
federated.ldap.attributes.mapping.portalName=ibm-primaryEmail, ibm-jobTitle
federated.ldap.attributes.mapping.entityTypes=PersonAccount
```

If you want to map attributes for your groups instead of users, set the **`entityTypes`** to `Group`.

`federated.ldap.attributes.mapping.entityTypes=``Group`

7. Save your changes to the `wkplc.properties` file.
8. Run the following task to update the LDAP user registry configuration with the following items:

   A list of unsupported attributes

   The correct mapping between WebSphere Portal Express and the LDAP user registry

   - Linux : `./ConfigEngine.sh wp-update-federated-ldap-attribute-config -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh wp-update-federated-ldap-attribute-config -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat wp-update-federated-ldap-attribute-config -DWasPassword=`*`password`*
9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
10. Optional: Complete the following steps to flag an attribute as either unsupported or required for the entire WebSphere Portal Express environment instead of just for the specified LDAP:
    a. Enter a value for the following required parameters in the `wkplc.properties` file:

       Note: Go to the properties file for specific information about the parameters.

       `user.attributes.required`

       `user.attributes.nonsupported`
    b. Save your changes to the `wkplc.properties` file.
    c. Run the following task:
       - Linux : `./ConfigEngine.sh wp-update-attribute-config -DWasPassword=`*`password`*
       - IBM i: `ConfigEngine.sh wp-update-attribute-config -DWasPassword=`*`password`*
       - Windows: `ConfigEngine.bat wp-update-attribute-config -DWasPassword=`*`password`*
    d. Stop and restart all necessary servers to propagate your changes.

Removing attributes

The Virtual Member Manager (VMM) has a limitation. There is no task to update an attribute.

About this task

Remove an attribute for any of the following circumstances:

- You added an attribute to a property extension database that was spelled incorrectly
- You adapted an attribute to match your LDAP server that was spelled incorrectly
- Your migration added the attribute

Use caution when you do these steps.

Important: Do not remove attributes that are populated with user values because it can cause inconsistencies.

Cluster note: In an idle-standby environment, complete these steps on the deployment manager and then resynch the nodes.

Procedure

1. Before you configure security, use the IBM WebSphere Application Server **backupConfig** task to create and store a backup of the IBM WebSphere Portal Express configuration. Read backupConfig command for information.
2. Complete the following steps to remove an attribute that is stored in a property extension database:
   a. Open the tool that you use to edit your database.
   b. Verify that your attribute name is available in the LAPROP table.
   c. Delete the required attributes from the LAPROP table.
   d. Open the `wimxmlextension.xml` file in the *dmgr_profile_root*`/config/cells/`*cellname*`/wim/model` directory.
   e. Locate and delete the **propertySchema** definition for the attributes that you deleted from the LAPROP table. For example:

```
<wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String"
    multiValued="true" propertyName="attribute_name">
  <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
</wim:propertySchema>
```

   f. Save your changes to the `wimxmlextension.xml` file.
   g. Open the `wimconfig.xml` file in the *dmgr_profile_root*`/config/cells/`*cellname*`/wim/config` directory.
   h. Locate and delete the **attributes** or **propertiesNotSupported** definitions for the attributes that you deleted from the LAPROP table. For example:

```
<config:attributes name="attribute_name" propertyName="attribute_name">
<config:entityTypes> PersonAccount </config:entityTypes>
<config:entityTypes> Group </config:entityTypes>
</config:attributes>
```

   or

```
<config:propertiesNotSupported name="attribute_name">
```

   i. Save your changes to the `wimconfig.xml` file.
   j. Stop and restart all the deployment manager, node agents, and WebSphere_Portal server to propagate the changes.
3. Complete the following steps to remove an attribute that is not stored in a property extension database:
   a. Open the `wimxmlextension.xml` file.
   b. Locate and delete the **propertySchema** definition for the attributes you previously added. For example:

```
<wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String"
        multiValued="true" propertyName="attribute_name">
   <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
    </wim:propertySchema>
```

c. Save your changes to the `wimxmlextension.xml` file.

d. Open the `wimconfig.xml` file.

e. Locate and delete the stanza that corresponds to the custom attribute you deleted from the `wimextension.xml` file. For example:

```
<config:attributes name="attribute_name" propertyName="property_name">
            <config:entityTypes>PersonAccount</config:entityTypes>
 </config:attributes>
```

f. Save your changes to the `wimconfig.xml` file.

g. Stop and restart the WebSphere_Portal server.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Enabling application groups

You can define user groups within the database user registry with members (users or groups) contained in the federated LDAP user registry you configured with application groups. The benefit of application groups is that you can create groups that are only used in IBM WebSphere Portal Express.

Before you begin

Before you enable application groups, from the Configuration Wizard run the Enable Federated Security configuration option to add all required federated LDAP user registries. Then, add all required database user registries. You must also set the `Group entity` type to the database user registry and the `Person entity` type to the LDAP user registry.

About this task

You can use application groups in the following scenarios:

Read-only LDAP
: If you have a read-only LDAP, you cannot change the group membership of users and groups. If you need to define access rights for certain users that are in different groups, you can create an application group for these users with the required access rights.

Special group setup for WebSphere Portal Express
: In this scenario, you need to set up a special group hierarchy that is used only by WebSphere Portal Express and not by other applications that access your LDAP server. This set up can help you apply special access control rules just for WebSphere Portal Express because the roles assigned to the application group also apply to all of its members.

Note: Application groups apply only to WebSphere Portal Express; it does not apply to external security managers. Also, application groups are not supported when you use the built-in file repository.

Perform the following steps to enable application groups:

Procedure

1. Run the following task to enable application groups:

Table 75. Task to enable application groups by operating system

Operating system	Task
IBM i	`ConfigEngine.sh wp-update-group-repository-relationship -DWasPassword=`*`password`* `-Drepository.id=`*`ldapid`* `-Drepository.forgroups=`*`dbid`* from the *wp_profile_root*`/ConfigEngine` directory
Linux	`./ConfigEngine.sh wp-update-group-repository-relationship -DWasPassword=`*`password`* `-Drepository.id=`*`ldapid`* `-Drepository.forgroups=`*`dbid`* from the *wp_profile_root*`/ConfigEngine` directory
Windows	`ConfigEngine.bat wp-update-group-repository-relationship -DWasPassword=`*`password`* `-Drepository.id=`*`ldapid`* `-Drepository.forgroups=`*`dbid`* from the *wp_profile_root*`\ConfigEngine` directory

   When you run the `wp-create-ldap` task, *ldapid* is the value that is specified in **`federated.ldap.id`** and when you run the `wp-create-db` task, the *dbid* is the value that is specified in **`federated.db.id`**

2. Stop and restart the WebSphere_Portal server.

Advanced group configurations

It is possible to use IBM WebSphere Portal Express ConfigEngine helper tasks to set up advanced Virtual Member Manager (VMM) group configurations. Specifically, it is possible to configure VMM to understand and use the "Group membership attribute" that many directories support.

Background: Group membership attribute

A group membership attribute is an LDAP directory feature. It allows an LDAP client to ask the LDAP directory for a list of groups that the user is a member of. It is as if the list is an attribute of the user object. It does not query the various groups to see whether a user is a member of any of them.

It is beyond the scope of this document to describe in detail all the various ways that different LDAP directory servers support a group membership attribute. Most LDAP directories have some variant of this support: Active Directory has the **`memberOf`** attribute. Sun/Oracle has **`nsroles`** or **`isMemberOf`** based on the version. IBM Directory Server has the **`ibm-allGroups`** attribute.

Many LDAP directories support complex group membership algorithms that include nesting of groups as members within other groups. They also support the use of dynamic group membership by querying against user attributes, instead of static lists of members. While VMM supports these features, in many cases it requires multiple operations between VMM and the directory to do so and thus becomes inefficient and a performance bottleneck. The use of the group

membership attribute shifts the burden of the calculations of these complex group structures to the directory itself, where it can be managed much more efficiently.

If your LDAP directory supports a group membership attribute and your use cases include group nesting or the use of dynamic groups, configure VMM to use the group membership attribute. Most LDAP directories implement this group membership attribute as a "real-time" attribute. It is calculated on demand rather than pre-calculated and stored as a persistent attribute of the user. There is likely extra processor cost on the LDAP directory for using this support. Usually this processor cost is worth the performance benefit that can be gained from offloading the work of resolving complex group relationships from VMM.

Configuring VMM to use the group membership attribute

To configure VMM to use the group membership attribute, two things must be specified:

- The name of the group membership attribute
- The scope of the attribute. This information tells VMM how complete the response is to a request for the group membership attribute value for a user.

The name is the attribute name in the LDAP directory implementation. For example, this attribute is **ibm-allGroups** for the IBM Directory Server. This attribute is set on the **federated.ldap.gc.name** property in the `wkplc.properties` file.

The scope is set on the **federated.ldap.gc.scope** property and is one of three possible values: `direct`, `nested`, or `all`. The setting for this property depends on how your LDAP directory implements the group membership attribute.

direct Direct means that the value returned holds only the list of static groups of which the user is a direct member. It does not attempt to account for group nesting or dynamic group memberships. The response here is functionally equivalent, for example, to a query of the form `(&(objectClass=groupOfNames)(member=<dn of the user>))`. In this case, there is little if any reason to prefer the group membership attribute over the traditional query.

Note: When the group membership attribute scope is `direct` or when you use the traditional query method, VMM must do extra work if it needs to resolve nested groups or dynamic groups.

- VMM tries to resolve dynamic groups if the dynamic group configuration information is set up within the VMM configuration files.
- VMM tries to resolve nested groups if the client application, which is WebSphere Portal Express, requests it to. By default, WebSphere Portal Express requests that nested groups are used. If your access control models do not use group nesting to inherit permissions, turn off the nested group function within portal. Read the documentation for the **enableNestedGroups** custom property within the **WP AccessControlDataManagementService** Resource Environment Provider.

Note: To avoid conflicts between how WebSphere Portal Express and WebSphere Application Server handle nested groups, globally turn off nested groups. Change the **com.ibm.ws.wim.registry.grouplevel** value to 1. Go to Disabling nested group searches for instructions.

nested Nested means that the response from the LDAP server to a request for the group membership attribute already includes any nested group

relationships, but not any dynamic group memberships. If the user is a member of group "A2" and "A2" is a member of group "A1", then the list of group memberships includes both A1 and A2. This information tells VMM that even if a client requests nested group information, the response already provides it. No further work needs to be done by VMM to satisfy the request.

all All means that the response from the LDAP server to a request for the group membership attribute already includes both nested groups and also dynamic groups, if any.

It is important to set the scope value to accurately reflect how your LDAP directory works to get correct and efficient operation. It is beyond the scope of this documentation to describe the unique characteristics of every directory. In some cases, the directory might require specific setup to fully support the advanced group features. For example, the IBM Directory Server must be set up with specific auxiliary object classes and special membership records to fully support nested groups and dynamic groups with the **ibm-allGroups** attribute. Consult your specific LDAP directory documentation or check with your LDAP administrator for specific details about your directory deployment.

ConfigEngine tasks for advanced group configuration

Set the **federated.ldap.gc.name** and **federated.ldap.gc.scope** properties before you run one of the following tasks:

- **wp-create-ldap**
- **wp-create-ldap-groupconfig**

  "Updating the group membership configuration"
  The initial federated repositories setup might not include the advanced set up for the group membership attribute. You can configure the group membership attribute after the initial setup. Specify the properties in the `wkplc.properties` file and then run the **wp-create-ldap-groupconfig** task manually.

  "Configuring WebSphere Portal Express to use dynamic groups" on page 581
  By default, IBM WebSphere Portal Express is enabled for static groups. However, the Virtual Member Manager (VMM) allows users to be members of either static or dynamic groups. Static groups have a persistent binding between a group and its members. Dynamic groups have a search query that is defined to retrieve the members of a group.

Updating the group membership configuration

The initial federated repositories setup might not include the advanced set up for the group membership attribute. You can configure the group membership attribute after the initial setup. Specify the properties in the `wkplc.properties` file and then run the **wp-create-ldap-groupconfig** task manually.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

Procedure

1. Go to the *wp_profile_root*`/ConfigEngine/properties` directory.
2. Open the `wkplc.properties` file with a text editor.

3. Update the following parameters in the `wkplc.properties` file under the VMM LDAP group member config heading:

   Note: Go to the properties file for specific information about the parameters.

   `gc.ldap.id`

   `gc.name`

   `gc.updateGroupMembership`

   `gc.scope`
4. Open a command prompt.
5. Change to the *wp_profile_root*`/ConfigEngine` directory.
6. Run the following task to update the group membership for the LDAP user registry:
   - Linux : `./ConfigEngine.sh wp-create-ldap-groupconfig -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh wp-create-ldap-groupconfig -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat wp-create-ldap-groupconfig -DWasPassword=`*`password`*
7. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Configuring WebSphere Portal Express to use dynamic groups

By default, IBM WebSphere Portal Express is enabled for static groups. However, the Virtual Member Manager (VMM) allows users to be members of either static or dynamic groups. Static groups have a persistent binding between a group and its members. Dynamic groups have a search query that is defined to retrieve the members of a group.

About this task

Disclaimer: The following procedure is to activate dynamic group support natively in VMM. It is preferable, if possible, to use the group membership attribute support to bring in dynamic group information from your LDAP server. Using the group membership attribute support for dynamic group membership is only possible if:

- Your LDAP server supports a group membership attribute
- The group membership attribute includes dynamic group membership information

Otherwise, complete the following steps to manually configure WebSphere Portal Express to use dynamic groups.

Clustered environments: Complete the following steps on the Deployment Manager and then synchronize the nodes.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Go to **Security** > **Global security**.
3. In **Available realm definitions**, select **Federated repositories** and click **Configure**.
4. In **Related Items**, click **Manage repositories**.

5. Select the appropriate repository from the list.
6. In **Additional Properties**, click **Group attribute definition** and then click **Dynamic member attributes**.
7. Click **New** and specify values for the **Name** and **Object class** fields as appropriate. For example:
   - **Name:** `memberurl`
   - **Object class:** `groupofurls`
8. Click **OK** and save the changes to the master configuration.
9. Stop and restart the appropriate servers to propagate the changes. For instructions, read "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Adding realm support

A realm is a group of users from one or more user registries that form a coherent group within IBM WebSphere Portal Express. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When you configure realm support, complete these steps for each base entry that exists in your LDAP and database user registry to create multiple realm support.

Before you begin

Before you configure realm support, add all LDAP user registries and database user registries to the federated repository. To create multiple realms, you must create all required base entries within your LDAP user registries and database user registries. All base entry names must be unique within the federated repository.

In a stand-alone server environment, you can complete this task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent and verify that they are able to synchronize.

Procedure

1. Use the IBM WebSphere Application Server **`backupConfig`** task to create and store a backup of the IBM WebSphere Portal Express configuration. Read backupConfig command for information.
2. Use a text editor to open the `wkplc.properties` file in the *wp_profile_root*`/ConfigEngine/properties` directory.
3. Required: Enter a value for the following parameters in the VMM realm configuration section:

   Note: Review the properties file for specific information about the parameters.

   `realmName`

   `securityUse`

   `delimiter`

   `addBaseEntry`
4. Save your changes.
5. Open a command line and change to the *wp_profile_root*`/ConfigEngine` directory.
6. Run the following task to add a realm to the Virtual Member Manager configuration:

Important: To create multiple realms, ensure that your federated repository contains the correct unique base entries. Stop and restart the appropriate servers for your installation environment, and then update the `wkplc.properties` file with the base entry information and rerun the **wp-create-realm** task. Repeat these steps until all realms are created.

- Linux :`./ConfigEngine.sh wp-create-realm -DWasPassword=`*`password`*
- IBM i: `ConfigEngine.sh wp-create-realm -DWasPassword=`*`password`*
- Windows: `ConfigEngine.bat wp-create-realm -DWasPassword=`*`password`*

7. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
8. Required: Enter a value for the following parameters in the `wkplc.properties` file in the VMM realm configuration section:

   realmName

   realm.personAccountParent

   realm.groupParent

   realm.orgContainerParent
9. Run the following task to update the default parents per entity type and realm:
   - Linux :`./ConfigEngine.sh wp-modify-realm-defaultparents -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh wp-modify-realm-defaultparents -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat wp-modify-realm-defaultparents -DWasPassword=`*`password`*
10. Stop and restart the appropriate servers to propagate the changes. You can rerun the **wp-modify-realm-defaultparents** task to create more entity types and realms.
11. Optional: Complete the following steps to add more base entries to the realm configuration:

    For example, you have two more base entries (base entry 1 and base entry 2) to add to the realm you created. You must update the `wkplc.properties` file with the information from base entry 1 and then run this task. Then, update the properties file with the information for base entry 2 and then run this task.

    a. Enter a value for the following parameters in the `wkplc.properties` file in the VMM realm configuration section:

       realmName

       addBaseEntry

    b. Run the following task to add more LDAP base entries to the realm configuration:
       - Linux :`./ConfigEngine.sh wp-add-realm-baseentry -DWasPassword=`*`password`*
       - IBM i: `ConfigEngine.sh wp-add-realm-baseentry -DWasPassword=`*`password`*
       - Windows: `ConfigEngine.bat wp-add-realm-baseentry -DWasPassword=`*`password`*

    c. Stop and restart all necessary servers to propagate your changes.
12. Optional: Complete the following steps to replace the WebSphere Application Server and WebSphere Portal Express administrator user ID:

Tip: Complete these steps if you changed the default realm.

a. Create a user in the **Manage Users and Groups** portlet to replace the current WebSphere Application Server administrative user.

b. Create a user in the **Manage Users and Groups** portlet to replace the current WebSphere Portal Express administrative user.

c. Create a group in the **Manage Users and Groups** portlet to replace the current group.

d. Run the following task to replace the old WebSphere Application Server administrative user ID and group ID with the new user and group:

- Linux :`./ConfigEngine.sh wp-change-was-admin-user -DWasUser=`*`adminid`* `-DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* `-DnewAdminGroupId=`*`newadmingroupid`*
- IBM i: `ConfigEngine.sh wp-change-was-admin-user -DWasUser=`*`adminid`* `-DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* `-DnewAdminGroupId=`*`newadmingroupid`*
- Windows: `ConfigEngine.bat wp-change-was-admin-user -DWasUser=`*`adminid`* `-DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* `-DnewAdminGroupId=`*`newadmingroupid`*

e. Verify that the task completed successfully. Stop and restart all servers.

f. Run the following task to replace the old WebSphere Portal Express administrative user ID and group ID with the new user and group:

- Linux :`./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* `-DnewAdminGroupId=`*`newadmingroupid`*
- IBM i: `ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* `-DnewAdminGroupId=`*`newadmingroupid`*
- Windows: `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=`*`password`* `-DnewAdminId=`*`newadminid`* `-DnewAdminPw=`*`newpassword`* `-DnewAdminGroupId=`*`newadmingroupid`*

Important: You must provide the full distinguished name (DN) for the **`newAdminId`** and **`newAdminGroupId`** parameters.

Additional parameter for stopped servers: This task verifies the user against a running server instance. If the server is stopped, add the **`-Dskip.ldap.validation`**`=true` parameter to the task to skip the validation.

g. Verify that the task completed successfully. Stop and restart all servers.

13. Complete the following steps to set the realm you created as the default realm:

Remember: Only users that are defined in base entries that exist in the default realm are able to log in to WebSphere Portal Express. If a user cannot log in to WebSphere Portal Express, check whether the base entry that contains the user exists in the default realm. You can run the **`wp-query-realm-baseentry`** task to see what base entries are part of the default realm. If the default realm is missing the base entry, run the **`wp-add-realm-baseentry`** task to add the base entry to the default realm.

a. Open the `wkplc.properties` file.

b. For **`defaultRealmName`**, type the **`realmName`** property value you want to use as the default realm.

c. Save your changes.

d. Run the following task to set this realm as the default realm:
   - Linux :./ConfigEngine.sh wp-default-realm -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-default-realm -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-default-realm -DWasPassword=*password*

e. Stop and restart all necessary servers to propagate your changes.

14. Complete the following steps to query a realm for a list of its base entries:
    a. Open the wkplc.properties file.
    b. For **realmName**, type the name of the realm you want to query.
    c. Save your changes.
    d. Run the following task to list the base entries for a specific realm:
       - Linux :./ConfigEngine.sh wp-query-realm-baseentry -DWasPassword=*password*
       - IBM i: ConfigEngine.sh wp-query-realm-baseentry -DWasPassword=*password*
       - Windows: ConfigEngine.bat wp-query-realm-baseentry -DWasPassword=*password*

15. Optional: Complete the following steps to enable the full distinguished name login if the short names are not unique for the realm:

    Tip: Run this task if the administrator name is in conflict with another user name in the attached repository. This command allows the Administrator to log in using the fully distinguished name instead of the short name.
    a. Open the wkplc.properties file.
    b. Enter a value for **realmName** or leave blank to update the default realm.
    c. Save your changes.
    d. Run the following task to list the base entries for a specific realm:
       - Linux :./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=*password*
       - IBM i: ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=*password*
       - Windows: ConfigEngine.bat wp-modify-realm-enable-dn-login -DWasPassword=*password*

       Note: You can run the **wp-modify-realm-disable-dn-login** task to disable the feature.
    e. Stop and restart all necessary servers to propagate your changes.

Updating your user registry

After you deploy IBM WebSphere Portal Express, you can adjustment your federated user repository configurations. You can update these configurations to achieve the correct user registry configuration.

About this task

Choose from the following tasks to update your user registry configurations:

"Updating the context pool configuration" on page 587
After you configure your LDAP user registry, you can adjust the number of context instances that the context pool concurrently maintains to improve performance.

Updating the context pool configuration

After you configure your LDAP user registry, you can adjust the number of context instances that the context pool concurrently maintains to improve performance.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

Procedure

1. Go to the *wp_profile_root*/ConfigEngine/properties directory.
2. Open the wkplc.properties file with a text editor.
3. Update the following parameters under the VMM LDAP context pool heading:

   Note: Go to the properties file for specific information about the parameters.

   cp.ldap.id

   cp.maxPoolSize

   cp.initPoolSize

   cp.prefPoolSize

   cp.poolTimeout

   cp.poolWaitTime
4. Save your changes to the wkplc.properties file.
5. Open a command prompt.
6. Change to the *wp_profile_root*/ConfigEngine directory.
7. Run the following task to update the context pool configuration for the LDAP user registry:
   - Linux : `./ConfigEngine.sh wp-update-ldap-contextpool -DWasPassword=`*password*
   - IBM i: `ConfigEngine.sh wp-update-ldap-contextpool -DWasPassword=`*password*
   - Windows: `ConfigEngine.bat wp-update-ldap-contextpool -DWasPassword=`*password*
8. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Creating the entity type

If an entity type exists within IBM WebSphere Portal Express but not within your LDAP user registry, create the entity type within your LDAP user registry. Then, add the relative distinguished name (RDN) to the entity type to map it between WebSphere Portal Express and your LDAP user registry.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

Procedure

1. Open a command prompt.
2. Change to the *wp_profile_root*/ConfigEngine directory.
3. Optional: Run the following task to list the names and types of configured repositories:
   - Linux : ./ConfigEngine.sh wp-query-repository -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-query-repository -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-query-repository -DWasPassword=*password*
4. Go to the *wp_profile_root*/ConfigEngine/properties directory.
5. Open the wkplc.properties file with a text editor.
6. Enter the following parameters under the VMM LDAP entity type configuration heading:

   Note: Go to the properties file for specific information about the parameters.

   et.ldap.id

   et.entityTypeName

   et.objectClass

   et.searchFilter

   et.objectClassesForCreate

   et.searchBases
7. Save your changes to the wkplc.properties file.
8. Run the following task to update a realm configuration:
   - Linux : ./ConfigEngine.sh wp-update-realm -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-update-realm -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-update-realm -DWasPassword=*password*
9. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
10. Open the wkplc.properties file.
11. Enter a value for the following parameters under the VMM LDAP entity type configuration heading:

    et.ldap.id

    et.entityTypeName

    et.objectClass

    et.searchFilter

    et.objectClassesForCreate

    et.searchBases

    et.rdnName
12. Save your changes to the wkplc.properties file.
13. Run the following task to add an LDAP entity type with a relative distinguished name (DN):
    - Linux : ./ConfigEngine.sh wp-add-ldap-entitytype-rdn -DWasPassword=*password*
    - IBM i: ConfigEngine.sh wp-add-ldap-entitytype-rdn -DWasPassword=*password*
    - Windows: ConfigEngine.bat wp-add-ldap-entitytype-rdn -DWasPassword=*password*

14. Stop and restart the appropriate servers to propagate the changes.

Changing from a stand-alone repository to a federated repository

If you originally configured a stand-alone LDAP user registry but require a robust security configuration, you can change to the federated user repository.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

About this task

Remember: Starting with IBM WebSphere Portal Express Version 8.5, the stand-alone LDAP repository is deprecated. Change to the federated LDAP user repository.

Use the `wp_security_federated.properties` helper file that is in the *wp_profile_root*`/ConfigEngine/config/helpers` directory. It ensures that the correct properties are entered. In the following instructions, where the step refers to the `wkplc.properties` file, use your `wp_security_federated.properties` helper file.

Procedure

1. Go to the *wp_profile_root*`/ConfigEngine/properties` directory.
2. Open the `wkplc.properties` file with a text editor.
3. Update the following parameters in the `wkplc.properties` file under the VMM Federated repository properties heading:

   Note: Go to the properties file for specific information about the parameters.

   `federated.primaryAdminId`

   `federated.realm`

   `federated.serverId`

   `federated.serverPassword`
4. Open a command prompt.
5. Change to the *wp_profile_root*`/ConfigEngine` directory.
6. Run the following task to change the configuration to use a federated repository:
   - Linux : `./ConfigEngine.sh wp-modify-federated-security -DWasPassword=`*`password`*` -Dskip.ldap.validation=true`
   - IBM i: `ConfigEngine.sh wp-modify-federated-security -DWasPassword=`*`password`*` -Dskip.ldap.validation=true`
   - Windows: `ConfigEngine.bat wp-modify-federated-security -DWasPassword=`*`password`*` -Dskip.ldap.validation=true`
7. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
8. Log in to WebSphere Portal Express as an administrator.
   a. Click **Administration**. Then, click **Virtual Portals** > **Manage Virtual Portals**.
   b. Edit each Virtual Portal using the pencil icon.
   c. Set **User realm** as blank.

d. Click **OK**.
e. Edit each Virtual Portal using the pencil icon.
f. Set **User realm** to match the realm ID that you set for **federated.realm**.
g. Click **OK**.

Restoring the VMM setup with a federated file repository

If your business changes or your user registry configuration is inoperable, run the **wp-restore-default-repository-configuration** task to restore the default VMM setup with a federated file repository. Then, reconfigure your user registry. The task deletes all existing repositories, creates a realm, and configures a file repository in VMM. The task also creates a user and group, which is set to the IBM WebSphere Portal Express administrator.

Procedure

1. Before you configure security, use the IBM WebSphere Application Server **backupConfig** task to create and store a backup of the WebSphere Portal Express configuration. Read backupConfig command for information.
2. Go to the *wp_profile_root*/ConfigEngine/properties directory.
3. Open the wkplc.properties file with a text editor.
4. Required: Enter a value for the following parameters under the VMM Federated repository properties heading:

   Note: Go to the properties file for specific information about the parameters.

   federated.primaryAdminId

   federated.realm

   federated.serverId

   federated.serverPassword
5. Open a command prompt.
6. Change to the *wp_profile_root*/ConfigEngine directory.
7. Run the following task to restore the default repository:
   - Linux : ./ConfigEngine.sh wp-restore-default-repository-configuration -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-restore-default-repository-configuration -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-restore-default-repository-configuration -DWasPassword=*password*
8. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
9. Run the following task to restore the default repository group member:
   - Linux : ./ConfigEngine.sh wp-restore-default-repository-add-group-member -DgroupUniqueName=*value* -DmemberUniqueName=*value* -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-restore-default-repository-add-group-member -DgroupUniqueName=*value* -DmemberUniqueName=*value* -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-restore-default-repository-add-group-member -DgroupUniqueName=*value* -DmemberUniqueName=*value* -DWasPassword=*password*
10. Stop and restart the appropriate servers to propagate the changes.

Updating an entity type

After you add your user registry, you can update a single entity type with the value of the default parent. For example, if you delete a repository, you must update the entity type if it points to the deleted repository.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

Procedure

1. Go to the *wp_profile_root*/ConfigEngine/properties directory.
2. Open the wkplc.properties file with a text editor.
3. Enter a value for the following parameters under the VMM supported entity types configuration heading:

   Note: Go to the properties file for specific information about the parameters.

   entityTypeName

   defaultParent

   rdnProperties
4. Save your changes to the wkplc.properties file.
5. Open a command prompt.
6. Change to the *wp_profile_root*/ConfigEngine directory.
7. Run the following task to delete the old entity types before you add the RDN attribute as the only entry in the RDN list:
   - Linux : ./ConfigEngine.sh wp-set-entitytype -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-set-entitytype -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-set-entitytype -DWasPassword=*password*
8. Run the following task to add an entity type to the existing list:
   - Linux : ./ConfigEngine.sh wp-update-entitytype -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-update-entitytype -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-update-entitytype -DWasPassword=*password*
9. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Updating the base entry

After you create your base entries, you can update the distinguished name (DN) in the repository that uniquely identifies the base entry name. This task applies only to federated repository configurations. This task does not update the base DN entry if you use a stand-alone repository.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

Procedure

1. Go to the *wp_profile_root*/ConfigEngine/properties directory.
2. Open the wkplc.properties file with a text editor.
3. Enter a value for the following parameters under the VMM repository base entry configuration heading:

   Note: Go to the properties file for specific information about the parameters.

   id

   baseDN

   nameInRepository
4. Save your changes to the wkplc.properties file.
5. Open a command prompt.
6. Change to the *wp_profile_root*/ConfigEngine directory.
7. Run the following task to delete the old entity types before you add the RDN attribute as the only entry in the RDN list:
   - Linux : ./ConfigEngine.sh wp-update-base-entry -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-update-base-entry -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-update-base-entry -DWasPassword=*password*
8. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Updating the database user registry

After you create and use the database user registry, you can update the database user ID, password, and where the data is stored. This task does not change the DN structure that is stored in the database repository.

Before you begin

If you plan to change the database where data is stored, populate the new database with all necessary VMM tables and create the data sources in WebSphere Application Server. Then, run this task. Read the following information for information about setting up a VMM database. After you populate the new database, restart the WebSphere_Portal server.

- Linux Windows: Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands
- IBM i: Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands

If you change the database administrator password, complete the steps in "Changing database passwords that are used by WebSphere Portal Express" on page 1677 before you run this task.

About this task

Note: Use the wp_add_DB.properties helper file in the *wp_profile_root*/ConfigEngine/config/helpers directory to ensure that the correct properties are entered. In the following instructions, where the step refers to the wkplc.properties file, use your wp_add_DB.properties helper file.

Procedure

1. Prepare your servers.

- In a stand-alone server environment, you can complete the following task when the servers are either stopped or started.
- In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

2. Go to the *wp_profile_root*/ConfigEngine/properties directory.
3. Open the wkplc.properties file with a text editor.
4. Enter the following parameters in the wkplc.properties file under Federated DB repository heading:

   Note: Go to the properties file for specific information about the parameters.

   federated.db.DataSourceName

   federated.db.DbType

   federated.db.DbUrl

   federated.db.id

   federated.db.DbUser

   federated.db.DbPassword
5. Save your changes to the wkplc.properties file.
6. Open a command prompt.
7. Change to the *wp_profile_root*/ConfigEngine directory.
8. Run the following task to delete the required repository:
   - Linux : ./ConfigEngine.sh wp-update-db -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-update-db -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-update-db -DWasPassword=*password*
9. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Updating a group member

After you create your LDAP user registry, you might find that your group member is not correct. You can update the group member in your LDAP user registry configuration.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

Procedure

1. Open a command prompt.
2. Change to the *wp_profile_root*/ConfigEngine directory.
3. Optional: Run the following task to list the names and types of configured repositories:

- Linux : `./ConfigEngine.sh wp-query-repository -DWasPassword=password`
- IBM i: `ConfigEngine.sh wp-query-repository -DWasPassword=password`
- Windows: `ConfigEngine.bat wp-query-repository -DWasPassword=password`

4. Go to the *wp_profile_root*`/ConfigEngine/properties` directory.
5. Open the `wkplc.properties` file with a text editor.
6. Enter a value for the following parameters under the VMM LDAP group member attribute configuration heading:

   Note: Go to the properties file for specific information about the parameters.

   gm.ldap.id

   gm.groupMemberName

   gm.objectClass

   gm.scope

   gm.dummyMember
7. Save your changes to the `wkplc.properties` file.
8. Run the following task to update the group member information for your LDAP user registry or to create the group member if it does not exist:
   - Linux : `./ConfigEngine.sh wp-update-ldap-groupmember -DWasPassword=password`
   - IBM i: `ConfigEngine.sh wp-update-ldap-groupmember -DWasPassword=password`
   - Windows: `ConfigEngine.bat wp-update-ldap-groupmember -DWasPassword=password`
9. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Updating the federated LDAP user registry

After you create and use the LDAP user registry in the default federated repository, you might find that your LDAP user registry is not working correctly. You can update the LDAP user registry and make the necessary changes. For example, you can change your LDAP Bind password.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

About this task

Note: The update federated LDAP user registry task does not modify the following attributes:

Administrative users

Entity types

LDAP entity types

LDAP group membership attributes

LDAP group configuration

LDAP context pool

There are separate tasks to update these attributes.

Note: Use the `wp_security_federated.properties` helper file, that is in the *wp_profile_root*`/ConfigEngine/config/helpers` directory to ensure that the correct properties are entered. In the following instructions, where the step refers to the `wkplc.properties` file, use your `wp_security_federated.properties` helper file.

Procedure

1. Go to the *wp_profile_root*`/ConfigEngine/properties` directory.
2. Open the `wkplc.properties` file with a text editor.
3. Enter the following parameters in the `wkplc.properties` file under Federated LDAP repository heading:

   Note: Go to the properties file for specific information about the parameters.

   federated.ldap.id

   federated.ldap.host

   federated.ldap.baseDN

   federated.ldap.ldapServerType

   federated.ldap.port

   federated.ldap.bindDN

   federated.ldap.bindPassword
4. Save your changes to the `wkplc.properties` file.
5. Open a command prompt.
6. Change to the *wp_profile_root*`/ConfigEngine` directory.
7. Run the following task to validate your LDAP server settings:
   - Linux : `./ConfigEngine.sh validate-federated-ldap -DWasPassword=`*password*
   - IBM i: `ConfigEngine.sh validate-federated-ldap -DWasPassword=`*password*
   - Windows: `ConfigEngine.bat validate-federated-ldap -DWasPassword=`*password*

   Note: In an environment that is configured with an LDAP with SSL, you are prompted to add a signer to the truststore. The prompt is `Add signer to the truststore now?`. If you do, press **y** and then **Enter**.
8. Run the following task to update the LDAP user registry in the default federated repository:
   - Linux : `./ConfigEngine.sh wp-update-federated-ldap -DWasPassword=`*password*
   - IBM i: `ConfigEngine.sh wp-update-federated-ldap -DWasPassword=`*password*
   - Windows: `ConfigEngine.bat wp-update-federated-ldap -DWasPassword=`*password*
9. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Updating the realm configuration

After you create and use the realm in the default federated repository, you might find that your realm configuration is not working correctly. You can update the realm configurations and make the necessary changes.

Procedure

1. Go to the *wp_profile_root*/ConfigEngine/properties directory.
2. Open the wkplc.properties file with a text editor.
3. Enter a value for the following parameters under the VMM realm configuration heading:

   Note: Go to the properties file for specific information about the parameters.

   realmName

   securityUse

   delimiter
4. Save your changes to the wkplc.properties file.
5. Open a command prompt.
6. Change to the *wp_profile_root*/ConfigEngine directory.
7. Run the following task to delete the old entity types before you add the RDN attribute as the only entry in the RDN list:
   - Linux : ./ConfigEngine.sh wp-update-realm -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-update-realm -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-update-realm -DWasPassword=*password*
8. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Configuring a property extension database

A property extension database stores attributes that the LDAP directory does not or cannot store, but that you want to include in your portal user registry. This situation often occurs when you are using an LDAP directory that does not allow schema extensions for new attributes to support portal applications. When you configure a property extension database, you effectively extend the user registry to make new attributes available as part of your portal user profile. However, it is preferable to store all user attributes in the main user registry. Complete this task only if you cannot add attributes to your LDAP directory.

Before you begin

Configure portal security with your main user registry before you configure your property extension database. If you complete these steps and then configure your user registry, your property extension database configuration does not work.

The Virtual Member Manager (VMM) has a limitation that includes no tasks to update attributes. To change an attribute, you must first remove the attribute then add it again. For this reason, ensure that you spell all attributes correctly and use caution when you add attributes to your property extension database.

The VMM database schema has a limit of 36 characters on the repository ID column. For this reason, you must use a repository ID that is 36 characters or less.

Procedure

1. This task requires server connections.
   - In a stand-alone environment, ensure the WebSphere_Portal server is running.

- In a clustered environment, stop all application servers on the system. Ensure that the WebSphere_Portal server is stopped. Then, start the node agent and deployment manager servers.

2. Complete the following steps to install the enterprise archive (`.ear`) file on WebSphere Application Server:
   a. Open a command prompt.
   b. Change to the *wp_profile_root*`/ConfigEngine` directory.
   c. Run the following task:

Table 76. Stand-alone and cluster tasks to install the enterprise archive file.. The **wp-la-install-ear** command.

Environment	Task
Stand-alone environment	• Linux : `./ConfigEngine.sh wp-la-install-ear -DWasPassword=`*`password`* • IBM i: `ConfigEngine.sh wp-la-install-ear -DWasPassword=`*`password`* • Windows: `ConfigEngine.bat wp-la-install-ear -DWasPassword=`*`password`*
Clustered environment	• Linux : `./ConfigEngine.sh wp-la-install-ear -DWasPassword=`*`dmgr_password`*` -DServerName=`*`dmgr_server_name`*` -DNodeName=`*`node_name`* • IBM i: `ConfigEngine.sh wp-la-install-ear -DWasPassword=`*`dmgr_password`*` -DServerName=`*`dmgr_server_name`*` -DNodeName=`*`node_name`* • Windows: `ConfigEngine.bat wp-la-install-ear -DWasPassword=`*`dmgr_password`*` -DServerName=`*`dmgr_server_name`*` -DNodeName=`*`node_name`* Where the default value for *`dmgr_server_name`* is `dmgr`. You can find the *`dmgr_server_name`* value in the WebSphere Integrated Solutions Console. Go to **System administrator** > **Deployment Manager** > **Configuration tab** > **General Properties** > **Name**. Where *`node_name`* is the name of the node where the deployment manager is located. You can find the *`node_name`* value in the WebSphere Integrated Solutions Console. Go to **System administrator** > **Deployment Manager** > **Runtime tab** > **General Properties** > **Node Name**.

3. Stop and restart the appropriate servers to propagate the changes. For specific instructions, read "Starting and stopping servers, deployment managers, and node agents" on page 1216.

4. Set up a new database. Create a user with the appropriate database privileges for accessing the database. The database user needs to have permissions to create tables in the database schema and permission to access the data in the database tables.

   Instructions for setting up databases: Refer to the appropriate documentation for the type of database you want to set up.

   Consulting your database administrator: A database administrator typically completes the task of setting up a new database. However, the following steps are provided for your reference in the event you create a stand-alone database for testing or demonstration purposes. Consult your database administrator if you plan to create a database for a production environment.

Table 77. Steps for creating a database to use as a database user registry.. This table describes the steps by database type to create a database for your database user registry.

Database	Steps
DB2	Complete the following steps to create a DB2 database: 1. Install DB2. 2. Enter the following commands to tune your database: `db2 "CREATE DB dbname using codeset UTF-8 territory us PAGESIZE 8192"` `db2 "UPDATE DB CFG FOR dbname USING applheapsz 4096"` `db2 "UPDATE DB CFG FOR dbname USING app_ctl_heap_sz 1024"` `db2 "UPDATE DB CFG FOR dbname USING stmtheap 32768"` `db2 "UPDATE DB CFG FOR dbname USING dbheap 2400"` `db2 "UPDATE DB CFG FOR dbname USING locklist 1000"` `db2 "UPDATE DB CFG FOR dbname USING logfilsiz 4000"` `db2 "UPDATE DB CFG FOR dbname USING logprimary 12"` `db2 "UPDATE DB CFG FOR dbname USING logsecond 20"` `db2 "UPDATE DB CFG FOR dbname USING logbufsz 32"` `db2 "UPDATE DB CFG FOR dbname USING avg_appls 5"` `db2 "UPDATE DB CFG FOR dbname USING locktimeout 30"` `db2 "UPDATE DB CFG FOR dbname using AUTO_MAINT off"`
Oracle	Complete the following steps to create an Oracle database: 1. Install Oracle with Unicode database and National character sets such as UTF8, AL32UTF8, or AL16UTF16. 2. Configure the database in Dedicated Server Mode. 3. Enter the initial buffer pool sizes or set them according to your business needs: **db_block_size** = 8192 **db_cache_size** = 300M **db_files** = 1024 **log_buffer** = 65536 **open_cursors** = 1500**open_cursors** = 1500 **pga_aggregate_target** = 200M **pre_page_sga** = true **processes** = 300 **shared_pool_size** = 200M
SQL Server	Complete the following steps to create an SQL Server database: 1. Create an SQL Server database with a name of your choice. 2. Create a SQL Server database user with the same permissions as your Portal database users for this new database. **Tip:** Do not use `userid=sa`. This ID is a special user ID that has restrictions. Instead, create a new user. Then, create a new schema with the user as owner and assign the user permissions to create database tables. **Note:** Install SQL Server with the appropriate portal database collation so that your **tempdb collation** setting matches the collation that you use for the property extension database. The **tempdb collation** is inherited from the master database, which you set when you install SQL Server.

5. Complete the following steps to create the IBM DB2 for i database:

Instructions for setting up databases: Refer to the appropriate documentation for the type of database you want to set up.

Consulting your database administrator: A database administrator typically completes the task of setting up a new database. However, the following steps are provided for your reference in the event you create a stand-alone database for testing or demonstration purposes. Consult your database administrator before you proceed with the following steps if you plan to create a database for a production environment.

a. Log in to a remote IBM i session.
b. Enter the `strsql` command to start the interactive sql session.
c. Enter the `create schema` *`database_name`* command, where *`database_name`* is the name you want to use for the database.

6. Complete the following steps to define the **`DbDriver`** and **`DbLibrary`** parameter values:
   a. Go to the *wp_profile_root*`/ConfigEngine/properties` directory.
   b. Open the `wkplc_dbtype.properties` file with a text editor.
   c. Enter a value for the following parameters in the appropriate database type properties heading:

      `db_type.DbDriver`

      `db_type.DbLibrary`

   d. Save your changes.
7. Specify values for the data source parameters in the `wp_add_LA.properties` file:
   a. Go to the *wp_profile_root*`/ConfigEngine/config/helpers` directory.
   b. Open the `wp_add_LA.properties` file with a text editor.
   c. Specify values for the following parameters:

      Note: Go to the properties file for specific information about the parameters.

      `la.JdbcProviderName`

      `la.DbType`

      `la.DbUrl`

      `la.DbName`

      `la.DataSourceName`

      `la.DbUser`

      `la.DbPassword`

      Adding parameters for a clustered environment: Add the following parameters to the `wp_add_LA.properties` if you are setting up the property extension database on a clustered environment:

      `la.schemaLocation=`*`WAS_install_location_on_DMGR`*`/AppServer/etc/wim/setup`

      `la.laPropXML=`*`WAS_install_location_on_DMGR`*`/AppServer/etc/wim/setup/wimlaproperties.xml`

      Where *`WAS_install_location_on_DMGR`* is the local path on your deployment manager node.

   d. Save your changes.
8. Change the value for the **`com.ibm.SOAP.requestTimeout`** parameter:

a. Go to the *wp_profile_root*\properties directory.
b. Open the soap.client.props with a text editor.
c. Locate the **com.ibm.SOAP.requestTimeout** parameter.
d. Ensure that the value is greater than 1000.
e. Save your changes.

9. Complete the following step in a clustered environment:
   a. Open the wkplc.properties file.
   b. Set the property value for **federated.db.DbType** if you are using a database user registry or if the cell is migrated from a previous version.
   c. Save your changes.
   d. Open a command prompt.
   e. Change to the *wp_profile_root*/ConfigEngine directory.
   f. Run the following task to create the local Deployment Manager WebSphere variable that is used to access the database JAR files:
      - Linux : `./ConfigEngine.sh wp-prep-vmm-db-secured-environment -DWasPassword=`*`password`* `-DDbDomain=la -D`*`db_type`*`.DmgrDbLibrary=`*`local path of the database jars on the Deployment Manager`* `-DDmgrNodeName=`*`dmgr_node_name`*
      - IBM i: `ConfigEngine.sh wp-prep-vmm-db-secured-environment -DWasPassword=`*`password`* `-DDbDomain=la -D`*`db_type`*`.DmgrDbLibrary=`*`local path of the database jars on the Deployment Manager`* `-DDmgrNodeName=`*`dmgr_node_name`*
      - Windows: `ConfigEngine.bat wp-prep-vmm-db-secured-environment -DWasPassword=`*`password`* `-DDbDomain=la -D`*`db_type`*`.DmgrDbLibrary=`*`local path of the database jars on the Deployment Manager`* `-DDmgrNodeName=`*`dmgr_node_name`*

      Note: Set the *db_type* in *db_type***.DmgrDbLibrary** to the type of database you are using, for example db2. The *local full path of the database jars on the Deployment Manager* is one of the following options:

      DB2 Type 2 driver: db2java.zip

      DB2 Type 4 driver: db2jcc4.jar:db2jcc_license_cu.jar

      DB2 for z/OS Type 2 driver: db2java.zip

      DB2 for z/OS Type 4 driver: db2jcc4.jar:db2jcc_license_cisuz.jar

      Oracle: ojdbc14.jar

      SQL Server JDBC driver that is provided by Microsoft: sqljdbc4.jar
   g. Run the following task on each node to create the variable that is used to access the VMM database JAR files. Include each node name as a comma-separated list in the command:
      - Linux : `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=`*`password`* `-DDbDomain=federated.db -DVmmNodeName=`*`node_name`*`,`*`node_name`*`,`*`node_name`* `-D`*`db_type`*`.NodeDbLibrary=`*`local full path of the database jars`*
      - IBM i: `ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=`*`password`* `-DDbDomain=federated.db -DVmmNodeName=`*`node_name`*`,`*`node_name`*`,`*`node_name`* `-D`*`db_type`*`.NodeDbLibrary=`*`local full path of the database jars`*
      - Windows: `ConfigEngine.bat wp-node-prep-vmm-db-secured-environment -DWasPassword=`*`password`* `-DDbDomain=federated.db`

```
-DVmmNodeName=node_name,node_name,node_name
-Ddb_type.NodeDbLibrary=local full path of the database jars
```

Note: VmmNodeName is a list of one or more WebSphere Portal Express nodes names in the cell which share database driver paths. Set the *db_type* in *db_type***.NodeDbLibrary** to the type of database you are using, for example db2.

h. Stop and restart all necessary servers to propagate your changes.

10. Run the following task to add a property extension repository to the federated LDAP repository:
    - Linux : `./ConfigEngine.sh wp-configure-la-complete -DWasPassword=password -DparentProperties=full path to wp_profile_root/ConfigEngine/config/helpers/wp_add_LA.properties`
    - IBM i: `ConfigEngine.sh wp-configure-la-complete -DWasPassword=password -DparentProperties=full path to wp_profile_root/ConfigEngine/config/helpers/wp_add_LA.properties`
    - Windows: `ConfigEngine.bat wp-configure-la-complete -DWasPassword=password -DparentProperties=full path to wp_profile_root/ConfigEngine/config/helpers/wp_add_LA.properties`
11. Stop and restart the appropriate servers to propagate the changes.
12. Specify values for the following parameters in `wp_add_LA.properties` file:

    Note: Go to the properties file for specific information about the parameters.

    la.providerURL

    la.propertyName

    la.entityTypes

    la.dataType

    la.multiValued

    Values for the dataType parameter: Available data types that are defined in `com.ibm.websphere.wim.SchemaConstants`:

    - `String`
    - `Int`
    - `Date`
    - `AnySimpleType`
    - `AnyURI`
    - `Boolean`
    - `Long`
    - `Double`
    - `Short`

    Note: A complete overview of valid **dataType** values can be found in the Configuring a property extension repository in a federated repository configuration file. All constant values of DATA_TYPE_* fields are valid input for **la.dataType**. Only the `String` data type is valid for displaying attributes in the Profile Management portlet. These attributes can be added to the Profile Management portlet through the configuration mode interface.

13. Complete the following steps to add the attribute to the property extension database:

    a. Run the following task:

Note: If the path name contains blank space, you must enclose the path in quotation marks.

- Linux : `./ConfigEngine.sh wp-add-la-property -DWasPassword=`*`password`* `-DparentProperties=`*`full path to wp_profile_root`*`/ConfigEngine/config/helpers/wp_add_LA.properties`
- IBM i: `ConfigEngine.sh wp-add-la-property -DWasPassword=`*`password`* `-DparentProperties=`*`full path to wp_profile_root`*`/ConfigEngine/config/helpers/wp_add_LA.properties`
- Windows: `ConfigEngine.bat wp-add-la-property -DWasPassword=`*`password`* `-DparentProperties=`*`full path to wp_profile_root`*`\ConfigEngine\config\helpers\wp_add_LA.properties`

b. Run the following task to add the attributes to Web Content Manager if you use user profiling or Category selection trees:

Note: If the path name contains blank space, you must enclose the path in quotation marks.

- Linux : `./ConfigEngine.sh add-wcm-la-attributes -DWasPassword=`*`password`* `-DparentProperties=`*`full path to wp_profile_root`*`/ConfigEngine/config/helpers/wp_add_LA.properties`
- IBM i: `ConfigEngine.sh add-wcm-la-attributes -DWasPassword=`*`password`* `-DparentProperties=`*`full path to wp_profile_root`*`/ConfigEngine/config/helpers/wp_add_LA.properties`
- Windows: `ConfigEngine.bat add-wcm-la-attributes -DWasPassword=`*`password`* `-DparentProperties=`*`full path to wp_profile_root`*`\ConfigEngine\config\helpers\wp_add_LA.properties`

Receiving an authentication prompt: This task makes an EJB call to WebSphere Application Server, which requires authentication. You might receive an authentication prompt. Enter the appropriate WebSphere Application Server user ID and password.

14. Stop and restart the appropriate servers to propagate the changes.

Deleting your user registry configurations

After you deploy IBM WebSphere Portal Express, you might not require some of the LDAP entity types, realms, realm base entries, or repositories that you created. You can delete these configurations to achieve the correct user registry configuration.

About this task

Choose from the following tasks to delete your user registry configurations:

"Deleting the LDAP entity type" on page 603
If you changed your LDAP user registry and no longer require an entity type, you can delete it.

"Deleting the base entry" on page 603
If you changed your LDAP user registry and no longer require a base entry, you can delete it.

"Deleting the LDAP group member" on page 605
If you changed your LDAP user registry and no longer require the group member, you can delete it from the LDAP user registry.

"Deleting the realm" on page 605
If you changed your IBM WebSphere Portal Express and no longer require a realm, you can delete it from your user registry.

"Deleting the realm base entry" on page 606
If you changed your realm and no longer require the base entry for that realm, you can delete it.

"Deleting the repository" on page 607
If you no longer require the use of a repository within your federated repository, you can delete it from your configuration.

Deleting the LDAP entity type

If you changed your LDAP user registry and no longer require an entity type, you can delete it.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

Procedure

1. Go to the *wp_profile_root*/ConfigEngine/properties directory.
2. Open the wkplc.properties file with a text editor.
3. Enter the following parameters under the VMM LDAP entity type configuration heading:

   Note: Go to the properties file for specific information about the parameters.

   et.ldap.id

   et.entityTypeName

   et.objectClass

   et.searchFilter

   et.objectClassesForCreate

   et.searchBases
4. Save your changes to the wkplc.properties file.
5. Open a command prompt.
6. Change to the *wp_profile_root*/ConfigEngine directory.
7. Optional: Run the following task to delete an LDAP entity type:
   - Linux : ./ConfigEngine.sh wp-delete-ldap-entitytype -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-delete-ldap-entitytype -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-delete-ldap-entitytype -DWasPassword=*password*
8. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Deleting the base entry

If you changed your LDAP user registry and no longer require a base entry, you can delete it.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

About this task

Important: If you delete a base entry from the default realm, then users who belong to that base entry can no longer log in to IBM WebSphere Portal Express. Therefore, the default realm must contain all the base entries for all active realms.

Procedure

1. Open a command prompt.
2. Change to the *wp_profile_root*/ConfigEngine directory.
3. Optional: Run the following task to list the base entries for a specific realm:
   - Linux : ./ConfigEngine.sh wp-query-realm-baseentry -DrealmName=*name_of_realm* -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-query-realm-baseentry -DrealmName=*name_of_realm* -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-query-realm-baseentry -DrealmName=*name_of_realm* -DWasPassword=*password*
4. Go to the *wp_profile_root*/ConfigEngine/properties directory.
5. Open the wkplc.properties file with a text editor.
6. Enter a value for the following parameters under the VMM realm configuration heading:

   Note: Go to the properties file for specific information about the parameters.

   realmName

   addBaseEntry
7. Save your changes to the wkplc.properties file.
8. Optional: Run the following task to delete a base entry from a realm configuration:
   - Linux : ./ConfigEngine.sh wp-delete-realm-baseentry -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-delete-realm-baseentry -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-delete-realm-baseentry -DWasPassword=*password*
9. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
10. Open the wkplc.properties file.
11. Enter a value for the following parameters under the VMM repository base entry configuration heading:

    id

    baseDN

    nameInRepository
12. Save your changes.

13. Optional: Run the following task to delete a base entry from a repository:
    - Linux : `./ConfigEngine.sh wp-delete-base-entry -DWasPassword=`*`password`*
    - IBM i: `ConfigEngine.sh wp-delete-base-entry -DWasPassword=`*`password`*
    - Windows: `ConfigEngine.bat wp-delete-base-entry -DWasPassword=`*`password`*
14. Stop and restart the appropriate servers to propagate the changes.

Deleting the LDAP group member

If you changed your LDAP user registry and no longer require the group member, you can delete it from the LDAP user registry.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

Procedure

1. Go to the *wp_profile_root*`/ConfigEngine/properties` directory.
2. Open the `wkplc.properties` file with a text editor.
3. Enter a value for the following parameters under the VMM LDAP group member attribute configuration heading:

   Note: Go to the properties file for specific information about the parameters.

   `gm.ldap.id`

   `gm.groupMemberName`
4. Save your changes to the `wkplc.properties` file.
5. Open a command prompt.
6. Change to the *wp_profile_root*`/ConfigEngine` directory.
7. Run the following task to delete the group member information for your LDAP user registry:
   - Linux : `./ConfigEngine.sh wp-delete-ldap-groupmember -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh wp-delete-ldap-groupmember -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat wp-delete-ldap-groupmember -DWasPassword=`*`password`*
8. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Deleting the realm

If you changed your IBM WebSphere Portal Express and no longer require a realm, you can delete it from your user registry.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

Procedure

1. Open a command prompt.
2. Change to the *wp_profile_root*/ConfigEngine directory.
3. Optional: Run the following task to list the names and types of configured repositories:
   - Linux : ./ConfigEngine.sh wp-delete-realm -DdeleteRealmName=*name_of_realm* -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-delete-realm -DdeleteRealmName=*name_of_realm* -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-delete-realm -DdeleteRealmName=*name_of_realm* -DWasPassword=*password*
4. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Deleting the realm base entry

If you changed your realm and no longer require the base entry for that realm, you can delete it.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

About this task

Important: If you delete a base entry from the default realm, then users who belong to that base entry can no longer log in to IBM WebSphere Portal Express. Therefore, the default realm must contain all the base entries for all active realms.

Procedure

1. Open a command prompt.
2. Change to the *wp_profile_root*/ConfigEngine directory.
3. Optional: Run the following task to list the base entries for a specific realm:
   - Linux : ./ConfigEngine.sh wp-query-realm-baseentry -DrealmName=*name_of_realm* -DWasPassword=*password*
   - IBM i: ConfigEngine.sh wp-query-realm-baseentry -DrealmName=*name_of_realm* -DWasPassword=*password*
   - Windows: ConfigEngine.bat wp-query-realm-baseentry -DrealmName=*name_of_realm* -DWasPassword=*password*
4. Go to the *wp_profile_root*/ConfigEngine/properties directory.
5. Open the wkplc.properties file with a text editor.
6. Enter a value for the following parameters under the VMM realm configuration heading:

   Note: Go to the properties file for specific information about the parameters.

   realmName

   addBaseEntry
7. Save your changes to the wkplc.properties file.

8. Optional: Run the following task to delete a base entry from a realm configuration:
   - Linux : `./ConfigEngine.sh wp-delete-realm-baseentry -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh wp-delete-realm-baseentry -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat wp-delete-realm-baseentry -DWasPassword=`*`password`*
9. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.

Deleting the repository

If you no longer require the use of a repository within your federated repository, you can delete it from your configuration.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

Procedure

1. Open a command prompt.
2. Change to the *wp_profile_root*`/ConfigEngine` directory.
3. Optional: Run the following task to list the names and types of configured repositories:
   - Linux : `./ConfigEngine.sh wp-query-repository -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh wp-query-repository -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat wp-query-repository -DWasPassword=`*`password`*
4. Go to the *wp_profile_root*`/ConfigEngine/properties` directory.
5. Open the `wkplc.properties` file with a text editor.
6. Enter the following parameters in the `wkplc.properties` file under VMM Delete federated repository heading:

   Note: Go to the properties file for specific information about the parameters.

   `federated.delete.baseentry`

   `federated.delete.id`
7. Save your changes to the `wkplc.properties` file.
8. Run the following task to delete the required repository:
   - Linux : `./ConfigEngine.sh wp-delete-repository -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh wp-delete-repository -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat wp-delete-repository -DWasPassword=`*`password`*
9. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
10. If the deleted repository contains the base entry where new users and groups are stored, run the update entity types task. Use this task to select a new base entry to store the new users and groups.

Search

You use Portal Search to search for text that is displayed in websites that are created by IBM Web Content Manager.

1. "Searching pages" on page 609
   By selecting a search type in Manage Pages, you can quickly locate and work with pages, labels, or URLs.
2. "Searching for tagged content" on page 610
   Users can search the tag space by using the browser search box.
3. "Planning and preparing for Portal Search" on page 611
   Learn about some planning considerations and first steps that you need to apply before working with Portal Search.
4. "Indexing web content" on page 616
   To search for web content, your content must first be indexed by the WebSphere Portal search engine. When the content is indexed, you can run searches by using the search center or by using a search component. If you search for documents in the WebSphere Portal search center, be aware that you see search results for published documents only. Unpublished pending changes in a project are not included in the results.
5. "Configuring Web Content Manager search options" on page 618
   You can edit the following search options to manage how the search service works with Web Content Manager search forms
6. Optional: "Configuring Search Center to search for web content" on page 620
   You can use the Search Center to search for web content by adding a web content search collection to the Search Center.
7. "Language and region support in Portal Search" on page 620
   Depending on your portal environment and your users, you might want to make multilingual content available and searchable in your portal.
8. "Crawling web content with search seedlists" on page 622
   Portal Search supports the use of seedlists to make crawling websites and their metadata more efficient and to provide content owners fine-grained control over how content and metadata are crawled. You can configure the portal to use seedlist support when crawling content generated with IBM Web Content Manager.
9. "Searching your local portal " on page 627
   View information on setting up your local portal for your users to search.
10. "Configuring your portal site for search by internet search engines" on page 636
    You can enable your portal site for search by using search services such as Google or Yahoo! Search on your portal site by external search services works for public portal pages only, that is, for pages that users can access without a user ID and password.
11. "Enabling anonymous users to search public pages of your portal" on page 641
    You can enable anonymous users (sometimes also called unauthenticated users) to search public pages of your portal by using the portal Search Center portlet. Search by anonymous users works only on public pages of your portal, as the users are not logged in to your portal.
12. "Configuring your custom portal themes to include the search box" on page 644
    Enable your portal users to use the Portal Search box and Search portlet in your own custom theme.

13. "Redirecting search requests from a custom search form to the Search Center" on page 645
    If you plan to develop a custom search form, you might want to redirect search requests issued by the search form to the Search Center.
14. "Remote search service" on page 645
    You can configure the search portlets for local operation, or you can configure them for remote search service. Depending on your configuration, remote search service might have performance benefits by offloading and balancing system load.
15. "Configuring search in a cluster" on page 662
    IBM WebSphere Portal Express provides two distinct search capabilities. You can use both types of search capabilities in a clustered environment.
16. "Configuring search in a portal farm" on page 664
    IBM WebSphere Portal Express provides two distinct search capabilities. You can use both types of search capabilities in a portal farm environment.
17. "Configuring search collections for a virtual portal" on page 666
    Configuring JCR search collections for a virtual portal might require additional administration, depending on how you set up the virtual portal.
18. "" on page 667
    Use Portal Search to facilitate indexing content sources and searching for information. You can administer search services, search collections, and search scopes, as well as enhance the search experience of your portal site with the portal search portlets.

Searching pages

By selecting a search type in Manage Pages, you can quickly locate and work with pages, labels, or URLs.

About this task

Follow these instructions to search for an item.

Procedure

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. Select the search type from the **Search by** drop-down menu.
3. Enter the search parameters in the **Search** field.
4. Click **Search**.

   Note: Searches for users or user groups can be case-sensitive, depending on the attributes that are used.

   Search Types:

   The following is a list of some search types that can be selected from the Search by: drop-down menu. The search types available depend on the resource type used.

   - **Title starts with**: Select this option to search on the beginning of a string in the title. This option is the default setting, and the input is expected in string format.
   - **Title contains**: Select this option to search on a string in the title. The input is expected in string format.
   - **Name starts with**: Select this option to search on the beginning of a string in the name. The input is expected in string format.

- **Name contains**: Select this option to search on a string in the name. The input is expected in string format.
- **Keyword starts with**: Select this option to search on the beginning of a keyword. The input is expected in string format.
- **Keyword contains**: Select this option to search on a keyword. The input is expected in string format.
- **Description starts with**: Select this option to search on the beginning of a string in the description. The input is expected in string format.
- **Description contains**: Select this option to search on a string in description. The input is expected in string format.
- **Unique Name contains**: Select this option to search on a string in the unique name. The input is expected in string format.
- **Markup supported**: Select this option to search the beginning of a string in the markup type. This option returns a list of pages that support that markup. The input is expected in string format.
- **Label**: Select this option to search on a URL context label.
- **Attributes**: Select this option to search on a user or group attribute.
- **Last modified**: Select this option to search by items that have been modified on or since a specific date. The input is expected in YYYY MM DD format.
- **All available**: Select this option to return a listing of all items. No input is required.

Searching for tagged content

Users can search the tag space by using the browser search box.

This works only for browsers that support OpenSearch. For details refer to http://www.opensearch.org/Home. OpenSearch is a collection of technologies that allow publishing of search results in a format suitable for syndication and aggregation. It is a way for Web sites and search engines to publish search results in a standardized and accessible format.

To be able to search for tagged content from non-portal pages, visit the portal site, navigate to where your browser allows you to add or remove search engines and add the search engine named WebSphere Portal Express Tagging Search Service. For details about how to do this refer to the documentation for your browser. After you added the search service to your browser, you can search the tag space of the Portal via this search service.

The tagging search service searches only the portal site at which the service was added. For example, if you use Firefox to access two different portal servers `server1` and `server2`, and you then add the WebSphere Portal Express Tagging Search Service at server1. If you then navigate to server2 and try to search for a tag, the search service searches server1 for the specified tag, not server2.

Advantages are as follows:

- Users can search for tagged content from pages that do not have a tag cloud, for example from Web pages external to the portal.
- When a user searches for a tag, the portal redirects the user to the All view of the tag cloud. The search results are shown in the tag results list. The user can now work the results.
- The tag result list shows **all** resources that have the searched tag.

- The search has type-ahead support. The following features make tag search easier:
  - As the user types text, one or more possible matches for the text are found and immediately presented to the user. This immediate feedback allows the user to stop short of typing the entire word or phrase they were looking for. The user can also choose a closely related tag from the presented list.
  - It starts after the user has typed the third character of the searched tag.
  - As the user types more characters, the type-ahead support filters and narrows the search progressively.
  - The suggested tags are sorted by their relevance: tags that have been applied more often will be suggested before tags that have not been assigned often.
  - Suggestions and the search results are provided according to the normalization configuration: if no normalization is configured, the suggestions and the search is case sensitive.

By default the searches are case sensitive. If you want to perform a case insensitive search, an administrator needs to enable tag normalization in the CP Configuration Service. For details refer to the topic about the CP Configuration Service for tagging and rating

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Related reference:

"Querying for the OpenSearch description document" on page 3190
You can query for the OpenSearch description document.

"CP Configuration Service for tagging and rating" on page 312
The CP Configuration Service provides the properties for tagging and rating.

"Type-ahead feature for the deprecated tag widget" on page 1306
The tag widget from earlier IBM WebSphere Portal Express versions provided a type-ahead feature. With portal V 8.5, that tag widget is deprecated. The type-ahead feature makes it easier for users to find suitable tags. Type-ahead supports users when they work with tags. For example, when users apply tags using the tag widget, or when they search for tags, for example by using the open search functionality, type-ahead provides users suggestions for tags that other users have applied already before. Type-ahead can also help reduce the number of variants of tags.

Planning and preparing for Portal Search

Learn about some planning considerations and first steps that you need to apply before working with Portal Search.

Make sure you read all of the following sections and also the topic about Hints and tips for using Portal Search.

For an administrative overview of the Portal Search portlets, refer to the topic about Portlets for working with Portal Search.

Portal Search is preconfigured with a search service, a portal site search collection, and scopes. You can add, modify, and remove search services, collections, and scopes.

To enhance your possibilities of working with search, you can install additional portlets related to Portal Search and apply special configurations. For information about how to do this refer to the subtopics of Administering Portal Search.

To prevent errors during crawls and ensure easy viewing of documents for users you need to enable Document Conversion Services. For more information see *Enabling Document Conversion Services*.

Security considerations

Learn about the security aspects that you need to consider with regards to content search in IBM WebSphere Portal Express Version 8.5.

"Search on secured Portal Search collections and other secured content sources" on page 613
Portal search collections are portal resources. You can therefore secure them through Portal Access Control. Consequently, users can only access and search collections to which they have access permission.

"Searching on secured portal sites and pages and content management items" on page 613
For search on a secured local portal site, Portal Search provides a pre-configured search collection. You can also set up your own search collection for searching your portal site.

"Encrypting sensitive data" on page 614
When you create a new content source using the Manage Search portlet, some secured content sources require that you enter sensitive data. For example, this can be the user ID and password of the crawler user ID required for accessing the secured content source. When you later export the configuration of the search collection, you might want to protect the sensitive data. You can encrypt such sensitive data so that it is not stored as plain text on the hard drive. If you do not encrypt such data, the data is not included in the export.

"Configuring web server security" on page 615
For security reasons, the portal search seedlist by default redirects to HTTPs. Therefore, you need to configure your web server for HTTPs.

Search on secured Portal Search collections and other secured content sources:

Portal search collections are portal resources. You can therefore secure them through Portal Access Control. Consequently, users can only access and search collections to which they have access permission.

About this task

The Search Center portlet checks for access permissions of the searching users. It searches only in those search collections to which the users have access permission. For example, in the Search Center users see only the scopes containing search collections to which they have access.

Apply special care when giving users access through the search portlets to sensitive information such as web pages that have been collected from a secured website. Ideally, give only those users access permission for a search collection who have also access to the corresponding website that is being indexed and searched. Otherwise users might see documents listed, but cannot actually access them by clicking the respective link or URL. A user might see part of the information via the document summary, even if the user cannot open the document.

Searching on secured portal sites and pages and content management items:

For search on a secured local portal site, Portal Search provides a pre-configured search collection. You can also set up your own search collection for searching your portal site.

About this task

If you want to set up your own search collection for searching your portal site, you must apply special security considerations. Create a dedicated crawler user ID. Then, give that user ID access permission to the portlets and portal pages that you want to be available for search by users. For detailed information, refer to *Customizing your search collection for secured portal pages*.

Notes:

1. IBM Web Content Manager documents can be searched by portal users, as they are secured by Portal Access Control. Users can search documents to which they have the required access permissions on sites where search is enabled. For details about content security, refer to *User roles and access*. For information about configuring Portal Search on Web Content Manager, refer to *Indexing web content*.
2. Set the preferred language of the portal site crawler user ID to match the language of the portal site search collection that it crawls. If you set the language after you started a crawl, you must reset the portal site collection. Refer to *Creating or resetting the portal site collection*.

Related concepts:

"User roles and access" on page 1560
Different users will have different access to items and functions in your system depending on the role they are assigned. Roles can be assigned at the library level, and also assigned on individual items.

"Indexing web content" on page 616
To search for web content, your content must first be indexed by the WebSphere Portal search engine. When the content is indexed, you can run searches by using the search center or by using a search component. If you search for documents in the WebSphere Portal search center, be aware that you see search results for published documents only. Unpublished pending changes in a project are not included in the results.

Related tasks:

"Customizing your search collection for secured portal pages" on page 635
Set up your own customized search collection for searching a secured portal site.

"Resetting the default search collection" on page 711
Under certain circumstances, you might want to change the configuration of the portal site search collection. In this case, you must re-create the collection, as search collections cannot be modified.

Encrypting sensitive data:

When you create a new content source using the Manage Search portlet, some secured content sources require that you enter sensitive data. For example, this can be the user ID and password of the crawler user ID required for accessing the secured content source. When you later export the configuration of the search collection, you might want to protect the sensitive data. You can encrypt such sensitive data so that it is not stored as plain text on the hard drive. If you do not encrypt such data, the data is not included in the export.

About this task

For example, consider the case of content sources in the form of secured portal sites or HTTP sites that require a user ID and password. This sensitive data is stored on the portal server hard drive in plain text unless you choose to encrypt it. In order to ensure that such sensitive data is encrypted, perform the following procedure after portal installation:

Procedure

1. Copy the file `searchsecret.xml` to a temporary directory *temp* . The original file is located in the following directory:
   - For Linux: *PortalServer_root*`/search/wp.search.admin/bin`
   - For IBM i: *PortalServer_root*`/search/wp.search.admin/bin`
   - For Windows: *PortalServer_root*`\search\wp.search.admin\bin`
2.
3. Replace the string *CHANGE TO YOUR SECRET KEY* with a random string of your choice.
4. Run the updated file `searchsecret.xml` by using the XML configuration interface command:

   ```
   xmlaccess.sh|bat -in searchsecret.xml -out results.xml
                    -user wpsadmin -pwd wpsadmin
                    -url http://local_host:local_port/wps/config
   ```

   a. Specify the file name using the `-in` option.
   b. Specify a result file using the `-out` option.
   c. Check the result file to make sure that the XML request was executed successfully.

The script creates a slot called `search.secret` in the credential vault. Portal search uses this slot to encrypt the passwords configured for crawlers. If this slot does not exist, the password is saved as clear text on the portal server hard drive. The file `xmlaccess.sh|bat` is located in the directory *PortalServer_root*`/bin`. Example of the full command syntax for running the script `searchsecret.xml`:

```
PortalServer_root/bin/xmlaccess.sh|bat -in temp/searchsearchsecret.xml
     -user wpsadmin -password wpsadmin -url http://localhost:10039/wps/config
```

For more details about how to use the XML configuration interface, refer to the topics about the XML configuration interface, especially about Working with the XML configuration interface.

5. Delete the copied file `searchsecret.xml` that contains your encryption key.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Configuring web server security:

For security reasons, the portal search seedlist by default redirects to HTTPs. Therefore, you need to configure your web server for HTTPs.

About this task

For information about how to do this, go to the *Installing* section of the WebSphere Portal Express documentation. Select the appropriate operating system for your installation, and then the subsection for a stand-alone or clustered environment. Then, select the topic about *Preparing a remote Web server*.

What to do next

If you do not want to provide HTTPs security for your portal search seedlist, you can configure portal search to use HTTP only. To do this, run the configuration task `action-modify-servlet-transport-guarantee-none-wp.search.servlets/seedlist/servletEAR`. Use the following syntax, depending on your environment:

IBM i
```
ConfigEngine.sh action-modify-servlet-transport-guarantee-none-
wp.search.servlets/seedlist/servletEAR -DPortalAdminPwd=password
-DWasPassword=password
```

Linux
```
./ConfigEngine.sh action-modify-servlet-transport-guarantee-none-
wp.search.servlets/seedlist/servletEAR -DPortalAdminPwd=password
-DWasPassword=password
```

Windows
```
ConfigEngine.bat action-modify-servlet-transport-guarantee-none-
wp.search.servlets/seedlist/servletEAR -DPortalAdminPwd=password
-DWasPassword=password
```

For your updates to take effect, restart your portal server.

Indexing web content

To search for web content, your content must first be indexed by the WebSphere Portal search engine. When the content is indexed, you can run searches by using the search center or by using a search component. If you search for documents in the WebSphere Portal search center, be aware that you see search results for published documents only. Unpublished pending changes in a project are not included in the results.

Creating a content source for a site area

The WebSphere Portal search engine defines content sources that index your web content. All the child site areas and content items of the selected site area is included in the index. Related content sources are grouped in a search collection.

1. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
2. Select or create a new collection. The default search collection that is named **WebContentCollection** is provided by default.
3. Click **New Content Source**.
4. Select **WCM site** as the content source type.
5. Enter a name in the **Content Source Name** field.
6. Enter the following URL in the **Collect documents linked from this URL** field:

   For a stand-alone server:

```
http://hostname:port_number/wps/seedlist/myserver?SeedlistId=library/sitearea1/childsitearea2
&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

   You need to replace **hostname**, **port_number**, **library**, and **site area** with values appropriate for your site. If your library name or site area names contain spaces, you need to replace the spaces with a "+" symbol. For example, the path `library one/site area one` would instead be defined as `library+one/site+area+one`

   For a cluster:

   In this case you to use the host and port of the HTTP server:

```
http://httpserver:port_number/wps/seedlist/myserver?SeedlistId=library/sitearea1/childsitearea2
&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

   You need to replace **httpserver**, **port_number**, **library**, and **site area** with values appropriate for your site. If your library name or site area names contain spaces, you need to replace the spaces with a "+" symbol. For example, the path `library one/site area one` would instead be defined as `library+one/site+area+one`

   For a virtual portal configured to use the URL Context as its access point:

```
http://httpserver:port_number/wps/seedlist/myserver/virtualPortalContext?SeedlistId=library/sitearea1/childsitearea2
&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

   You need to replace **httpserver**, **port_number**, **virtualPortalContext**, **library**, and **site area** with values appropriate for your site. If your library name or site area names contain spaces, you need to replace the spaces with a "+" symbol. For example, the path `library one/site area one` would instead be defined as `library+one/site+area+one`

   For a virtual portal configured to use a different hostname as its access point:

```
http://vphostname:port_number/wps/seedlist/myserver/?SeedlistId=library/sitearea1/childsitearea2
&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

You need to replace **vphostname**, **port_number**, **library**, and **site area** with values appropriate for your site. If your library name or site area names contain spaces, you need to replace the spaces with a "+" symbol. For example, the path `library one/site area one` would instead be defined as `library+one/site+area+one`

Note: The seedlist ID can be any of the following:

- library
- library/site area
- library/site area/sub-site area/...
- the JCRID of a site area

7. If the content to be indexed is secured, go to the **Security** tab. Then, enter the user name and password of the user that is used to access the secured site. You must then click **Create** on the search tab itself.
8. If your site uses remote actions, you need to filter these actions out of your search index. Go to the **Filter** tab:
   a. Type a name in the **Rule Name** field
   b. Select **Apply rule while Collecting documents**
   c. Select the rule type of **Exclude**
   d. Select the rule basis of **URL text**
   e. Type `*&wcmAuthoringAction=*` in the **URL text** field
   f. Click **Create** in the Filter tab
9. Click **Create**.

If you have multiple parent site areas and want your searches to run across all site areas, create a content source for each of them in the same collection. If you do not want your searches to run across all parent site areas, create a separate collection for each parent site area or group of related parent site areas.

Searching web content in a virtual portal

Search services and search collections are separate for individual virtual portals and are not shared between individual virtual portals. You set up an individual search service and separate search collections for each virtual portal. These collections can be used to crawl and search the same set of documents.

If you are using a website that is shared across virtual portals, then to search that website in a virtual portal environment you must:

1. Create new search collection for the virtual portal. You can create a new content source by copying the URL from your original search collection.
2. Create new search component, or copy an existing search component, and configure it to use the new virtual portal search collection that is created in step 1.
3. Create new search form, by using an HTML component, which is configured to use the search component that is created in step 2.
4. Create new content item to display the HTML component that is created in step 3.

You must do these steps for each virtual portal in your system.

"Indexing web content in a multilingual environment" on page 618
Learn about the best practices for indexing web content if you are working with a multilingual Web Content Manager site.

Indexing web content in a multilingual environment

Learn about the best practices for indexing web content if you are working with a multilingual Web Content Manager site.

For example, if you work in French and Italian languages in your Web Content Manager site, consider the following recommendations:

1. Organize your web content in language-specific libraries. Create one library per language, for example, one library for French and one library for Italian. You can specify the language when you create the library.
2. Create language-specific search collections for the libraries you created. For example, create a search collection for your French library and a separate search collection for your Italian library. You can specify the language when you create the collection.
3. For each search collection, create one content source for each content source type. For example, for the French library search collection, create one content source for French site content and one for French Portal site content. Similarly, create content sources for your Italian library search collection as well.
   - To create a content source for site content, in the **Content source type** field, specify **WCM site**. In the **Collect documents linked from this URL** field, enter the URL that refers to the language-specific library that you want to use. Ensure that the language of your library matches the language of the search collection.
   - To create a content source for each of your supported portal site languages. In the **Content source type** field, specify **Portal site**. Add the content source to the search collection that you already created for the web content of the same language.

For more information about searching multilingual sites, go to Crawling a multilingual portal site in the related links.

Configuring Web Content Manager search options

You can edit the following search options to manage how the search service works with Web Content Manager search forms

About this task

You can edit the following search options to manage how the search service works with Web Content Manager search forms

Procedure

1. Open WebSphere Integrated Solutions Console to configure the **WCM SearchService** properties. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
2. Select **WCM SearchService, Custom** properties.
3. Specify values for the search parameters.

   SearchService.DateFormatString
   This parameter is used to set the date format when dates are entered in

search forms and for displaying search results. Enter a supported Java date format string. If this property is not set, then the default format is *MMM dd yyyy HH:mm:ss z*.

SearchService.RecrawlInterval
This parameter is the recrawl interval in hours.

SearchService.BrokenLinksExpirationAge
This parameter is the default broken links expiration age in days.

SearchService.MetaFields
This parameter is used to specify extra elements to crawl when searching for metadata.

The format for this parameter value is: `elementName,key1`

To specify more than one metadata field maps, use the following format:

```
elementName1,key1;elementName2,key2;elementName3,key3
```

For example, to crawl for metadata in a text element named metaText:

- `SearchService.MetaFields=metaText,meta`
- `elementName` is the name of element you would like to search for metadata. Any valid element with that name in a searchable site area or content item is crawled.
- `key` is the "key" that is specified in an element tag that is used as part of a search element design. In the previous example, the key of "meta" is used. To render the content of the metaText element in a search element design, you would use the following tag: `<Element context="autoFill" type="content" key="meta"/>`

Note:

- Only text elements and short text elements can be searched.
- Only site areas that are configured to be searchable are crawled.

SearchService.SearchSeed.ExcludeFileAttachments=false
Set this parameter to `true` to prevent file resource component attachments from being included in the search results.

If set to false, the files that are stored in file resource elements in content items can also be searched. Files that are stored in file resource elements in a site area can also be searched so long as a default content item is selected.

SearchService.SearchSeed.excludeExtensions
Set this parameter to a list of file name extensions that you want to exclude from search results. Separate each item in the list with a comma. Any file resource component attachments and file resource element attachments that have these extensions are excluded from search results. For example, `SearchService.SearchSeed.excludeExtensions=avi,mpeg,zip`.

4. Click **Apply** and then **OK**.
5. Restart the portal for the new settings to take effect.
6. Delete and create a new search collection for changes to take effect.

Configuring Search Center to search for web content

You can use the Search Center to search for web content by adding a web content search collection to the Search Center.

Procedure

1. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
2. Click **Search Scopes**.
3. Click **New Scope**.
4. Click **Select Locations** and select your web content search collection.
5. Complete the search scope and click **OK**.

Language and region support in Portal Search

Depending on your portal environment and your users, you might want to make multilingual content available and searchable in your portal.

"Language support and multilingual sites"
Internet search engines usually take care of language support in terms of language determination and language specific processing.

"Region support and multi-regional sites"
Global companies might choose to publish content, and offer products or services specifically for certain regions. While today a language can be detected, there is no technical solution available to detect a region.

Language support and multilingual sites

Internet search engines usually take care of language support in terms of language determination and language specific processing.

The language information need not be carried in the URLs itself, nor in language specific metadata in the HTML source of the respective page. In most cases it is good practice to encode the content of pages by using UTF-8 encoding.

If the site is a multilingual site, then enable the web crawlers to get to the content in the various languages through links. Enabling language switching or selection based on either the cookie of a returning customer or using JavaScript to switch from one language to the other, will lock out web crawlers. Therefore in such a case the crawler picks up the content in the default language only. You can also check the webmaster recommendations published by the internet search providers for further details and suggestions.

Region support and multi-regional sites

Global companies might choose to publish content, and offer products or services specifically for certain regions. While today a language can be detected, there is no technical solution available to detect a region.

In this context you need to distinguish between the various regions; in this context the term 'region' is sometimes used synonymous with 'country'.

As was described for language identification in the topic about language support by Portal Search, Internet search engines also find that location or region specific metadata is not reliable enough to use it for region detection. Consequently crawlers expect the URL to carry region specific information. The most obvious is that the top-level domain name carries the country code and thereby the region

information. For example, a domain name such as XYZ-Co.fr or XYZ-Co.co.jp strongly indicates that the company resides or operates either in France or Japan.

If top-level domain names are used, no further action is required to allow region identification of that website. However, for more generic domain names such as .com or .eu , additional steps are required for enablement. In such cases you need to encode the region information in the URL, and pair it with tools provided by Internet search engines, such as Google Webmaster Tools for Geographic Targeting.

"Enabling region identification in WebSphere Portal Express"
You can use geographic targeting tools to associate a URL pattern with a specific region. However not all URL patterns are typically supported.

Enabling region identification in WebSphere Portal Express:

You can use geographic targeting tools to associate a URL pattern with a specific region. However not all URL patterns are typically supported.

About this task

URL patterns that are not supported have the region or country information encoded as a string value in a parameter list, such as www.XYZ-Co.com/products/information/?article=ABC123?country=UK . The following options are supported:

- Subdomains with generic domains, such as de.XYZ-Co.com
- Subdirectories with generic domains, for example www.XYZ-Co.com/es/...

You can configure top-level domain names with country codes and subdomains with generic domain by using standard portal configuration steps. However, when you write the region information into the relative path of a Portal URL, you need to adapt the portal site structure to differentiate between pages and page groups for a specific country. If you use Web Content Manager to deliver the content into the portal, this has implications as to how the content is managed and organized in the library or libraries. In both cases, the portal capabilities of rendering user friendly URLs is important. You have two options to handle this situation. They are described in the following.

Procedure

- The first option is based on the assumption that the site is split up at a certain point to reflect the different regions or countries. A typical scenario can be either an online shop or a product overview specific to the countries in which a company operates. Example URLs might then look as follows:
  - For the US: http://www.xyz-co.com/home/products/us/
  - For France: http://www.xyz-co.com/home/products/fr/
  - For Italy: http://www.xyz-co.com/home/products/it/

  To achieve this, set the friendly name of the top-level page that serves as the entry page for a specific country, with the appropriate country code as the identifier that is then published by means of the URL. Note that you need to assign friendly names in the whole hierarchy of all pages that can be identified as a page for a certain region. The previous example would result in two main unique portal pages:
  - home
  - products This has three region specifics pages: us , fr , and it .
- The second option has the same first two levels in its page hierarchy as the first: home and products . The products page renders the content based on user

selection or preference. Then Web Content Manager delivers the content for the chosen country. The association of a web page with a set of content items in the Web Content Manager library is done by using site areas. The names of the site areas represent the country codes. Three portal "content" pages are added to the `products` page associated with the site areas. In the example, this adds three region-specific portal pages that are associated with the site areas `us` , `fr` , and `it` . For more information, about friendly URLs see the topics about friendly URLs.

Related concepts:

"About friendly URLs for web content" on page 2041
With friendly URLs for web content, you can construct URLs to content items that are clear and concise. Although you can construct friendly URLs that reference web content items, IBM Web Content Manager itself does not generate friendly URLs by default. However, to cause the web content viewer to generate friendly URLs, you can create a plug-in that implements a content URL generation filter.

Related tasks:

"Using friendly URLs" on page 1280
You can associate friendly URLs with portal pages and labels. You and your users can use these friendly URLs to access specific portal pages or labels by using a human readable path, which is easy to remember.

Crawling web content with search seedlists

Portal Search supports the use of seedlists to make crawling websites and their metadata more efficient and to provide content owners fine-grained control over how content and metadata are crawled. You can configure the portal to use seedlist support when crawling content generated with IBM Web Content Manager.

About this task

By default Portal Search is configured to use seedlist format 1.0 when indexing content for search collections. When used with web content, seedlist format 1.0 makes it possible to use the web content page type to render content that is found in the search results on the corresponding web content page. You can also include custom metadata fields from a web content item that appears in the search seedlist but not in the HTML source.

Search seedlist 1.0 can make access control information available in a way that makes pre-filtering of contents possible. Pre-filtering provides the fastest filtering approach because it takes place in the search index level. An extra advantage of pre-filtering is that remote secured content sources can be searched from the portal. The filtering mode is defined as part of the search service configuration parameters.

Note: Support for generic seedlist 1.0 crawling is only available with IBM OmniFind® Enterprise Edition Version 9.1 and later.

"The search seedlist 1.0 format"
Portal Search is configured to support the IBM Web Content Manager search seedlist 1.0 format by default.

The search seedlist 1.0 format

Portal Search is configured to support the IBM Web Content Manager search seedlist 1.0 format by default.

About this task

Search seedlist 1.0 provides several features:

- You can use the web content page type to render content that is found in the search results on the corresponding web content page.
- You can include custom metadata fields from a web content item that appear in the search seedlist but not in the HTML source.
- You can search within a specific library or site area, across all web content libraries, or across a list of libraries.
- You can run incremental crawling of libraries for faster seedlist processing. With incremental crawling, when a crawl requests new items, only items that have been added, changed, or deleted since the previous crawl are retrieved.

Important: The syntax of the seedlist URL has changed with seedlist format 1.0. Older search collections that are created by using seedlist format 0.9 cannot be reused or migrated to the new format. Be sure that you index all your content again after you update the Web Content Manager seedlist format from 0.9 to 1.0.

Search seedlist 1.0 can make access control information available in a way that makes pre-filtering of contents possible. Pre-filtering provides the fastest filtering approach because it takes place in the search index level. Another advantage of pre-filtering is that remote secured content sources can be searched from the portal. The filtering mode is defined as part of the search service configuration parameters.

Restriction: The seedlist must only be used for search. For example, do not use the seedlist as an alternative logging method. For the purposes of event logging, the Java messaging service (JMS) is used.

"Enabling support for search seedlist 1.0"
If you want to use Portal Search to crawl your web content and use features like web content pages, you must enable seedlist 1.0 support for the Portal Search crawler.

"Customizing metadata field search support" on page 624
With the search seedlist 1.0 support, custom metadata fields that are specified on content items are added to the search seedlist as metadata information, without requiring the metadata to appear in the HTML source for the content items.

"Seedlist 1.0 REST service API" on page 625
The IBM Web Content Manager API for retrieving application content through a seedlist is based on the REST architecture style. To obtain seedlist content, third-party crawlers or administrator applications need to construct and send only HTTP requests to the application servlet.

Enabling support for search seedlist 1.0:

If you want to use Portal Search to crawl your web content and use features like web content pages, you must enable seedlist 1.0 support for the Portal Search crawler.

Procedure

1. Log in to the portal as an administrator.
2. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
3. To create a new search collection,

a. Click **Search Collections**.
b. Create a new search collection for your web content. Be sure that the new search collection uses the portal search service that is edited in the previous steps.

4. Add the following custom properties to the `WP ConfigService` resource environment by using the WebSphere Integrated Solutions Console:
   a. wcm.config.seedlist.version=1.0
   b. wcm.config.seedlist.servletpath=/seedlist
   c. wcm.config.seedlist.metakeys=<metakey1>,<metakey2> This is an optional step and is only required if you want to specify your own metadata.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Customizing metadata field search support:

With the search seedlist 1.0 support, custom metadata fields that are specified on content items are added to the search seedlist as metadata information, without requiring the metadata to appear in the HTML source for the content items.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP ConfigService**.
4. Under **Additional Properties**, click **Custom Properties**.
5. Click **New**, and enter the property name `wcm.config.seedlist.metakeys` , and set the string value to a comma-delimited list of your own metadata (for example, *<metakey1, metakey2>*).

   Add the names of the text element from your content to include in the search results to the `wcm.config.seedlist.metakeys` property. If you want to add more than one text element, separate them with commas. The name of the text element on your content item included in the search seedlist must match the name that is configured for this configuration key.

   For example, set `wcm.config.seedlist.metakeys=language,region` in the WP ConfigService resource environment provider, and add a IBM Web Content Manager text component as an element with the name `language` to a content item or authoring template. In your content item, you can enter the value `german` into the text component for the language. After you save the content item, the search crawler will add the value `german` into a metadata field that is called `language` within the search seedlist. Then, you can filter the search results based on your metadata information.
6. Click **OK**, and save the changes to the master configuration.
7. Restart the portal.

Seedlist 1.0 REST service API:

The IBM Web Content Manager API for retrieving application content through a seedlist is based on the REST architecture style. To obtain seedlist content, third-party crawlers or administrator applications need to construct and send only HTTP requests to the application servlet.

All REST API requests are synchronous calls. The order of the parameters in the requests does not matter. The parameter names are case-sensitive and must be entered in the format described here. An HTTP error response (for example, status code 404) is generated in the following situations:

- An unknown or unsupported parameter is submitted as part of the request.
- Web Content Manager cannot resolve the site area path or ID.
- Web Content Manager cannot find any items.
- The search seedlist enterprise application (Seedlist_Servlet) is not running.

The request is a standard HTTP GET command. The URL is formed by combining the seedlist servlet host name, port number, and path, followed by a collection of input parameters that are separated by ampersand (&) characters. The input parameters are entered as name-value pairs.

For example:

```
http://host_name:port_number/wps/seedlist/myserver?SeedlistId=library_list&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=action&Range=number_of_entries
```

library_list
One or more web content libraries, which are separated by commas. If no value is specified, all libraries are used.

action The action to run on the request. The following actions are available:

GetDocuments
Retrieves a list of content items with their associated information.

number_of_entries
For each seedlist page that is returned, this value specifies the number of entries in the list of content items. If no value is specified, 100 items are returned.

Examples

In these examples, replace the following variables with values that are appropriate for your environment:

- *host_name*
- *virtual_portal_host_name*
- *http_server*
- *port_number*
- *library*
- *site_area*
- *site_area_id*

For the **SeedlistId** parameter, you can specify the value in the following formats:

- No value
- A specific library (for example, *library1*)
- A specific site area (for example, *site_area1*)

- A list of libraries, which are separated by commas (for example, *library1*,*library2*,*library3*)
- The JCRID of a site area

Retrieve a maximum of 100 items from a stand-alone server by using the path to the site area

```
http://host_name:port_number/wps/seedlist/myserver?SeedlistId=library/site_area&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

Retrieve a maximum of 200 items from a stand-alone server by using the ID of the site area

```
http://host_name:port_number/wps/seedlist/myserver?SeedlistId=site_area_id&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments&Range=200
```

Retrieve a maximum of 100 items from a specific library

```
http://host_name:port_number/wps/seedlist/myserver?SeedlistId=library&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

Retrieve a maximum of 100 items from all libraries

Note: To use all libraries, leave `SeedlistId` value empty.

```
http://host_name:port_number/wps/seedlist/myserver?SeedlistId=&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

Retrieve a maximum of 100 items from a specified list of libraries

```
http://host_name:port_number/wps/seedlist/myserver?SeedlistId=library1,library2&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

Retrieve a maximum of 100 items from a cluster

Note: When referencing a cluster, specify the request with the host name and port number of the HTTP server.

```
http://http_server:port_number/wps/seedlist/myserver?SeedlistId=library/site_area&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

Retrieve a maximum of 100 items from a virtual portal that is configured to use the URL context as the access point

```
http://http_server:port_number/wps/seedlist/myserver/virtual_portal_context?SeedlistId=library/site_area&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

Retrieve a maximum of 100 items from a virtual portal that is configured to use a different host name as the access point

```
http://virtual_portal_host_name:port_number/wps/seedlist/myserver?SeedlistId=library/site_area&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=GetDocuments
```

Important: You can access the REST API for the Web Content Manager search seedlist 1.0 with a secured connection (HTTPS) or with an unsecured connection (HTTP). Depending on the method, ensure that you use the correct port. However, if you access this REST API with an unsecured connection, you are automatically redirected to a secured connection.

Parameter	Default Value	Description
SeedlistID	No default; must be specified.	Identifies the seedlist. This parameter can be specified in the following ways: • An empty value causes all libraries to be used. • A specific library (for example, *library1*) • A specific site area (for example, *site_area1*) • A list of libraries, which are separated by commas. For example, `library1,library2,library3` • The JCRID of a site area
Start	0	Defines the start number for currently returned section.
Range	100	Defines the number of returned entries for current section.

Parameter	Default Value	Description
Date	No default. If not specified, all applicable results are returned.	Indicates that entries (documents) that were updated after this date are retrieved. The date format (compliant to standard ISO 8601) is the following : *date*T*timezone*, where *date* is yyyy-MM-dd, *time* is HH:mm:ss, and *zone* is ±hhmm. This format includes time zone information, which is critical if the client and server are in different time zones. **Important:** Proper HTML URL encoding must be performed (for example, represent the plus symbol + as %2B).
Action	GetDocuments	Defines requested action to execute. • GetDocuments retrieve all underlying documents. • GetNumberOfDocuments returns the number of all underlying documents, typically for debug purposes. This value must be the same as the number of all documents that are returned from an appropriate GetDocuments request.
Format	ATOM	Defines the output format : ATOM / HTML/ XML.
Timestamp	No default.	Indicates the content provider timestamp from a previous crawling session. The timestamp represents for the content provider some snapshot of the content and allows the crawler to get only the content changes on the next crawling. This parameter is used for incremental crawling.

Searching your local portal

View information on setting up your local portal for your users to search.

About this task

The portal default search collection combines two content sources and their related crawlers:

- The Portal Content Source. This contains the local portal site, where users can search for portal pages and portlets.
- The Web Content Manager (WCM) Content Source, which users can search for web content.

"Configuring a crawler to search your local portal site" on page 628
Configure and run a search crawler on your local portal site to gather information and create a search collection that enables your users to search your portal site.

"Crawling a multilingual portal site" on page 631
View the steps to set up search on a multilingual portal for users with different language preferences.

"Configuring search on a secured portal site" on page 632
Crawling and searching secured portal sites might require some additional configuration.

Configuring a crawler to search your local portal site

Configure and run a search crawler on your local portal site to gather information and create a search collection that enables your users to search your portal site.

About this task

Portal Search provides a default portal site search collection that enables your users to search your portal site. Before your users can search the portal site collection, do the following tasks.

Procedure

1. Set the crawler user ID. Set a dedicated crawler user ID for crawling the portal site content source. Proceed as follows:
   a. Define the crawler user ID by using the Manage Users and Groups portlet. Proceed as follows:

      Note: It is of benefit to define a dedicated crawler user ID. The pre-configured default portal site search uses the default administrator user ID `wpsadmin` with the default password of that user ID for the crawler. If you changed the default administrator user ID during your portal installation, the crawler uses that default user ID. If you changed the password for the `wpsadmin` or other administrative user ID, or if you changed the default administrator user ID to an ID other than `wpsadmin`, or if you want to use a separate user ID, you must set the crawler user ID.
   b. Set the preferred language of the portal site crawler user ID to match the language of the portal site search collection that it crawls. If you do this task after you started a crawl on the portal site search collection, you must reset the portal site collection. For details, see the topic about Resetting the default search collection.
   c. Edit the portal site collection content source and enter the crawler user ID and its password. To do this task, proceed as follows:
      1) To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
      2) Click **Search Collections.**.
      3) Select **Default Search Collection** from the Search Collection list.
      4) In the Content Source Name list of the search collection, click the **Portal Content Source** search collection.
      5) Click the **Edit** icon next to the Portal Content Source collection name.
      6) Select the **Security** tab.
      7) Click the **Edit** icon next to the security realm that you want to modify.
      8) Type the crawler user ID and password into the appropriate fields.
      9) Click **Update**.
      10) Click **Save** to save your changes.
   d. Optional: For content sources of type **Web Site**, you can configure the crawler to follow external links from inside the portal. To do this task, modify the value in the field **Levels of links to follow** under the tab **General Parameters**. Set the level to a value higher than 1. In addition, you can configure filters for those external links from the Filters tab. The default filter suppresses all links that point back to portal pages. The default filter is displayed only after you save the configuration of the content source.
2. Start the initial crawl. Start the initial crawl on the portal site content source:

a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.Then, click **Search Collections**.
b. In the search collection list, click **Default Search Collection**.
c. Click the **Start Crawler** icon next to the Portal content source name.

3. Configure regular crawls. If you want regular crawls on the portal site content source, do either of the following tasks:
   - Enable the default scheduler. To do this task, proceed as follows:
     a. Click the **View Content Source Schedulers** icon next to the collection name.
     b. In the Manage Schedulers page, click **Disabled**. This action changes the status of the scheduler to Enabled and displays a confirmation message.
   - Set up your own scheduler. To do this task, proceed as follows:
     a. Click the **Edit** icon for the content source.

        Note: You can have only one schedule at a time. Therefore, to create your own schedule, you first must delete the existing schedule.
     b. Select the **Schedulers** tab.
     c. Configure your own scheduler as needed. For more information, see *Manage Search portlet help*.
     d. Click **Save** to save your changes.

Example

For more information about how to work with content sources, see *Managing the content sources of a search collection* and *Manage Search portlet help*.

Notes:

1. The local portal site is visible through a service that requires SSL. Therefore, if your portal is configured with a web server and you configure the content source root URL through the web server, you must configure the web server for SSL.
2. By default, items in the result lists from portal site searches provide no summary information. If you want to have the summary information that is added, configure the portlet with the summary parameter enabled as follows: `PortalCollectionSummarizer=on`.
3. When you crawl a portal site, be aware that a Portal Search crawl can use extended memory and time, depending on your Portal Search environment and configuration. For details, see the topic about Hints and tips for Portal Search crawls.
4. Do not change the default value of 1 for the option **Levels of links to follow**. Changing this value initiates web crawling logic and might result in unexpected results. For example, crawler might trigger unwanted in some of the administration portlets.
5. Set the preferred language of the crawler user ID to match the language of the search collection that it crawls.
6. The portal site search collection is created when an administrator goes to the Manage Search portlet. However, you must start the crawl for users to be able to search the portal site. Depending on your portal configuration and environment and possible customization, you might need to reset the portal site

search collection that was created. For details about such scenarios and the necessary tasks to perform see the topic about Resetting the default search collection.

7. If your users search the portal site search collection on a secured portal site, refer to the topic *Enabling search on a secured portal site with the default configuration*.
8. The portal search crawler indexes static content pages and all pages that include portlets.

When users search a portal site, they can access portal pages of two types:

- The Public or anonymous portal pages are pages that users can view without authentication by user ID and password. The crawler can crawl public pages on the portal site on which it is located, or on a remote portal.

  If you want anonymous users to be able to search the public pages of your portal site, see *Enabling anonymous users to search public pages of your portal*.
- The secured portal pages are pages that users can view only if they authenticate themselves to the portal by logging in to the portal with a user ID and password. For details, see *configuring search on a secured portal site*.

  Note: You can crawl, index, and search secured portal pages only on your local portal installation. For security reasons, you cannot crawl secured pages of one portal site from another portal site.

If you customize search on your portal site, you might find useful information under the topics about configuring the default location for search collections and Resetting the default search collection.

If your portal site is multilingual and your users use different languages to search your portal, see the topic about Crawling a multilingual portal site.

Related tasks:

"Resetting the default search collection" on page 711
Under certain circumstances, you might want to change the configuration of the portal site search collection. In this case, you must re-create the collection, as search collections cannot be modified.

"Managing the content sources of a search collection" on page 701
Search collections consist of one or more content sources. You can administer the content sources.

Crawling a multilingual portal site

View the steps to set up search on a multilingual portal for users with different language preferences.

About this task

If your portal site is multilingual and your users use different languages to search your portal, you set up multiple search collections under one scope. Proceed as follows:

Procedure

1. Before you start creating search collections, make sure that the parameter `MULTILINGUAL_COLLECTION_ENABLED` is set to `false` for the search service. If the parameter has not been set, add it and set it to `false`.
2. **Note:** CF05 If you are using the combined cumulative fix readme 05 (CF05) or later, you do not need to complete this step.
   Create a separate crawler user ID for each language that your users might use for search. Set the language preference for each user ID to a different one of the required languages.
3. Create a portal content search collection for each language that your users might use. Set that language for the collection by selecting it from the pull-down list within **Specify Collection Language**.
4. Depending upon your Portal environment, do one of the following tasks:
   - If you are using the combined cumulative fix readme 04 (CF04) or earlier, create a single content source for each of these collections. For each content source, select the crawler user ID that you created before so that the language preference setting matches the language of the collection to which each content source belongs.
   - CF05 If you are using the combined cumulative fix readme 05 (CF05) or later, create a single content source for each of these collections. When you save the content source settings, Manage Search appends the locale information of the collection to the content source URL, unless you already added locale information.
5. **Note:** CF05 If you are using the combined cumulative fix readme 05 (CF05) or later, you do not need to complete this step.
   For each content source, append `&Locale=`*`locale_name`* to the content source URL. For example, for Spanish append `&Locale=es`.

6. Populate the collections by starting crawls on them. For load and performance reasons, run the crawls one after another rather than all at the same time. Refer to the topic about Hints and tips for Portal Search crawls.
7. Create a scope, and add all collections that you just created. You can name this scope `My preferred language`.

Results

- If you are using the combined cumulative fix readme 04 (CF04) or earlier, the Search Center portlet returns results only from the collection in the user's preferred language.
- CF05 If you are using the combined cumulative fix readme 05 (CF05) or later, the Search Center portlet returns results only from the collection in the user's preferred language, unless the Search Center is configured to display search results of all available content sources regardless of their language information. For more information on setting up search in multilingual sites, go to "Configuring search for multilingual sites" on page 684.

Configuring search on a secured portal site

Crawling and searching secured portal sites might require some additional configuration.

About this task

For search on secured portal sites Portal Search provides a pre-configured default setup. For more information, go to "Configuring a crawler to search your local portal site" on page 628. You can use that setup as is, or you can modify it as required. You can also set up your own search collection for search on portal sites. The following sections describe all of these options.

Security notes:

1. You can crawl, index, and search secured portal pages only on your local portal installation. For security reasons, you cannot crawl secured pages of one portal site from another portal site.
2. When you create a content source for enabling search, you must enter sensitive data. For example, a user ID and password for the crawler. This sensitive data is stored on the portal server in plain text unless you choose to encrypt it. To ensure encryption of this sensitive data when it is stored, update and run the `searchsecret.xml` file with the XML configuration interface before you enable search on the secured portal site. For information, refer to "Encrypting sensitive data" on page 614.
3. When users search a secured portal, the resulting portal pages or resources are filtered based on Portal Access Control. Portal Search filters the results according to the access permissions of the user who is searching. It applies to the following resources: portal pages, portlets, and Web Content Manager content. Portal Search does not provide security-filtering for other HTTP accessible information, such as secured websites. The portal cannot filter the resulting documents by portal security for these types of content source.

"Enabling search on a secured portal site with the default configuration"
By modifying some of the settings, you can use the default search collection to configure search of a secured portal site.

"Customizing your search collection for secured portal pages" on page 635
Set up your own customized search collection for searching a secured portal site.

Related tasks:

"Configuring a crawler to search your local portal site" on page 628
Configure and run a search crawler on your local portal site to gather information and create a search collection that enables your users to search your portal site.

"Encrypting sensitive data" on page 614
When you create a new content source using the Manage Search portlet, some secured content sources require that you enter sensitive data. For example, this can be the user ID and password of the crawler user ID required for accessing the secured content source. When you later export the configuration of the search collection, you might want to protect the sensitive data. You can encrypt such sensitive data so that it is not stored as plain text on the hard drive. If you do not encrypt such data, the data is not included in the export.

Enabling search on a secured portal site with the default configuration:

By modifying some of the settings, you can use the default search collection to configure search of a secured portal site.

About this task

In order for you to use Portal Search for searching your portal site, WebSphere Portal Express already prepared a search collection and a content source during installation. For more information, see the topic about configuring a crawler to search your local portal site. To enable that search collection on a secured portal site for search by users, encrypt the user ID and activate the search collection by starting the crawl and indexing process.

Procedure

1. To ensure encryption of the user ID and password for the crawler, update and run the file `searchsecret.xml` by using the XML configuration interface. For more information, see the topic about Encrypting sensitive data.
2. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
3. Click **Search Collections**, which opens the Search Collections panel.
4. From the list of search collections, click the portal site search collection **Default Search Collection**. This step opens the Content Sources panel for the portal site search collection. It lists the Portal Search content sources.
5. For the Portal Content Source, set the crawler user ID as described in the following procedure.

   Note: It is of benefit to define a dedicated crawler user ID. The pre-configured default portal site search uses the default administrator user ID `wpsadmin` with the default password of that user ID for the crawler. If you changed the default administrator user ID during your portal installation, the crawler uses that default user ID. If you want the crawler to use the user ID `wpsadmin` and its default password, you can omit the following substeps and proceed with the next main step. If you changed the password for the `wpsadmin` or other

administrative user ID, or if you changed the default administrator user ID to an ID other than `wpsadmin`, or if you want to use a separate user ID, proceed as follows:

a. For the Portal Content Source, click the **Edit** icon.
b. Update the user ID and password as needed in the Security tab.
c. Click **Save** to save your changes.

Note: Set the preferred language of the portal site crawler user ID to match the language of the portal site search collection that it crawls. If you already started a crawl on the portal site search collection, you must reset the portal site collection. For details, see the topic about Resetting the default search collection.

6. Click the **Start Collecting** icon to start the crawl. The crawler starts collecting and indexing portal pages. By default, the crawl is scheduled to run for 1 hour. The scheduler for regular repeated crawls is disabled by default. If you enable it, the interval for scheduled crawls is every hour. You can set these parameters by using the **Manage Search** portlet:
   a. You can change the duration of the crawl, depending on the size of your portal installation. Edit the portal site content source under **General Parameters**.
   b. You enable scheduled crawls by clicking the icon **View Content Source Schedulers** for the content source and clicking **Disabled** in the status column for the scheduler. The status changes to **Enabled**.
   c. You change the interval for scheduled crawls by editing the portal site content source, selecting the **Schedulers** tab, deleting the default scheduler, and defining a new one.

Results

Notes:

1. When you crawl a portal site, be aware that a Portal Search crawl can use extended memory and time, depending on your Portal Search environment and configuration. For details, see the topic about Hints and tips for Portal Search crawls.
2. If a user tried to use the Search Center by entering a search string in the portal search box in the theme and clicking search *before* an administrator enabled the portal site search collection, the user must log out of the portal and log back in again to be able to search the portal search collection. This action includes the administrator who enabled the portal search collection.

Related tasks:

"Configuring a crawler to search your local portal site" on page 628
Configure and run a search crawler on your local portal site to gather information and create a search collection that enables your users to search your portal site.

"Encrypting sensitive data" on page 614
When you create a new content source using the Manage Search portlet, some secured content sources require that you enter sensitive data. For example, this can be the user ID and password of the crawler user ID required for accessing the secured content source. When you later export the configuration of the search collection, you might want to protect the sensitive data. You can encrypt such sensitive data so that it is not stored as plain text on the hard drive. If you do not encrypt such data, the data is not included in the export.

"Resetting the default search collection" on page 711
Under certain circumstances, you might want to change the configuration of the portal site search collection. In this case, you must re-create the collection, as search collections cannot be modified.

Related reference:

Customizing your search collection for secured portal pages:

Set up your own customized search collection for searching a secured portal site.

Procedure

1. Plan and determine which portlets and portal pages you want to be accessed by the crawler and made available for search. This must be the sum of all of the portal resources that you want to be available for search by all users that you want to be able to search those resources.
2. Make a conscious decision about the user ID that you use when you configure crawling and indexing, and which access permissions that user ID requires.
3. To ensure encryption of sensitive data that is stored, such as the crawler user ID and password, update and run the file `searchsecret.xml` by using the XML configuration interface. For details about encryption, see the topic about Encrypting sensitive data.
4. Create a dedicated crawler user with a user ID and password in the portal.
5. Give the crawler user ID the required access permissions to the portal resources as determined by the planning step: Access to all portlets and pages that must be indexed and thus be made available for search by users.
6. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
7. Click **Search Collections** to open the Search collections panel.
8. Create a search collection for the portal site.
9. Create the content source. The root URL for the portal is already completed. Select **Portal Site** for the type of content source. Complete the user ID and password for the crawler user that you created. Complete the other fields and select the options as needed.
10. To enable search on the portal site for users, click **Start Collecting**.

    Note:

    a. You can crawl, index, and search secured portal pages only on your local portal installation. For security reasons, you cannot crawl secured pages of one portal site from another portal site.

    b. Under normal circumstances, exclude all administrative portlets and all portlets that represent highly dynamic content from being accessible to the crawler user. This includes such portlets that contain action links with Delete actions. Otherwise, the Delete action can be started through the crawler.

    c. Instead of creating a new search collection and content source for the portal site search you can also use the collection and content source of the

default portal site search setup. In this case, replace the completed user ID and password in the Edit Content Source Configuration panel with the one that you want to use.

d. For details about how to create a search collection and a content source, see the topics *Creating and configuring search collections* and *Managing the content sources of a search collection*, and the *Manage Search* portlet help.

Related tasks:

Configuring your portal site for search by internet search engines

You can enable your portal site for search by using search services such as Google or Yahoo! Search on your portal site by external search services works for public portal pages only, that is, for pages that users can access without a user ID and password.

About this task

To make your portal available for search by internet search engines, you configure search with external search services. Register your portal with the external search service(s) of your choice. Give the URL of your portal to the search service providers so that they can crawl and index your portal site. Depending on how you customize your portal, you might consider indicating the Site Map page rather than your portal home page, or otherwise enhancing the configuration.

Optionally, you can configure several additional aspects for search on your portal by external search services:

- By default, the Site Map portlet is available on the portal Welcome page. This way the external crawler crawls only the links of the Site Map portlet. If you change your portal, place the Site Map portlet on your portal home page. Otherwise the crawler can crawl all portal links and might trigger unwanted actions by action links, such as a Delete button. If you do not want your users to be able to see the Site Map portlet, choose one of the following options for placing the Site Map portlet:
  - Place the Site Map portlet in the theme of the portal home page.
  - Place the Site Map portlet on a separate page, and omit that page from the portal navigation.

The location of the Site Map portlet in your portal determines the URL by which you register to the external search service.

- You can configure the Site Map portlet to determine the depth to which your portal can be searched.
- You can configure client identification for the external search engines.
- You can configure the URL normalization. You do this by setting a property in the portal configuration service named portal WP State Manager Service in the WebSphere Integrated Solutions Console.

"Configuring the Search Sitemap portlet for search by external search engines"
The **Search Sitemap** portlet generates a navigable list of all public pages of the portal. You can configure the **Search Sitemap** portlet to determine the limit to the number of links that are displayed per page.

"Client identification for search of the portal by external search engines" on page 639
For the portal to recognize external search engines, portal provides a client that covers several popular search engines. This client is implemented according to the Composite Capability/Preference Profiles (CC/PP) standard. It has the capability `HTML_SEARCH` set. If you want to add more search engines, you can configure the client as required.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Related reference:

"State Manager Service" on page 347
The portal State Manager Service is the access point for managing the navigational state of the portal. The navigational state represents the current view of portal resources as displayed to a user.

Configuring the Search Sitemap portlet for search by external search engines

The **Search Sitemap** portlet generates a navigable list of all public pages of the portal. You can configure the **Search Sitemap** portlet to determine the limit to the number of links that are displayed per page.

About this task

IBM WebSphere Portal Express provides the **Search Sitemap** portlet. It serves two purposes:

- You can use the Search Sitemap portlet to navigate the portal site. For more information, see *Managing pages*.
- The Search Sitemap portlet enables external search crawlers to collect portal pages more efficiently. This topic gives more information about configuring the Search Sitemap portlet for search by external search engines.

The Search Sitemap portlet generates a list of all public pages of the portal. You can configure the Search Sitemap portlet to determine the limit to the number of links per page. The Search Sitemap portlet lists portal pages to that maximum figure per page and then starts a new page. Set this figure to a maximum of 50 - 200 links per page for the portal site. For example, the Google search engine recommends fewer than 100 links per page.

Procedure

Configure the maximum number of links per page for search of the portal by setting the value for the parameter MAX_LINKS in the portlet preferences. You can do this either by using the administration portlet **Manage Portlets** or by updating the portlet preferences in the portlet.xml file of the Search Sitemap portlet.

Option	Description
Using the administration portlet Manage Portlets	Use this option to update the MAX_LINKS parameter for the Search Sitemap portlet. Proceed as follows: 1. To open the Manage Portlets portlet, click the **Administration menu** icon. 2. Then, click **Portlet Management** > **Applications**. 3. Locate the Search Sitemap portlet by searching for wp.ap.sitemap. 4. Click the **Configure portlet application** icon for the Search Sitemap portlet. 5. Add the MAX_LINKS parameter by typing it in the **New parameter:** field. 6. Click **OK** to save your updates.
Updating the portlet preferences in the portlet.xml file of the Search Sitemap portlet	Use this option to set the general default for the parameter MAX_LINKS. Proceed as follows: 1. Locate the WAR file of the Search Sitemap portlet in your portal installation. The WAR file is named sitemap.war. 2. Edit the file portlet.xml in that WAR file. 3. In the section portlet-preferences set the parameter MAX_LINKS to the required value, for example 50. Refer to this example code snippet: `<portlet-preferences>` `<preference>` `<name>MAX_LINKS</name>` `<value>50</value>` `</preference>` `</portlet-preferences>` 4. Redeploy the Search Sitemap portlet. 5. Restart your portal.

Results

What to do next

Note: The Search Sitemap portlet lists only public pages of your portal, that is pages, which users can access without logging in to the portal with a user ID and password. Secured portal pages are not available for search by anonymous users and therefore not listed by the Search Sitemap portlet.

Search on your portal by external search engines requires more configuration. For more information, see *Search by external search services* and *Client identification for search of the portal by external search engines*.

Client identification for search of the portal by external search engines

For the portal to recognize external search engines, portal provides a client that covers several popular search engines. This client is implemented according to the Composite Capability/Preference Profiles (CC/PP) standard. It has the capability `HTML_SEARCH` set. If you want to add more search engines, you can configure the client as required.

The client has been implemented with the following settings:

User agent:

```
(.*(B|b)ot.*)|(.*BOT.*)|(.*(S|s)pider.*)|(.*(S|s)earch.*)|
(.*(C|c)rawl(er)?.*)|(.*(G|g)rabber.*)|(.*(Y|y)ahoo.*)|
(.*(S|s)lurp.*)|(.*Lycos.*)|(.*Wget.*)
```

This user agent covers most available large search engines, such as Google, Yahoo!, Lycos, or MSN. This pattern list also accommodates all other search engines that include segments of `bot`, `spider`, `search`, or `crawler`.

Capability:

For each search engine that you want to be able to crawl your portal, you need to set the capability `HTML_SEARCH`. Search engines usually visit a website twice, the first time to crawl the site, and the second time to validate the content. When a search engine visits a site for the second time, it usually does so by using a normal browser. Therefore enter additional capabilities for supporting the different browser settings. Examples: `(HTML_4_0, HTML_IFRAME, HTML_FRAME, HTML_NESTED_TABLE, HTML_2_0, HTML_JAVASCRIPT, HTML_3_2, HTML_3_0, HTML_CSS, HTML_TABLE)`.

Manufacturer:

Search

Markup:

HTML

If you want to include search engines that are not covered by the default set, you can do so by using either the administration portlet Manage Clients or the XML configuration interface. For more information see the following topics.

Notes:

1. The search mechanism works correctly for the portal only if the search engine robots are identified to the portal in advance.
2. Search on your portal by external search engines requires additional configuration beyond client identification. For more details about this see the topics about *Configuring your portal site for search by external search services* and *Configuring the Search Sitemap portlet for search by external search engines*.

   "Adding search engines by using the administration portlet Manage Clients" on page 640
   To add search engines by using the administration portlet **Manage Clients**, follow the procedure that is given here.

   "Adding search engines by using the XML configuration interface" on page 640
   To add search engines by using the XML configuration interface, you import them by an XML script file. To make sure that the search mechanism works correctly, you need to add the capability `HTML_SEARCH`.

Adding search engines by using the administration portlet Manage Clients:

To add search engines by using the administration portlet **Manage Clients**, follow the procedure that is given here.

Procedure

1. Go to the Manage Clients portlet. Click the **Administration menu** icon. Then, click **Portal Settings** > **Supported Clients**. Portal opens the Manage Clients portlet.
2. Depending on whether you want to add more search clients to the default user agent or add a complete new client, do one of the following steps:
   - Select the client that starts with `(.*(B|b)ot.*)|(.*BOT.*)|(.*(S|s)pider.*)` `. . .` from the list of clients and edit it. Use this option if you simply want to add one or more search engines.
   - Add a new client. For example, you can use this option, if you want to give the newly added search engine priority by setting it to the **First** position in the client list.

   For details about how to do this refer to the Manage Clients portlet help.
3. Update or fill the fields and select the options as required. For brief descriptions of the available fields and options, see the list later in this topic. For a more detailed description of the fields and options, refer to the Manage Clients portlet help.
4. Click **OK** to save your changes.

What to do next

Fields and options in the manage Clients portlet help:

User agent:
Type your new search engine user agent.

Markup:
html

Manufacturer
Search Engine Manufacturer. This field is optional.

Capability:
`HTML_SEARCH, HTML_4_0, HTML_IFRAME, HTML_FRAME, HTML_NESTED_TABLE, HTML_2_0, HTML_JAVASCRIPT, HTML_3_2, HTML_3_0, HTML_CSS, HTML_TABLE`

Position:
First. Set the specified search engine to the first position so that it is correctly recognized. The reason for this is that the pattern matching for the comparison of the user agents to the supported clients is done from concrete and specific to general.

For a more detailed description of the fields and options, refer to the Manage Clients portlet help.

Adding search engines by using the XML configuration interface:

To add search engines by using the XML configuration interface, you import them by an XML script file. To make sure that the search mechanism works correctly, you need to add the capability `HTML_SEARCH`.

About this task

Here is an example XML script, with the HTML_SEARCH capability highlighted:

```
<?xml version="1.0" encoding="UTF-8"?>
<request    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xsi:noNamespaceSchemaLocation="PortalConfig_1.4.xsd"
            type="update" create-oids="true">
    <portal action="locate">

        <client action="update" uniquename="wps.client.search.Your Search Engine Name"
                manufacturer="Your Search Engine Manufacturer" markup="html">

            <useragent-pattern>Your User-Agent Pattern</useragent-pattern>

            <client-capability update="set">HTML_SEARCH</client-capability>
            <client-capability update="set">HTML_4_0</client-capability>
            <client-capability update="set">HTML_IFRAME</client-capability>
            <client-capability update="set">HTML_FRAME</client-capability>
            <client-capability update="set">HTML_NESTED_TABLE</client-capability>
            <client-capability update="set">HTML_2_0</client-capability>
            <client-capability update="set">HTML_JAVASCRIPT</client-capability>
            <client-capability update="set">HTML_3_2</client-capability>
            <client-capability update="set">HTML_3_0</client-capability>
            <client-capability update="set">HTML_CSS</client-capability>
            <client-capability update="set">HTML_TABLE</client-capability>

        </client>
    </portal>
</request>
```

Related concepts:

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Enabling anonymous users to search public pages of your portal

You can enable anonymous users (sometimes also called unauthenticated users) to search public pages of your portal by using the portal Search Center portlet. Search by anonymous users works only on public pages of your portal, as the users are not logged in to your portal.

About this task

To enable anonymous users to search public pages of your portal, you need to complete the following tasks:

- Make the Search Center portlet available on a public page of your portal so that users can access it without having to log in to the portal.
- Enable public sessions for your portal. The reason is that the Search Center portlet needs a valid session for its run time, and by default, sessions are not enabled on anonymous pages in the portal. By default, sessions are only created when a user authenticates and logs in to the portal.
- Have or create your own custom search scope. You can edit your own custom scopes, but you cannot modify the default search scopes to give anonymous users access.

Proceed as follows:

Procedure

1. Place the Search Center portlet on a public page. For more information, see the following subtopic.
2. Give the Anonymous Portal User group access permission to the Search portlet that you make available to anonymous users, and to the page on which that portlet is. To give access permission, you can use the User and Group Permissions portlet, the Resource Permissions portlet, or the Manage Portlets and Manage Pages portlets.
3. Give the Anonymous Portal User group access to the Search collections. To complete this step, use the User and Group Permissions portlet or the Resource Permissions portlet. From the list of Resource Types, select PSE Sources, then select the required search collections that you make available to public users, and assign the Anonymous Portal User access to those search collections.
4. Optional: Create a custom search scope, if you did not create one before already. For more information, see *Managing and administering Portal Search*, section *Creating a new search scope*.
5. Give the Anonymous Portal User group access to the Search scope:
   a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   b. Click **Search Scopes**
   c. Locate the scope that you want the anonymous user to use and click **Edit Search Scope**.
   d. Click **Yes** to enable the option **Visible to Anonymous Users**.
6. Enable public sessions by setting the parameter `public.session` to `true` in the portal Navigator Service in the WebSphere Integrated Solutions Console. For details about the portal Navigator Service and about how to set portal service configuration parameters see the respective topics.
7. Restart both WebSphere Application Server and WebSphere Portal Express for your changes to take effect.

"Placing the Search Center on a public portal page" on page 643
Depending on your environment, you might want to place the Search Center portlet on a public page of your IBM WebSphere Portal Express and have the search box in the portal theme take users who do a search to that public Search Center.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Manage Search

Placing the Search Center on a public portal page

Depending on your environment, you might want to place the Search Center portlet on a public page of your IBM WebSphere Portal Express and have the search box in the portal theme take users who do a search to that public Search Center.

About this task

To do this, you need to create your custom search center page, place a copy of the Search Center on it, and adapt the file `search.jsp` accordingly. Proceed as follows:

Procedure

1. Create your custom search center page. Complete the fields and select options as required. Make sure to specify a Search and Tag Center profile for the page as follows:
   - If you create the page by using the Manage Pages functionality in the site toolbar, proceed as follows:
     a. From the site toolbar, select **Page** to edit the new search center page.
     b. From the General tab, select **Edit Page Properties**.
     c. In the Manage Page Properties window, select the **Advanced** tab.
     d. Scroll to the Metadata section of the Manage Page Properties window.
     e. To specify the Search and Tag Center profile for the custom search center page, add the key `resourceaggregation.profile` with the value of `profiles/profile_search_tag.json` to the list of key value pairs.

        Note: If you created the custom search center page as a child to the original Search Center page, the Search and Tag Center profile is inherited from the parent page.
     f. Click **Save**.
   - If you create the page by using the Manage Pages administration portlet, proceed as follows:
     a. Select **Edit Page Properties** for the page.
     b. Select **Advanced options**.
     c. Select **I want to set parameters**.
     d. Add the parameter `resourceaggregation.profile` with a value of `profiles/profile_search_tag.json` .
     e. Click **OK** > **OK**.
2. Add the Search Center portlet to the custom search center page by completing the following steps:
   a. From the custom search center page, select the **Create** tab in the site toolbar.
   b. From the Applications tab, select the **Search Center** portlet.
   c. Select **Add to Page ...** to add the Search Center portlet to the page.
3. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
4. Locate your custom Search Center page in the Manage Pages portlet.
5. Give your custom Search Center page a unique name by completing the following steps:
   a. Select **Edit Page Properties**.
   b. Specify a value for the **Unique name**.

c. Click **OK**.

6. Give the portlet window for the Search Center a unique name:
   a. Select **Edit Page Layout**.
   b. From the portlet menu, select **Set portlet window unique name**.
   c. Specify a value for the **Unique name**.
   d. Click **OK** > **Done**.
7. Change to the directory *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/modules/search/jsp
8. Edit the file search.jsp.
9. Locate the following code snippet that points to the default Search Center page:

```
<input type="hidden" name="uri" value="searchCenter:query">
<input type="hidden" name="contentNode" value="ibm.portal.Search Center">
<input type="hidden" name="layoutNode" value="ibm.portal.Search Center Portlet Window">
```

10. Change the values for the two parameters contentNode and layoutNode as follows:
    - Change the value for contentNode to the unique name of your custom Search Center page.
    - Change the value for layoutNode to the unique name that you gave to the window of the copy of your Search Center portlet.

    After your updates, the code snippet might look like the following:

```
<input type="hidden" name="uri" value="searchCenter:query">
<input type="hidden" name="contentNode"
     value="ibm.portal.your_public_search_center_page_unique_name">
<input type="hidden" name="layoutNode"
     value="ibm.portal.your_public_search_center_portlet_window_unique_name">
```

11. Restart your portal server.

Results

When your portal users do a search by using the search box in the theme, they are now directed to the Search Center on your public portal page.

Configuring your custom portal themes to include the search box

Enable your portal users to use the Portal Search box and Search portlet in your own custom theme.

The Portal Search box is included as part of the themes of a portal installation. If you use your own custom themes with your portal and want your users to be able to use the Portal Search box and Search portlet, make sure that your custom themes include the Portal Search box.

The code for including the search box in a theme is located in the file *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/modules/search/jsp/search.jsp . To make the search box available for users in your custom theme, do either of the following:

- Copy the contents of the file into your custom theme files.
- Copy the file into your theme and include it directly.

Redirecting search requests from a custom search form to the Search Center

If you plan to develop a custom search form, you might want to redirect search requests issued by the search form to the Search Center.

The following example form implements a button that is named **Search**:

```
<form name="myQueryForm" method="get" action=".">
     <input type="hidden" name="uri" value="searchCenter:query">
     <input type="hidden" name="contentNode" value="ibm.portal.Search Center">
     <input type="hidden" name="layoutNode" value="ibm.portal.Search Center Portlet Window">
     <input type="text" name="query">
     <input type="Submit" name="SearchButton" value="Search">
</form>
```

If a user selects the **Search** button, the form sends a request to the Portal server. The Portal server redirects the request to the Search Center by using the following parameters:

uri
This parameter must be set to `searchCenter:query` to address the query functionality of the Search Center portlet.

contentNode
This parameter is optional and specifies the unique name of the page where the Search Center portlet is placed. The default value is `ibm.portal.Search Center.`

layoutNode
This parameter is optional and specifies the unique name of the Search Center portlet window. The default value is `ibm.portal.Search Center Portlet Window`.

query
The Search Center uses the value of this parameter to search for the terms that a user specified.

If you placed the Search Center on a different page, for example, a public page, the values for the parameters **contentNode** and **layoutNode** might be different.

For more information, see *Placing the Search Center on a public portal page.*

Related tasks:

"Placing the Search Center on a public portal page" on page 643
Depending on your environment, you might want to place the Search Center portlet on a public page of your IBM WebSphere Portal Express and have the search box in the portal theme take users who do a search to that public Search Center.

Remote search service

You can configure the search portlets for local operation, or you can configure them for remote search service. Depending on your configuration, remote search service might have performance benefits by offloading and balancing system load.

You can provide the remote search service either as an EJB or as a web service through SOAP. Security can be enabled with EJB but not with SOAP. Also, separate WebSphere Portal environments cannot use the same remote search service. Only multiple WebSphere Portal nodes in the same cluster can use the same remote search service.

Note: SOAP support for remote search services was deprecated with WebSphere Portal Express Version 8.0.

When you want to index and search portal sites, search results are filtered according to the user security credentials. This filtering occurs independently of whether security is enabled on the remote search server or not. However, if security is not enabled, an unauthorized user can connect to the remote server and obtain unfiltered search results. If you want to prevent this issue, you must use EJB and enable security on the remote server. For information about enabling security on the remote search server, read *Preparing security for remote search service in a single-signon domain*.

"Installing remote search service by using IBM Installation Manager"
View the steps to install remote search service by using IBM Installation Manager.

"Installing remote search service by using manual steps" on page 647
You can install remote search service by using manual steps instead of the IBM Install Manager.

"Configuring user repositories on the remote search server" on page 652
The remote search server must have the same user repositories that are configured in WebSphere Application Server that are configured on the WebSphere Portal Express server. For example, if your WebSphere Portal Express server is configured to an IBM Directory Server LDAP in a federated repository configuration, then the remote search server must also be configured to the same IBM Directory Server LDAP in a federated repository configuration.

"Creating a single-sign on domain between WebSphere Portal and the remote search service" on page 652
View the steps to create a single-sign on (SSO) domain between WebSphere Portal Express and the remote search service. Set up remote search service by using EJB, since SOAP support for remote search services was deprecated with WebSphere Portal Express version 8.0.

"Setting the search user ID" on page 654
If you work with EJB on a secure server, you need to set the search user ID on the remote search server.

"Removing search collections" on page 656
If you plan to use search in a cluster, you must configure a remote search server. If you created any search collections, you must re-create them on the remote search server. If your search collection has data, export the collection before you delete it. Then, import it to the remote server.

"Configuring a remote search service" on page 657
Configure a remote search service for Portal Search.

"Configuring HTTP for the seedlist servlet" on page 661
Learn how to configure HTTP for the seedlist servlet. The seedlist servlet requires HTTPs by default. Therefore, when you access the servlet through HTTP, WebSphere Application Server redirects you to HTTPs.

Installing remote search service by using IBM Installation Manager

View the steps to install remote search service by using IBM Installation Manager.

Before you begin

- WebSphere Application Server v8.5 must be installed.
- WebSphere Portal Express and Web Content Manager must not be installed.

About this task

Use the WP8.5_iim.remotesearch installation package to install remote search service by using Installation Manager.

Procedure

1. Enter the installation directory of the remote search service in the installation directory field.
2. Select a language.
3. Select a package to install. You can select either remote search service, remote document conversion service (DCS), or both.
4. Enter the location of the target WebSphere Application Server root directory.
5. Specify which user is able to access and use remote search service from the portal server by entering their user name and password.

   Notes:

   - It is possible to manually install remote search service without using Installation Manager. For more information about how to perform the manual installation of remote search service, see "Installing remote search service by using manual steps."
   - Additional installation and configuration of remote DCS is no longer required with WebSphere Portal Express Version 8.5.
   - Installing remote search service by using Installation Manager will create a new WebSphere Application Server profile for remote search service.

Installing remote search service by using manual steps

You can install remote search service by using manual steps instead of the IBM Install Manager.

Before you begin

- For SOAP: If you use SOAP, the following security and performance considerations apply:
  1. Application security: If you use SOAP over a secure server, the SOAP service itself is not secure.
  2. Java 2 security: If you use SOAP, you must disable Java 2 security.

  Note: SOAP support for remote search services was deprecated with WebSphere Portal Express Version 8.0. EJB is still supported.
- For EJB: If you use EJB, complete the following security administration tasks:
  1. Prepare security for remote search service in a single-signon domain (SSO).
  2. Add the signer certification of the remote search service server into the portal search server. To do this addition, proceed by the following steps:
     a. Access the WebSphere Integrated Solutions Console of the portal search server.
     b. Click **Security** > **SSL certificate and key management** > **Key stores and certificates** > **NodeDefaultTrustStore** > **Signer certificates** > **Retrieve from port**.

        Cluster note: In a clustered environment, the path is **Security** > **SSL certificate and key management** > **Key stores and certificates** > **CellDefaultTrustStore** > **Signer certificates** > **Retrieve from port**.

c. Enter the remote search service server host name, its HTTPS port, and an alias.
d. Click **OK**.

Procedure

1. Copy `PseLibs.zip` and depending on the requirements of your environment, copy one of the two files `WebScannerSoap.ear` or `WebScannerEjbEar.ear` to the directory *AppServer_root*`/installableApps`. You find these files in the following locations of your portal installation:
   - The files `WebScannerSoap.ear` and `WebScannerEjbEar.ear` are in the directory *PortalServer_root*`/prereq/prereq.webscanner/installableApps/`
   - The file `PseLibs.zip` is located under directory *PortalServer_root*`/search/wp.search.libs/installableApps`
2. Depending on the requirements of your environment, install one of the two applications `WebScannerEJbEar.ear` or `WebScannerSoap.ear` on a remote server. For example, this can be `server1`. Proceed by the following steps:
   a. Access the WebSphere Integrated Solutions Console.
   b. Click **Applications** > **WebSphere Enterprise Application**.
   c. Click **Install**.
   d. Browse and select **WebScannerEjbEar.ear** or **WebScannerSoap.ear**, depending on whether you are using EJB or web service through SOAP.
   e. Click **Next**.
   f. On the following panels, accept the default settings.
   g. A message confirms that the application PSEStandalone (for EJB) or the application WebScannerEar (for SOAP) was installed successfully.
   h. Click **Save to Master Configuration**.
   i. Click **Save**.
3. Required: This step is required if you use Document Conversion Services.
   a. Install remote document conversion services on the remote server.
   b. Invoke the WebSphere Integrated Solutions Console and select **Environment** > **Shared Libraries**. Create a new shared library named `PSE` with a class path as follows:

```
$(APP_INSTALL_ROOT)/cell_name/dcs_war.ear/dcs.war/WEB-INF/lib/convertors.jar
$(APP_INSTALL_ROOT)/cell_name/dcs_war.ear/dcs.war/WEB-INF/lib/Export.jar
```

      where *cell_name* is the IBM WebSphere Application Server cell name where DCS is installed.
   c. Click **Apply** > **Save** > **Save** to save your changes.
4. Extract the Portal Search libraries to the remote server and add them to the class path on the remote server. To do this step, proceed as follows:
   a. Create a directory with the name *extract* under the directory `installableApps`.
   b. Locate the file `PseLibs.zip` in the directory `installableApps` and extract its content into the directory `extract` that you created in the previous step.
   c. Open the WebSphere Integrated Solutions Console.
   d. Click **Environment** > **Shared Libraries**.
   e. Create or modify the new shared library names PSE. When you create the library, check the option **Use an isolated class loader for this shared library**.

f. Add the libraries `extract/lib` to the class path by adding a new line to the class path and giving the full path: *AppServer_root*`/installableApps/extract/lib`. *AppServer_root* is the profile directory of your WebSphere Application Server installation. For example, this path can be:

```
/usr/WebSphere/AppServer/profiles/profile_name
```

g. Click **Apply** > **Save** to save your changes to the configuration.

5. Depending on the requirements of your environment, add a reference from the application `WebScannerEJbEar.ear` or `WebScannerSoap.ear` to the shared library. To add a reference, proceed as follows:
   a. Access the WebSphere Integrated Solutions Console of the remote server.
   b. Go to **Websphere enterprise applications**.
   c. For EJB: Click the application **PSEStandalone** > **Shared library references**.
      For SOAP: Click the application **WebScannerEar** > **Shared library references**.
   d. For EJB: On the window that opens up click the check box for **PSEStandalone**, then click the button **Reference shared library**.
      For SOAP: On the window that opens up click the check box for **WebScannerEar**, then click the button **Reference shared library**.
   e. From the **Available** list, select **PSE**.
   f. Click the appropriate arrow so that **PSE** displays in the **Selected** list.
   g. Click **OK** > **OK**.
   h. Save the configuration.
   i. For EJB: Restart the application PSEStandalone.
      For SOAP: Restart the application WebScannerEar.
6. On the WebSphere Integrated Solutions Console, determine the required values for configuring the portlet parameters, depending on whether you are using EJB or web service through SOAP:
   - For EJB: Determine the value for the port under **Servers** > **Server Types** > **WebSphere application servers** > ***YourAppServer1*** > **Communications** > **Ports** > **BOOTSTRAP_ADDRESS**.
   - For SOAP: Determine the value for the port number for the SOAP URL parameter. The appropriate port number for the SOAP URL parameter is the port on which the application server runs, in other words, the HTTP transport on which the remote server is configured to run. Determine the correct port number from **Application servers** > **server1** > **Ports** > **WC_defaulthost**. The `WC_defaulthost` value is 10014; therefore, if you did not change the default, you can use this value. Make sure that the port number that is set in the following file matches this port:

```
AppServer_root/installedApps/cell/WebScannerEar.ear/WebScannerSoap.war/
     wsdl/com/ibm/hrl/portlets/WsPSE/WebScannerLiteServerSOAPService.wsdl
```

     Replace the variables as follows:
     – *AppServer_root* is the profile directory of your WebSphere Application Server installation. For example, this directory can be:

```
/usr/WebSphere/AppServer/profiles/profile_name
```

     – ***cell*** is the cell name of your remote search computer.
     – ***WebScannerEar.ear*** is the name that you gave to the Enterprise Application when you installed the `WebScannerSoap.war` file.

     Edit the file and look for the port that is given in the value for the SOAP address location. Example:

```
<soap: address location="http://localhost:your_port_no/WebScannerSOAP/servlet/rpcrouter"/> .
```

In the example the port is *your_port_no*. The default value for the WC_defaulthost is 10014.

7. In the WebSphere Integrated Solutions Console, under **Resources** > **Asynchronous beans** > **Work managers**, create a new Work manager named PSEWorkManager with the following attributes:

```
Name:                          PSEWorkManager
JNDI Name:                     wps/searchIndexWM
Minimum Number of Threads:     20
Maximum number of Threads:     60
Growable =                     True (Ensure that the Growable check box is selected.)
Service Names:                 Application Profiling Service, WorkArea, Security, Internationalization
```

8. Click **Apply** > **Save** to save your changes to the configuration.
9. Start the application:
   a. Open the WebSphere Integrated Solutions Console.
   b. Click **Applications** > **Application Types** > **WebSphere enterprise applications**.
   c. Scroll to PSEStandalone or WebScannerEar. You can use the filter feature to search for these names.
   d. Click the check box and click **Start**. A message confirms that the application started successfully.
10. This step is required only if you work with EJB on a secure server: "Setting the search user ID" on page 654.
11. Restart the WebSphere Application Server.
12. In the portal server enable CSIv2 identity assertion. To complete this step, proceed as follows:

    Cluster note: In a clustered environment, complete these steps on the Deployment Manager WebSphere Integrated Solutions Console.

    a. Enable CSIv2 Identity Assertion on the outbound connection:
       1) Access the WebSphere Integrated Solutions Console of the portal server.
       2) Go to **Security** > **Global Security** > **RMI/IIOP security** > **CSIv2 outbound communications**.
       3) Check **Use identity assertion**.
       4) When you are done, restart the portal server.
    b. Enable CSIv2 Identity Assertion on the inbound connection:
       1) Access the WebSphere Integrated Solutions Console of the remote server.
       2) Go to **Security** > **Global Security** > **RMI/IIOP security** > **CSIv2 inbound communications**.
       3) Check **Use identity assertion**.
       4) Under **Trusted identities**, enter either an asterisk (*) or the identity of the portal server.
       5) When you are done, restart the remote server.

       For more detailed information, refer to the WebSphere Application Server information center.
13. Back on your portal, configure Portal Search for remote search service.

    Cluster note: In a clustered environment, complete this step on the primary node only.

"Updating remote search service by using manual steps"
If you originally installed the remote service by using manual steps, then you must use manual steps to upgrade it after you apply the combined cumulative fix on the portal server.

Updating remote search service by using manual steps:

If you originally installed the remote service by using manual steps, then you must use manual steps to upgrade it after you apply the combined cumulative fix on the portal server.

Before you begin

Apply the combined cumulative fix on the portal server. For more information about applying the combined cumulative fix, go to IBM WebSphere Portal V8.5.0.0 combined cumulative fix instructions: remote search.

Procedure

1. Copy `PseLibs.zip` and depending on the requirements of your environment, copy one of the two files `WebScannerSoap.ear` or `WebScannerEjbEar.ear` to the directory *AppServer_root*`/installableApps`. You find these files in the following locations of your portal installation:
   - The files `WebScannerSoap.ear` and `WebScannerEjbEar.ear` are in the directory *PortalServer_root*`/prereq/prereq.webscanner/installableApps/`
   - The file `PseLibs.zip` is located under directory *PortalServer_root*`/search/wp.search.libs/installableApps`
2. Depending on the requirements of your environment, update one of the two applications `WebScannerEJbEar.ear` or `WebScannerSoap.ear` on a remote server. For example, this can be `server1`. Proceed by the following steps:
   a. Access the WebSphere Integrated Solutions Console.
   b. Click **Applications** > **WebSphere Enterprise Application**.
   c. Depending upon what you originally installed, specify either **PSEStandalone** or **WebScannerEar**.
   d. Click **Update**.
   e. Specify the option to **Replace the entire application**.
   f. Browse and select **WebScannerEjbEar.ear** or **WebScannerSoap.ear**, depending on whether you are using EJB or web service through SOAP.
   g. Click **Next**.
   h. On the following panels, accept the default settings.
   i. A message confirms that the application PSEStandalone (for EJB) or the application WebScannerEar (for SOAP) was updated successfully.
   j. Click **Save to Master Configuration**.
   k. Click **Save**.
3. Extract the Portal Search libraries to the remote server and add them to the class path on the remote server. To do this step, proceed as follows:
   a. Delete the contents of the directory `installableApps/extract` that you created when you first installed the remote search service.
   b. Locate the file `PseLibs.zip` in the directory `installableApps` and extract its contents into the empty directory `installableApps/extract`.
   c. Open the WebSphere Integrated Solutions Console.
   d. Click **Environment** > **Shared Libraries**.

e. Create or modify the new shared library named PSE. When you create the library, check the option **Use an isolated class loader for this shared library**.

f. Click **Apply** > **Save** to save your changes to the configuration.

4. Restart the WebSphere Application Server.

Configuring user repositories on the remote search server

The remote search server must have the same user repositories that are configured in WebSphere Application Server that are configured on the WebSphere Portal Express server. For example, if your WebSphere Portal Express server is configured to an IBM Directory Server LDAP in a federated repository configuration, then the remote search server must also be configured to the same IBM Directory Server LDAP in a federated repository configuration.

After the user repositories are configured the same between the WebSphere Portal Express server and the remote search server, it is possible to configure a dedicated search user from the repository as described in *Setting the search user ID*.

Follow the WebSphere Application Server product documentation *Configuring Lightweight Directory Access Protocol in a federated repository configuration* to configure LDAP settings on the remote search server.

After configuring user repositories on the remote search server, you must enable single-sign on (SSO) between WebSphere Portal Express and the remote search server. For details about how to do this step, refer to *Creating a single-sign on domain between WebSphere Portal and the remote search service*.

Related tasks:

"Setting the search user ID" on page 654
If you work with EJB on a secure server, you need to set the search user ID on the remote search server.

"Creating a single-sign on domain between WebSphere Portal and the remote search service"
View the steps to create a single-sign on (SSO) domain between WebSphere Portal Express and the remote search service. Set up remote search service by using EJB, since SOAP support for remote search services was deprecated with WebSphere Portal Express version 8.0.

Related information:

Configuring Lightweight Directory Access Protocol in a federated repository configuration

Creating a single-sign on domain between WebSphere Portal and the remote search service

View the steps to create a single-sign on (SSO) domain between WebSphere Portal Express and the remote search service. Set up remote search service by using EJB, since SOAP support for remote search services was deprecated with WebSphere Portal Express version 8.0.

Procedure

1. Export the LTPA keys from the WebSphere Portal Express server by completing the following steps.

   Cluster note: In a clustered environment, complete these steps on the Deployment Manager.

   a. Open the WebSphere Integrated Solutions Console.

b. Select **Security** > **Global Security** > **Authentication** > **LTPA**.
c. Enter a password for the key.
d. In the field for the fully qualified key name, enter a key file name and click the **Export keys** button. The keys are written to the file *profile_root*/Key File Name, where *portal_root* is either the Deployment Manager profile or the WebSphere Portal Express profile.

2. Import the key file to the remote search server. If your environment contains extra application servers, complete the following steps on all other servers that you want to be a part of this SSO domain:
   a. Copy the key file that you exported in step 1 from the WebSphere Portal Express server to the remote search server.
   b. Log in to the WebSphere Integrated Solutions Console.
   c. Select **Security** > **Global Security** > **Authentication** > **LTPA**.
   d. In the field for the fully qualified key name, enter the directory and key file name that you specified in step 2a and click **Import keys**. The keys are propagated to all servers of the SSO domain.
   e. Restart all WebSphere Application Server profiles on this server.
3. Ensure that automatic LTPA key generation is disabled on all servers of the SSO domain by completing the following steps:
   a. Log in to the WebSphere Integrated Solutions Console.
   b. Select **Security** > **Global Security**. In the Authentication mechanisms and expiration pane, click **LTPA**.
   c. Within **Key generation**, select **Key set groups**
   d. Click **NodeLTPAKeySetGroup**.

      Cluster note: In a clustered environment, click **CellLTPAKeySetGroup**.
   e. In the Key generation pane, disable the **Automatically generate keys** check box.
   f. Click **OK**.
   g. Click **Save** to save your changes to the master configuration.
   h. Log out of the WebSphere Integrated Solutions Console.
4. Verify that the system clocks are within 5 minutes of each other between the WebSphere Portal Express server or servers and the remote search service server.

   Note: Failure to have the clocks in sync will lead to an import failure in the next step.
5. Add the signer certification of the remote search service server into the portal server by completing the following steps:
   a. Access the WebSphere Integrated Solutions Console of the portal server.

      Cluster note: In a clustered environment, complete these steps on the Deployment Manager.
   b. Click **Security** > **SSL certificate and key management** > **Key stores and certificates** > **NodeDefaultTrustStore** > **Signer certificates** > **Retrieve from port**.

      Cluster note: In a clustered environment, the path is **Security** > **SSL certificate and key management** > **Key stores and certificates** > **CellDefaultTrustStore** > **Signer certificates** > **Retrieve from port**.

c. Enter the remote search service server host, its SSL port, and an alias.
d. Click **Retrieve Signer Information**.
e. Click **OK**.

6. Add the signer certification of the portal server into the remote search service server by completing the following steps:
   a. Access the WebSphere Integrated Solutions Console of the remote search service server.
   b. Click **Security** > **SSL certificate and key management** > **Key stores and certificates** > **NodeDefaultTrustStore** > **Signer certificates** > **Retrieve from port**.
   c. Enter the portal server host, its SSL port, and an alias.
   d. Click **Retrieve Signer Information**.
   e. Click **OK**.
7. In the portal server enable CSIv2 identity assertion. To complete this step, proceed as follows:

   Cluster note: In a clustered environment, complete these steps on the Deployment Manager WebSphere Integrated Solutions Console.
   a. Enable CSIv2 Identity Assertion on the outbound connection:
      1) Access the WebSphere Integrated Solutions Console of the portal server.
      2) Go to **Security** > **Global Security** > **RMI/IIOP security** > **CSIv2 outbound communications**.
      3) Check **Use identity assertion**.
      4) When you are done, restart the portal server.
   b. Enable CSIv2 Identity Assertion on the inbound connection:
      1) Access the WebSphere Integrated Solutions Console of the remote server.
      2) Go to **Security** > **Global Security** > **RMI/IIOP security** > **CSIv2 inbound communications**.
      3) Check **Use identity assertion**.
      4) Under **Trusted identities**, enter either an asterisk (*) or the identity of the portal server.
      5) When you are done, restart the remote server.

      For more detailed information, refer to the WebSphere Application Server information center.

What to do next

For more details about exporting the LTPA token, refer to the WebSphere Application Server information center by going to**Administering** > **Security** > **Managing security** > **Configuring authentication mechanisms** > **Configuring Lightweight Third Party Authentication** > **Lightweight Third Party Authentication settings**. You can also locate this topic by opening the search feature of the WebSphere Application Server information center and searching for `ltpa key export`.

If you work with EJB on a secure server, you must set the search user ID. For details about how to do this step, refer to "Setting the search user ID."

Setting the search user ID

If you work with EJB on a secure server, you need to set the search user ID on the remote search server.

Before you begin

Ensure that your **SearchAdminUser** alias matches your WebSphere Portal Express administrator information. Complete the following steps to view or change the information that is stored in your **SearchAdminUser** alias:

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Security** > **Global security**.
3. In the Authentication section, click **Java Authentication and Authorization Service** > **J2C authentication data**.
4. Edit the **SearchAdminUser** alias.
5. Update the user ID and/or password to match your WebSphere Portal Express administrator information.
6. If you are working in a clustered environment, you must synchronize the nodes of your cluster. To synchronize the nodes of your cluster, complete the following steps:
   a. Log on to the Deployment Manager.
   b. Go to **System Administration** > **Nodes**.
   c. Select the nodes to synchronize from the list.
   d. Click **Full Resynchronize**.
7. Restart the portal servers.

About this task

In a remote search environment, the remote search server must be configured for the same LDAP as WebSphere Portal Express.

Procedure

1. Open the WebSphere Integrated Solutions Console.
2. Click **Applications** > **Application Types** > **WebSphere enterprise applications**.
3. Locate the application **PSEStandalone**.
4. Enter this application and click **Security roles to user/group mapping**.
5. Select the role **SearchUser** and click **Map users**.
6. On the portal that accesses the EJB, search for the user ID that is set as the WebSphere Application Server Admin User. For example, you can find this ID by using the following procedure:
   a. Open the WebSphere Integrated Solutions Console.
   b. Click **Global Security** > **Federated LDAP registry**.
   c. Determine the primary administrative user ID.
7. To continue installing remote search service manually, proceed by the following steps:
   a. Return to the WebSphere Integrated Solutions Console of the machine where the EJB is installed.
   b. Type the name that you found as the user ID in a previous step as the search string and click **Search**. As a result, the user ID and its configuration parameters are displayed in the **Available** box.
   c. Add this user ID to the **Selected** box by clicking the double-angled bracket **> >** button.
   d. Click **OK** to save your updates.

e. Restart the WebSphere Application Server on which the PSEStandalone is installed.

Removing search collections

If you plan to use search in a cluster, you must configure a remote search server. If you created any search collections, you must re-create them on the remote search server. If your search collection has data, export the collection before you delete it. Then, import it to the remote server.

Procedure

1. Prevent the creation of search collections. To do so, complete the substeps listed here.

   Note: CF07 If you have CF07 or a later fix pack installed, start the portal configuration engine task `suppress-automatic-search-service-creation` to prevent the creation of search collections. You do not need to perform the substeps listed here. After running the configuration task, continue with the next main step that deletes all search collections from the primary node.

   a. Log in to the WebSphere Integrated Solutions Console.

      Cluster note: If this web content server is part of a cluster, log on to the Deployment Manager WebSphere Integrated Solutions Console.

   b. Go to **Resources** > **Resource Environment** > **Resource Environment Providers** > **JCR ConfigService PortalContent** > **Custom properties**.

   c. Set the **`jcr.textsearch.enabled`** parameter to `false`.

   d. Go to **Resources** > **Resource Environment** > **Resource Environment Providers** > **WP ConfigService** > **Custom properties**.

   e. Set the `search.service.suppress_automatic_creation` property to `true`. If the property does not exist, create it.

   f. Click **Apply** and save your changes to the master configuration.

   g. Restart your server.

2. Delete all existing search collections from the primary node. To do so, complete the following substeps:

   a. Log on to WebSphere Portal Express.

   b. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.and then click **Search Collections**.

   c. Click the **Delete Collection** icon for each search collection and then click **OK** until they are all deleted.

   d. Restart the WebSphere_Portal server and then go back to the **Search Collections** page to verify that all search collections are deleted.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Related reference:

"Configuration Service" on page 297
The portal Configuration Service is responsible for collecting the most essential configuration data of the IBM WebSphere Portal Express engine.

Configuring a remote search service

Configure a remote search service for Portal Search.

About this task

To configure a remote search service for Portal Search, proceed as follows:

Cluster note: In a clustered environment, complete these steps on the primary node.

Procedure

1. Log in to your portal as an administrator.
2. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
3. Click **Search Services**.
4. Click **New Search Service**.
5. For the **Search service implementation** select **Portal Search Service Type**.
6. To configure a remote search service by using EJB, proceed as follows:
   a. Edit the search service parameter `PSE_TYPE` and change its value to `ejb`.
   b. Modify the parameter `IIOP_URL`. Set its value to `iiop://` *`your_ejb_search_server.your.example_domain.com:port`*, where *`your_ejb_search_server.your.example_domain.com`* is the name of the remote search server and *`port`* is the port number that you obtained in the step to determine the port for EJB under Preparing for remote search service. For example, this can be `iiop://ejb_server.your_company.com:2809`.
   c. Modify the parameter `EJB`. Set it to the following value: `ejb/com/ibm/hrl/portlets/WsPse/WebScannerLiteEJBHome`. This is the default JNDI name. If you modified the EJB parameter to a JNDI name of your own choice, use that name instead.
7. Modify the parameter `DefaultCollectionsDirectory` to the portal search service. Use it to determine the default directory where your search collections are created on the server that hosts the remote search service. This parameter does not have a default value.
8. Add the parameter `CONFIG_FOLDER_PATH` to the portal search service. Use it to determine where the configuration data for search collections is stored on the server that hosts the remote search service. The default is *`wp_profile_root`*`/CollectionsConfig`.
9. Depending on, whether you are using EJB or web service through SOAP, type `Remote PSE service EJB` or `Remote PSE service SOAP` for the service name.

   Note: Configuring for remote search service as a web service through SOAP is not supported on Portal 8.5.
10. Click **OK** to save the new search service. The **Manage Search** portlet now lists the new search service in the list of search services. A green check in the status column indicates that the new search service is working correctly. If the search service is not working properly, it has a red cross, and a message is displayed. Click the **View details** link of the message for more information about the problem and how to resolve it.
11. Restart all servers in your configuration for your changes to take effect.

What to do next

For more information about the search service configuration parameters, see to "Search service configuration parameters" on page 674.

1. "Creating a new search service"
   Learn about creating a new search service for Portal Search.
2. "Creating new search collections" on page 659
   Before you can begin using remote search service, you must create two new search collections, one for JCR search, and one for Portal search.
3. "Creating a new content source" on page 660
   Before you can begin using remote search service, you must create three new content sources, one for the Web Content Manager, one for your portal site, and one for JCR search.

Creating a new search service:

Learn about creating a new search service for Portal Search.

About this task

Cluster note: In a clustered environment, complete these steps on the primary node.
For more detailed information about the search service configuration parameters refer to "Search service configuration parameters" on page 674.

Procedure

1. Log in to your portal as an administrator.
2. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**. Then, click **Search Services**.
3. Click **New Search Service**.
4. Depending on whether you are using EJB or Web service via SOAP, type `Remote PSE service EJB` or `Remote PSE service SOAP` for the service name.

   Note: Configuring for remote search service as a Web service via SOAP is not supported on Portal 8.5.
5. For the **Search service implementation** select **Portal Search Service Type**.
6. To configure a remote search service by using EJB, proceed as follows:
   a. Edit the search service parameter `PSE_Type` and change its value to `ejb`.
   b. Modify the parameter `IIOP_URL`. Set its value to `iiop://` *`your_ejb_search_server.your.example_domain.com:port`*, where *`your_ejb_search_server.your.example_domain.com`* is the name of the remote search server and *`port`* is the port number that you obtained in the

step to determine the port for EJB under Preparing for remote search service. For example, this can be `iiop://ejb_server.your_company.com:2809`.

c. Modify the parameter `EJB`. Set it to the following value: `ejb/com/ibm/hrl/portlets/WsPse/WebScannerLiteEJBHome`. This is the default JNDI name. If you have modified the EJB parameter to a JNDI name of your own choice, use that name instead.

7. Modify the parameter `DefaultCollectionsDirectory` to the portal search service. Use it to determine the default directory where your search collections are created on the server that hosts the remote search service. This parameter does not have a default value.
8. Add the parameter `CONFIG_FOLDER_PATH` to the portal search service. Use it to determine where the configuration data for search collections is stored on the server that hosts the remote search service. The default is *wp_profile_root*`/CollectionsConfig`.
9. Click **OK** to save the new search service. The **Manage Search** portlet now lists the new search service in the list of search services. A check mark in the status column indicates that the new search service is working correctly. If the search service is not working properly, it has a red cross, and a message is displayed. Click the **View details** link of the message for more information about the problem and how to resolve it.
10. Restart all servers in your configuration for your changes to take effect.

What to do next

Manually create new search collections for JCR search and Portal search.

Creating new search collections:

Before you can begin using remote search service, you must create two new search collections, one for JCR search, and one for Portal search.

Procedure

1. Manually create a JCR search collection by following the instructions that are outlined in *Setting up a JCR search collection* in the related links.

   Important: The steps that are outlined in *Setting up a JCR search collection* include instructions on how to create the new content source for the JCR search collection. Create the new content source for the JCR search collection before you create the Portal search collection.
2. Manually create a Portal search collection by completing the following steps:
   a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   b. Click **Search collections.**
   c. To create a new search collection, click **New collection**.
   d. Specify the following values for the parameters as required:

      Search Service
      Select **Remote Search Service**.

      Location of collection
      The directory location for the collection where you intend the search collection to be created. This parameter is to be specified as *index directory location*`/`*collection name*.

Name of collection.
Specify the name of the collection.

Description of collection
This parameter is optional.

Specify Collection language
Specify the collection language. By default this parameter is set to English (United States).

e. Click **OK**. The collection displays in the Collections from All Services pane.

What to do next

Manually create new content sources for the Portal search collection.

Related tasks:

"Setting up a JCR search collection" on page 698
A JCR search collection is a special purpose search collection that is used by WebSphere Portal applications. It is not designed to be used alongside user-defined search collections. A JCR search collection requires a special setup. This setup includes the creation of a new content source for the search collection. Under normal circumstances, you do not need to re-create the JCR search collection. However, in rare cases you might need to re-create it, for example if you deleted the default JCR search collection.

Creating a new content source:

Before you can begin using remote search service, you must create three new content sources, one for the Web Content Manager, one for your portal site, and one for JCR search.

Before you begin

Create the new search collection for the remote search service. For detailed instructions about how to create new search collections, see *Creating new search collections*.

Important: The steps that you used to create the JCR search collection in *Setting up a JCR search collection* also included instructions about how to create the new JCR content source. If you created the JCR content source immediately after creating the JCR search collection, you do not need to create the JCR content source again.

Procedure

1. If you did not manually create a new JCR content source when you created the JCR search collection, create the JCR content source now. For detailed instructions about how to create JCR content sources, see *Setting up a JCR search collection*.
2. Manually create the new content source for your Portal site by completing the following steps:
   a. Click the name of the search collection that you created in *Creating new search collections*.
   b. Click **New Content Source**.
   c. In the **Content source type** field, specify **Portal site**. The portal URL is completed by default.

Note: If you are using a webserver, change the portal URL to specify the webserver host name and port.

d. Click the **Security** tab.

e. Specify your portal user name and password.

f. Specify the host name.

g. In the Define security realm pane, click **Create**. The security realm displays in the Security realms pane.

h. In the Manage Search pane, click **Create**. If the content source was created successfully, the following message displays: `EJPJB0025I: Content source source_name in collection collection_name is OK.`

i. Start the crawler to verify that the content source is working.

3. Manually create the new content source for your Web Content Manager site by completing the following steps:

a. Click the name of the search collection that you created in *Creating new search collections*.

b. Click **New Content Source**.

c. In the **Content source type** field, specify **WCM site**.

d. In the **Collect documents linked from this URL** field, specify the following URL: `http://server_name:port_number/wps/seedlist/myserver?SeedlistId=&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Actio`

Note: If you are using a webserver, in the **Collect documents linked from this URL** field, specify the webserver host name and port.

e. Click the **Security** tab.

f. Specify your portal user name and password.

g. Specify the host name.

h. In the Define security realm pane, click **Create**. The security realm displays in the Security realms pane.

i. In the Manage Search pane, click **Create**. If the content source was created successfully, the following message displays: `EJPJB0025I: Content source source_name in collection collection_name is OK.`

j. Start the crawler to verify that the content source is working.

Configuring HTTP for the seedlist servlet

Learn how to configure HTTP for the seedlist servlet. The seedlist servlet requires HTTPs by default. Therefore, when you access the servlet through HTTP, WebSphere Application Server redirects you to HTTPs.

About this task

This is an optional step that can be completed while installing and configuring remote search service.

Procedure

1. On the portal server, open the following file with an editor: `PortalServer_root/search/wp.search.servlets/seedlist/servletEAR/installableApps/wp.search.seedlist.ear/wp.search.servlets.seedlist.war/WEB-INF/web.xml`

Cluster note: In a clustered environment, complete this step on the primary node and all secondary nodes.

2. Update the following code:

   Cluster note: In a clustered environment, complete this step on the primary node and all secondary nodes.

   ```
   <user-data-constraint>
        <transport-guarantee>CONFIDENTIAL</transport-guarantee>
   </user-data-constraint>
   ```

   Replace it by the following code:

   ```
   <user-data-constraint>
        <transport-guarantee>NONE</transport-guarantee>
   </user-data-constraint>
   ```

3. Save the file.

   Cluster note: In a clustered environment, complete this step on the primary node and all secondary nodes.

4. Run the following portal ConfigEngine script:

   Cluster note: In a clustered environment, complete this step on the primary node only.

   ```
   ./ConfigEngine.sh action-update-ear-wp.search.servlets/seedlist/servletEAR
   ```

5. Restart all servers in your configuration for your updates to take effect.

What to do next

Remove any local search collections that are defined in WebSphere Portal Express and create new search collections by using the remote search server. For more information about deleting and creating search collections, see the following topics:

- If your system is operating in a portal farm, continue on to *Configuring search in a portal farm*.
- If your system is operating in a clustered environment, continue on to *Configuring search in a cluster*.

Configuring search in a cluster

IBM WebSphere Portal Express provides two distinct search capabilities. You can use both types of search capabilities in a clustered environment.

"Configuring Portal Search in a cluster"
To support Portal Search in a cluster, you must install and configure a remote search service on an IBM WebSphere Application Server node that is not part of the cluster.

"Configuring JCR search in a cluster" on page 663
To enable search in a cluster for content that is stored in the JCR database, you must configure each server in the cluster to access a directory. JCR-based content includes content that is created with Web Content Manager or Personalization.

Configuring Portal Search in a cluster

To support Portal Search in a cluster, you must install and configure a remote search service on an IBM WebSphere Application Server node that is not part of the cluster.

Procedure

1. Install the remote search service. For more information on installing remote search service, see *Remote search service* in the related links section.

2. Configure the remote search service. For more information on configuring the remote search service, see *Configuring a remote search service* in the related links section.

Related concepts:

"Remote search service" on page 645
You can configure the search portlets for local operation, or you can configure them for remote search service. Depending on your configuration, remote search service might have performance benefits by offloading and balancing system load.

Related tasks:

"Configuring a remote search service" on page 657
Configure a remote search service for Portal Search.

Configuring JCR search in a cluster

To enable search in a cluster for content that is stored in the JCR database, you must configure each server in the cluster to access a directory. JCR-based content includes content that is created with Web Content Manager or Personalization.

Before you begin

Set up remote search service on the primary node of the cluster. For more information about setting up remote search service, see *Configuring a remote search service* in the related links.

Procedure

1. Log in to the WebSphere Integrated Solutions Console of the deployment manager.
2. Select **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. In the Resource environment providers page, make the appropriate selection to update the custom properties for all of the servers in the cluster. Choose one of the following two options:
   - Select the appropriate cluster from the Scopes list.
   - Clear the **Show Scope** check box and select **Browse Clusters** to specify the portal cluster.
4. Select **JCR ConfigService PortalContent** > **Custom properties**.
5. Change the value of the **jcr.textsearch.indexdirectory** property to point to a directory on the remote search server. For example, **jcr.textsearch.indexdirectory**=C:/JCR.
6. Change the **jcr.textsearch.PSE.type** property to EJB.
7. Change the **jcr.textsearch.EJB.IIOP.URL** property to the URL of the naming service that is used to access the WebScanner EJB. For example, iiop://localhost:2811.
8. Change the **jcr.textsearch.EJB.EJBName** property to the name of the WebScanner EJB. For example, ejb/com/ibm/hrl/portlets/WsPse/WebScannerLiteEJBHome.
9. Change the **jcr.textsearch.enabled** value to true.
10. Save your changes.
11. Restart your servers.
12. Required: In a cluster, you must drop the JCRCollections in the default search service and then re-create them in a remote search service, otherwise you receive display errors in your search. Complete the following steps to delete the JCRCollections from the Manage Search portlet:

a. Log on to WebSphere Portal Express as an administrator.
b. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
c. Click **Search Collections**.
d. Click the **Delete Collection** icon for the JCRCollection1 search collection.
e. Click **OK**.
f. Restart the WebSphere Portal Server.
g. Go to the Manage Search portlet and confirm that the JCRCollection1 search collection was deleted.
h. Manually create a JCR search collection called `JCRCollection1`. For more information about creating the JCR search collection, see *Setting up a JCR search collection* in the related links.

Related tasks:

"Setting up a JCR search collection" on page 698
A JCR search collection is a special purpose search collection that is used by WebSphere Portal applications. It is not designed to be used alongside user-defined search collections. A JCR search collection requires a special setup. This setup includes the creation of a new content source for the search collection. Under normal circumstances, you do not need to re-create the JCR search collection. However, in rare cases you might need to re-create it, for example if you deleted the default JCR search collection.

"Configuring a remote search service" on page 657
Configure a remote search service for Portal Search.

Related reference:

"JCR search service configuration parameters" on page 680
The following search service configuration parameters can be modified to enable and configure searching for content that is stored in the JCR database. These JCR search service configuration parameters can be modified by accessing the **JCR ConfigService PortalContent** resource environment provider.

Configuring search in a portal farm

IBM WebSphere Portal Express provides two distinct search capabilities. You can use both types of search capabilities in a portal farm environment.

"Configuring a remote Search in a portal farm"
To support Search in a portal farm, you must install and configure a remote search service. Install and configure it on an IBM WebSphere Application Server instance that is not part of the farm.

"Configuring JCR search in a portal farm" on page 665
JCR-based content includes content that is created with Web Content Manager or Personalization.

Configuring a remote Search in a portal farm

To support Search in a portal farm, you must install and configure a remote search service. Install and configure it on an IBM WebSphere Application Server instance that is not part of the farm.

About this task

Procedure

1. Install the remote search service. Go to the installation topics in "Remote search service" on page 645 for specific steps.

The service is on a remote WebSphere Application Server instance that is not part of the portal farm. You can provide the remote search service either as an EJB or as a web service with SOAP. Deploy the appropriate EJB or SOAP EAR file on the remote WebSphere Application Server instance. For details, refer to the WebSphere Application Server documentation.

2. Configure the search portlets for remote search service so that they access the remote server.
3. Complete the following steps to ensure that the Seedlist Servlet is started:
   a. Log on to the WebSphere Integrated Solutions Console on the remote server.
   b. Go to **Applications** > **Application Types** > **WebSphere enterprise applications**.
   c. Search for the **Seedlist Servlet**.
   d. Ensure that the **Application Status** is set to the arrow. If it is not started, click **Start**.
   e. Save your changes and then log out of the WebSphere Integrated Solutions Console.

What to do next

Notes:

1. You must configure the default location for search collections to a directory on the remote server that has write access.
2. The portal site default search collection is created the first time when an administrator selects the Manage Search portlet. If this occurred *before* you configure the remote search portlet, the default portal site search collection is only available on the primary farm instance. However, it is not available on the remote server. In this case, you must re-create the portal site collection to make it available for search on all instances of the farm.

Configuring JCR search in a portal farm

JCR-based content includes content that is created with Web Content Manager or Personalization.

About this task

Note: If you create content in a portal farm with the **Authoring** portlet, extra configuration steps are required. The steps enable content that is created by these content features to be searchable in a farm.

Procedure

1. Log in to WebSphere Integrated Solutions Console.

   Cluster note: In a clustered environment, log in to the Deployment Manager WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **JCR ConfigService PortalContent** > **Custom properties**.
3. Change the value of the **jcr.textsearch.enabled** property to `false`.
4. Change the value of the **jcr.textsearch.indexdirectory** property to the index directory on the remote search server.

   For example, `jcr.textsearch.indexdirectory=\\\\your_server\\your_remotesearch\\jcr\\search`. You can specify the directory value in the following format:

Universal Naming Convention (UNC) format

`\\\\your_server\\your_remotesearch\\jcr\\search`

Example: `\\\\hostname.example.com\\share\\jcr\\search`

5. Based on the configuration of your remote search service, change the **jcr.textsearch.PSE.type** property to either `EJB` or `SOAP`; then choose the appropriate extra steps:

*Table 78. The steps depend on the value for the **jcr.textsearch.PSE.type** property.*

Value	Extra steps
EJB	Complete the following steps if you have an EJB service: 1. Change the **jcr.textsearch.EJB.IIOP.URL** property to the URL of the naming service that is used to access the WebScanner EJB; for example `iiop://localhost:2811`. 2. Change the **jcr.textsearch.EJB.EJBName** property to the name of the WebScanner EJB; for example `ejb/com/ibm/hrl/portlets/WsPse/WebScannerLiteEJBHome`.
SOAP	If you have a SOAP service, change the **jcr.textsearch.SOAP.url** property to the SOAP URL of the WebScanner for the search service.

6. Save your changes.
7. Restart your server.
8. Required: Complete the following steps to delete the default search collections from the Manage Search portlet:
   a. Log on to WebSphere Portal Express as an administrator.
   b. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   c. Click **Search Collections**.
   d. Click the **Delete Collection** icon for the **Portal Content** search collection.
   e. Click **OK**.
   f. Restart the WebSphere_Portal server.
   g. Go to the Manage Search portlet and confirm that the **Portal Content** search collection was deleted.
   h. Manually create a JCR collection called `JCRCollection1`; refer to Setting up JCR Search Collection for information.

Related reference:

"JCR search service configuration parameters" on page 680
The following search service configuration parameters can be modified to enable and configure searching for content that is stored in the JCR database. These JCR search service configuration parameters can be modified by accessing the **JCR ConfigService PortalContent** resource environment provider.

Configuring search collections for a virtual portal

Configuring JCR search collections for a virtual portal might require additional administration, depending on how you set up the virtual portal.

When you create a virtual portal, the creation of the JCR search collection depends on whether you create the virtual portal with or without content:

- If you create the virtual portal with content, the portal creates the JCR collection for the virtual portal by default.
- If you create only the virtual portal and add no content to it, the portal creates no JCR collection with it. It gets created only when content is added to the virtual portal.

You can view the URL of the JCR search collection in the search administration portlet Manage Search of the virtual portal. The URL looks as follows:

```
 http://host_name:port_number/wps/seedlist/myserver/
hello?Action=GetDocuments&Format=ATOM&Locale=en_US&Range=100
&Source=com.ibm.lotus.search.plugins.seedlist.retriever.jcr.JCRRetrieverFactory&Start=0&
```

Where *wsid* is the actual workspace ID of the virtual portal. The workspace ID is the identifier of the workspace in which the content item is created, stored, and maintained. For example, if the workspace ID of the virtual portal is 10, then the URL looks as follows:

```
http://host_name:port_number/wps/seedlist/myserver/
hello?Action=GetDocuments&Format=ATOM&Locale=en_US&Range=100
&Source=com.ibm.lotus.search.plugins.seedlist.retriever.jcr.JCRRetrieverFactory&Start=0&
```

If the JCR search collection was deleted, or if you added content to an originally empty virtual portal and the JCR search collection was not automatically created, complete the following steps:

- If you are using a virtual portal, go to the Security tab of the content source to verify that the workspace ID of the virtual portal is correct.
- If the JCR search collection was deleted, run the **`ConfigEngine`** task `create-textsearch-collections` to re-create the JCR search collection.

If neither of the preceding options succeed in creating the JCR search collection, manually set up the JCR search collection.

To view the steps to manually set up a JCR search collection, see *Setting up a JCR search collection* in the related links.

Related tasks:

"Setting up a JCR search collection" on page 698
A JCR search collection is a special purpose search collection that is used by WebSphere Portal applications. It is not designed to be used alongside user-defined search collections. A JCR search collection requires a special setup. This setup includes the creation of a new content source for the search collection. Under normal circumstances, you do not need to re-create the JCR search collection. However, in rare cases you might need to re-create it, for example if you deleted the default JCR search collection.

Portal Search

Use Portal Search to facilitate indexing content sources and searching for information. You can administer search services, search collections, and search scopes, as well as enhance the search experience of your portal site with the portal search portlets.

 Technotes for portal search

Portlets for working with Search

Get an overview of the portal search portlets.

The portal search portlets are briefly described in the following sections:

- Overview of Portal Search portlets
- Search administration portlet **Manage Search**
- **Search Center** portlet for search by users

For more details about enhancements to the search portlets for IBM WebSphere Portal Express Version 8.5, refer to Portal Search.

Overview of Portal Search portlets

The following portlets are all installed and deployed as part of the default portal installation:

- For use by administrators: Manage Search
- For users: Search Center

If you want to use the other search-related portlets in your portal, you have to install them and configure them according to your requirements. Here is an overview of the Portal Search administration and user portlets:

Table 79. Administration portlet and installation status

Administration portlet	Installation status
Manage Search	Installed and deployed

Table 80. User portlets and installation status

User portlets	Installation status
Search Center	Installed and deployed
Suggested Links	Installed and deployed
External Search Results	Installed and deployed

You can install additional copies of the Suggested Links and External Search Results portlets and apply special configurations. For details refer to the topics about adding and configuring these portlets and about customizing the Search Center.

Portal Search portlets are not compatible with WSRP

The Portal Search portlets cannot be provided as WSRP services, as some additional and more advanced WebSphere Portal Express concepts and features are not yet reflected by the current WSRP standard. This includes the Portal Search portlets Manage Search and the Search Center.

Search administration portlet Manage Search

Manage Search is the Portal Search administration portlet. It has three main sections:

- **Search Services**: Use this section to manage search services.
- **Search Collections**: Use this section to manage search collections and their content sources.
- **Search Scopes**: Use this section to manage search scopes and custom links to web search locations.

You can use the Manage Search portlet to perform the following administrative tasks:

1. Manage search services. You can use the search services that are provided with portal, or you can add one or more search services to Portal Search. For example, this is required in scenarios where you set up remote search or your portal is set up in a cluster.
2. Manage search collections. You can define one or more search collections for a search service.
3. Manage the content sources of search collections. You can combine content sources of different types in one search collection.
4. Perform administrative tasks required as preparatory steps for the search feature, such as indexing.
5. Manage search scopes. You can define search scopes to limit search results to specific content locations and specific document types. This enables users to target their searches better.
6. Manage custom links. You can add custom links with web link shortcuts to search locations. This enables users to do direct searches to popular web search engines, such as Google or Yahoo!
7. Search and browse a search collection. Manage Search provides a user interface with administrative tasks for search collections. For example, you can edit documents, or you can select documents that you do not want to make available to users for search and delete them.

For detailed information about how to use the Manage Search portlet, refer to the portlet help. Depending on your requirements, you might have to perform other administrative tasks for Portal Search. For example, you can prepare security for Portal Search, or configure remote search or search in a portal cluster. For more information about the Manage Search portlet and other administrative tasks related to search, refer to the other topics in the Portal Search section.

Search Center portlet for search by users

The Search Center portlet provides a central starting point to all searchable content sources made available to the Portal. Users can use the Search Center to search documents and content. The default search scope is **All Sources**. This searches through all search collections that are available to the user by the access permission rights. You can allow more focused searches by providing additional search scopes. Refer to Search scopes for more information.

The Search Center portlet is installed as part of the default portal installation. Note that it is deployed and placed on a hidden portal page. The portal takes users to the Search Center when they enter a search using the portal Search Box.

Starting with Version 8 of WebSphere Portal Express the Search and Browse portlet provided with earlier portal versions is no longer available. The Search Center has been enhanced with advanced search options previously available in the Search and Browse portlet. Categorization and taxonomy are no longer available.

Note: By default both the Search Center portlet and the Search box are available only to authenticated users, that is for users who have logged on with a user ID and password. Anonymous users, that is users who access the portal without logging in, cannot use the Search Center or the search box. For more information about how to use the search portlets on anonymous pages refer to Enabling anonymous users to search public pages of your portal.

For more details about the Search Center portlet, refer to the following information:

- For more information about how to work with the Search Center, refer to the portlet help.
- For hints about using the Search Center for remote search on web sites with different languages, refer to Hints and tips for using Portal Search.

Related tasks:

"Administering Portal Search" on page 671
You can administer and configure many details for Portal Search.

"Managing search scopes and custom links" on page 687
Get an overview of search scopes and custom links and how you can manage them.

"Enabling anonymous users to search public pages of your portal" on page 641
You can enable anonymous users (sometimes also called unauthenticated users) to search public pages of your portal by using the portal Search Center portlet. Search by anonymous users works only on public pages of your portal, as the users are not logged in to your portal.

"Customizing the Search Center" on page 687
Customize the Search Center by adding, removing and configuring additional portlets, such as External Search Results or Recommended Links. The external search results portlet displays search results from third-party external search engines such as Yahoo and Google. Using the recommended links portlet, display search results from a collection of predefined links with predefined keywords. You can also configure the All Sources scope or replace it with a customized scope.

"Configuring the Suggested Links view" on page 692
Customize the display of search results to show users the preferred or recommended results and associated links.

"Adding and configuring the External Search Results portlet" on page 688
Configure a portlet that retrieves and displays search results from third-party search engines, then add the External Search Results portlet to the Search Center.

Administering Portal Search

You can administer and configure many details for Portal Search.

About this task

Note: Before you start administering Portal Search, review the topic about Planning and Preparing for Portal Search.

Manage Search is the Portal Search administration portlet. It has three main sections:

- Search Services: Use this section to manage search services.
- Search Collections: Use this section to manage search collections and their content sources.
- Search Scopes: Use this section to manage search scopes and custom links to Web search locations.

In order to enable Portal Search and make documents available for search by users, you perform administrative tasks such as the following:

Procedure

1. Create search services. You can use the default search services provided with portal, or you can create additional search services, for example, for setting up remote search or search in a portal cluster.
2. Configure Portal Search. You do this by configuring the search service.
3. Configure the search portlets for various environments and requirements, for example, for local or remote search service, or for search on anonymous pages.
4. Manage Portal Search for users:
   a. Create a search collection and define its properties, thereby allowing for fast and efficient searches.
   b. Create one or more content sources for that collection and have them crawled.

   For more details about these tasks refer to the topic about Setting up search collections.

Migrating search collections: Starting with WebSphere Portal Express Version 6.1 the syntax of the seedlist URL has changed to seedlist format 1.0. Older search collections created before portal V 6.1 use seedlist format 0.9 and cannot be reused or migrated to the new format. Starting with WebSphere Portal Express Version 7 JCR was added as 1.0 seedlist format. Be sure that you index all content again before using seedlist format 1.0.

Results

What to do next

Portal Search is preconfigured with a search service, a portal site search collection, and scopes. You can add and remove search services, collections, and scopes.

You can perform most of the configuration tasks for Portal Search by using the administration portlet **Manage Search**. By alternative, you can also administer Portal Search by using the WebSphere Integrated Solutions Console and resource providers in XML format.

All search collections are available by the **All Sources** selection option of the Search Center portlet.

"Managing search services" on page 673
Get an overview of how you manage the portal search services. This task includes creating a new search service or editing an existing search service.

Managing search services

Get an overview of how you manage the portal search services. This task includes creating a new search service or editing an existing search service.

About this task

To create or edit a portal search service, proceed as follows:

Procedure

1. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
2. Click **Search Services**. Manage Search displays the Search Services panel.
3. If you want to create a new search service, click the **New Search Service** button. If you want to modify an existing search service, click the **Edit** icon for that search service. Manage Search lists the parameter key and value pairs for the search service.

Results

Set or edit the parameter values depending on your requirements and configuration.

Notes for configuring a search service:

1. Unless otherwise stated, the values that you set for parameters of a portal search service apply to that search service and all its collections. They do not affect other search services of the portal or their search collections.
2. Unless otherwise stated, changing the value of a parameter changes both the existing search collections and newly created search collections. Some parameters affect only newly created search collections. These parameters cannot be updated for existing search collections.
3. The search administration portlet Manage Search lists the Default Portal Search Service and its collection Portal Content or other collections in the default portal language and not in the language that the user selected as preferred language for the portal or set in the browser. For example, if the portal default language is set to English and the user selected German as the preferred portal language or set the browser language to German, the Default Portal Search Service and its collections show in English.
4. SOAP support for remote search services was deprecated with WebSphere Portal Express Version 8.0. EJB is still supported.
5. If you delete a search service, the portal does not delete the search collections that are related to this search service. Delete the search collections by using the Manage Search administration portlet. If you delete the default search service, it is re-created new when you restart the portal.

What to do next

For more detailed steps about how to manage search services refer to the Manage Search portlet help. For a list of the search service parameters and possible values, refer to *Search service configuration parameters*.

If you want to create a search service for remote Portal Search, refer to *Configuring a remote search service*.

Related tasks:

Search service configuration parameters

Learn about the portal search service parameters and possible values.

To configure a portal search service, use the following parameters. For details about how to set the values for these parameters refer to *Managing search services* or the Manage Search administration portlet help.

Notes for configuring a search service:

1. Unless otherwise stated, the values that you set for parameters of a portal search service apply to that search service and all its collections. They do not affect other search services of the portal or their search collections.
2. Unless otherwise stated, changing the value of a parameter changes both the existing search collections and newly created search collections. Some parameters affect only newly created search collections. These parameters cannot be updated for existing search collections.
3. The search administration portlet Manage Search lists the Default Portal Search Service and its collection Portal Content or other collections in the default portal language and not in the language that the user selected as preferred language for the portal or set in the browser. For example, if the portal default language is set to English and the user selected German as the preferred portal language or set the browser language to German, the Default Portal Search Service and its collections show in English.
4. SOAP support for remote search services was deprecated with WebSphere Portal Express Version 8.0. EJB is still supported.
5. If you delete a search service, the portal does not delete the search collections that are related to this search service. Delete the search collections by using the Manage Search administration portlet. If you delete the default search service, it is re-created new when you restart the portal.

Notes related to the search service configuration parameter list:

1. The parameter list in both the search services pane of the Manage Search portlet and in the following information shows several parameters that end with the suffix `_EXAMPLE`. These example parameters are not used by the portal. They serve as an example for the same parameter without the suffix `_EXAMPLE`. They give an example value that you might use. Deleting these parameters or modifying their value has no effect.

2. If you want to set a parameter that is listed here, but not in the portlet, add it. To add a parameter, type the parameter and the value in the entry fields **Parameter key:** and **New parameter value:** and click the **Add Parameter** button.
3. In the following list, the abbreviation **pse** in parameters or values stands for Portal Search Engine.
4. The following list is arranged in alphabetical order. Parameters might be listed in a different order in the portlet.

boostingSettings

Use this parameter to specify which metadata fields are given extra weight in an overall rank score during a search. You can also specify how much the selected metadata fields contribute to relevance circulation when you run a search. Specify the following values:

fieldBoost

This value defines which metadata fields have extra weight when search results are returned, and how much extra weight is given to the specified fields. Provide the following attributes:

field The relevant string-based metadata field that you would like search to focus on. Some common or default field values are `title`, `description`, and `keywords`.

boost The relative amount of extra weight added to the rank score. This value should be set between a range of 1.0 and 10.0. However, the suggested range of the attribute is between 1.0 and 3.0.

phraseBoost

This value is a nonessential variable that focuses search results on specified languages, for example, English.

boostingSetting_Example

The following is an example value for the parameter **boostingSettings**:

```
phraseBoost: {Enabled:true},
fieldBoost: {field:title, boost:3.0},
            {field:description, boost:3.0},
            {field:keywords, boost:2.0}
```

CLEAN_UP_TIME_OF_DAY_HOURS

Time of day at which the portal runs the maintenance process for search collections to remove outdated files and broken links. Possible values are positive integers 0 - 24 for the full hours of the day. The default value is `0` , which runs the cleanup at midnight.

Note: If you modify the value for this parameter, the new value is applied only to newly created collections of the search service. You cannot update this parameter for existing search collections.

DefaultCollectionsDirectory

You can use this parameter to specify the default directory for search collections. If you use Portal Search locally, this parameter is optional. If you specify no value for this parameter, the default collection directory is *wp_profile_root*`/PortalServer/collections`. If you set up a remote search service, this parameter is mandatory. For details about setting this parameter, refer to "Configuring the default location for search collections" on page 682.

DEFAULT_SEARCH_OPERATOR
Use this parameter to specify how the Portal search engine responds to search queries with two or more terms. The default value is `or`. Only one search term must be in the document in order for that document to be displayed in the search results list. Change this value to `and` to retrieve only those documents that contain all of the search terms that are listed in the query.

Note: After you change this parameter, you must restart the Portal server and remote search service.

CONFIG_FOLDER_PATH
Use this parameter to determine where the configuration data for search collections is stored. The default is *wp_profile_root*`/CollectionsConfig`.

EJB If you set up a remote search service by using EJB, use this parameter to specify the EJB name in JNDI. An example value is `ejb/com/ibm/hrl/portlets/WsPse/WebScannerLiteEJBHome` .

If you set this parameter, you also need to set the `IIOP_URL` parameter.

EJB_Example
This parameter is an example that gives an example value for the parameter `EJB` . The example value is `ejb/com/ibm/hrl/portlets/WsPse/WebScannerLiteEJBHome` .

ExternalSecurityResolverUrl
Use this parameter to configure the Portal Search service with the information about an external security resolver. This parameter is required for security filtering of Connections resources to function properly. An example value of the resolver URL is `https://host:port/`*`ConnectionsResourceId`*`/seedlist/authverify/getACLTokens` where *ConnectionsResourceID* is any Connections resource identifier.

HTTP_MAX_BODY_SIZE_MB
Use this parameter to limit how much content is fetched during a crawl from application files, such as PDF or Microsoft Word. The specified unit is MB. The default value is `20` MB. If a file exceeds the specified limit, the document is truncated, and Portal Search indexes the fetched portion as is possible. However, indexing might fail on truncated documents; in this case the document is not listed under search results at all.

Notes:

1. If you modify the value for this parameter, the new value is applied only to newly created collections of the search service. You cannot update this parameter for existing search collections.
2. Document Conversion Services might not be able to convert the content of truncated application files. If Document Conversion Services fails to convert a truncated application file, it logs an error to the `SystemErr.log` file. If tracing is enabled for the portal, Portal Search logs a warning message to the portal log file.

HTTP_MAX_SEEDLIST_SIZE_MB
This parameter limits how much portal content is fetched during a crawl from your own portal site. It determines the amount of space that is reserved for listing portal site resources or managed web content resources. The specified unit is MB. The default value is `4` MB. If a crawl exceeds the limit set for this parameter, the crawl fails, and Portal Search logs an error

message. In this case, or if returned search results do not represent to complete extent of your portal site resources, increase this value.

Note: If you modify the value for this parameter, the new value is applied only to newly created collections of the search service. You cannot update this parameter for existing search collections.

HTTP_NON_APPL_MAX_BODY_SIZE_MB
Use this parameter to limit how much content of each HTML page is fetched from websites of collections that belong to this search service. The specified unit is MB. The default value is `0.2` MB. This value means that the amount of content that is sent for indexing is always the first 0.2 MB of text.

Note: If you modify the value for this parameter, the new value is applied only to newly created collections of the search service. You cannot update this parameter for existing search collections.

IIOP_URL
If you set up a remote search service by using EJB, use this parameter to specify the IIOP URL. An example value is `iiop://localhost:2811`.

IIOP_URL_Example
This is an example that gives an example value for the parameter `IIOP_URL`. The example value is `iiop://localhost:2811`.

PSE_TYPE
Use this parameter to specify the type of search service. Possible values are `localhost`, `ejb`, and `soap`. The default value is `localhost` for local search service.

If you use Portal Search locally, this parameter is optional.

If you set up a remote search, this parameter is mandatory. In this case specify the type of remote service that you use, EJB or SOAP. If you specify `ejb` here, you also need to specify the values for the parameters `EJB` and `IIOP_URL`. If you specify `soap` here, you also need to specify the values for the parameter `SOAP_URL`.

SEARCH_SECURITY_MODE
This parameter defines access control enforcement during search. Three filter modes are supported. Specify one of the following values, depending on the filter mode that you want to use:

SECURITY_MODE_PREFILTER
Specify this value to use pre-filtering mode. Pre-filtering provides the fastest filtering, as it is performed in the search index level. An extra advantage of this filtering mode is that remote secured content sources can be searched from portal. However, as it is based on search index only, the search result list can be temporarily inconsistent with user access rights if these access rights were changed after the last crawl:

- If users who had their access rights restricted after the last crawl, they might get search results listed to which they had access before, but to which they no longer have access. When these users click such a link in the search result list, they cannot access the document.

- If a user was given access rights on documents after the last crawl, the user will not get these documents listed among the search results until after the next crawl.

Note: If the search service contains Portal content (a collection that contains a content source of type **`Portal site`**), then this security mode is invalid and must not be used.

SECURITY_MODE_POSTFILTER
Post-filtering

Specify this value to use post-filtering mode. Post-filtering provides the safest but costly filtering approach. It checks access permission in real time for each returned search result against Portal Access Control. As a result you can use it only for local content sources. This was the only filtering mode available before portal V 7.0.

SECURITY_MODE_PRE_POST_FILTER
Pre-post-filtering

Specify this value to use pre-post-filtering mode. This is the default. Pre-post-filtering combines the two filter modes previously mentioned. It provides a balanced method for enforce access control. It filters most irrelevant documents at the pre-filtering phase based on the search index. This results in fewer rejections in the post-filtering phase. As it still uses post-filtering, you can apply it only for local content sources. As it uses pre-filtering, search result lists might be temporarily inconsistent with users' access rights until after the next crawl.

SEEDLIST_PAGE_TIMEOUT
Use this parameter to increase the timeout for fetching the seedlist page. The specified unit for the value is seconds. The default value is 150 sec. This value means that the portal search attempts to fetch the seedlist main URL for 150 seconds.

Note: If you modify the value for this parameter, the new value is applied only to newly created collections of the search service. You cannot update this parameter for existing search collections.

SOAP_URL
If you set up a remote search service by using SOAP, use this parameter to specify the SOAP URL. An example value is `http://localhost:10000/WebScannerSOAP/servlet/rpcrouter`.

SOAP_URL_Example
This is an example that gives an example value for the parameter `SOAP_URL`. The example value is `http://localhost:10000/WebScannerSOAP/servlet/rpcrouter`.

CF05 **dateFieldPattern**
By default, portal search does not know whether a field contains a date. Use this parameter to enable search for documents by date. A regular expression is used to check whether a field must be handled as a date field or not. The default pattern is `".*date$"`, and matches all fields that end with the word “date”.

Note: After you change this parameter, you must restart the Portal server and remote search service.

CF05 **dateFormat**

Specify the format that is used for date queries. The default is `yyyy-MM-dd`. You can specify a different format by using the Java date syntax with the exception that spaces cannot be used, since that would break the date range queries. Make sure to communicate any changes in format to search users. To verify that the format is supported, you can enable tracing for `com.ibm.lotus.search.index.lucene.search.PseSiapiQueryParser=all` and then perform a series of searches. Do not forget to disable the trace after you verify that the format is supported.

Note: After you change this parameter, you must restart the Portal server and remote search service.

CF05 **dateTimeFormat**

Specify the format that is used for date queries with a time part. The default is `yyyy-MM-dd,hh:mm`. You can specify a different format by using the Java date syntax with the exception that spaces cannot be used, since that would break the date range queries. Make sure to communicate any changes in format to search users. The typical letters that are used in the format are:

yyyy Specifies the year.

MM Specifies the numerical month in the year. For instance, the month of December would be represented by 12.

dd Specifies the numerical day in the month.

hh Specifies the hour in the day. By default, the hour is specified in the 24-hour format. For instance, the number 18 specifies 6 PM. However, you can specify a custom format that uses the 12-hour time format instead.

mm Specifies the minute in the hour.

ss Specifies the second in the minute.

Z Specifies the time zone. For example, `-0800`.

To verify that the format is supported, you can enable tracing for `com.ibm.lotus.search.index.lucene.search.PseSiapiQueryParser=all` and then perform a series of searches. Do not forget to disable the trace after you verify that the format is supported.

Note: After you change this parameter, you must restart the Portal server and remote search service.

CF05 **dateFormatLocale**

This parameter specifies the locale that is used when parsing a date. The portal default locale is used as the default value.

Note: After you change this parameter, you must restart the Portal server and remote search service.

The following parameters are reserved for internal use only. Do not change their values.

CONTENT_SOURCE_TYPE_FEATURE_NAME

This parameter is reserved for internal use only. Do not change its value. The default value is `ContentSourceType`.

CONTENT_SOURCE_TYPE_FEATURE_VAL_PORTAL
This parameter is reserved for internal use only. Do not change its value. The default value is `Portal`.

CONTENT_SOURCE_TYPE_FEATURE_VAL_WEB
This parameter is reserved for internal use only. Do not change its value. The default value is `Web`.

SecurityResolverId
This parameter is reserved for internal use only. Do not change its value. The default value is `com.ibm.lotus.search.plugins.provider.core.PortalSecurityResolverFactory`.

SetProperties
This parameter is reserved for internal use only. Do not change its value. Possible values are `on` or `off`. The default value is `on`.

startup
This parameter is reserved for internal use only. Do not change its value. The default value is `false`.

VALIDATE_COOKIE
This parameter is reserved for internal use only. Do not change its value. The default value is `123`.

WORK_MANAGER
You can use this parameter to specify the work manager. This parameter is reserved for internal use only. Do not change its value. The default value is `wps/searchIndexWM`.

WORK_MANAGER_DEPLOY
This is an example of the deployed `WORK_MANAGER` parameter. The example value is `wps/searchIndexWM`.

WORK_MANAGER_NATIVE
This is an example of the parameter `WORK_MANAGER` for native threads for debug purposes only. The example value is `force.hrl.work.manager.use.native.threads`.

WORK_MANAGER_NAME
This parameter specifies the JNDI name of the work manager that Portal Search uses.

"JCR search service configuration parameters"
The following search service configuration parameters can be modified to enable and configure searching for content that is stored in the JCR database. These JCR search service configuration parameters can be modified by accessing the **JCR ConfigService PortalContent** resource environment provider.

Related tasks:

"Managing search services" on page 673
Get an overview of how you manage the portal search services. This task includes creating a new search service or editing an existing search service.

"Configuring the default location for search collections" on page 682
You can modify the default directory location under which search collections are created on a per search service basis. View some related information.

JCR search service configuration parameters

The following search service configuration parameters can be modified to enable and configure searching for content that is stored in the JCR database. These JCR search service configuration parameters can be modified by accessing the **JCR ConfigService PortalContent** resource environment provider.

To access the JCR search service configuration parameters that are stored in the **JCR ConfigService PortalContent** resource environment provider, complete the following steps:

1. Log in to WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers** and select **JCR ConfigService PortalContent**.
3. In the Additional Properties section of the Configuration window, select **Custom properties**.

Important: There are many configuration parameters in the **JCR ConfigService PortalContent** resource environment provider that must not be modified. Do not modify any configuration parameters that are not referenced in the following list, unless you are directed to do so by IBM support.

jcr.textsearch.enabled

This parameter enables or disables text search. The default value is `true`. Set this value to `false` to disable the text search run time. This parameter is required.

jcr.textsearch.indexdirectory

This parameter specifies the directory where indexes are stored, for example,`/opt/IBM/WebSphere/wp_profile/PortalServer/jcr/searchIndexes`. This parameter is required if text search is enabled (**jcr.textsearch.enabled**=`true`).

jcr.textsearch.PSE.type

This parameter specifies whether the search service is a local search service or a remote search service. The default value is `localhost`. Specify one of the following values:

localhost
This value specifies the search service as a local search service.

EJB
This value specifies the search service as a remote search service.

Notes:

- SOAP support for remote search service was deprecated with WebSphere Portal Express Version 8.0.
- If you are using a remote search service, you must also specify the**jcr.textsearch.EJB.IIOP.URL** and**jcr.textsearch.EJB.EJBName** parameters.

jcr.textsearch.EJB.IIOP.URL

This parameter specifies the URL of the naming service that is used to access the WebScannerEJB, for example, `iiop://localhost:2811`. Specify this parameter if you are using a remote search service (**jcr.textsearch.PSE.type**=`EJB`).

jcr.textsearch.EJB.EJBName

This parameter specifies the name of the WebScanner EJB, for example, `ejb/com/ibm/hrl/portlets/WsPse/WebScannerLiteEJBHome`. Specify this parameter if you are using a remote search service (**jcr.textsearch.PSE.type**=`EJB`).

jcr.query.collation.db2.enabled

This parameter enables or disables collation support for the ordering of results in the JCR XPath queries. This parameter is for all DB2 platforms. The default value is `false`. Specify `true` to enable collation support.

Configuring the default location for search collections

You can modify the default directory location under which search collections are created on a per search service basis. View some related information.

About this task

The default directory location under which search collections are created is as follows:

- Linux: *wp_profile_root*`/PortalServer/collections`
- IBM i: *wp_profile_root*`/PortalServer/collections`
- Windows: *wp_profile_root*`\PortalServer\collections`

This default can be applied when you create a new search collection, depending on the value you specify in the entry field **Location of Collection** when you create a search collection:

- If you type a relative directory location of your choice, the location for the new search collection is combined from the default directory for search locations and the location that you type. Example: If you type `my_collection_location`, the new search collection is created under the directory *wp_profile_root*`/PortalServer/collections/my_collection_location`.
- If you want to create the search collection in a location that is different from the default search collection location, type the full directory location. The new search collection is created under the directory location that you specified.

You can customize this default directory location under which search collections are created. To complete this process, you set the directory location of your choice as the value for the parameter `DefaultCollectionsDirectory` for the search service. You can configure this parameter for each search service separately. The value that you set for this parameter is prefixed to the relative location that you specify when you are creating a search collection for that search service.

The specified value determines the default directory location for the search collections that you create. When you create a search collection and specify only a relative path (not a full path location), the default value that is set by this parameter and the relative path that you specify are combined. These values form the full directory path under which the search collection is created. If you do not specify a value for `DefaultCollectionsDirectory`, the default directory for search collections remains as set by the installation as described previously.

To configure a different default search collection location, proceed by the following steps:

Procedure

1. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
2. Click **Search Services**.
3. Click the **New Search Service** button. Or, if you want to customize the default collection location for an existing search service, click the **Edit** icon for that search service.

4. Set the value of your choice for the parameter `DefaultCollectionsDirectory` for the search service. The value that you set for this parameter is prefixed to the relative location that you specify when you are creating a search collection. For details about the value, refer to the previous description.
5. Click **OK** to save your updates. Manage Search returns to the Search Services panel.

   Note:

   a. The directory location that you specify can be on a different hard disk drive or workstation.
   b. If you change the value for the **DefaultCollectionsDirectory** parameter, make sure that you do all of the following steps:
      - Specify a full directory path, for example, `/root/our_search_collections`.
      - On the specified hard disk drive, create the directory that you specify as the value for the **DefaultCollectionsDirectory** parameter.
      - Manage the write access to the directory to enable creation of search collections in that directory.
   c. The value that is set for this parameter is used only if during the creation of a new search collection you specify a relative directory for the location of the new search collection. If you specify a full directory for the location of the search collection, the collection is created in that directory. In this case, the value that is set for the default directory under the search service has no effect. Instead, it is overwritten by the full directory location that you specify for the search collection.
   d. The initial default directory is created during the installation. The process has write access to this default directory.
   e. The default site collection that is part of the installation is created under the default directory. Creation of the site collection is started when you navigate to the Manage Search portlet. If you created the site collection by navigating to the Manage Search portlet before you changed the default directory for the collection location, you might want to relocate the site collection to your new default directory. For details about how to do this step, see the topic about Resetting the default search collection.
   f. If you set up a remote search service, for example for a cluster, then this parameter is mandatory. You must configure the default location for search collections to a directory on the remote server that has write access.
   g. The file path length for search collections is limited to 118 characters. If this limit is exceeded, the collection cannot be created. In this case specify a shorter value for the parameter **DefaultCollectionsDirectory**. For details about this process, read *Creating the portal site search collection fails*.

      This issue can occur particularly when the site collection is created under one of the following operating systems.
      - Linux

Configuring the Search Center portlet

Get an overview of how you configure the Search Center.

About this task

The Search Center is installed and ready to use in a default portal installation. It is available to authenticated users through the search box in the portal theme header action bar. Users can use the Search Center for basic searches.

If required, you can configure the Search Center for search by metadata that is contained within the meta elements and by search scopes. See the following topics for details.

If your users use external search services to perform searches in different languages, refer to "Using the Search Center with external search services with different languages" on page 714.

CF05 "Configuring search for multilingual sites"
By default, the Search Center uses the preferred language of the user to analyze search terms and to refine the search results. Search results in different languages are not displayed. You can enable users to search for terms in a language other than their preferred language.

"Configuring search scopes for the Search Center portlet" on page 685
The Search Center provides scopes for users to select different sources for the search. A search scope is a means of filtering the search request to a predefined set of content or content source.

"Configuring search by metadata for the Search Center portlet" on page 686
You can configure the Search Center so that users can refine their search by metadata.

Configuring search for multilingual sites

By default, the Search Center uses the preferred language of the user to analyze search terms and to refine the search results. Search results in different languages are not displayed. You can enable users to search for terms in a language other than their preferred language.

Procedure

- Complete the following steps to configure the Search Center for use in a multilingual environment where users have different preferred languages and information is distributed in multilingual content sources:
  1. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
  2. Locate the Search Center portlet by either navigating through the pages or searching for it in the search field.
  3. Click the **Configure portlet** icon for the Search Center portlet.
  4. Click the **Edit value** icon for the preference **SEARCH_LANG**, and set it to ALL. This enables the display of search results of all available content sources regardless of their language information.
  5. Click the **Edit value** icon for the preference **QUERY_LANG**, and set it to COLLECTION. This enables the Search Center to analyze the search terms by using the language of each collection to be searched.
  6. Click **OK** to activate the changes.
- To enable the default behavior, complete the following steps:
  1. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
  2. Locate the Search Center portlet by either navigating through the pages or searching for it in the search field.
  3. Click the **Configure portlet** icon for the Search Center portlet.
  4. Click the **Edit value** icon for the preference **SEARCH_LANG**, and set it to PREFERRED.
  5. Click the **Edit value** icon for the preference **QUERY_LANG**, and set it to PREFERRED.
  6. Click **OK** to activate the changes.

Configuring search scopes for the Search Center portlet

The Search Center provides scopes for users to select different sources for the search. A search scope is a means of filtering the search request to a predefined set of content or content source.

About this task

For search collections provided by Portal Search you can configure the search scopes in the two following ways:

- Each individual search collection is available through its own scope and selection option in the scope pull-down menu.
- The search scope **All Sources** makes all search collections available for search. In other words, if a user selects the option **All Sources** selection option from the pull-down menu, the user's search will search all search collections that are available in the portal.

You can configure additional scopes. For more information about search scopes and how to configure them refer to Managing search scopes and custom links.

Related tasks:

Delete or replace the All Sources default scope.

Configuring search by metadata for the Search Center portlet

You can configure the Search Center so that users can refine their search by metadata.

About this task

To do this, proceed as follows:

Procedure

1. Open the **Manage Portlets** portlet.
2. Locate the Search Center portlet.
3. Click **Configure portlet** for the Search Center portlet.
4. Click **Edit value** for the preference `displaySearchFilters` , and set it to `true` . This enables search by metadata filters for your users. By default, the meta elements title, keywords, and description of documents are provided as search filters. The actual set of available meta elements depends on the types of content sources that you indexed.
5. Optional: You can add your own custom metadata search filters. Proceed as follows:
   a. Determine which metadata you want to use as search filters. This depends on the metadata that the documents in your search collections provide.
   b. Click **Edit value** for the preference `searchFiltersFields` .
   c. Add the required filters to the list of values.

Replacing the search administrator user ID

If you changed the portal administrator user ID or password, you need to update the search administrator user ID to match the same values.

About this task

Proceed as follows:

Procedure

1. Complete the following steps to change the information stored in the **SearchAdminUser** alias:
   a. Log in to the WebSphere Integrated Solutions Console.
   b. Click **Security** > **Global security**.
   c. Under Authentication, click **Java Authentication and Authorization Service** > **J2C authentication data**.

d. Edit the **SearchAdminUser** alias.
e. Update the user ID and/or password to match your WebSphere Portal Express administrator information.

2. To make sure that the changed administrator user ID takes effect, use one of the following two options:
   - Change the administrator user ID and the password by using the Manage Search administration portlet.
   - Delete the default portal search services and collections. After a portal restart as by the next step, the portal recreates these search services and collections.
3. Restart the WebSphere Portal Express servers.

Customizing the Search Center

Customize the Search Center by adding, removing and configuring additional portlets, such as External Search Results or Recommended Links. The external search results portlet displays search results from third-party external search engines such as Yahoo and Google. Using the recommended links portlet, display search results from a collection of predefined links with predefined keywords. You can also configure the All Sources scope or replace it with a customized scope.

"Managing search scopes and custom links"
Get an overview of search scopes and custom links and how you can manage them.

"Adding and configuring the External Search Results portlet" on page 688
Configure a portlet that retrieves and displays search results from third-party search engines, then add the External Search Results portlet to the Search Center.

"Adding and configuring suggested links" on page 690
As an administrator you can promote specific pages, documents, or other pieces of content by adding search keywords to them in the search results list. The portal then lists these documents as suggested links.

"Customizing the All Sources scope" on page 692
Delete or replace the All Sources default scope.

Managing search scopes and custom links

Get an overview of search scopes and custom links and how you can manage them.

About this task

Search Scopes: You can define Search Scopes to limit search results to specific content locations and specific document types. This enables users to target their searches better. The portal is shipped with two scopes:

All sources
This includes documents with all features from all content sources in the search by a user.

Managed Web Content
This restricts the user's search to sites that were created by IBM Web Content Manager. This scope is only enabled when there is a search collection that is associated with a Web Content Manager site and the site has been crawled.

You can create your own custom search scopes and specify which search locations or content sources they cover.

Note: If you delete a content source, then the documents that were collected from this content source remains available for search by users under all scopes, which included the content source before it was deleted. These documents are available until their expiration time ends. You can specify this expiration time under **Links expire after (days):** under **General Parameters** when you create the content source.

Custom Links: You can add Custom Links with web link shortcuts to search locations. This includes links to external web locations. For example, you can enable users to do direct searches to popular web search engines, such as Google or Yahoo!

Users can select the scopes and custom links from a selection menu that is provided with the search box in the theme and with the Search Center portlet.

You can add icons for the scopes and custom links. Users see these icons in the pull-down selection list of scopes with the Search box and the Search Center.

Note: When you create a custom link, you enter the URL to the target web search engine. Be careful to use the correct format for the URL, as the user query search terms are appended to the URL. For the correct web interface syntax, refer to the help documentation of the target search engine. In some cases it might be possible to determine the web interface syntax as follows:

1. Perform a search with some distinctive search text on the target search engine, for example, an unusual name.
2. Review the browser **URL** field and locate your search string. The part of the URL that precedes your search string is likely to be the Link URL for your target search engine.
3. If your search string is not at the end of the URL, it might be helpful to edit the URL and experiment with different versions with a search string added.

Examples for web interface syntax are:

- For Google: `http://www.google.com/search?&q=`
- For Yahoo: `http://search.yahoo.com/search?p=`

Working with search scopes and custom links: To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**. To work with search scopes and custom links, click **Search Scopes** Portal Search displays the Search Scopes panel. It lists the search scopes and the custom links, shows their status and related information. You can do tasks on the scopes and custom links. For more information about these tasks and the available options, see the **Manage Search** portlet help.

Results

What to do next

Adding and configuring the External Search Results portlet

Configure a portlet that retrieves and displays search results from third-party search engines, then add the External Search Results portlet to the Search Center.

About this task

The External Search Results is a specialized portlet that administrators can add to Portal Search. When you add that portlet to Portal Search, the results of a search that is initiated from the Search page include results from third-party external

search engines. You can add more than one copy of the External Search Results portlet to the Portal Search page. You can also configure each of these portlets to display a specific number of search results.

Note:

1. You must be logged in as Administrator to add an External Search Results portlet to the Search Center.
2. The External Search Results portlet can be added only to the Search Center on the Portal Search page. It does not function anywhere else.

To add the External Search Results portlet to the Portal Search page and configure it, proceed as follows:

Procedure

1. Optional: Add the portlet to the Search Center. You must add the portlet only if the External Search Results portlet was removed from the Search Center.
   a. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
   b. Locate the Search Center page, under **Content Root** > **Search**.
   c. Click **Edit Page Layout**.
   d. Click **Add Portlets**.
   e. Select the **External Search Results** portlet by clicking the check box.
   f. Click **OK** to add the portlet to the page.
   g. Click **Done**.
   h. Go to the Search Center page.
2. Configure the External Search Results portlet:
   a. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
   b. In the list of portlets, locate **External Search Results**, and click the **Configure** icon next to the portlet name.
   c. Edit the value of the **searchEngineUrl** parameter. This value represents the URL of the third-party search engine that you want to be queried. The value of the **searchEngineUrl** parameter returns a feed of search results for the specified search terms. The feed is in RSS or ATOM syndication format. The string `${searchTerms}` must be included in the value. This string is replaced by the actual query during the search. For example:

      ```
      http://www.ibm.com/developerworks/views/rss/customrssatom.jsp?zone_by=Lotus&search_by=${searchTerms}
      ```

   d. Optional: Edit the value of the parameter **searchEngineFullPageUrl**. This parameter is optional. You can delete it or leave it empty. When you set this parameter, a **More** link is added to the portlet. It links to the website of the external search engine. The value represents a parameterized form of the URL used to locate the search engine that is queried. The string `${searchTerms}` must be included in the parameter value. During the search, the portlet replaces the string by the actual query. For example:

      ```
      http://www.ibm.com/developerworks/search/searchResults.jsp?searchSite=dW&searchScope=dW&query=${searchTerms}
      ```

      This URL returns the public HTML page of the search engine.
   e. Edit the value of the **numOfEntries** parameter. This parameter determines the maximum number of search results, which are displayed. The default number is 3, but you can enter a different numeric value to increase the maximum.

f. Optional: If the external search engine returns search results in a format that is not supported, or if the provided rendering of the search results is not acceptable, an XSLT file can be specified. Edit the value of the **externalXsltUrl** parameter to supply a URL for such an external XSLT file.

   Note: The XSLT does not create an entire HTML document, but an HTML fragment that can be embedded inside a page.

g. On the page for editing the preference `searchEngineFullPageUrl`, click **OK**.

h. On the page for configuring the External Search Results portlet, click **OK** to save your changes.

Users can now use the External Search Results portlet.

3. If you want to add external search engines, or modify the existing search engine, you must modify the proxy configuration of the portlet. All HTTP requests from the portlet to the external search engines are directed through the outbound HTTP connection service, which is included in the portal. The External Search Results portlet includes an application-specific configuration for this service. In a standard portal installation, it allows only connections to the URL of the default external search engine `http://www.ibm.com/developerworks/views/rss/*`. To change this, you must modify the `proxy-config.xml` file that is bundled with the portlet. To modify the file, proceed as follows:

   a. Go to the file `searchCenter.war`. It is in the directory *`PortalServer_root`*`/search/wp.search.portlets/search/portlet/installableApps` .

   b. Edit the file `proxy-config.xml`. It is in the directory `WEB-INF`.

   c. Add an `proxy:policy` element, or modify the existing one. For more information, read *Creating an outbound HTTP connection configuration profile*. The current policy element allows connections to the following URL: `http://www.ibm.com/developerworks/views/rss/*`. You can change the URL attribute to specify another site, for example `http://www.ibm.com/products/*`. If you want to add several instances of the portlet on a page that show search results from different sources, duplicate the `proxy:policy` element. Add a `policy` element for each instance of the portlet, with the URL attribute that matches the search source.

   d. Repackage the WAR file and update the Search Center web module.

   Searches by users are now done by the modified search configuration.

Related tasks:

"Creating an outbound HTTP connection configuration profile" on page 3014
This configuration task creates an outbound HTTP connection configuration profile by using the settings that you specify in an XML document. Use this task if you want to initially create outbound HTTP settings for your configuration. You can create a global configuration or an application-scoped configuration.

Adding and configuring suggested links

As an administrator you can promote specific pages, documents, or other pieces of content by adding search keywords to them in the search results list. The portal then lists these documents as suggested links.

Before you begin

- You must be logged in as an administrator to add the Suggested Links portlet to the search center.
- Ensure that tagging is enabled. For more information, see "Tagging and rating" on page 1297.

- Ensure that Dojo tagging and rating options are enabled for your Search and Tag Center profile. For more information, see "Enabling and disabling the Dojo tagging and rating options for additional profiles" on page 1341.

About this task

To add or edit keywords for suggested links, proceed as follows:

Procedure

1. Use the portal Search Center to search for the kind of documents that you want to promote. The Search Center lists the documents in the search results list.
2. Click the option **Edit keywords for Suggested Links** for the document that you want to promote. The Search Center opens a dialog window named **Edit keywords for Suggested Links**. This option is available only for users with the administrator role on the Search Center.
3. Add one or more keywords to the selected document. Separate the individual keywords by blanks. You can also edit or delete keywords as required.
4. Click **Save**.
5. Add more keywords as required and save them.
6. Click **Close**.

Results

- When your users search for a search string that you added to documents as a keyword, these documents display in the **Suggested Links** portlet.
- For assigned administrators, the **Suggested Links** portlet provides an **Edit** link for each suggested link. When an administrator clicks that link, the portlet opens the dialog box **Edit keywords for Suggested Links**. The administrator can now add more tags or delete existing tags. This administrator role assignment must be the same as for the Search Center to display the option **Edit keywords for Suggested Links**.

Adding keywords to documents uses the portal tagging functions. You can configure the Tag Cloud to display a **Suggested links** tab and a corresponding view to users. When you click that tab, the tag cloud shows only tags that you added as keywords, and the related documents to which those keywords were added. You can use the **Suggested Links** tab of the Tag Center to view all suggested links that you created by adding your keywords.

In a typical example scenario, you can work in two stages:

1. To add new tags or edit or delete existing keywords, you can use the Search Center, either from the main results view or from the Suggested Links portlet.
2. To browse an overview of the keywords that exist already, you can use the Suggested Links tab of the Tag Center. You can add and remove keywords from documents as required.

Note: Suggested links are case-sensitive. The tagging and rating normalization parameter `com.ibm.wps.cp.tagging.normalization.displayNormalizedNames` does not apply to suggested links. For example, if an administrator adds a suggested link of `WebSphere`, a user search for `websphere` does not return `WebSphere` as a result. This action is independent of whether the tagging and rating parameter `com.ibm.wps.cp.tagging.normalization.displayNormalizedNames` is set to `true` or `false`.

"Configuring the Suggested Links view"
Customize the display of search results to show users the preferred or recommended results and associated links.

Configuring the Suggested Links view:

Customize the display of search results to show users the preferred or recommended results and associated links.

About this task

The Suggested Links view of the Tag Cloud displays predefined search results and links to users separately from the regular result set. You can add keywords to documents in the Search Center result list to control which results appear in the Suggested Links list.

To configure the Suggested Links view, proceed as follows:

Procedure

1. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
2. Click the **Configure** icon next to the **Suggested Links** portlet.
3. Add or edit the following parameter and the appropriate value:

   numberOfLinks = (3)
   Determines the maximum number that is displayed by the Suggested Links portlet. The default number is 3.
4. Click **OK** to save the portlet configuration. Users can now use the Suggested Links portlet.

Customizing the All Sources scope

Delete or replace the All Sources default scope.

About this task

When the user clicks the **Search Center** menu list to select a scope, the first scope on the list is the default scope. By default, All Sources is set to be the default scope.

All Sources scope is a special scope in portal. This scope has a unique ID and it searches in all the search collections that are accessible to the user, including collections from existing local and remote search services. The All Sources scope can be deleted or customized just like other search scopes. Three possible actions can be done on the All Sources scope:

- Choose a different default scope
- Delete the All Sources scope
- Readd the All Sources scope

To change the default search scope from All Sources to a different scope, reorder the scopes by using search administration:

1. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
2. Click **Search Scopes**.

3. Move the scope that you want to be the default scope to the beginning of the scopes list by clicking the up-arrow icon next to the scope name. The first scope on the list becomes the default search scope.

Note: Users must clear their browser cache for the new scope to be available and displayed in the correct position.

The All Sources scope is created by using a mechanism that is called out-of-the-box (OOB) scopes registration and it is stored as a property in the WebSphere Integrated Solutions Console. Since the All Sources scope is added by using the OOB scopes registration mechanism, you must delete the All Sources scope by using both the WebSphere Integrated Solutions Console and the search administration interface:

Procedure

1. Remove the All Sources scope from the scopes list by using search administration:
   a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   b. Click **Search scopes**.
   c. Delete the All Sources scope.
2. Remove the All Sources property from the WebSphere Integrated Solutions Console:
   a. In the navigation click **Resources** > **Resources Environment** > **Resource Environment Providers**.
   b. Make the appropriate selection, depending on your version of WebSphere Application Server and your portal environment:
      - In the Resource Environment Providers page, select the appropriate node or cluster from the scopes drop-down list, or uncheck the Show Scope selection drop-down check box and select one of the following options, depending on your portal environment:
        – If your portal is running as a single server, select **Browse Nodes** and select the node.
        – If your portal is installed in a cluster, select **Browse Clusters** and select the portal cluster.
   c. Select the **WP ScopeConfigService** service.
   d. Click **Custom Properties**.
   e. Select the **All Sources** property and delete it.

Results

You can readd the All Sources scope only if this scope does not exist in the current scopes list. The All Sources scope is added by using the WebSphere Integrated Solutions Console. Once you add it using the console, it is automatically added to the Search Center scopes list. A service that is called ScopeConfigService is registered and the configured All Sources scope is added as custom property of this service. The scope is implemented based on a scope XML element.

1. In the navigation click **Resources** > **Resources Environment** > **Resource Environment Providers**.
2. Make the appropriate selection, depending on your portal environment:

- In the Resource Environment Providers page, select the appropriate node or cluster from the scopes drop-down list, or uncheck the Show Scope selection drop-down check box and select one of the following options, depending on your portal environment:
  - If your portal is running as a single server, select **Browse Nodes** and select the node.
  - If your portal is installed in a cluster, select **Browse Clusters** and select the portal cluster.

3. Select the **WP ScopeConfigService** service.
4. Click **Custom Properties**.
5. Click **New** to create a new scope property.
6. Name the new property **All Sources**. Enter this XML scope element as the property value:

```
<scope id="com.ibm.lotus.search.ALL_SOURCES">
<title xml:lang="en">All Sources</title>
<description xml:lang="en">All Sources accessible by the user</description>
<scopeProperty key="iconURI" value="/wps/images/icons/scope_search_all.gif"/>
<scopeProperty key="isVisibletoAnonymousUser" value="true"/>
<scopeElement></scopeElement>
</scope>
```

   Note: You can change the name, description, and icon for the new scope. To create a scope in a language other than English, change the xml:lang attribute to the required locale, such as *de* for German.
7. Click **Save** to save the new property.

Using the WebSphere Integrated Solutions Console to administer Portal Search

You can administer Portal Search by using the WebSphere Integrated Solutions Console and using resource providers in XML format.

About this task

You can administer search services, search collections, and search scopes. You can create, configure, or delete these.

To administer Portal Search by using the WebSphere Integrated Solutions Console, proceed by the following steps.

Procedure

1. Open the WebSphere Integrated Solutions Console.
2. Select **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Locate and then click **WP_SearchConfigService**.
4. Under **Additional Properties**, click **Custom properties**.
5. Click **PortalSearchService** to edit the resource.
6. Edit the **Value** field, which displays the value from the XML file that is used to configure Search, and set the parameter as required.

   Tip: Refer to the following file for information about the XML schema : *PortalServer_root*/search/wp.search.provider/core/service/schema/WplcSearchService.xsd.
7. Apply and then save the change.

8. Restart the portal.

Creating and configuring search collections

Get an overview of how you manage search collections and their content sources.

To administer search collections, go to the **Manage Search** portlet. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**. Then, click **Search Collections**. This panel includes creating, updating, and removing search collections, and other administrative tasks that refer to search collections. For more information and step-by-step instructions for performing administrative tasks, refer to the portlet help.

Managing search collections:

When you select **Search Collections**, **Manage Search** displays the Search Collections panel. It lists the search collections in your portal and related information, and it allows you to select options and do tasks on the search collections and their content sources.

Note: The selectable options that are displayed and available for collections and content sources depend on their type and setup.

In the Search Collections panel you can select the following option icons and do the following tasks:

- **Change the search collection** with which you want to work. To do this, select another search collection from the pull-down list.
- **New collection**. Select this option to create a new search collection.

  Notes:

  1. You cannot create additional search collections for the default Content Model search service.
  2. When you specify the directory location for the collection, be aware that creating the collection can overwrite files in that directory.
- **Refresh** the list of collections.
- **Locate a collection** and do one of the following tasks by clicking the appropriate icon for that collection:
  - **Search and Browse Collection**. Use this option to work with the documents of the selected collection. You can complete the following administrative tasks:
    - Browse the documents of the selected collection.
    - View the individual documents of the selected collection.
    - Search the documents of the selected collection.
    - Edit the fields of the documents in the selected collection.
    - Delete documents from the selected collection.
  - **Import or Export Collection**. Use this option to import or export the selected search collection. Portal Search provides a Portal Search XML interface for this feature. The export and import operations can be of benefit when you upgrade to software levels, which are not necessarily compatible with the data storage format of older versions of the software. To prevent loss of data, you export all data of search collections to XML files before you upgrade the software. Then after you upgrade the software level, you can use the previously exported files to return the search collection data back into the new software level.

    Notes:

    1. Before you export a collection, make sure that the user who is running the portal application process has write access to the target directory location. Otherwise, you might get an error message, such as `File not found`.
    2. You can import collection data only into an empty collection. You cannot import collection data into a target collection that has content sources or documents already.
    3. When you import collection data into a collection, all collection settings are overwritten by possibly imported settings. For example, the language setting is overwritten.
    4. When you import a collection, a background process fetches, crawls, and indexes all documents that are listed by URL in the previously exported file.
  - **Delete Collection**. Use this option to delete the selected search collection.
- **Select a collection** by clicking the collection name link. Portal Search displays the Content Sources and the Status of the selected collection. You can select the following option icons and perform the following tasks:
  - **New Content Source**. Use this option to create a new content source for this collection. You can create more than one content source for a search collection.
  - **Refresh** the list of content sources and the status that is shown for this collection.

- **Work with the content sources of the collection**.
- **View** the **Collection Status** information of the selected search collection. The status fields show the following data that changes over the lifetime of the search collection:

  Search Collection Name:
  Shows the name of the selected search collection.

  Search Collection Location:
  Shows the location of the selected search collection in the file system. This is the full path where all data and related information of the search collection is stored.

  Collection Description:
  Shows the description of the selected search collection if available.

  Search Collection Language:
  Shows the language for which the search collection and its index are optimized. The index uses this language to analyze the documents when indexing, if no other language is specified for the document. This feature enhances the quality of search results for users, as it allows them to use spelling variants, including plurals and inflections, for the search keyword.

  Summarizer used:
  Shows whether a static summarizer is enabled for this search collection. The static summarizer creates a summary of the page, which is based on the page's full content. The page's full content can include metadata, HTML elements, and Web Content Manager templates. These additional elements might be interpreted as text and thus become a part of the page's summary. Do not use the static summarizer if the page's summary contains a large amount of noise from these additional elements.

  Last update completed:
  Shows the date when a content source defined for the search collection was last updated by a scheduled update.

  Next update scheduled:
  Shows the date when the next update of a content source that is defined for the search collection is scheduled.

  Number of active documents:
  Shows the number of active documents in the search collection, that is, all documents that are available for search by users.

  Notes:

  1. To update the status information, click **Refresh**. Clicking the refresh button of the browser does not update the status information.
  2. If you delete a portlet from the portal after a crawl of the portal site, the deleted portlet is no longer listed in the search results. However, refreshing the view does not update the status information about the **Number of active documents**. This information is not updated until after the next cleanup run of portal resources.

Setting up a JCR search collection

A JCR search collection is a special purpose search collection that is used by WebSphere Portal applications. It is not designed to be used alongside user-defined search collections. A JCR search collection requires a special setup. This setup includes the creation of a new content source for the search collection. Under normal circumstances, you do not need to re-create the JCR search collection. However, in rare cases you might need to re-create it, for example if you deleted the default JCR search collection.

About this task

The portal installation has the JCR search collection that is created by default. It is named JCRCollection1. If this collection is removed or does not exist for other reasons, you can manually re-create the JCR search collection. The portal also re-creates the JCR search collection if you edit Web Content Manager content. Web Content Manager Authoring and its search capability are required to have the JCR search collection available, paired with the respective content source. If the JCR search collection gets deleted, a search is not possible by using the Authoring portlet. The JCR search collection can be used only by a search portlet that knows how to present and deal with the search result in which the returned information is useless in a more generic context of search. This search collection is also flagged so that it does not participate in search by using the All Sources search scope. An administrator cannot manually add it. The JCR search collection is a special purpose search collection that the JCR requires to allow specialized application to do low-level searches in the repository. The JCR search collection is required to be available only once.

Notes:

For Web Content Manager:

If you use Web Content Manager, the `JCRCollection1` collection is created the first time that you create a web content item, if it does not exist. In this case, it might not be necessary to create the collection manually, although it is fine to create it manually first, if required. It is used by the search feature within the Web Content Manager authoring portlet. If you delete this search collection, you might not be able to search for items within the authoring portlet.

For virtual portals:

When you create a virtual portal, the creation of the JCR search collection depends on whether you create the virtual portal with or without content:

- If you create the virtual portal with content, the portal creates the JCR collection for the virtual portal by default.
- If you create only the virtual portal and add no content to it, the portal creates no JCR collection with it. It gets created only when content is added to the virtual portal.

You can view the URL of the JCR search collection in the search administration portlet Manage Search of the virtual portal. The URL looks as follows:
```
 http://host_name:port_number/wps/seedlist/myserver/
hello?Action=GetDocuments&Format=ATOM&Locale=en_US&Range=100
&Source=com.ibm.lotus.search.plugins.seedlist.retriever.jcr.JCRRetrieverFactory&S
```
Where *wsid* is the actual workspace ID of the virtual portal. The workspace ID is the identifier of the workspace in which the content item is created, stored, and maintained. For example, if the workspace ID of the virtual portal is 10, then the URL looks as follows:
```
http://host_name:port_number/wps/seedlist/myserver/
hello?Action=GetDocuments&Format=ATOM&Locale=en_US&Range=100
&Source=com.ibm.lotus.search.plugins.seedlist.retriever.jcr.JCRRetrieverFactory&S
```
If the JCR search collection was deleted, or if you added content to an originally empty virtual portal and the JCR search collection was not automatically created, complete the following steps:

- If you are using a virtual portal, go to the Security tab of the content source to verify that the workspace ID of the virtual portal is correct.
- If the JCR search collection was deleted, run the **ConfigEngine** task `create-textsearch-collections` to re-create the JCR search collection.

If neither of the preceding options succeed in creating the JCR search collection, manually set up the JCR search collection.

To set up a JCR search collection manually, proceed as follows:

Procedure

1. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
2. Click **Search collections.**
3. To create a new search collection, click **New collection**.
4. Specify the following values for the parameters as required:

   Search Service
   Select the required search service the JCR collection uses. If you have a stand-alone environment, select **Default Portal Service**. If you have a clustered environment, select **Remote Search Service**.

   Location of collection
   The directory location for the collection where you intend the search collection to be created. This parameter is to be specified as *index directory location/collection name*. For example, if the index directory is `c:/JCR` and the collection name is JCRCollection1, then the location of the collection must be specified as `c:/JCR/JCRCollection1`.

   Note: Verify that the **jcr.textsearch.indexdirectory** resource value is updated with `c:/JCR`. To view this resource and corresponding value, complete the following steps:

   a. Go to **Resources** > **Resource Environment** > **Resource Environment Providers** and select **JCR ConfigService PortalContent**.
   b. In the Additional Properties section of the Configuration window, select **Custom properties**.
   c. Find **jcr.textsearch.indexdirectory** and update the value if needed.

Name of collection.
The name of the collection must be `JCRCollection1`.

Description of collection
This parameter is optional. Specify `JCR seedlist collection`.

Specify Collection language
Specify the collection language. By default this parameter is set to English (United States).

After you create the new collection, you can see the name of the collection you created in the list.

5. Double-click the collection that you created.
6. To create the content source for the new search collection, click **New Content Source**.
7. Specify the collection parameters as follows:
   - For the type of the content source, select **Seedlist Provider**.
   - Provide the name for the new Content Source in the field **Content Source Name**. For example, you can specify `JCRSource`.
   - Specify the value for the **URL** field **Collect documents linked from this URL:** as follows:

     ```
     http://server_name:port_number/wps/seedlist/myserver?Action=GetDocuments
        &Format=ATOM&Locale=en_US&Range=100
        &Source=com.ibm.lotus.search.plugins.seedlist.retriever.jcr.JCRRetrieverFactory&Start=0
        &SeedlistId=1@OOTB_CRAWLER1
     ```

     In this URL the range parameter specifies 100 documents in one page of a session and the workspace ID of the base portal is 1.

     If you are working in a virtual portal, specify the content source URL for the virtual portal as follows:

     ```
     http://server_name:port_number/wps/seedlist/myserver/
        virtual_portal_context?Action=GetDocuments
        &Format=ATOM&Locale=en_US&Range=100
        &Source=com.ibm.lotus.search.plugins.seedlist.retriever.jcr.JCRRetrieverFactory&Start=0
        &SeedlistId=1@OOTB_CRAWLERwsid
     ```

     Where *wsid* is the workspace ID of the virtual portal. To determine the workspace ID of the virtual portal, complete the following steps:

     a. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Enable Tracing**.
     b. In the **Append these trace settings:** field, add `com.ibm.icm.ts.*=finest` to enable the JCR **`TextSearch`** trace.
     c. Save all Web Content Manager documents in the virtual portal.
     d. In `trace.log`, you can find trace information similar to the following:

        ```
        [6/5/13 18:51:04:337 IDT] 000001c3 BaseDBImpl 3 insertSeedlistEvents:
         Inserted event: Event:
        action='Update_Node(3)', timestamp='2013-06-05 18:51:04.337', document id=,<workspace: 3,
        ```

8. Go to the **Security** tab.
9. Enter the user ID and password of the WebSphere Portal Express administrator.
10. Click **Create** to create the new content source. If the Content Source was created successfully, the following message is displayed on the page:

    `EJPJB0025I: Content source source_name in collection collection_name is OK.`
11. You can start the crawler manually or schedule it to run at regular intervals.
    - To start the crawler manually, go to the content source and click the **Start Crawler** button for the content source.

- To schedule the seedlist crawler, click the **Edit Content Source** button, and click the **Scheduler** tab. Specify the date and time and the frequency for the crawl. The crawler is triggered automatically at the time that you scheduled.

"Re-creating a JCR search collection after it was deleted"
The portal installation has the JCR search collection created by default. It is named JCRCollection1. If this collection is removed or does not exist for other reasons, you can re-create the JCR search collection.

Related reference:

"JCR search service configuration parameters" on page 680
The following search service configuration parameters can be modified to enable and configure searching for content that is stored in the JCR database. These JCR search service configuration parameters can be modified by accessing the **JCR ConfigService PortalContent** resource environment provider.

Re-creating a JCR search collection after it was deleted:

The portal installation has the JCR search collection created by default. It is named JCRCollection1. If this collection is removed or does not exist for other reasons, you can re-create the JCR search collection.

Procedure

- If you are using a virtual portal, navigate to the Security tab of the content source to verify that the workspace ID of the virtual portal is correct.
- If the JCR search collection was deleted, run the **`ConfigEngine`** task `create-textsearch-collections` to re-create the JCR search collection.
- If neither of the preceding options succeed in creating the JCR search collection, manually re-create the JCR search collection. Refer to *Setting up a JCR search collection* to view these steps.

Managing the content sources of a search collection

Search collections consist of one or more content sources. You can administer the content sources.

About this task

To work with content sources of a collection, go to the **Manage Search** portlet. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**. Then, click **Search Collections**. Then, select a search collection by clicking the collection name link. Portal Search displays the Content Sources panel. It shows the status of the selected search collection and lists its content sources and their status. It shows information that is related to the individual content sources, and you can do tasks on these content sources.

You can select the following option icons and do the following tasks in relation to the search collection, which you selected from the Search Collections list:

- **New Content Source**. Use this option to create a new content source for the search collection that you selected from the Search Collections list. For detailed instructions, refer to the portlet help.

  Notes:

  1. WebSphere Portal Express search crawler supports basic authentication, therefore Unicode character set for user and password is not supported.

2. You can configure a search collection to cover multiple content source of different types. For example, you can combine portal sites, websites, and local document collections.
3. The selectable options and data entry fields that are displayed under the different configuration tabs depend on which type of content source you select.
4. If you select Portal site, the appropriate data for your portal site is already complete.
5. If you select WCM site (Web Content Manager site), you need to enter the appropriate data. For information about how to construct the URL for the content source refer to *Seedlist 1.0 REST service API* in the Web Content Manager documentation.
6. For some content sources, you might need to enter sensitive data, such as a user ID and password. For example, this action applies to secured WebSphere Portal Express sites or HTTP sites that require a user ID and password. To ensure encryption of this sensitive data when it is stored, update and run the file `searchsecret.xml` by using the XML configuration interface before you create the content source.
7. If you are using form-based authentication, specify the following fields:

   Note: Each host name within a crawler can have a single form-based security definition, a single basic authentication definition, or multiple basic authentication realm definitions.

   User name and Password
   The user name and password that is associated with the login form.

   URL of login FORM
   Specify the submit URL value of the login form for the site that will be crawled. The crawler issues a POST request to this URL and passes it on to the user name and password, through the Ajax proxy.

   User FORM field name
   Specify the user name field value in the login form, where the user name is defined.

   Password FORM field name
   Specify the password field value in the login form, where the password is defined.
8. When you create a portal site content source in a portal cluster environment that is configured with SSL, you need to provide the cell security information for the web server and the nodes. For example, in a cluster with the cluster URL `https://web_server/wps/portal`, the primary node URL `http://node_1:10039/wps/portal`, and the secondary node URL `http://node_2:10050/wps/portal` you need to provide the user ID and password for the web server and both nodes 1 and 2.
9. Under the **General parameters** tab, you must set the URL for the content source in a field **Collect documents linked from this URL:** . The crawler needs this URL for crawling. For information about how to construct the URL for the content source refer to *Seedlist 1.0 REST service API* in the Web Content Manager documentation.

   Note: A crawler failure can be caused by URL redirection problems. If this occurs, try by editing this field accordingly, for example, by changing the URL to the redirected URL.

10. For crawling a website content source, you can set a timeout under the **General parameters** tab under the option **Stop collecting after (minutes):** . This timeout works as follows:
    a. The timeout works only for website content sources.
    b. The timeout works as an approximate time limit. It might be exceeded by some percentage.
    c. The crawl action is put in a queue. It might therefore take several minutes until it is run and the time counter starts. It might therefore seem that the crawl takes longer than the timeout that you set.

    Therefore, when you start the crawl by clicking **Start Crawler**, allow for some time tolerance and be aware of the time that is required for crawls and imports and availability of documents.
11. In the **Advanced Parameter** tab, the entry field for the Default Character Encoding contains the initial default value `windows-1252`, regardless of the setting for the Default Portal Language. To go to the Default Portal Language, Click the **Administration menu** icon. Then, click **Portal Settings** > **Global Settings**. Enter the required default character encoding, depending on your portal language. Otherwise, documents might be displayed incorrectly under Browse Documents.
12. Before you start the crawl, set the preferred language of the crawler user ID to match the language of the search collection that it crawls.
13. You start the initial crawl on a newly created content source by either of the following options:
    – After you created a new content source, click the **Start Crawler** icon. This starts an immediate crawl.
    – When you create the content source, define a schedule under the **Schedulers** tab. The crawl starts at the next possible time that you specified.

- **Refresh**. Use this option to update the list of content sources and the status that is shown for this collection.
- Select the following option icons and do the following tasks on a content source:
  – **View Content Source Schedulers**. Use this option to view and manage schedulers. This option is only available if you defined schedulers for the content source.
  – **Start Crawler**. Click this icon to start a crawl on the content source. This action updates the contents of the content source by a new run of the crawler. While a crawl on the content source is running, the icon changes to **Stop Crawler**. Click this icon to stop the crawl. Portal Search refreshes different content sources as follows:
    - For website content sources, documents that were indexed before and still exist in the content source are updated. Documents that were indexed before, but no longer exist in the content source are retained in the search collection. Documents that are new in the content source are indexed and added to the collection.
    - For WebSphere Portal Express sites, the crawl adds all pages and portlets of the portal to the content source. It deletes portlets and static pages from the content source that were removed from the portal. The crawl works similarly to the option Regather documents from Content Source.
    - For IBM Web Content Manager sites, Portal Search uses an incremental crawling method. Additionally to added and updated content, the Seedlist explicitly specifies deleted content. In contrast, clicking Regather documents

from Content Source starts a full crawl; it does not continue from the last session, and it is therefore not incremental.

- For content sources created with the seedlist provider option, a crawl on a remote system that supports incremental crawling, such as IBM Connections, behaves like a crawl on a Web Content Manager site.

– **Regather documents from Content Source**. This option deletes all existing documents in the content source from previous crawls and then starts a full crawl on the content source. Documents that were indexed before and still exist in the content source are updated. Documents that were indexed before, but no longer exist in the content source are removed from the collection. Documents that are new in the content source are indexed and added to the collection.

– **Verify Address of Content Source**. Click this icon to verify that the URL of the content source is still live and available. Manage Search returns a message about the status of the content source.

- **For web site content sources:** Documents that were indexed before and still exist in the content source are updated. Documents that were indexed before, but no longer exist in the content source are retained in the search collection. Documents that are new in the content source are indexed and added to the collection.
- **For WebSphere Portal Express sites** the crawl adds all pages and portlets of the portal to the content source. It deletes portlets and static pages from the content source that were removed from the portal. The crawl works similarly to the option Regather documents from Content Source described later.
- **For Web Content Manager sites** Portal Search uses an incremental crawling method. Additionally to added and updated content, the Seedlist explicitly specifies deleted content. In contrast, clicking Regather documents from Content Source starts a full crawl; it does not continue from the last session, and it is therefore not incremental.

–

Notes:

- It is of benefit to define a dedicated crawler user ID. The pre-configured default portal site search uses the default administrator user ID `wpsadmin` with the default password of that user ID for the crawler. If you changed the default administrator user ID during your portal installation, the crawler uses that default user ID. If you changed the user ID or password for the administrative user ID and still want to use that user ID for the Portal Search crawler, you need to adapt the settings .

  To define a crawler user ID, select the **Security** tab, and update the user ID and password. Click **Save** to save your updates.
- If you modify a content source that belongs to a search scope, update the scope manually to make sure that the scope still covers that content source. Especially if you changed the name of the content source, edit the scope and make sure that it is still listed there. If not, add it again.
- If you delete a content source, then the documents that were collected from this content source remains available for search by users under all scopes, which included the content source before it was deleted. These documents are available until their expiration time ends. You can specify this expiration time under **Links expire after (days):** under **General Parameters** when you create the content source.

– **Delete Content Source**. Click this icon to delete the selected content source.

Note: If you delete a content source, then the documents that were collected from this content source remains available for search by users under all scopes, which included the content source before it was deleted. These documents are available until their expiration time ends. You can specify this expiration time under **Links expire after (days):** under **General Parameters** when you create the content source.

– **Start Crawler**. Click this icon to start a crawl on the content source. This updates the contents of the content source by a new run of the crawler. While a crawl on the content source is running, the icon changes to **Stop Crawler**. Click this icon to stop the crawl. Portal Search refreshes different content sources as follows:
  - **For web site content sources:** Documents that were indexed before and still exist in the content source are updated. Documents that were indexed before, but no longer exist in the content source are retained in the search collection. Documents that are new in the content source are indexed and added to the collection.
  - **For WebSphere Portal Express sites** the crawl adds all pages and portlets of the portal to the content source. It deletes portlets and static pages from the content source that were removed from the portal. The crawl works similarly to the option Regather documents from Content Source described later.
  - **For Web Content Manager sites** Portal Search uses an incremental crawling method. Additionally to added and updated content, the Seedlist explicitly specifies deleted content. In contrast, clicking Regather documents from Content Source starts a full crawl; it does not continue from the last session, and it is therefore not incremental.

• **View** information about the status and configuration of the content source.

Note: To update the status information, click the **Refresh** button or the refresh button of the browser.

• **View** the **Collection Status** information of the selected search collection. The status fields show the following data that changes over the lifetime of the search collection:

Search Collection Name:
Shows the name of the selected search collection.

Search Collection Location:
Shows the location of the selected search collection in the file system. This is the full path where all data and related information of the search collection is stored.

Collection Description:
Shows the description of the selected search collection if available.

Search Collection Language:
Shows the language for which the search collection and its index are optimized. The index uses this language to analyze the documents when indexing, if no other language is specified for the document. This feature enhances the quality of search results for users, as it allows them to use spelling variants, including plurals and inflections, for the search keyword.

Summarizer used:
Shows whether a static summarizer is enabled for this search collection. The static summarizer creates a summary of the page, which is based on the page's full content. The page's full content can include metadata,

HTML elements, and Web Content Manager templates. These additional elements might be interpreted as text and thus become a part of the page's summary. Do not use the static summarizer if the page's summary contains a large amount of noise from these additional elements.

Last update completed:
Shows the date when a content source defined for the search collection was last updated by a scheduled update.

Next update scheduled:
Shows the date when the next update of a content source that is defined for the search collection is scheduled.

Number of active documents:
Shows the number of active documents in the search collection, that is, all documents that are available for search by users.

Notes:

1. To update the status information, click **Refresh**. Clicking the refresh button of the browser does not update the status information.
2. If you delete a portlet from the portal after a crawl of the portal site, the deleted portlet is no longer listed in the search results. However, refreshing the view does not update the status information about the **Number of active documents**. This information is not updated until after the next cleanup run of portal resources.

For more details about the available options for content sources, see the **Manage Search** portlet help.

"Applying filter rules"
Portal Search provides a facility for applying filter rules to the crawler process. The crawler filters control the crawler progress and the type of documents that are indexed and cataloged.

Web Content Manager - Seedlist 1.0 REST service API

Applying filter rules:

Portal Search provides a facility for applying filter rules to the crawler process. The crawler filters control the crawler progress and the type of documents that are indexed and cataloged.

You can define the filter rules when creating a content source of type **Web site** only. You define the filters under the **Filters** tab. You can combine any combination of the following filtering options for a filtering rule:

Table 81. Filter rule options

Filter option	Possible settings	
Apply rule while:	Collecting documents	Indexing documents
Rule type:	Exclude	Include
Rule basis:	URL text	File type

Depending on your choices on the options, the filter rules result in the following behavior for selection of documents or pages:

Table 82. Document selection behavior by filter rules

Option for applying the rule	Selected rule type option: Exclude	Selected rule type option: Include
Apply rule while **Collecting documents**	The page or document is excluded, and links on the page are **not** explored.	Only pages or documents that meet the criteria and that have a link on a parent page that meets the criteria, starting with the initial site.
Apply rule while **Adding documents to index**	The page or document is excluded, and links on the page are explored.	The entire site is searched, and pages or documents that meet the filtering criteria will be included.

Note: When you use the option **Apply rule while Collecting documents** with **Rule type: Include**, make sure that the URL in the field **Collect documents linked from this URL:** fits the specified rule; otherwise no documents will be collected. For instance, crawling the URL `http://www.ibm.com/products` with the URL filter `*/products/*` will not give any results, because the rule has a trailing slash, but the URL does not. But either crawling `http://www.ibm.com/products/` with the URL filter `*/products/*` (both with trailing slash) or crawling `http://www.ibm.com/products` with the URL filter `*/products*` (no trailing slash) will work.

For more details about filter rules and how to apply them refer to the **Manage Search** portlet and its help.

Exporting and importing search collections

View the steps to export search collections from a source portal and import them into a target portal.

About this task

The following are possible use cases for exporting and importing search collections:

- You verified your search collections on a test portal, and you want to move these collections to your production portal.
- You verified your search collections locally on a portal, and you want to move these collections to a configuration with remote search.
- You verified your portal search configuration and search collections on a single portal, and you want to move these collections to a portal cluster environment.
- You are staging your portal to production by using the ReleaseBuilder.

To export and import your search collections, use the **Import or Export Collection** option of the Manage Search portlet. You can use that option for both exporting and importing. For more details about these tasks and the Manage Search portlet,

refer to the portlet help. To export and import your search collections, proceed by the following steps:

Procedure

1. To include the security information when you export the search collection, add the **WS_KEY** parameter to the search service that contains the source search collection that you want to export. Complete the following steps:
   a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   b. Click **Search Services**.
   c. Click the **Edit** icon for the search service that contains the search collection that you want to export.
   d. In the **Parameter key** field, enter `WS_KEY`.
   e. In the **New parameter value** field, enter `secret`.
   f. Click **Add Parameter**.
   g. Click **OK**.

   Note: If you do not export the security information when you export a search collection, you must manually add the user name and password to each content source after you import the search collection into the target portal.
2. On the source portal, export your search collections. This exports the configuration data and all document URLs of your search collections.

   Notes:
   a. Before you export a collection, make sure that the user who is running the portal application process has write access to the target directory location.Otherwise, you might get an error message, such as `File not found`.
   b. When you specify the target directory location for the export, be aware that the export can overwrite files in that directory.
3. Document all of the following data:
   - The target file names and directory locations to which you export the collections. For example, `C:\ibm\wp_profile\PortalServer\collections`.
   - The following configuration data of the collections: The **location, name, description**, and **language** for each collection.
4. Create the search collections on the target portal. This task creates the empty shell for the search collection. Complete the following data entry fields and select the following options according to the data that you documented:
   - **Location of Collection:** Specify the new collection location.
   - **Name of Collection:** Specify the collection name. The name can match the old setting, but does not have to match it.
   - **Description of Collection:** Specify a collection description. The description can match the old setting, but does not have to match it.
   - **Specify Collection Language:** Select this to match the old setting.
   - **Select Summarizer:** You do not need to select this option. The value is overwritten by the import.

   You do not have to add content sources or documents; that is completed by the import task.

5. To include the security information when you import the search collection, add the **WS_KEY** parameter to the search service that contains the target search collection. Complete the following steps:
   a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   b. Click **Search Services**.
   c. Click the **Edit** icon for the search service that contains the target search collection.
   d. In the **Parameter key** field, enter `WS_KEY`.
   e. In the **New parameter value** field, enter `secret`.
   f. Click **Add Parameter**.

   Note: If you do not import the security information when you import a search collection, you must manually add the user name and password to each content source after you import the search collection into the target portal.
6. Import the data of your search collections into the target portal. For the import source information, use your documented file names and directory locations to which you exported the collections before the portal upgrade.

What to do next

Notes:

1. Additionally to exporting and importing your search collections, you must configure Portal Search on the target portal. This depends on the requirements of your target portal environment and configuration. For details about how to do this refer to the appropriate topics of the Portal Search documentation, such as Planning and preparing for Portal Search and Administering Portal Search.
2. Before you export a collection, make sure that the portal application process has write access to the target directory location. Otherwise, you might get an error message, such as `File not found`.
3. Import collection data only into an empty collection. Do not import collection data into a target collection that has content sources or documents already.
4. When you import search collection data into a collection, most of the collection configuration data are also imported. For example, this includes the content sources, schedulers, filters, and language settings. If you configured such settings when creating the new collection, they are overwritten by the imported settings.
5. If you want to migrate from one portal version to a higher version, you need to delete the search collections between the export and the reimport. Follow the steps that are described in the topic about Migrating web search collections.
6. When you import a portal site collection from a Version 5.1 portal to a Version 6 portal, the collection configuration data are imported, but not the documents. Therefore, to enable users to search the portal site collection on the target portal, you can either import the portal site collection and then start a crawl, or re-create the portal site collection. For details about how to do this see the topic abut Resetting the default search collection. This restriction does not apply if you migrate your portal site search collections between Version 6 portals.
7. When you import a collection, a background process fetches, crawls, and indexes all documents that are listed by URL in the previously exported file. Therefore, be aware that the crawling process can require extended memory and time, depending on your Portal Search configuration. For more information, see the topic about Hints and tips for Portal Search crawls.

Searching and crawling portal and other sites

Configure your local portal site, and crawl remote portal sites, so that they are searchable by users. Run crawlers against other, external Web sites to make them searchable by local portal users.

Users of your portal can search across various types of sites. In addition to searching the local portal site, you can crawl remote portal sites, and external Web sites, to make search results from those sites available to your local portal users. Examples of search scenarios include:

- Users of your portal search your own local portal site. This can include public and secure pages of your portal.
- Users of your portal search the Web Content Manager collection provided with the portal. This includes all Web Content Manager sites and libraries,
- Users of your portal site search other portal sites. This works only for public pages of the other portals.
- Users of your portal search external Web sites such as yahoo.com or google.com or cnn.com. When you run a crawler against external Web sites, you can collect and display external search results next to results from your local portal site.
- External users search your portal site. This works only for public pages of your portal.

"Resetting the default search collection"
Under certain circumstances, you might want to change the configuration of the portal site search collection. In this case, you must re-create the collection, as search collections cannot be modified.

"Crawling a remote portal site" on page 712
Configure Portal Search to crawl and index a remote, public portal site.

"Crawling an external site using a seedlist provider" on page 713
The seedlist crawler is a special HTTP crawler that can be used to crawl external sites which publish their content using the seedlist format. The seedlist format is an ATOM/XML-based format specifically for publishing application content, including all its metadata. The format supports publishing only updated content between crawling sessions for more effective crawling. You can configure the seedlist crawler with general parameters, filters and schedulers, then run the crawler.

Resetting the default search collection

Under certain circumstances, you might want to change the configuration of the portal site search collection. In this case, you must re-create the collection, as search collections cannot be modified.

About this task

The portal site default search collection is created at the first time when an administrator navigates to the search administration portlet Manage Search. This process requires considerations about the configuration tasks that are related to the portal and Portal Search. Consideration must also be given about the sequence by which you complete these tasks. An example scenario might be that you want to run a portal database transfer, for example, from the default database to a different database. In this case, you must create the portal site collection by navigating to the Manage Search portlet *before* you transfer the database. Otherwise, your portal site collection is not available after the database transfer.

If you created the portal site collection by navigating to the Manage Search portlet *before* you configured your portal and Portal Search, you might need to re-create the search collection. Example scenarios are as follows:

- If the preferred language for the portal site crawler user ID did not match the language of the portal site search collection.
- If you decide to change the default directory location for search collections in your portal installation. For information about how to do this configuration, see the topic about Configuring the default location for search collections.
- If the file path length for search collections exceeds its limit of 118 characters, the collection cannot be created. In this case specify a shorter value for the parameter **`DefaultCollectionsDirectory`**. For details about how to configure this parameter see the topic about Configuring the default location for search collections.

  This file path length problem can occur particularly when the portal site collection is created on one of the following operating systems:

  – Linux

  For details about this length limitation, see the topic about what to do if Creating the portal site search collection fails.
- If you want to turn the summarizer off so summary information is not generated for your portal and web content.
- If you want to change the name of the search collection.

Procedure

1. Complete the required configuration tasks, such as language or path settings
2. Create a search collection with the appropriate configuration settings.
3. Export the content sources from the default search collection. In a default portal installation, these sources are the Portal Content Source, which contains portal pages and portlets, and the Web Content Manager Content Source, which contains web content. For more information about exporting a search collection, see the section about *Exporting and importing search collections* in the related links or the Manage Search portlet help.
4. Import these exported content sources into your new search collection. For more information about importing a search collection, see the section about *Exporting and importing search collections* in the related links.
5. You can now delete the default search collection.

Results

Portal Search starts a new crawl on the portal site search collection.

Notes:

1. On a multilingual portal site, you can create multiple collections in different languages. For details, see the topic about Crawling a multilingual portal site.
2. When you start the crawl for the first time, a warning message might display. You can ignore this message. For more information, see the topic about Hints and tips for Portal Search crawls.

Manage Search

Crawling a remote portal site

Configure Portal Search to crawl and index a remote, public portal site.

About this task

You can enable search on other portal sites. However, only the public pages of other portals can be searched.

To have Portal Search crawl and index a public portal site, proceed as follows:

1. Create a new content source using the Manage Search portlet.
2. Select Web site from the pull-down menu.
3. Enter the URL of the portal site that you want to make available for search by your users.

When you start the crawl, the public portion of the portal site is crawled. The search collection will only contain public pages.

Crawling an external site using a seedlist provider

The seedlist crawler is a special HTTP crawler that can be used to crawl external sites which publish their content using the seedlist format. The seedlist format is an ATOM/XML-based format specifically for publishing application content, including all its metadata. The format supports publishing only updated content between crawling sessions for more effective crawling. You can configure the seedlist crawler with general parameters, filters and schedulers, then run the crawler.

Before you begin

Before configuring the seedlist crawler, collect the following information:

- Root URL, which is the URL of the seedlist page.

  The seedlist page is a special ATOM/XML page containing metadata that directs the crawler to the actual links that should be fetched and indexed to become searchable later. The seedlist page also contains document level metadata that is stored along with the document in the search index. In order to make seedlist crawler results searchable, you must provide the crawler with a URL to a page containing a seedlist. The crawler retrieves the seedlist and crawls the pages indicated by the seedlist.
- User ID and Password, which are used by the crawler to authenticate the seedlist page.

About this task

To configure and create the seedlist crawler:

Procedure

1. Click **Manage Search** > **Search Services**.
2. Click the relevant Portal Search Service.
3. Click the name of an existing search collection, or create a new search collection.
4. Click **New Content Source**.
5. Click the drop-down menu icon next to **Content source type** and click **Seedlist provider** to indicate that the content source is a seedlist.
6. Under the tabs **General Parameters**, **Advanced parameters**, **Schedulers** and **Security**, provide the information in the fields and select options as required. For details refer to the topic *Managing and administering Portal Search*.
7. Click **Create**. This creates the new content source.

8. To run the crawler, click the start crawler icon for the content source on the Content Sources page. If you have defined a crawler schedule under the **Schedulers** tab, the crawler will start at the next possible time that you specified.

Hints and tips for using Portal Search

View some useful tips for using Portal Search.

Content Model has only one search collection

Currently, the Content Model Search Service has only one search collection. This search collection is provided with the installation by default. You cannot modify this default Content Model search collection or create more search collections under the Content Model Search Service. The content model search service is listed because you can include it in scopes.

Using the Search Center with external search services with different languages

In order to use external search services such as Google and Yahoo! with an English search keyword, a URL such as the sample URL mentioned in the Search Center portlet help for configuring the portlet works fine as is: `http://www.google.com/search?q=` . However, if you search in other languages, consult the documentation of the remote search service that you use to ensure that the web interface is set up and used appropriately for the language that you use for your search. This can avoid problems with the displayed results, depending on the combination of languages set for WebSphere Portal Express, your browser, and the search.

Dynamic portal pages are not added to the search seedlist

Dynamic WebSphere Portal Express pages are not added to the Portal Search seedlist. Dynamic pages can have portlets, and portlets are added to the seedlist; therefore, if such pages are added to the seedlist, users get duplicate result list items. If you want to make HTML on a page searchable, create a static portal page and add the HTML. The static page is then added to the seedlist and listed among search results. For more detailed information about static and dynamic pages, see *Creating and adding static content* and *Dynamic user interfaces*.

Search collections unavailable in cluster if failover occurs

If a cluster member in a cluster fails, users who were using the affected cluster member when the failover occurred can no longer access search collections. This problem can occur with horizontal scaling when a node fails or with vertical scaling when a particular cluster member fails.

Users who are logged in to the cluster member that failed must log out of WebSphere Portal Express and then log back in before they are able to access search collections again.

Search can return documents based on metadata

Search can return documents that are based on metadata of these documents, not just on words that are found in the fields or actual text of the document. It might appear to Portal Search users that their searches return documents that do not appear to match the search criteria. Metadata for documents is also indexed for search. Therefore, if the metadata of documents matched the search criteria, these documents are also returned as results for the search. Metadata works as designed and is usually considered to be of benefit.

Documents from deleted content source can remain available under scope

If you delete a content source, then the documents that were collected from this content source will remain available for search by users under all scopes which included the content source before it was deleted. These documents will be available until their expiration time ends. When you create the content source, you can specify the expiration time by modifying the **Links expire after (days)** field in the General Parameters tab.

Documents from deleted web content library can remain available in the search collection

When you delete a web content library, you must also delete the corresponding entries from the search collection. When a web content library is deleted and crawled, deleting the corresponding crawler deletes the entries from the search index. If you use one Web Content Manager content source, which automatically crawls all web content libraries, then delete and re-create the content source, or you can select **Regather documents from Content Source**. This step deletes all existing documents in the content source from previous crawls and then starts a full crawl on the content source. Documents that were indexed before, but no longer exist in the content source are removed from the collection.

Note: If you plan on deleting web content libraries frequently, then it is suggested to define one content source per web content library. When that library is deleted, only the respective content source needs to be deleted as well.

Portal Search portlets are not compatible with WSRP

The Portal Search portlets cannot be provided as WSRP services, as some additional and more advanced WebSphere Portal Express concepts and features are not reflected by the current WSRP standard yet. These Portal Search portlets include Manage Search and the Search Center.

Default Portal Search Service and its collections show in the portal default language

The search administration portlet Manage Search lists the Default Portal Search Service and its collection Portal Content or other collections in the default portal language and not in the language that the user selected as preferred language for the portal or set in the browser. For example, if the portal default language is set to English and the user selected German as the preferred portal language or set the

browser language to German, the Default Portal Search Service and its collections show in English.

Virtual portals have separate search services and collections

Search services and search collections are separate for individual virtual portals and are not shared between individual virtual portals. Set up separate search services and separate search collections for each individual virtual portal. These collections can be used to crawl and search the same set of documents.

"Hints and tips for improving quality of Portal Search results"
There are three options available to improve the quality of search results and thus the overall search experience for your site visitors. The three options are using the Suggested Links portlet, changing the default query operator from `Or` to `And`, and applying boost factors to specific metadata fields.

If the preferred language of the crawler user ID does not match the language of the search collection, users might not see search results in their language.

Hints and tips for improving quality of Portal Search results

There are three options available to improve the quality of search results and thus the overall search experience for your site visitors. The three options are using the Suggested Links portlet, changing the default query operator from `Or` to `And`, and applying boost factors to specific metadata fields.

Using the Suggested Links portlet

Use the Suggested Links portlet to ensure that a specific document is listed at the beginning of a set of search results. When a site visitor runs a search, the Suggested Links portlet displays the documents that are tagged with the same keywords from the search. To edit the keywords for Suggested Links, complete the following steps:

1. Log in to WebSphere Portal Express as an administrator and navigate to the Search Center.
2. Select **Edit keywords for Suggested Links** for the document that you would like to edit.
3. Specify what tags you would like to associate with that specific document.
4. Click **Save**.

The keywords that you specified are now associated with that item. If a site visitor searches for any of those keywords that are associated with that specific document, that document displays as a link in the Suggested Links portlet.

Changing the default search operator from "Or" to "And"

When a site visitor enters more than one search term, the Portal search engine applies a logical `Or` operator as a default. In order for a document to display in the search results list, the document must have only one of those search terms. However, search engines such as Google often use `And` as the default search operator. Using `And` as the default search operator means that all of the terms used in the search query must be found in each of the returned documents. For more details on changing the default search operator, see *Search service configuration parameters* in the related links.

Applying boost factors to specific metadata fields

When a site visitor runs a search, any values from metadata fields such as `title`, `description`, or `keywords` are automatically added to the generic `content` field in the search index. The values in these fields contribute equally to relevance calculation for any qualifying documents that are returned in the search results list. Use the search service configuration parameter **`boostingSettings`** to give extra weight to specified metadata fields, such as `title` or `description`. You can also use **`boostingSettings`** to specify how much extra weight specified metadata fields receive. For more information on the parameter **`boostingSettings`**, see *Search service configuration parameters* in the related links.

Improving search quality in Portal Search

Hints and tips for Portal Search crawls

View some useful tips about crawls that Portal Search performs. For example, crawling can require extended memory and time, depending on your Portal Search environment and configuration.

HTTP crawler does not support JavaScript

The HTTP crawler of the Portal Search Service does not support JavaScript. Therefore some text of web documents might not be accessible for search by users. This depends on how the text is prepared for presentation in the browser. Specifically text that is generated by JavaScript might or might not be available for search.

Crawling a portal site for the first time can result in a message

When you start the crawl on a portal site for the first time, this can result in the following message:

```
EJPJP0009E: Wrong root url for Portal site crawler: https://root_url
```

You can ignore this message. The crawl runs correctly.

To resolve this problem, edit the content source, select the **General Parameters** tab, and the set the parameter **Stop fetching documents after (seconds):** to a value of `90` seconds.

Memory required for crawls

Depending on your Portal Search environment, crawling can require large amounts of memory. Therefore, before you start a crawl, make sure that WebSphere Portal Express has enough free memory. Memory shortage can cause a corrupted search collection and eventually lead to a system freeze.

To resolve this problem, raise the limit to the number of open files by using the `ulimit` command as root administrator.

Due to the resources needed for a crawl and index, it is recommended that you schedule crawls to occur when user activity is relatively low.

Time required for crawls and imports and availability of documents

The following search administration tasks can require extended periods of time:

- Crawling a content source. During the crawl documents might not be immediately available for searching or browsing.
- Indexing the documents fetched by a crawl. When a crawl has been complete and all documents have been collected, building the index takes some more time.
- Importing a search collection. When you import data to a collection, it can take some time until the content sources for the collection are shown in the Content Sources in Collection box and the documents of the imported collection are available for crawling.

These tasks are put in a queue. It might therefore take several minutes until they are executed and the respective time counters start, for example, the crawl **Run time** and the timeout for the crawl set by the option **Stop collecting after (minutes):** . The time required for these tasks is further influenced by the following factors:

- The number of documents in the content source that is being crawled
- The size of the documents in the content source that is being crawled

- Speed and availability of your processors, hard drive storage systems, and network connection.
- The value that you selected from the **Stop collecting after (minutes):** drop-down menu when you created or edited the content source.

Therefore both the time limits that you can specify and the times that are shown for these processes work as approximate time limits. This applies, for example, to the following scenarios:

- When you start a crawl by selecting a content source in the **Content Sources in Collection** box and clicking **Start collecting**.
- When you import a search collection and when you start a crawl on the imported search collection.
- When an installation is complete and you initialize the pre-configured portal site collection by selecting the portal site content source and clicking **Start collecting**.
- The time shown under **Last update completed** in the collection status information is later than you might assume by just adding the crawler time limit specified by **Stop collecting after (minutes):** to the crawling start time. This delay is caused by the additional time required by building the index.

Furthermore, this influences other status indicators given in the Manage Search portlet. For example, the number of documents shown for a content source can show with an unexpectedly low figure or even at zero (**0**) until the crawl on that content source has been completed.

How Portal Search handles special characters when indexing

Portal Search indexes words that are composed of consecutive literals, that is letters, digits, and special characters. Learn how Portal Search handles special characters during indexing.

This includes the following characters:

- The hash or pound sign (**#**).
- The percent sign (**%**).
- The plus sign (**+**).
- The asterisk (*****).

During indexing special characters are handled as follows:

Blank or white space; this includes the tab
Blanks separate words and are not indexed. Example: The string `key board` is indexed as two separate words `key` and `board` .

Line break or new line
Line breaks separate words and are not indexed unless they are preceded by a dash (**-**). Examples:

- The string

  ```
  key
  board
  ```

  is indexed as two separate words `key` and `board` .
- The string

  ```
  key-
  board
  ```

  is indexed as one word `keyboard`.

Dot or sentence end period (.) and comma (,)
Dots and commas separate words and are not indexed, unless they are both preceded *and* followed by a letter or digit. Example: The string `www.ibm.com` is indexed as `www.ibm.com` and not as three separate words.

Question mark (?) and exclamation mark (!)
Question marks and exclamation marks separate words and are not indexed unless they are followed by a letter.

Other punctuation: ( ) { } [ ] < > ; : / \ | " _ -
These characters separate words and are not indexed.

Other characters
All other characters are removed from the strings in which they appear but do not separate words.

Notes:

1. All characters that split words are discarded during indexing and searching.
2. The previous statements apply to **indexing**. However, in a **search query** all characters that can be part of the search syntax are treated in that capacity and not as part of the search query. These are the plus (+) and minus (-) signs, double quotation marks (`"`), and the asterisk wild card character (*). If users want to include such characters in their search query, they must enclose them in double quotation marks. For example `"+hello"` searches for the string `+hello`; `"*Hello*"` searches for the string `*Hello*`.
3. The less than (<) and greater than (>) symbols are special HTML characters that Search cannot handle.

Uninstalling WebSphere Portal Express does not delete search collections

When you uninstall WebSphere Portal Express, the directories and files for the search collections are not deleted. Therefore, before you uninstall WebSphere Portal Express, delete all search collections by selecting the collections individually and clicking the option **Delete Collection**. If you do not delete, these files and directories remain on the hard disk drive. If you want to delete the search collection data after uninstalling WebSphere Portal Express, you need to delete manually.

The directory path of a search collection is determined by what you typed in the field Location of Collection when you created the search collection. You can look up the collection location by doing the following steps:

1. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
2. Click **Search Collections**.
3. Select the collection from the **Search Collections** box.
4. The collection location is shown in the list under **Search collection status information**.

Linux operating systems might require higher limit of open files for Portal Search to work properly

The limit for the number of open files in a Linux operating system might be too low for Portal Search to work properly. This might result in a `Portlet Unavailable` error.

To resolve this problem and allow a higher number of files to be handled, raise the limit to the number of open files by issuing the following command as root administrator:

```
ulimit -n 4096
```

Creating the portal site search collection can fail

Creating the portal site search collection can fail due to a file path length restriction.

Problem: If the file path length for the location of search collections exceeds its limit, the collection cannot be created.

Cause: The file path length for the portal search collection is limited to 118 characters. If this limit is exceeded, the default collection cannot be created. The following items contribute to the length of the file path:

- The installation directory path.
- By default, the search collection for the portal site content is created under the path *your_portal_install_directory*/PortalServer/collections.
- The name of the virtual portal.
- The name of the search collection.

Solution: Complete the following steps to resolve the issue:

1. Change the default directory location for the portal site search collection to a shorter path. The complete path and file name must not exceed a length of 118 characters. For information, go to *Configuring the default location for search collections*.
2. Re-create the portal site search collection. For information, go to *Resetting the default search collection*.

Related tasks:

"Resetting the default search collection" on page 711
Under certain circumstances, you might want to change the configuration of the portal site search collection. In this case, you must re-create the collection, as search collections cannot be modified.

"Configuring the default location for search collections" on page 682
You can modify the default directory location under which search collections are created on a per search service basis. View some related information.

On IBM i set USER.REGION variable

Under IBM i, Portal Search collections might fail to collect documents.

In this case the logs will provide the following or similar information:

```
[8/24/08 23:19:47:164 EDT] 000000cd ServletWrappe E
         Uncaught init() exception thrown by servlet SearchSeedlistServletSecured
[8/24/08 23:19:47:175 EDT] 000000cd ServletWrappe E
         Deregister the mbean because of uncaught init() exception thrown by
         servlet SearchSeedlistServletSecured: javax.servlet.ServletException:
         Could not load resource bundle nls.SeedlistServletMessages using locale
         en_${USER.REGION} - Java Exception Message: java.util.MissingResourceException:
         Can't find bundle for base name nls.SeedlistServletMessages,
         locale en_${USER.REGION}
```

Solution: In order for portal collections to work on a IBM i system, set the system variable USER.REGION.

Users cannot see portal site search results in their preferred language

If the preferred language of the crawler user ID does not match the language of the search collection, users might not see search results in their language.

Therefore, set the preferred language of the portal site crawler user ID to match the language of the portal site search collection that it crawls. If you do this after you started a crawl on the portal site search collection, you need to reset the portal site collection. Refer to the topic about Resetting the default search collection.

If your portal site is multilingual and your users use different languages to search WebSphere Portal Express, set the portal site collections up as described under the topic about Crawling a multilingual portal site.

Related tasks:

"Resetting the default search collection" on page 711
Under certain circumstances, you might want to change the configuration of the portal site search collection. In this case, you must re-create the collection, as search collections cannot be modified.

"Crawling a multilingual portal site" on page 631
View the steps to set up search on a multilingual portal for users with different language preferences.

Setting limits on searches for users and groups

Searching for users or groups is a time consuming task. A search may time out or return more results than the system can handle or the user may expect. To prevent this behavior, you can set limits on searches for users or groups.

You can limit searches for users or groups in two ways:

- Setting a number of search results
- Setting a timeout for searches in the user repository

Set the **maxSearchResults** and **searchTimeOut** parameters in the following file:

Table 83. Location of the `wimconfig.xml` file

Operating system	Directory path
Windows:	*wp_profile_root*\config\cells*cell_name*\wim\config\wimconfig.xml
Linux:	*wp_profile_root*/config/cells/*cell_name*/wim/config/wimconfig.xml
IBM i:	*wp_profile_root*/profiles/config/cells/*cell_name*/wim/config/wimconfig.xml

The **maxSearchResults** parameter specifies the number of search results. The **searchTimeOut** parameter specifies the time out in milliseconds.

If you set **maxSearchResults**=200 and **searchTimeOut**=120000, it returns a number of 200 users or groups and terminates the search if the back end does not respond within two minutes. These settings affect the user or groups shown in portlets (for example the **User Manager** portlet) and XML export scripts.

If not all search results are returned, and you are using an LDAP server as the user repository, a `SizeLimitException` can be thrown instead of returning the items. The search result can exceed the limit defined in LDAP. Perform one of the following actions:

- Refine your search conditions to return fewer results.
- Change the setting in LDAP to allow a larger search size limit.

Important: If your user repository contains more users or groups than the value configured in **maxSearchResults**, a complete export of users and groups with XML access is not possible.

LDAP search filter expressions

The rules for rule-based user groups are based on the LDAP search filter syntax.

For information about the LDAP search filter syntax, see RFC2254 - The String Representation of LDAP Search Filters in the related links section.

You can use this subset of the LDAP search filter syntax:

- The `AND` operator represented by an ampersand (`&`).
- The `OR` operator represented by a vertical slash (`|`).
- The `NOT` operator represented by an exclamation mark (`!`).
- Equality comparison represented by an equal sign (`=`) for name and value expressions.
- Wildcards represented by an asterisk (`*`) at the beginning or end of values in name and value expressions.

Note: Attributes must not start with one of the operator symbols `AND`, `OR`, or `NOT` (`&`, `|`, or `!`), and they must not contain a comparison equal sign (`=`), or parentheses.

For example:

`(uid=testuser)`
: Matches to all users that have exactly the value `testuser` for the attribute `uid`.

`(uid=test*)`
: Matches to all users that have values for the attribute `uid` that start with `test`.

`(!(uid=test*))`
: Matches to all users that have values for the attribute `uid` that do not start with `test`.

`(&(department=1234)(city=Paris))`
: Matches to all users that have exactly the value `1234` for the attribute `department` and exactly the value `Paris` for the attribute `city` .

`(|(department=1234)(department=56*))`
: Matches to all users that have exactly the value `1234` or a value that starts with `56` for the attribute `department`.

`(&(department=12*)(!(department=123*)))`
: Matches to all users that have a value starting with `12`, but not starting with `123` for the attribute `department`.

Syntax validation

When you define or modify a rule base user group, the rule-based user groups adapter validates the syntax for the LDAP search filter expression. For example:

Invalid rule specified:
If you provide a rule that is not valid, rule-based user groups return the appropriate error message. However, it does not check whether the attribute names that you use exist in the user configuration. You can verify the configuration by using the code that calls the search filter.

Invalid attribute specified:
If an invalid attribute name is contained in a rule, the group membership determination for rule-based user groups does not work and logs an error. Existing rules might break if your attribute configuration in the system changes, for example, when an attribute is removed or renamed.

Related information:

 RFC2254 - The String Representation of LDAP Search Filters - http://www.faqs.org/rfcs/rfc2254.html

Creating the portal site search collection can fail

Creating the portal site search collection can fail due to a file path length restriction.

Problem: If the file path length for the location of search collections exceeds its limit, the collection cannot be created.

Cause: The file path length for the portal search collection is limited to 118 characters. If this limit is exceeded, the default collection cannot be created. The following items contribute to the length of the file path:

- The installation directory path.
- By default, the search collection for the portal site content is created under the path *your_portal_install_directory*/PortalServer/collections.
- The name of the virtual portal.
- The name of the search collection.

Solution: Complete the following steps to resolve the issue:

1. Change the default directory location for the portal site search collection to a shorter path. The complete path and file name must not exceed a length of 118 characters. For information, go to *Configuring the default location for search collections*.
2. Re-create the portal site search collection. For information, go to *Resetting the default search collection*.

Related tasks:

"Resetting the default search collection" on page 711
Under certain circumstances, you might want to change the configuration of the portal site search collection. In this case, you must re-create the collection, as search collections cannot be modified.

"Configuring the default location for search collections" on page 682
You can modify the default directory location under which search collections are created on a per search service basis. View some related information.

Portal Search trace and log files

Portal Search provides logging and tracing so that you can get additional information for resolving possible problems.

Portal Search has the following trace strings:

com.ibm.portal.search
Use to turn on **all** Portal Search messages.

com.ibm.portal.search.notIndexed
Enable to obtain messages about URLs that are discovered by the crawler but could not be fetched and indexed for different reasons.

com.ibm.portal.search.crawler
Enable to obtain messages about the crawling process.

com.ibm.portal.search.crawler.failure
Enable to obtain messages about failures that happen during a crawl.

com.ibm.portal.search.index
Enable to obtain messages about the indexing process.

com.ibm.portal.search.index.failure
Enable to obtain messages about failures that happen during the indexing process.

Enabling logging for a remote search configuration

If you have set up Portal Search in a remote configuration on a WebSphere Application Server server, the log messages are filtered and printed out according to the WebSphere Application Server logging and tracing configuration. In this case refer to the WebSphere Application Server information center.

Related concepts:

"Logging and tracing" on page 3541
If you are experiencing a problem, you might want to enable tracing and then re-create the problem to capture more log information. You can enable logging and tracing for software that is included with WebSphere Portal Express. Enabling tracing makes log output more verbose. For example, you can enable tracing within WebSphere Application Server to obtain information about application servers and other processes.

Chapter 6. Document Conversion Services

Document Conversion Services are used when you work with the Common Mail Portlet, IBM Web Content Manager authoring and previewing, and search.

About this task

Documents that are produced by many standard applications (such as word processors or spreadsheet editors) can be viewed as HTML pages with Document Conversion Services. Documents that are received as attachments to email can be viewed in the browser even if the application that created the document is not installed. Document Conversion Services also allows documents to be searched by content. Document pages can also be converted into an image format such as GIF, BMP, JPG, or PNG.

"Configure Document Conversion Services"
Learn how to configure the Document Conversion Services in WebSphere Portal. A knowledge of these prerequisites steps can assist you in preventing, identifying, and correcting problems that are related to Document Conversion Services.

"Supported operating systems for document conversion services" on page 731
Some operating systems support running the DCS locally while others do not. The following table lists the operating systems and versions that support running the document conversion services. On operating systems that do not support running the DCS locally, document conversion must be done on a remote IBM WebSphere Application Server that supports document conversion services.

"Setting up file type definitions to enable Document Conversion Services" on page 731
Set up file definition types to ensure that document conversions works for Microsoft Office, Lotus® SmartSuite®, and OpenOffice file types.

"Using Document Conversion Services with Stellent" on page 734
For Linux, when using Stellent version 8.1.0 and later, the X-server dependency has been removed.

"Configuring a remote Document Conversion Service" on page 734
To balance processing power, you can run document conversion services on a remote IBM WebSphere Application Server that supports document conversion services. Enabling the delegation of document conversion services to a remote server requires steps on both IBM WebSphere Portal Express and the remote server.

"Files conversion supported by DCS" on page 737
View a list of file types that are supported by DCS for conversion.

Configure Document Conversion Services

Learn how to configure the Document Conversion Services in WebSphere Portal. A knowledge of these prerequisites steps can assist you in preventing, identifying, and correcting problems that are related to Document Conversion Services.

Visual C++ libraries are required for Windows

To run Document Conversion Services on Windows, download Visual C++ libraries included in the latest Visual C++ Redistributable Package available from the Microsoft download site. There are three versions of this package, x86, x64, and IA64 for the 86-bit, 64-bit, and 64-bit Itanium systems.

You must search the Microsoft download site for the `vcredist_x86.exe`, `vcredist_x64.exe`, or `vcredist_IA64.exe` files.

Exporter task

Run the **exporter** task from the *wp_profile_root*`/PortalServer/config/oiexport/exporter` directory to ensure that you installed all the libraries.

A successful task displays the following message:

```
Error: no input file was specified
Error: no output file was specified
Error: No output id was specified
```

"Configuring Document Conversion Services for systems other than Windows" Configure the Document Conversion Services to complete document conversions in an operating system other than Windows. You must complete the following steps whenever you start the Portal server from a new terminal window.

"Configuring Document Conversion Services for IBM i" on page 729 Configure the Document Conversion Services to perform document conversions on IBM i systems. You need to complete the following steps whenever you start the Portal server from a new terminal window.

"Configuring images for Document Conversion Services" on page 729 Configure the Document Conversion Services to view images in an operating system other than Windows.

Configuring Document Conversion Services for systems other than Windows

Configure the Document Conversion Services to complete document conversions in an operating system other than Windows. You must complete the following steps whenever you start the Portal server from a new terminal window.

Procedure

1. Ensure that the `oiexport` directory is in the PATH as *wp_profile_root*`/PortalServer/config/oiexport:$PATH`.

   For example, `export PATH=`*wp_profile_root*`/PortalServer/config/oiexport:`*AppServer_root*`/java/jre/bin:$PATH`
2. Export `LD_LIBRARY_PATH/LIBPATH/SHLIB_PATH` to point to the `oiexport` directory and the graphics library directory. This environment variable is different for different systems, as detailed in the following table:

Table 84. Library path variables by operating system

Platform	Library path variable
Linux	LD_LIBRARY_PATH

Required library: On Linux, you must install the following library to run document conversion services: `libstdc++.so.5`. This library is included with GNU Compiler Collection (GCC) 3.2 to 3.3.6.

You must install `libstdc++.so.5` and include the folder that contains the library in the library path variable. The command might be `export LD_LIBRARY_PATH=`*`wp_profile_root`*`/PortalServer/config/oiexport:/usr/X11R6/lib:/user/lib`

3. Run the **exporter** task from the *wp_profile_root*`/PortalServer/config` directory to ensure that you installed all the libraries.

   A successful task displays the following message:

   ```
   Error: no input file was specified
   Error: no output file was specified
   Error: No output id was specified
   ```

Configuring Document Conversion Services for IBM i

Configure the Document Conversion Services to perform document conversions on IBM i systems. You need to complete the following steps whenever you start the Portal server from a new terminal window.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Select **Servers** > **Server Types** > **WebSphere application servers**
3. Click the **WebSphere_Portal** server to open the configuration window.
4. Select **Server Infrastructure** > **Java and Process Management** > **Process definition**.
5. Select **Additional Properties** > **Environment Entries**.
6. Click **LIBPATH** to open the configuration window.
7. In the **Value** field, add the following information: `:/QOpenSys/usr/bin:/QOpenSys/usr/bin/X11:/QOpenSys/usr/sbin`.
8. Click **Apply** and save your changes to the master configuration. The value for the **LIBPATH** environment entry displays as follows: `${WPS_HOME}/lwo/prereq.odc/shared/app/oiexport:/QOpenSys/usr/bin:/QOpenSys/usr/bin/X11:/QOpenSys/usr/sbin`
9. Restart WebSphere Application Server.

Configuring images for Document Conversion Services

Configure the Document Conversion Services to view images in an operating system other than Windows.

About this task

The following steps do not apply to IBM i. For information about viewing images on IBM i, read *Rendering documents on IBM i*.

Procedure

1. Connect to one of the following workstations from your Windows workstation with PuTTY or any other Telnet client.
   - Linux
2. The `oiexport` directory should be in the PATH as *wp_profile_root*`/PortalServer/config/oiexport:$PATH`.

For example, export PATH = *wp_profile_root*/PortalServer/config/oiexport:*AppServer_root*/java/jre/bin:$PATH

3. Export LD_LIBRARY_PATH /LIBPATH/ SHLIB_PATH to point to the oiexport directory and the graphics library directory. This environment variable is different for different operating systems, as detailed in the following table:

Table 85. Library path variables by operating system.

Platform	Library path variable
Linux	LD_LIBRARY_PATH

For example, in case of Linux, the command might be export LD_LIBRARY_PATH = *wp_profile_root*/PortalServer/config/oiexport:/usr/X11R6/lib

4. Now connect to another workstation through XBrowser.
5. Start the XBrowser and enter the host name. When you log in successfully, type echo $DISPLAY at the prompt. Which gives you <machine-ip>:0.0,, where <machine-ip> refers to the ip of the workstation from where XBrowser was started.
6. In the same Telnet/ssh session where you exported PATH and LD_LIBRARY_PATH/LIBPATH/SHLIB_PATH, type the command export DISPLAY=<machine-ip>:0.0. This value is the same as the value you get in the previous step.
7. Change directory to the location where the xclock and xhost files are present, such as, /usr/X/bin.
8. Type the command ./xclock &.
9. Type ./xhost + on the workstation through which you are connected through XBrowser. Which gives you the message access control disabled, clients can connect from any host.

   Note: Changing directory is required because by entering the commands xclock& or xhost+, the error message command not found is displayed.
10. The Xclock menu comes up on the desktop of the workstation to which you are connected through X-Browser.
11. Change directory to *AppServer_root*/bin.
12. Restart the server.
13. Open a web browser and try viewing the file that contains the images.

Starting the X server by using Exceed or X virtual frame buffer (Xvfb)

The previous steps are given to start the X server by using XBrowser. The following steps are used to start the X server by using Exceed or X virtual frame buffer (Xvfb).

Procedure

1. Start Exceed.
2. Connect to one of the following workstations with PuTTY and then type export PATH.
   - Linux
3. Type export LD_LIBRARY_PATH/LIBPATH/SHLIB_PATH.
4. Type export DISPLAY.

5. Type `echo $DISPLAY` on the workstation to which you connected by using Exceed or Xvbf.
6. Enter `xclock &` (if `xclock` displays on the desktop of the workstation to which you are connected through Exceed or Xvfb, then X server is running).
7. If `xhost + {xhost + <IP>}` displays, this means conversion works for this particular IP and only + means for all workstations.

   You must start WebSphere Portal Express from the console or an X Server-enabled client with the same privileges (xhost+) as the console. The graphical conversions require access to an X Window System server, since they require access to the Xm, Xt and X11 libraries. Also, the DISPLAY environment variable must be set to the account that Portal is running under. The DISPLAY must be valid at the point that Portal is started. Otherwise, telnetting to a workstation and starting Portal from there does not work. You must start Portal from an X terminal.

Supported operating systems for document conversion services

Some operating systems support running the DCS locally while others do not. The following table lists the operating systems and versions that support running the document conversion services. On operating systems that do not support running the DCS locally, document conversion must be done on a remote IBM WebSphere Application Server that supports document conversion services.

The following operating systems are supported by DCS.

Table 86. Supported Platforms

Platform	Version
IBM AIX® 64 bit	6.1, 7.1
Linux X86-64	RHLE 5, SLES 10, 11
Solaris SPARC	v10

Setting up file type definitions to enable Document Conversion Services

Set up file definition types to ensure that document conversions works for Microsoft Office, Lotus SmartSuite, and OpenOffice file types.

Procedure

1. Locate the `content-types.properties` file in the following directory:
   - , , Linux, , Windows: *AppServer_root*`/java/jre/lib`
   - IBM i:
     - JDK 7: `/QOpenSys/QIBM/ProdData/JavaVM/jdk70/64bit/jre/lib`
     - JDK 7.1: `/QOpenSys/QIBM/ProdData/JavaVM/jdk71/64bit/jre/lib`
2. Update the `content-types.properties` file as follows. These extensions are case-sensitive.

   Microsoft Office 2007

```
application/vnd.openxmlformats-officedocument.wordprocessingml.document: \
   description=Microsoft Word 2007 file;\
   file_extensions=.docx

application/vnd.openxmlformats-officedocument.presentationml.presentation: \
   description=Microsoft PowerPoint 2007 file;\
```

```
   file_extensions=.pptx

application/vnd.openxmlformats-officedocument.spreadsheetml.sheet: \
   description=Microsoft Excel 2007 file;\
   file_extensions=.xlsx
```

Microsoft Office (before 2007)

```
application/msword: \
 description=Microsoft Word;\
 file_extensions=.doc

application/vnd.ms-excel: \
 description=Microsoft Excel;\
 file_extensions=.xls

application/vnd.ms-powerpoint: \
 description=Microsoft PowerPoint;\
 file_extensions=.ppt
```

Lotus SmartSuite

```
application/vnd.lotus-freelance: \
        description=Lotus Freelance;\
        file_extensions=.prz

application/vnd.lotus-1-2-3: \
        description=Lotus 1-2-3;\
        file_extensions=.123

application/vnd.lotus-wordpro: \
        description=Lotus WordPro;\
        file_extensions=.lwp
```

OpenOffice

```
application/vnd.sun.xml.writer: \
 description=Open Office;\
 file_extensions=.sxw

application/vnd.sun.xml.writer.template: \
 description=Open Office;\
 file_extensions=.stw

application/vnd.sun.xml.writer.global: \
 description=Open Office;\
 file_extensions=.sxg

application/vnd.sun.xml.calc: \
 description=Open Office;\
 file_extensions=.sxc

application/vnd.sun.xml.calc.template: \
 description=Open Office;\
 file_extensions=.stc

application/vnd.sun.xml.impress: \
 description=Open Office;\
 file_extensions=.sxi

application/vnd.sun.xml.impress.template: \
 description=Open Office;\
 file_extensions=.sti

application/vnd.sun.xml.draw: \
 description=Open Office;\
 file_extensions=.sxd

application/vnd.sun.xml.draw.template: \
 description=Open Office;\
```

```
 file_extensions=.std

application/vnd.sun.xml.math: \
 description=Open Office;\
 file_extensions=.sxm
```

3. Install the appropriate package for your system.

Table 87. Systems and packages

Systems	Extra Packages
IBM i (v7r1)	X11R6
Linux	X11R6 LessTif or Motif with libXm.so.1 (Stellent 8.0.1) LessTif or Motif with libXm.so.2 (Stellent 7.75 or earlier)
Windows	n/a

If OpenMotif is included on the Linux server, do not need to install the LessTif Rational Portfolio Manager package. The binary files for the LessTif package are already included.

Example

A temporary directory is used for document conversion.

- Windows: `c:\temp`
- , , Linux, : `/tmp`

  Note: The default `/tmp` directory is in the root system. If it does not exist, it must be created.
- IBM i: `/temp`

To create a temporary directory other than the default, edit the `convertors.xml` file in *wp_profile_root*`/PortalServer/dcs`. Add the property **tempDir** to the `<global>` tag as follows:

```
<global>
<property name="tempDir" value="yourtempDirectory"/>
</global>
```

What to do next

To start the native application when you click the attachment, the following MIME types must be registered in WebSphere Application Server to enable browsers to properly display documents of that type. The following extra types must be registered:

- `application/msword doc`
- `application/vnd.ms-excel xls`

For , , Linux, , you must start IBM Workplace Services Express from the console or an X-Server-enabled client with the same privileges (**xhost+**) as the console.

Note: Graphical conversions require access to an X Windows server. They require access to the **Xm**, **Xt**, and **X11** libraries. Also, the DISPLAY environment variable must be set to the account that Portal is running under. The DISPLAY must be valid at the point that Portal is started. Therefore, telnetting to a server and starting Portal from there does not work. You must start the portal from an X terminal.

For IBM i, refer to the prerequisites as described in "Configuring images for Document Conversion Services" on page 729.

Using Document Conversion Services with Stellent

For Linux, when using Stellent version 8.1.0 and later, the X-server dependency has been removed.

About this task

Procedure

1. Prepare the system using the steps outlined in "Configuring images for Document Conversion Services" on page 729.
2. Install **libXm.so.3** and **ln -sf /usr/X11R6/lib/libXm.so.3.0.2 /usr/X11R6/lib/libXm.so.2.0.1**.
3. Use the command **find / -name *.ttf** to locate the fonts folder on your machine. Set **GDFONTPATH** to point to the fonts folder. For example:

   ```
   export GDFONTPATH=/opt/IBM/WebSphere/AppServer/java/jre/lib/fonts
   ```

4. Make sure that the environment variable **GDFONTPATH** includes one or more paths to the fonts folder.

   Only TrueType fonts (*.ttf or *.ttc files) are supported. If the variable GDFONTPATH is not found, the current directory is used. If fonts are called for and cannot be found, HTML Export will exit with an error. When copying Windows fonts to a Unix system, the font extension for the files (*.ttf or *.ttc) must be lowercase, or the fonts will not be detected during the search for available fonts. Stellent does not provide fonts with any Outside In product.

What to do next

On platforms that support local document conversion, document conversion services can be delegated to a remote server to better balance processing power and manage server performance.

IBM i: You can choose to run the X Server on the portal server or a remote server. You can also use a frame-buffer device or XVFB to emulate X Windows servers on a headless server. The conversion filters are installed with WebSphere Portal Express. There is no need for configuration. However, you can configure the `export.cfg` file, located under the *wp_profile_root*`/PortalServer/config` directory, if you want to fine tune conversion properties such as graphics size and resolution.

Configuring a remote Document Conversion Service

To balance processing power, you can run document conversion services on a remote IBM WebSphere Application Server that supports document conversion services. Enabling the delegation of document conversion services to a remote server requires steps on both IBM WebSphere Portal Express and the remote server.

Before you begin

- If the remote Document Conversion Service (DCS) was set up on a remote machine with the remote search installer, then skip steps 1 - 7.
- Update the `content-types.properties` file to ensure that document conversions are configured for different file types. For instructions, read *Enabling Document Conversion Services*.

- Copy the RemoteDCS.zip file to your file system. Locate the RemoteDCS.zip file in your WebSphere Portal Express installation directory under *PortalServer_root*/lwo/prereq.odc/RemoteSearchInstaller.

  Note: Updated versions of RemoteDCS.zip might be available online. Check the *Recommended fixes and updates for WebSphere Portal and Web Content Management* site.

About this task

Procedure

1. Install WebSphere Application Server on the remote system.

   Restriction: Stellent version 8.01 must support the remote system.
2. Copy RemoteDCS.zip to the remote server and extract it in any directory with an appropriate archiving tool. A directory that is named dcs becomes available. This directory contains several files and subdirectories.
3. Deploy dcs.war to WebSphere Application Server.
   a. Log in to the WebSphere Integrated Solutions Console.
   b. Select **Applications** > **Install New Application**.
   c. Browse to the directory where you extracted RemoteDCS.zip then locate and select dcs.war.
   d. Specify dcs as the context root and click **Next**.
   e. Leave all other values as default.

      Restriction: The application name must be dcs_war. Do not change the default name.
   f. Map the application to the appropriate servers and specify the installation options as required.
   g. Click **Finish** and save your changes to the master configuration.
4. Ensure dcs.war is running.
   a. Log in to the WebSphere Integrated Solutions Console.
   b. Select **Applications** > **Enterprise Applications**.
   c. Locate **dcs_war** in the list of installed applications.
   d. Select **dcs_war** and click **Start** if the application is not started.
5. Run the configuration script.
   a. Open a command prompt.
   b. Change to the dcs directory. The configuration script is in the root of the dcs directory that is in the directory where you extracted RemoteDCS.zip.
   c. Run the following command:

      Linux : ./setupremotedcs.sh

      IBM i: setupremotedcs.sh

      Windows: setupdcs.bat
   d. When prompted, specify the WebSphere Application Server installation directory. For example, *AppServer_root*.
   e. When prompted for the profile, specify the directory where dcs.war is installed. For example, *AppServer_root*/profiles/*profile_name*/installedApps/*node_name*/dcs_war.ear

The configuration script copies all the files to the oiexport directory where you installed dcs.war; for example, *AppServer_root*/profiles/*profile_name*/installedApps/*node_name*/dcs_war.ear/dcs.war/WEB-INF/lib/oiexport

6. Complete the following steps to add environment variables to your remote search server:
   a. Log on to the WebSphere Integrated Solutions Console.
   b. Go to **Servers** > **Server Types** > **WebSphere application servers**.
   c. Select your remote DCS server.
   d. Go to **Java and Process Management** > **Process definition**.
   e. Click **Environment Entries**.
   f. Click **New** to create the following entries:

      Note: If the entries exist, click the entry and update the value.

      LD_LIBRARY_PATH
      AppServer_root/profiles/*profile_name*/installedApps/*node_name*/dcs_war.ear/dcs.war/WEB-INF/lib/oiexport

      LIBPATH
      AppServer_root/profiles/*profile_name*/installedApps/*node_name*/dcs_war.ear/dcs.war/WEB-INF/lib/oiexport

      PATH
      AppServer_root/profiles/*profile_name*/installedApps/*node_name*/dcs_war.ear/dcs.war/WEB-INF/lib/oiexport

      SHLIB_PATH
      AppServer_root/profiles/*profile_name*/installedApps/*node_name*/dcs_war.ear/dcs.war/WEB-INF/lib/oiexport

   g. Save your changes.
7. Restart the server. Document Conversion Services is now installed on the remote server.
8. Complete the following steps:
   a. Open wkplc.properties with any text editor from the *wp_profile_root*/ConfigEngine/properties directory.
   b. Add the following property and value to wkplc.properties: DcsRemoteHost=*URL of the remote host*.

      Where *URL of the remote host* is the URL of the remote server to which you plan to delegate document conversion services. For example, DcsRemoteHost=http://*server_name*:*port_number*/dcs/dcs. The *server_name* is the fully qualified host name of the remote DCS server. The *port_number* is the port number of the default host where DCS is run. For example, the URL might be **DcsRemoteHost=http://example.mycompany.com:9080/dcs/dcs**.

      Important: This property does not exist in the wkplc.properties file by default. You must add this property and specify a value before you proceed to the next step.
   c. Run the appropriate task to delegate some or all of the document conversion functions to the remote server.
      1) Open a command prompt.
      2) Change to the following directory:

         Linux : *wp_profile_root*/ConfigEngine

         IBM i: *wp_profile_root*/ConfigEngine

Windows: *wp_profile_root*\ConfigEngine

3) Run the following task:

Note: Run the following command on all nodes in a cluster, if applicable.

Linux : ./ConfigEngine.sh *task_name*

IBM i: ConfigEngine.sh *task_name*

Windows: ConfigEngine.bat *task_name*

Where *task_name* is one of the following configuration tasks:

Table 88. Tasks to delegate document conversion functions to a remote server.

Task	Description
delegate-all-conversions	This task delegates all file conversion services to a remote server.
delegate-text-conversions	This task delegates text document conversions to a remote server.
remove-conversion-delegation	This task ends the delegation of all file conversion services to a remote server.

d. Restart WebSphere Portal Express.

Files conversion supported by DCS

View a list of file types that are supported by DCS for conversion.

IBM WebSphere Portal Express has a feature that allows you to view documents as HTML files. This feature is useful if you do not have access to the application used to create the file. The following table lists file types that are supported by DCS for file conversion.

Table 89. Archive file types that are supported by DCS

Archive	Version
7z (BZIP2 and split archives not supported)	
7z Self Extracting exe (BZIP2 and split archives not supported)	
LZA Self Extracting Compress	
LZH Compress	
Microsoft Office Binder	95 – 97
Microsoft Cabinet (CAB)	
RAR	1.5, 2.0, 2.9
Self-extracting.exe	
UNIX Compress	
UNIX GZip	
UNIX tar	
Uuencode

Chapter 7. IBM Connections

IBM Connections portlets give the IBM WebSphere Portal Express users access to more collaboration and social networking features such as activities, blogs, and bookmarks.

"Configuring Portal to work with IBM Connections"
For WebSphere Portal Express to work with IBM Connections you must configure the portal Ajax proxy, and set up single sign-on.

"Configuring IBM Connections to work with your portal" on page 748
Configure IBM Connections to work with your WebSphere Portal Express by Importing the SSL certificate.

"Configuring the IBM Connections portlets" on page 750
Install and configure the IBM Connections Portlets for WebSphere Portal Express.

"Configuring IBM Connections features" on page 750
Configure the features that site visitors need to use from your portal site.

"Configuring community pages" on page 758
Configure how you want community pages access to work in your portal site. For example you can configure community pages to automatically grant access to the page, how many child pages affected by community associations, and more.

CF03 "Configuring Portal to work with Connections in SmartCloud for Social Business" on page 762
The Connections integration assets that are used to integrate WebSphere Portal Express with on-premise Connections can be used to integrate WebSphere Portal Express with IBM Connections in SmartCloud for Social Business as well.

IBM Connections Portlets for WebSphere Portal

IBM Connections: Configuring search integration

Configuring Portal to work with IBM Connections

For WebSphere Portal Express to work with IBM Connections you must configure the portal Ajax proxy, and set up single sign-on.

"Set up Ajax proxy" on page 748
The support for community pages uses the Ajax proxy to access the remote server. The Ajax proxy is updated for the base Connections URLS during the Connections Portlets installation. If FileNet is used, you must still configure the Ajax proxy manually to update for FileNet. Configure the Ajax proxy so that direct requests that the CCM portlet makes to the FileNet server are allowed to pass through the proxy Server.

"Set up single sign-on" on page 748
Site visitors want to sign in one time. Set up single sign-on to ensure that visitors receive only one authentication challenge. The instructions for deploying the IBM Connections portlets include multiple options for configuring authentication for the portlets. If you did not complete the

procedures in the IBM Connections documentation, you must configure single sign-on using the applications server. For best results, follow the procedures that are provided in the IBM Connections documentation.

Set up Ajax proxy

The support for community pages uses the Ajax proxy to access the remote server. The Ajax proxy is updated for the base Connections URLS during the Connections Portlets installation. If FileNet is used, you must still configure the Ajax proxy manually to update for FileNet. Configure the Ajax proxy so that direct requests that the CCM portlet makes to the FileNet server are allowed to pass through the proxy Server.

Set up single sign-on

Site visitors want to sign in one time. Set up single sign-on to ensure that visitors receive only one authentication challenge. The instructions for deploying the IBM Connections portlets include multiple options for configuring authentication for the portlets. If you did not complete the procedures in the IBM Connections documentation, you must configure single sign-on using the applications server. For best results, follow the procedures that are provided in the IBM Connections documentation.

Before you begin

About this task

You can configure single sign-on using IBM WebSphere Application Server or by using IBM Security Access Manager. This procedure uses WebSphere Application Server. Instructions for using Security Access Manager are included in the IBM Connections documentation.

Procedure

1. Retrieve the LTPA token from the WebSphere Application Server where your portal is installed.
2. Import the LTPA token into the IBM Connections server.
3. Enable single sign-on on the Connections server.

Related information:

IBM Connections: Deploying the IBM Connections portlets

WebSphere Application Server:Single sign-on for authentication

Configuring IBM Connections to work with your portal

Configure IBM Connections to work with your WebSphere Portal Express by Importing the SSL certificate.

"Import SSL certificate to set up trust association" on page 749
To prevent security alert pop-up windows, add Connections certificates to your

portal server. The signer certificate that is used by the Connections server must be trusted by the portal server. The instructions for deploying the IBM Connections portlets include a procedure to import the SSL certificate. If you did not complete that procedure, you must import the certificate to use community pages. For best results, follow the procedures that are provided in the IBM Connections documentation.

Import SSL certificate to set up trust association

To prevent security alert pop-up windows, add Connections certificates to your portal server. The signer certificate that is used by the Connections server must be trusted by the portal server. The instructions for deploying the IBM Connections portlets include a procedure to import the SSL certificate. If you did not complete that procedure, you must import the certificate to use community pages. For best results, follow the procedures that are provided in the IBM Connections documentation.

Before you begin

About this task

Retrieve the certificate for the Connections server. Then, import the SSL certificate to the portal server.

Procedure

1. Enter the URL for the Connections server into a web browser. For example: `https://your_Lotus_Connections_server.com/activities`
2. Save the certificate as a PEM certificate. Save it to the portal server in the directory where IBM WebSphere Application Server was installed. For example: *AppServer_root*
3. Import the saved certificate to the portal server.
   a. Open the WebSphere Integrated Solutions Console.
   b. Select **Security** > **SSL certificate** > **key management** > **Key stores** > **certificates**.
   c. Click **NodeDefaultTrustStore**.
   d. Select **Signer certificates** and click **Add**.
   e. On the Add signer certificate page, provide a name for the certificate that you added, and enter the full qualified name of the saved certificate.
4. Import the saved certificate to the portal server.

Related tasks:

CF03 "Configuring single sign-on (SSO) for backend calls to IBM Connections in SmartCloud for Social Business" on page 765
The Connections integration assets use a common infrastructure that is called HTTP Outbound to complete calls to the Connections backend server. Learn about the steps that are required to configure the HTTP outbound component to complete calls to IBM Connections in SmartCloud for Social Business.

Configuring the IBM Connections portlets

Install and configure the IBM Connections Portlets for WebSphere Portal Express.

About this task

To install the IBM Connections by using the Portal Solutions Installer follow the installation procedure provided in the IBM Connections Documentation.

Documentation resource:

Installing the IBM Connections Portlets for WebSphere Portal

"Configuring common directory service"
IBM Connections use the common Directory Services to enable directory lookup from Connections in the WebSphere Portal Express environment

"Configuring authentication for the portlets"
Configure authentication to enable access to the portlets.

Configuring common directory service

IBM Connections use the common Directory Services to enable directory lookup from Connections in the WebSphere Portal Express environment

About this task

To configure the common Directory Services to work with your security configuration, follow the steps that are provided in the Connections Document.

Documentation resource:

Configuring common directory services for your security configuration

Configuring authentication for the portlets

Configure authentication to enable access to the portlets.

About this task

To configure authentication for the portlets, follow the steps that are provided in the connections documentation.

Documentation resource:

Configuring authentication for the portlets

Configuring IBM Connections features

Configure the features that site visitors need to use from your portal site.

"Integrating Connections profile " on page 751
You can enable the Connections profile in WebSphere Portal Express so that users can view Connections business card information and link to features such as communities, blogs, and activities.

"Integrating IBM Connections tags" on page 752
You can integrate tags from IBM Connections into the IBM WebSphere Portal Express tag cloud. The Connections portlets are required to get full function.

"Integrating IBM Connections files" on page 755
To integrate files with your portal, register the Content Management Interoperability Services (CMIS) entry points with the WP FederatedDocumentsService resource environment provider. After this

configuration is complete, content authors insert links to documents hosted on the Connections server. Using personalization, authors can also render inventories of folders that are hosted in files.

Integrating Connections profile

You can enable the Connections profile in WebSphere Portal Express so that users can view Connections business card information and link to features such as communities, blogs, and activities.

Before you begin

About this task

Note: You must enable **Show Email** on the Connections server to ensure that portal users can view profile information.

Procedure

1. Search the Connections LDAP directory for the user whose profile you want to enable in WebSphere Portal Express and then add that user to the portal LDAP directory.
2. Ensure that `ibm-primaryEmail` is mapped to the appropriate attribute in the LDAP and that the email address in the Connections LDAP matches the email address in the portal LDAP. For example, `mail` or `email`
3. Register the Connections server. For stand-alone portal, complete the steps on the node. For a clustered environment, complete the steps on the WebSphere Application Server Network Deployment.
   a. Open the WebSphere Integrated Solutions Console.
   b. Click **Resources** > **URL** > **URL Providers**.
   c. Select the **Default URL Provider** at the beginning of the hierarchy.
   d. Under **Additional Properties**, select **URLs**.
   e. Click **New** and then specify these settings under General Properties:

      Name `CONNECTIONS_PEOPLE_CARD`

      JNDI name
      `JNDI_CONNECTIONS_PEOPLE_CARD`

      Specification
      Card for Connections version 2.5, or earlier:`https://`*`yourConnectionsServer.domain.com`*`/profiles/html/businessCard`

      For example: `https://w3.ibm.com/`*`connections`*`/profiles/html/`*`businessCard`*

      Card for later versions of Connections (post version 2.5):
      `https://`*`yourConnectionsServer.domain.com:portno`*
      For example: `https://w3.ibm.com/`*`connections`*
      The url you type fetches the JavaScript file `file/profiles/portalJS/portalBizCard.js`.. You do not have to type in the entire url to the JavaScript file, only type in the Connections https address. If you are using an HTTP server in front of the Connections environment, the port number can be omitted.

      Category
      `CATEGORY_CONNECTIONS_PEOPLE_CARD`
   f. Click **Save** to save the changes to the master configuration.

4. Restart the WebSphere_Portal server.

Results

After you enable the Connections profile for a particular user, when you move the cursor over that person's active (underlined) name in WebSphere Portal Express, and then click **Click for Person Card**, you see the Connections profile for that person. The profile is displayed in the business card section of the Person card, with links to more Connections features. Click **Profile** to see the user's full Connections profile. To return to the WebSphere Portal Express page, click **Back** in the browser.

Note: If you integrate Connections and then select a user who does not have a Connections profile, portal displays the message `profile does not exist`. Click **Back** to return to WebSphere Portal Express.

Integrating IBM Connections tags

You can integrate tags from IBM Connections into the IBM WebSphere Portal Express tag cloud. The Connections portlets are required to get full function.

"Configure authentication" on page 753
Portal requests data from the IBM Connections server through the Connections search API. By default, access to public data is not secured. In case security is enabled for that application, authentication is required. You can use on of the following authentication methods: basic authentication and LTPA forwarding.

"Configuring task to retrieve tags" on page 753
When you integrate Connections with your portal server, the portal uses a task to retrieve tags and related resources from the various Connections features (such as activities, blogs, bookmarks, communities, files, forums, profiles, and wikis). Then, the portal integrates the tags in the portal tag cloud. You can schedule the task to retrieve the tags to run periodically.

Results

Connections tags are available in theWebSphere Portal Express tag cloud after the scheduled task runs to retrieve tags from the Connections server.

Configure authentication

Portal requests data from the IBM Connections server through the Connections search API. By default, access to public data is not secured. In case security is enabled for that application, authentication is required. You can use on of the following authentication methods: basic authentication and LTPA forwarding.

About this task

This procedure helps you set up authentication by using a shared slot in the portal credential vault. You need an Connections user ID to configure the credential vault. The user ID does not need to belong to a real user. It can be an ID that is only used for integration. This user ID needs to be able to authenticate to the Connections server. No other access rights are required.

Configure authentication for either basic authentication or LTPA forwarding.

Procedure

Option 1: Basic authentication

1. If basic authentication is used, specify the credentials for the user ID in the portal credential vault.
   a. Click the **Administration menu** icon. Then, click **Access** > **Credential Vault**.
   b. Add a vault slot for the following name:
   `com.ibm.wps.cp.tagging.federation.credentialSlot.search.basic_auth`
   c. Select a shared vault slot, and enter the user ID and password of the Connections user.
   d. Specify an existing resource or specify a new one.

Option 2: LTPA forwarding

2. If LTPA forwarding is used, specify the full distinguished name (DN) of a user ID in the portal credential vault.
   a. Click the **Administration menu** icon. Then, click **Access** > **Credential Vault**.
   b. Add a vault slot for the following name:
   `com.ibm.wps.cp.tagging.federation.credentialSlot.search.ltpa`
   c. Select a shared vault slot, and enter the DN of the Connections user ID.
   d. Enter an arbitrary password. The password is not necessary to create the LTPA token, but the credential vault portlet requires a password for a vault slot.
   e. Specify an existing resource or specify a new one.
3. Restart the WebSphere_Portal server.

Configuring task to retrieve tags

When you integrate Connections with your portal server, the portal uses a task to retrieve tags and related resources from the various Connections features (such as activities, blogs, bookmarks, communities, files, forums, profiles, and wikis). Then, the portal integrates the tags in the portal tag cloud. You can schedule the task to retrieve the tags to run periodically.

Before you begin

The piece of content (POC) resolver is required to render tagged Connections resources within Connections portlets. The instructions for installing the Connections portlets included a step to copy the POC resolver to the portal.

About this task

Depending on your database system, it might be beneficial to reorganize some tables in the community domain. You can also gather current catalog statistics for the tables after an import of Connections data is done. This action helps the SQL optimizer determine an efficient access path. Review your database system documentation for instructions on how to accomplish this task. The database tables that are most affected by an import include:

CP_CUSTOMRESOURCE

CP_CATEGORY

CP_RESOURCE_TAG

LOC_DATA

LOC_DATA_LOD
