The Personalization rating bean logs each user rating to the LikeMinds database. There are a few requirements to remember when using the rating bean:

- The session attribute "pzn.userName" must be set with the user resource ID. This is how LikeMinds pairs the user with an item rating.
- If you log an item that previously did not exist in the LikeMinds database table, an entry will automatically be created for that item.
- In the same way, if an item is logged for a user who does not exist in the LikeMinds database table, LikeMinds creates an entry for that user. This is how a "new user" is to be entered into the LikeMinds system.
- The resource collection that is sent as a parameter to the logging bean is case sensitive.

Database Access

Developers are responsible for maintaining their own database tables. In MovieSite's case, this includes MovieSite's user table, item table, and also genre tables. All MovieSite tables begin with **MS*** and LikeMinds tables begin with **Lps***. To implement filtering, the filter ID columns must be added to the LPS_ITEM_DATA table. These filter IDs are populated when a movie is logged for the first time, or the IDs are set directly. For more information on filtering, see the section about filtering recommendations that follows.

Filtering Recommendations based on filter IDs

LikeMinds implements a filtering system for each of the Personalization rules that query LikeMinds. This system filters items at the LikeMinds level according to any number of filter ID's associated with each item. Only the items which satisfy the filter are surfaced to the content spot in the JSP.

"Exploring Movie Site"
Movie Site demonstrates the LikeMinds Recommendation Engine, guiding you through a Personalization scenario that is based on factual data from a site on the internet. The website uses a personalization solution to analyze visitor behavior and to recommend individualized content information and services while the visitor is actively engaged on the site.

Exploring Movie Site:

Movie Site demonstrates the LikeMinds Recommendation Engine, guiding you through a Personalization scenario that is based on factual data from a site on the internet. The website uses a personalization solution to analyze visitor behavior and to recommend individualized content information and services while the visitor is actively engaged on the site.

Notes:

- The provided Resource Collections are for IBM DB2 Universal Database Enterprise Server Edition and DB2 for z/OS only. If you want to use the sample on other database types, you can regenerate them using Rational Application Developer. For information about Resource Collections, see the topic *Resources, resource instances, and resource collections*.
- It is assumed that you are the Movie Site user, `likeminds`. This user previously rated some movies and registered preferences as configured in the installation.

To set up the Movie Site sample, choose the appropriate option:

- Linux : `./ConfigEngine.sh cfg-likeminds-samples -DWasPassword=password -DLikemindsDbPassword=password`
- IBM i: `ConfigEngine.sh cfg-likeminds-samples -DWasPassword=password -DLikemindsDbPassword=password`
- Windows: `ConfigEngine.bat cfg-likeminds-samples -DWasPassword=password -DLikemindsDbPassword=password`

Note: Check the output for any error messages before you proceed with the next task. If any of the configuration tasks fail, verify the values in the `wkplc.properties` file.

Complete the following steps to start the application:

1. Open the WebSphere Integrated Solutions Console.
2. Go to `http://machine:port_number/ibm/console` where *port_number* is the port number for WebSphere Portal Express.
3. Click **Applications** > **Application Types** > **WebSphere enterprise applications**.
4. Select **Movie Site Application**, and click **Start**.
5. Rate movies by using the Movie Site home page.

Table 360. A quick demonstration of how to rate movies by using the Movie Site home page

Step number	Description	Action to be taken
1	Navigate to the Movie Site Home Page. For this demo, we concentrate on the recommendation engine, which uses mathematical algorithms to provide collaborative filtering.	Open a separate browser window to the Movie Site home page. The URL is `http://hostname:port/MovieSite` where *port* is the port number for WebSphere Portal
2	Log in as the LikeMinds user. Log on as the user, `likeminds`. This login name is the default user who registered to the site and rated some movies.	1. Type `likeminds` in the login field. 2. Type `likeminds` in the password field 3. Click **Enter**.

Table 360. A quick demonstration of how to rate movies by using the Movie Site home page (continued)

Step number	Description	Action to be taken
3	Sample previous ratings. Look at the movie ratings by selecting **Sample Previous Ratings**. This section of the site contains a few sample movie ratings the user `likeminds` previously placed.	1. Click **Sample Previous Ratings**. 2. Select **Get more movies** from the menu. 3. Click the **To Lobby** icon. You can show all of the movies or certain rated movies by selecting one of the ratings. You can look at the ratings of other movies by clicking **Get More Movies**. This demonstration allows you to rate movies. For more movies, type the name of a movie into the search panel to see whether specific movies are stored in the database.
4	Use the SuperRater to rate a movie. In Super-Rater mode, clicking the drop-down menu that is associated with each movie of the movie reveals a rating choice. You can rate any movies on the list and click **Submit** to log your rating choice. If you click the movie title, it links you to information about the movie by using the `imdb.com` site. Notice the prediction of the recommendation engine of how much you, as the LikeMinds login user, would like this movie.	1. Click **To Lobby**. 2. Click **Rate more movies**. 3. Click **Turn on Superrater**. 4. Click the dropdown menu that is associated with the rating to see the options. 5. Click **Movie title**. **Note:** This action opens a new window.
5	End demonstration.	Click **To Lobby**.

The LikeMinds collaborative filtering technology considers each user to be the center of their own preference cluster, instead of trying to find the best preordained preference category for every user, which is typical of profile-based approaches. LikeMinds recommendations can adapt to these changes much more quickly than aggregated, profile based techniques.

Choose the appropriate task to remove the application:

Linux : `./ConfigEngine.sh remove-likeminds-samples -DWasPassword=`*`password`* `-DLikemindsDbPassword=password`

IBM i: `ConfigEngine.sh remove-likeminds-samples -DWasPassword=password -DLikemindsDbPassword=password`

Windows: `ConfigEngine.bat remove-likeminds-samples -DWasPassword=password -DLikemindsDbPassword=password`

Note: Check the output for any error messages before you proceed with the next task. If any of the configuration tasks fail, verify the values in the `wkplc.properties`, `wkplc_dbdomain.properties`, and `wkplc_dbtype.properties` files.

Using the LikeMinds utilities:

Learn about the four utilities LikeMinds uses to update the database, `buildvisit` (for the Preference Engine), `sifter`, `buildstats`, and `lpsIAA` (for the Item Affinity Engine's accumulator utility).

The LikeMinds utilities are run from the LikeMinds utility servlet.

You must configure these utilities to run at appropriate times. See "Scheduling LikeMinds Events" on page 2322 for more information.

"Sifter"
The `sifter`, which is used for all the Recommendation engines except for Item Affinity, assigns mentors to users and updates its assignments as users rate items. When no users are rating items, the sifter updates the mentor assignments of all users based on changes to the pool of available mentors.

"`Buildstats`"
The `buildstats` utility updates database statistics. You can use `buildstats` for all of the Recommendation engines except for the Item Affinity Engine.

"Accumulator" on page 2343
Use the `accumulator` utility if you are using the Item Affinity Engine. This utility accumulates the number of times every possible item-to-item combination occurs.

Sifter:

The `sifter`, which is used for all the Recommendation engines except for Item Affinity, assigns mentors to users and updates its assignments as users rate items. When no users are rating items, the sifter updates the mentor assignments of all users based on changes to the pool of available mentors.

The `sifter` must be running whenever the LikeMinds server is running. However, you can install the `sifter` across multiple machines to distribute load.

`Buildstats:`

The `buildstats` utility updates database statistics. You can use `buildstats` for all of the Recommendation engines except for the Item Affinity Engine.

When you install the LikeMinds utilities, the installer sets `buildstats` to run daily at 3:30 a.m. This run time is because the best time to run `buildstats` is daily, at a time when the LikeMinds server receives relatively little use. The `buildstats` utility connects directly to the LikeMinds database and processes the transactional or ratings data that is constantly being written to the LikeMinds database. Because this utility does not use many resources, it is typically installed on the same server as the LikeMinds server. `buildstats` runs a number of data analysis functions on the information in the LikeMinds database and persistently writes out the results

into the LikeMinds schema. However, the function and the number of functions to test differ depending on the type of LikeMinds engines in use. If both a Preference and ClickStream are in use, `buildstats`, by default, analyze both the ratings and the transactional data.

For ratings data, `buildstats` writes to the following fields in the Lps_Item_Data table:

- **`num_rtg`**: Total number of ratings for the item.
- **`total_rtg`**: Sum of all ratings for the item.
- **`total_square_rtg`**: Sum of the squares of all ratings for the item.
- **`ratability`**: Priority for an item's presentation to users for rating. **`ratability`** is non-negative value. Higher numbers indicate a higher priority for rating.
- **`score`**: Popularity or unpopularity of an item. If you prefer to have your own applications update this field, you can disable `buildstats` from writing to score.

For transactional data, `buildstats` writes to these fields in Lps_User_Trx:

- **`value`**: Data value that is associated with the transaction.
- **`adj_count`**: Adjusted count of transactions. If a new activity is recorded in the transaction table, this value increases. It might diminish over time.

Accumulator:

Use the `accumulator` utility if you are using the Item Affinity Engine. This utility accumulates the number of times every possible item-to-item combination occurs.

Similar to the `sifter` for the other LikeMinds engines, the `accumulator` runs in the background processing item event data. It writes this data to the table specified by the `<item_affinity_set>.item_affinity.output.table` setting. The `accumulator` is installed as part of the PZN_Utilities.ear. It is run through the LikeMinds scheduling mechanism.

Filtering LikeMinds recommendations:

When LikeMinds makes recommendations, it can make the recommendations based on all items in your resource collection, or it can limit the predictions to only items that have certain characteristics.

Tell LikeMinds about an item by including key/value pairs describing its characteristics as you log actions and ratings that occur against it. The format for the key/value pair is

```
Key = LMFilter.<item_characteristic>
value = <value>
```

For example, to tell LikeMinds that an item's color is blue, and its category is sports, you would add the 2 key/value pairs:

```
LMFilter.color,blue
LMFilter.category,sports
```

Specify which characteristics that you want LikeMinds to use in making predictions by setting request attributes in the RequestContext object immediately before the content spot that contains the LikeMinds rule. To specify characteristics for filtering, do the following:

- Add a request attribute that tells LikeMinds which characteristic or characteristics you want to filter on. The name of that attribute should be

LMFilter and the value should be a string or an array of strings, where the string or each string in the array is a characteristic that you would like to filter on.

For example, to return predictions only from among items whose category is "clearance" and season is "spring" or "summer", you would add the following code before the content spot:

```
com.ibm.websphere.personalization.RequestContext.context =
com.ibm.servlet.personalization.context.PersonalizationContext.getRequestContext(httpRequest);

context.setRequestAttribute("LMFilter", new String[] { "LMFilter.category", "LMFilter.season" });

context.setRequestAttribute("LMFilter.category", "clearance");

context.setRequestAttribute("LMFilter.season", new String[] { "spring", "summer" });
```

To return predictions only from items whose color is blue, you would add the following code before the content spot:

```
com.ibm.websphere.personalization.RequestContext.context =
com.ibm.servlet.personalization.context.PersonalizationContext.getRequestContext(httpRequest);

context.setRequestAttribute("LMFilter", "LMFilter.color");

context.setRequestAttribute("LMFilter.color", "blue");
```

Feedback and analytics

Personalization provides a complete logging framework for collecting data on how visitors are using your Web site. If Feedback is enabled, data is automatically collected about each Personalization rule that is fired. In addition, development tools enable Web sites to collect a variety of data related to visitors' actions and behavior. By default this data is logged to a standard database schema for later analysis and reporting. The framework is also extensible, allowing Web sites to customize and supplement the way data is collected and stored to more fully meet their needs.

Personalization provides a complete logging framework for collecting data on how visitors are using your website. If Feedback is enabled, data is automatically collected about each Personalization rule that is fired. In addition, development tools enable Web sites to collect a variety of data related to visitors' actions and behavior. By default this data is logged to a standard database schema for later analysis and reporting. The framework is also extensible, allowing Web sites to customize and supplement the way data is collected and stored to more fully meet their needs. Using the Personalization Feedback framework you can collect data to help answer questions such as:

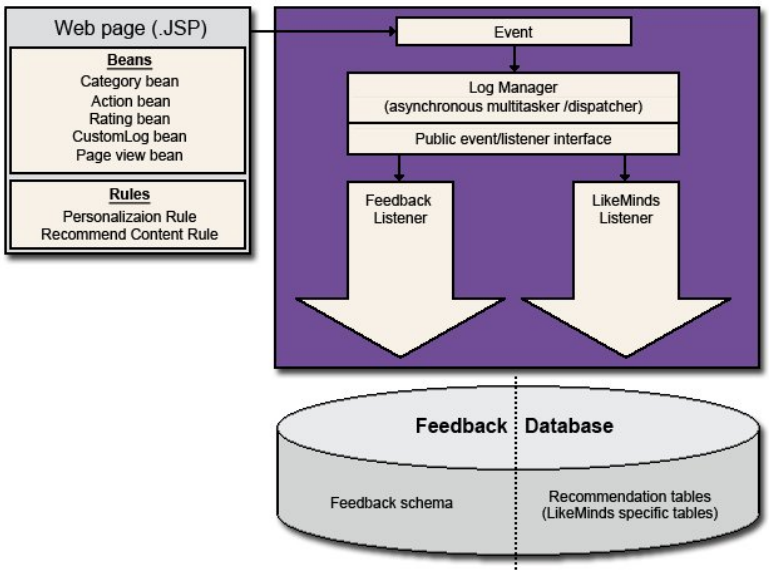
- How effective are the new campaign initiatives?
- Which items have the highest clickthrough ratio?
- What is the clickthrough ratio for health care products?
- Which items have the highest view to purchase ratio?
- What is the ratio for health care products?
- Which rules are resulting in the most number of downloads?
- During the month of December, which categories of pages were browsed most often (my special Christmas pages, or the regular part of my site)?

"Feedback subsystem overview" on page 2345
The Feedback listener captures data and writes it to the Feedback database schema for subsequent reporting, a capability which can be used to persist data in ways that specifically meet your requirements.

Feedback subsystem overview:

The Feedback listener captures data and writes it to the Feedback database schema for subsequent reporting, a capability which can be used to persist data in ways that specifically meet your requirements.

Logging occurs when a rule or logging bean is present in JSP or servlet a user visits. In either case, during execution an event containing data to be logged is generated and dispatched by the log manager to a set of listeners.Personalization supplies two such listeners. The first is the Feedback listener, which captures data and writes it to the Feedback database schema for subsequent reporting. The second is the LikeMinds listener (LMListener), which captures data for subsequent use by the LikeMinds recommendation engine. Web site developers can optionally extend the provided listeners or create additional custom listeners to persist data in ways that specifically meet their needs.



- Logging events are generated by Personalization rules or logging beans.
- The Feedback subsystem's multithreaded implementation prevents HTTP clients from waiting.
- The Log Manager maintains internal queue of events.
- Event is dropped on queue then control returned to web client.
- Events are dispatched from the queue to all registered listeners.
- Listeners in turn persist and process the data contained in the logging event.

Enable logging:

Create and set up the Feedback database. Then, enable logging on the runtime server that hosts Feedback data.

About this task

Choose the appropriate option to create, set up, and enable logging of the Feedback database:

Table 361. Operating system options to create, set up, and enable logging of the Feedback database

Operating system	Task
Linux	Complete the following steps: 1. Change to the *wp_profile_root*/ConfigEngine directory. 2. Create the Feedback database using the following command: `./ConfigEngine.sh feedback-database -DInitalizeFeedbackDB=true -DWasPassword=password` 3. Set up the Feedback database using the following command: `./ConfigEngine.sh setup-feedback -DWasPassword=password` 4. Open the FeedbackService.properties file from the *wp_profile_root*/PortalServer/config/config/services/ directory. 5. Set **loggingEnabled** to true. 6. Restart WebSphere Portal Express.
IBM i	Complete the following steps: 1. Change to the *wp_profile_root*/ConfigEngine directory. 2. Create the Feedback database using the following command: `ConfigEngine.sh -profileName profile_root feedback-database -DInitalizeFeedbackDB=true -DWasPassword=password` 3. Set up the Feedback database using the following command: `ConfigEngine.sh -profileName profile_root setup-feedback -DWasPassword=password` 4. Open the FeedbackService.properties file from the *wp_profile_root*/PortalServer/config/config/services/ directory. 5. Set **loggingEnabled** to true. 6. Restart WebSphere Portal Express.

Table 361. Operating system options to create, set up, and enable logging of the Feedback database (continued)

Operating system	Task
Windows	Complete the following steps: 1. Change to the *wp_profile_root*\ConfigEngine directory. 2. Create the Feedback database using the following command: `ConfigEngine.bat feedback-database -DInitalizeFeedbackDB=true -DWasPassword=password` 3. Set up the Feedback database using the following command: `ConfigEngine.bat setup-feedback -DWasPassword=password` 4. Open the FeedbackService.properties file from the *wp_profile_root*\PortalServer\config\config\services\ directory. 5. Set **loggingEnabled** to true. 6. Restart WebSphere Portal Express.

Feedback properties file:

The FeedbackService.properties file contains several customizable properties that are used by the Feedback component. These properties are used to enable custom log listeners, to tune the performance of the Feedback data collection system.

The FeedbackService.properties file is installed to the *wp_profile_root*/PortalServer/config/config/services directory.

To modify the properties:

- Edit the FeedbackService.properties file.
- Restart the IBM WebSphere Application Server where the Portal Personalization Runtime is installed.

loggingEnabled

Before information about the usage of your site can be recorded, logging must first be enabled. To enable logging, set the loggingEnabled property to true.

```
loggingEnabled = true
```

schemaName

It is possible to customize the name of the feedback schema used in the database. For most platforms the Personalization installer will create the feedback tables under a schema named FEEDBACK.

For IBM i installations, the schemaName property must be set to the name of the database library that contains the Feedback tables (for example, QWPS51).

```
schemaName = FEEDBACK
```

logListeners

Log events are generated whenever the log method of a bean is called or whenever a rule is fired. Log listeners process these log events and can store the event data or perform other actions as a result of these events. The Feedback component provides two default log listeners, the `LMListener` that collects data for use by the `LikeMinds` Recommendation Engine and the `FeedbackListener` that collects data for use in the Feedback reports. Custom log listeners can be used to modify the default behavior of the `FeedbackListener` or to provide a listener that processes the Feedback events in a user-specified manner.

After being developed, custom listener class files must be placed in the `classpath` of the server where Personalization run-time is installed. The class names of these listeners must be identified in the logListeners property. Multiple custom listener class names are separated by semicolons:

```
logListeners =
LogListenerClassName1;LogListenerClassName2
```

logBufferSize

When log events are produced by logging beans or rules, they are placed on a process queue. Each of the registered log listeners consumes events from this queue. This enables listeners to consume log events at independent rates, minimally impacting the performance of other listeners. It also enables the Feedback component to queue events originating from Web page requests with minimal impact on the Web site performance.

The log event queue (or log buffer) has a default maximum size of 10,000 events. The optimal size of this buffer is affected by Web site volume, Web site usage spikes, and many other Web application performance factors. You can change the maximum size of the log buffer by modifying the `logBufferSize` property in the `FeedbackService.properties` file:

```
logBufferSize = 10000
```

logWarningLevel

As the log buffer begins to fill due to heavy Web site loads or slow log listener performance, a warning message can be logged to the WebSphere Integrated Solutions Console. The `logWarningLevel` specifies the log buffer load that will trigger warning messages. The `logWarningLevel` is specified as a percentage value between 0 and 100. Specifying a value of 0 will repeatedly output the current log buffer load whereas a percentage value of 100 will result in no warning messages as the buffer fills. Once the log buffer is full, an error message is logged to the WebSphere Integrated Solutions Console and logging is discontinued until room becomes available in the log buffer. The default value for the log warning level is 75%. You can change this warning level by modifying the `logWarningLevel` property in the `FeedbackServices.properties` file:

```
logWarningLevel = 75
```

requestFlushInterval

Multiple rules or logging beans can be placed on a single Web page or JSP. The Feedback component collects all the data from the rules and log beans on a page and then updates the Feedback database with all of the information for the page

(HTTP request). Updating the Feedback database only once per page improves the performance of the Feedback component. It is necessary to determine when all of the data for a page request has been collected. Two mechanisms are used in the current release to determine when the log data for a page request should be written to the Feedback database. The first method is to flush all of the log data for a page request whenever a new page request is received from the same user session. The second method uses a time interval to determine when the response to a page request has been completed and, thus, all the logging data for the request has been generated.

The `requestFlushInterval` applies to this second method of flushing the logging data for a page request. It is the time interval during which no new logging data has been received during a user session after which the log data for the most recent request is assumed to be complete and is flushed to the database. The default value for the request flush interval is 10 seconds. You can modify this interval by changing the `requestFlushInterval` property (specified in milliseconds) in the `FeedbackService.properties` file:

```
requestFlushInterval = 10000
```

inactiveListenerInterval

It is possible for a log listener to become inactive due to a run-time error or resource deadlock. The result of such a deadlock would be an accumulation of data in the log buffer that will never be processed. Since the log buffer is finite in size, it will eventually reach capacity. Once it reaches capacity, no new data will be logged and all active listeners will be unable to collect and process additional log data. To protect against this scenario, the activity of all listeners is monitored. If log data is available for a listener to process and the listener remains inactive for a pre-determined, the log listener will be removed from the set of registered log listeners. The default period of inactivity is 2 minutes. You can modify this interval by changing the `inactiveListenerInterval` property (specified in milliseconds) in the `FeedbackService.properties` file:

```
inactiveListenerInterval = 120000
```

workManager

If running in an environment that supports it, the Feedback component uses the WebSphere Application Server `workmanager` system for asynchronous operations. Using the `workManager` property, you can specify the name of the `workmanager` that Feedback will use.

```
workManager = wm/default
```

Rule logging:

If logging is enabled, rule information is automatically logged whenever a rule is executed.

When a content spot's rule retrieves content, a RuleEvent object is constructed from the request, campaign name, rule name, resource collection name, and items. This event object is routed to all registered log listeners and the logged data are stored in the Feedback schema.

Logging beans:

Use logging beans to log data about a Web site visitor's actions, category interests, and ratings.

You can also use custom beans to log information specific to your Web application. You insert logging beans into your JSPs. The types of logging beans are:

- Action beans
- Rating beans
- Category beans
- CustomLog beans
- Page View beans

"Action beans"
You use Action beans to log specific actions of your Web site visitors.

"Category beans" on page 2354
Content categories enable you to classify Web user interests. You use Category beans to log content categories.

"Rating beans" on page 2356
The Rating bean is a specialized logging bean. You use Rating beans in applications that solicit user ratings for web content or other personalization resources.

"CustomLog beans" on page 2357
CustomLog beans give you the flexibility to log data that does not easily map to the other logging beans. You use CustomLog beans to log application specific data. You define the required key name(s) as well as the value(s) for that key.

"PageView beans" on page 2358
You use PageView beans to log HTTP request data for JSPs (JavaServer pages).

Action beans:

You use Action beans to log specific actions of your Web site visitors.

As a Web site visitor navigates your Web pages, an Action bean logs the visitor's events within the session. Action beans maintain action information for the current session including the actions logged and their corresponding log counts. This session data can be used within rules of from your JSPs. Action information is also routed to all registered log listeners.

All actions are logged to the Feedback schema and to the user session. The actions logged include the pre-defined actions listed in Table 362 on page 2352 and user defined actions. The actions that are logged to the Feedback schema and user session do not need to be pre-defined.

If you have LikeMinds installed, only the pre-defined actions listed in Table 362 on page 2352 are logged to the LikeMinds schema. These actions must be defined to LikeMinds in the lps_trx_type table. (You can also add to the list of predefined actions by adding items to the lps_trx_type table.) The actions logged through an Action bean provide the transaction data necessary for the LikeMinds Clickstream Engine. This set of actions may be accessed after deployment and configuration of a Web application.

Actions can be logged with or without respect to a specific resource. For example, the "OrderCancel" pre-defined action does not apply to a specific resource whereas the "BrowseContent" pre-defined action applies to a specific content resource.

You can create rules based on the activity of the current session, for example:

```
WebSite Visitor is
    Undecided when
       current Action Count.ShoppingCartDelete > 0
     Otherwise Decided
```

Table 362. Pre-defined Actions

Action ID	Action Name
1000	DetailedView
1001	Purchase
1002	Rated
1003	ShoppingCartInsert
1004	ShoppingCartDelete
1005	OrderCancel
1006	ItemView
1007	WishlistAdd
1008	WishlistDelete
1009	BrowseContent
1010	Search
1011	ShoppingCartUpdate

"Implementing action logging"
To implement action logging, insert an Action bean into your JSP. To log additional application data associated with the action, add key/value pair information to the log method call.

"Action beans reference" on page 2353
View some additional information related to Action beans and associated methods.

Implementing action logging:

To implement action logging, insert an Action bean into your JSP. To log additional application data associated with the action, add key/value pair information to the log method call.

About this task

To implement action logging, insert an Action bean into your JSP, for example:

```
<jsp:useBean class="com.ibm.wcp.analysis.beans.Action" id="action" scope="session"/>

<%
   // Note: Both the resource id and collection name were added to the request
   // by the referral page.
   action.log( request,
               request.getParameter( "resourceId" ),
               request.getParameter( "collectionName" ),
               "ItemView" );
%>
```

To log additional application data associated with the action, add key/value pair information to the log method call in. For example:

```
<jsp:useBean class="com.ibm.wcm.analysis.beans.Action" id="action" scope="session"/>

<jsp:useBean class="ShoppingCart" id="cart" scope="session"></jsp:useBean>

<%
   // Log last item added to shopping cart with quantity and size data.
   Hashtable actionInfo = new Hashtable();
   Product[] cartItems = cart.getItems();
   actionInfo.put( "quantity",
                   new String( cartItems[cartItems.length - 1].getQuantity() ));
   actionInfo.put( "size", cartItems[cartItems.length - 1].getSize() );
   action.log( request,
               cartItems[cartItems.length - 1].getId(),
               null,
               "Shopping Cart Insert",
               actionInfo );
%>
```

Action beans reference:

View some additional information related to Action beans and associated methods.

The `com.ibm.wcp.analysis.beans.Action` bean method signatures are:

Table 363. Descriptions for action bean method signatures

Action bean method signatures	Description
`public void log( HttpServletRequest request, String actionName )`	Logs a non-resource specific action
`public void log( HttpServletRequest request, String resourceId, String collectionName, String actionName )`	Logs a resource specific action
`public void log( HttpServletRequest request, String resourceId, String collectionName, String actionName, String key, String value )`	Logs a resource specific action with key/value action datum
`public void log( HttpServletRequest request, String resourceId, String collectionName, String actionName, Hashtable keyValueData )`	Logs a resource specific action with multiple key/value action data. Each key can have a single value specified by a string object or multiple values specified by a string array

Action beans should be instantiated as session beans. They maintain user action information for the current session including the actions logged by resource and their corresponding log counts.

The following methods are accessible from rules. These methods are provided through a custom application object.

```
public String[] getActionNames(HttpServletRequest request);
public int      getActionCount(HttpServletRequest request, String actionName );
```

Actions can be logged with or without respect to a specific resource. For example, the "OrderCancel" action does not apply to a specific resource whereas the "BrowseContent" action applies to a specific content resource.

If the call to the action log method specifies a `resourceId` and the `collectionName` is `null`, the name of a `ResourceCollection` is inferred. The `ResourceCollection` used will be any one containing a `resource` with the specified `resourceId`. The determination of the `ResourceCollection` used in this scenario is non-deterministic. Note that these variants are suitable for user implementations supporting one and only one `ResourceCollection` per `resource` class. If an implementation utilizes multiple `ResourceCollections` for the same `resource` class, the `collectionName` should be specified.

Category beans:

Content categories enable you to classify Web user interests. You use Category beans to log content categories.

As a Web site visitor navigates your Web pages, a Category bean logs the different categories viewed by the visitor during the session. For example, if a Web site visitor goes to your Web site and views information about the weather, the category "Weather" can be logged. Another Web site visitor might be more interested in sports, so you would log the "Sports" category for this user. Category beans maintain category information for the current session including the categories logged and their corresponding log counts. Category information is routed to all registered log listeners.

All categories are logged to the Feedback schema and to the user session. Category information is not logged to the LikeMinds schema.

You can create rules that access the category counts in the current session, for example:

```
News Interest is
    Weather when
      current Category Count.Weather > 5
    Sports when
      current Category Count.Sports > 5
   Otherwise Headlines
```

You can also create rules that access the category names from the current session, for example:

```
Select content
    whose News.Topics is included in current CategoryNamesCategory Names.Category Names
    order as is
```

"Implementing category logging"

"Category beans reference" on page 2355
Learn about the various method signatures of Category beans.

Implementing category logging:

To implement category logging, insert a Category bean into your JSP.

About this task

Consider the following code for inserting a category bean in your JSP.

```
<jsp:useBean class="com.ibm.wcp.analysis.beans.Category" id="category" scope="session"/>
<% category.log( request, "Sports" ); %>
```

You can also pass an object to a JSP and implicitly log the content category. For example:

```
<jsp:useBean class="com.ibm.wcp.analysis.beans.Category" id="category" scope="session"/>

<%
   NewsManager newsManager = new NewsManager();
   News news = newsManager.findById( request.getParameter( "newsId" ), null );
   category.log( request, news );
%>
```

In the previous example, the category bean logs the news category by querying the `LoggableResource` interface to get the category.

Category beans reference:

Learn about the various method signatures of Category beans.

The `com.ibm.wcp.analysis.beans.Category` bean method signatures are:

Table 364. Descriptions for CustomLog bean method signatures

CustomLog bean method signatures	Description
`public void log( HttpServletRequest request, String category )`	Logs a single category literal.
`public void log( HttpServletRequest request, String[] categories )`	Logs an array of category literals.
`public void log( HttpServletRequest request, LoggableResource resource )`	Logs categories of interest by querying the `LoggableResource` interface of the object.

The `LoggableResource` interface can be implemented in addition to the Resource interface in order to facilitate logging. The categories of you resources can then be stored and retrieved from a database. By using this interface, you avoid the specification of category literals in your JSPs.

```
public interface LoggableResource
{
   String[] getTopics( );
}
```

Each of the topics returned by `getTopics` is logged as a category. If `getTopics` returns null, no category will be logged.

The log methods create a CategoryEvent with the request and category. The CategoryEvent is routed to all of the registered log listeners.

Category beans should be instantiated as session beans. They maintain category information for the current session including the categories logged and their corresponding log counts.

The following methods are accessible through rules. They can also be accessed directly through the category bean.

```
public String[] getCategoryNames( HttpServletRequest request)
public int      getCategoryCount( HttpServletRequest request,
                                  String category )
```

Rating beans:

The Rating bean is a specialized logging bean. You use Rating beans in applications that solicit user ratings for web content or other personalization resources.

The ratings logged through the Rating bean provide the user data necessary for the LikeMinds preference engine. This engine uses explicitly specified user ratings to predict user preferences. You can generate reports based on the ratings of your website content or resources.

Note: The concept of ratings logged through the Rating bean is different from the concept of ratings generated from tagging and rating. Tagging and rating allows users to assign ratings directly to an object to indicate likes and dislikes and is not used to collect data for future recommendations.

All rating data is logged to the Feedback schema and to the LikeMinds schema. Rating data are not logged to the user session.

"Implementing rating logging"
To implement rating logging, insert a Rating bean into your JSP.

"Rating beans reference"
Learn about the various method signatures of Rating beans.

Implementing rating logging:

To implement rating logging, insert a Rating bean into your JSP.

About this task

Following is an example that demonstrates implementation of rating logging by inserting a Rating bean in a JSP.

```
<jsp:useBean class="com.ibm.wcp.analysis.beans.Rating" id="pref" scope="session" />

<%
    // Note:  The mediaId, collectionName, and rating were added to the request
    //          by the referring page.
    pref.log( request,
              request.getParameter( "mediaId" ),
              request.getParameter( "collectionName" ),
              request.getParameter( "rating" ));
%>
```

Note: Web applications implementing preference logging must provide a user interface (UI) to enable preference setting. Once retrieved from the UI, the preference settings can be logged with the Rating bean.

Rating beans reference:

Learn about the various method signatures of Rating beans.

The `com.ibm.wcp.analysis.beans.Rating` bean method signatures are:

Table 365. Descriptions for rating bean method signatures

Rating bean method signatures	Description
`public void log( HttpServletRequest request,` `Resource resource,` `int prefRating );`	Logs a rating for a Resource object. A ResourceCollection with the same resource type will be determined and used for logging the collection name. If you have multiple ResourceCollections containing objects of the same class, you should use the log method that accepts the resourceId and collectionName.
`public void log( HttpServletRequest request,` `String resourceId,` `String collectionName,` `int prefRating );`	Logs a rating using a resource id and collection name.
`public void log( HttpServletRequest request,` `String resourceId,` `String collectionName,` `int prefRating,` `Hashtable ratingData )`	Logs a resource-specific rating with multiple key/value rating data. Each key can have a single value specified by a string object, or multiple values specified by a string array.

The log methods generate a RatingEvent object with the request and rating data. These events are routed to all of the registered log listeners.

Rating beans should be instantiated as session beans; however, they do not maintain rating information for the current session.

CustomLog beans:

CustomLog beans give you the flexibility to log data that does not easily map to the other logging beans. You use CustomLog beans to log application specific data. You define the required key name(s) as well as the value(s) for that key.

Logged data is stored in the Feedback schema in the HITPARMS, KEY_VALUE_COMBO, KEY_VALUE_PAIR, KEY, and VALUE tables. If you use CustomLog beans, you may want to create custom report elements.

All custom log data is logged to the Feedback schema. Custom log data is not logged to the LikeMinds schema nor to the user session.

"Implementing custom logging"
To implement custom logging, insert a CustomLog bean into your JSP.

"CustomLog beans reference" on page 2358
View the CustomLog bean method signatures.

Implementing custom logging:

To implement custom logging, insert a CustomLog bean into your JSP.

About this task

The following code provides an example:

```
<jsp:useBean class="com.ibm.wcp.analysis.beans.CustomLog" id="custom" scope="session" />

<% custom.log( request, "version", "1.0" ); %>
```

You can also log multiple values. For example:

```
<jsp:useBean class="com.ibm.wcp.analysis.beans.CustomLog" id="custom" scope="session" />

<%
   Hashtable customInfo = new Hashtable();
   customInfo.put( "version", "1.0" );
   customInfo.put( "custLevel", new String[] { "gold", "preferred" } );
   customInfo.put( "custRegion", "West" );
   custom.log( request, customInfo );
%>
```

CustomLog beans reference:

View the CustomLog bean method signatures.

The `com.ibm.wcp.analysis.beans.CustomLog` bean method signatures are:

Table 366. Descriptions for CustomLog bean method signatures

CustomLog bean method signatures	Description
`public void log( HttpServletRequest request,` `String key,` `String value );`	Logs a single pair of custom key/value data.
`public void log( HttpServletRequest request,` `Hashtable keyValueData );`	Logs multiple pairs of custom key/value data.

The log methods generate a CustomLogEvent with the request and custom data. The CustomLogEvent is routed to all of the registered log listeners.

CustomLog beans should be instantiated as session beans; however, they do not maintain any session data.

PageView beans:

You use PageView beans to log HTTP request data for JSPs (JavaServer pages).

The HTTP request data logged by PageView beans provides basic Web usage data that can be used during Web traffic analysis. The Action, Category, CustomLog, and Rating beans automatically collect the same basic HTTP data that is collected by the PageView bean. HTTP request data is also collected whenever a rule is executed. Use the PageView bean if the JSP of interest has no other logging beans or content spots, and you want to include the JSP in usage analysis.

"Implementing PageView logging"
To implement Web usage logging, insert a PageView bean in your JSP.

"PageView beans reference" on page 2359
Learn about the `com.ibm.wcp.analysis.beans.PageView` bean log method and instantiation of PageView beans.

Implementing PageView logging:

To implement Web usage logging, insert a PageView bean in your JSP.

About this task

Following is an example of implementing PageView logging:

```
<jsp:useBean class="com.ibm.wcp.analysis.beans.PageView"; id="pageView" scope="session"; />

<%
   pageView.log( request );
%>
```

PageView beans reference:

Learn about the `com.ibm.wcp.analysis.beans.PageView` bean log method and instantiation of PageView beans.

The `com.ibm.wcp.analysis.beans.PageView` bean log method signature is:
`public void log( HttpServletRequest request )`

The log method creates a new `PageViewEvent` with the request. The `PageViewEvent` is routed to all registered log listeners.

PageView beans should be instantiated as session beans; however, they will not maintain any session data.

LogManager:

When data is logged by either logging beans or rules, log events are generated and are routed to a controller for processing. LogManager is the class that implements this controller. There is a single instance of the LogManager within the Personalization run-time. It is responsible for receiving all logged events and distributing these events to listener objects that implement the LogListener interface and are registered with the LogManager.

The LogManager queues log events as they are received. In order to protect listeners from performance degradation due to inefficiencies and/or problems in other listeners, a separate notification thread is managed for each active listener. A nanny thread monitors the notification threads and suspends any non-responsive listener. Since the "queue" is processed by multiple consumers, an event is removed from the queue after all of the notification threads have read the event. You can alter the settings that govern the non-responsive time interval and event queue size by modifying the `FeedbackService.properties` file, located in the *wp_profile_root*`/PortalServer/config/config/services`.

Listeners and persistence:

Log listeners process the log events originating from either logging beans or rules.

Log listeners process the log events originating from either logging beans or rules and will typically store the data in some fashion (such as a database). Separate LogListener implementations are provided for processing log data into the Personalization Feedback schema and for processing data into the LikeMinds schema. These listeners always run whenever logging is enabled. Additionally, it is possible to extend the provided listeners and also write custom listeners from scratch to process logging events and log data as you see fit.

A log listener is registered with and receives log events from the LogManager. All log listeners must either implement the LogManager interface or extend the LogAdapter class. The LogAdapter class provides a default (empty) implementation of each of the handleEvent methods in the LogListener interface.

The logging component uses cache and multi-threading to optimize performance, and to allow each listener to process events at a difference rate without affecting other listeners.

The log listener interface

```
public interface com.ibm.wcp.analysis.event.LogListener extends java.util.EventListener
{
   /**
    * Method called by LogManager after adding the listener to the
    * set of active listeners.  This method can be used to perform
    * initialization during startup.
    */

   public void startHandlingEvents( );

   /**
    * Method called by LogManager when the listener is removed
    * from the set of active listeners.  This method can be
    * used to perform cleanup during termination processing.
    */

   public void stopHandlingEvents( );

   /**
    * Method to handle rule trigger events.
    */

   void handleEvent( RuleEvent event );

   /**
    * Method to handle category logging events.
    */

  void handleEvent( CategoryEvent event );

   /**
    * Method to handle action logging events.
    */

  void handleEvent( ActionEvent event );

   /**
    * Method to handle explicit rating events.
    */

   void handleEvent( RatingEvent event );

  /**
    * Method to handle custom logging events.
    */

 void handleEvent( CustomLogEvent event );

   /**
    * Method to handle basic Web traffic events.
    */
   public void handleEvent( PageViewEvent  event );

  /**
    * Method to handle Personalization audit events.
    */

  void handleEvent( AuditEvent event );
}
```

"FeedbackListener"
The FeedbackListener class routes data to the Feedback schema.

"LMListener"
The LMListener routes data of interest to the LikeMinds database layer.

"Custom log listeners"
When the log method of a logging bean is called, the feedback facility generates a log event. A log event is also generated when a rule is executed. Log listeners process these log events and either store the event data or perform custom processing with these events.

FeedbackListener:

The FeedbackListener class routes data to the Feedback schema.

The FeedbackListener processes all log event types. Each page request (JSP invocation) maps to one row in the Feedback schema HIT_FACTS table. Data for each log event is stored in a separate entry in the Feedback schema HITPARMS table. This distinguishes the data related to each rule or log method call and enables the reporting of information specific to individual content spots or method call. This storage design correlates of all of the data logged by the rules or method calls in a JSP enabling page level reporting.

An instance of the FeedbackListener is active on all run-time servers whenever logging is enabled.

Related concepts:

"Feedback database schema" on page 2372
The Feedback schema, within the Feedback database, stores data about your Web site visitors' actions. This schema is closely aligned with the Tivoli Site Analyzer schema.

LMListener:

The LMListener routes data of interest to the LikeMinds database layer.

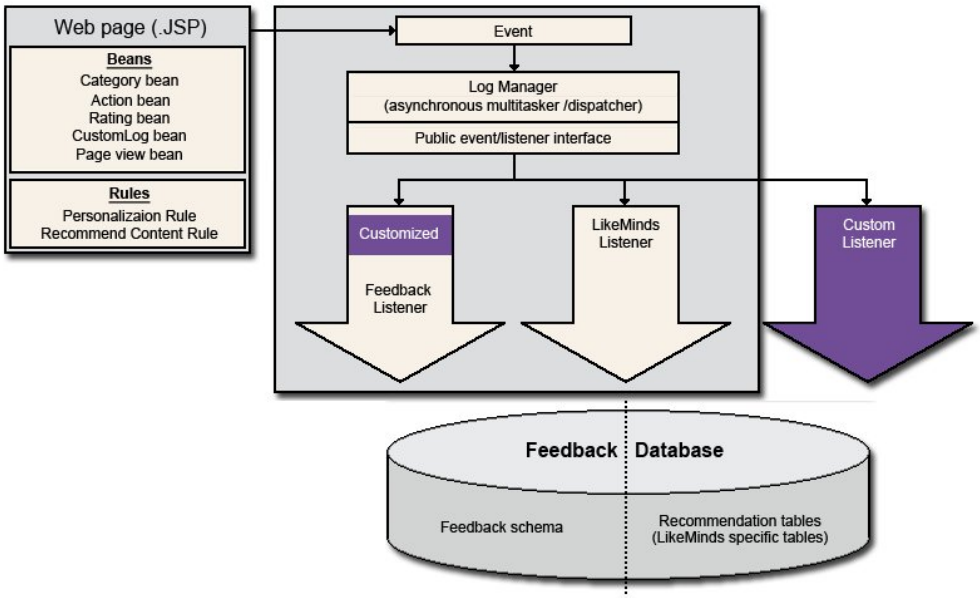
The LMListener only processes ActionEvent and RatingEvent data. These events result in LikeMinds addTransaction calls. Only action names defined in the LikeMinds lpx_trx_type table are logged by this listener. All other actions are ignored.

An instance of the LMListener is active after LikeMinds configuration tasks are run.

Custom log listeners:

When the log method of a logging bean is called, the feedback facility generates a log event. A log event is also generated when a rule is executed. Log listeners process these log events and either store the event data or perform custom processing with these events.

The Feedback component provides two default log listeners, the LMListener that collects data for use by the LikeMinds recommendation engine and the FeedbackListener that collects data for use in the feedback reports. Custom log listeners can be used to modify the default behavior of the FeedbackListener or to implement a listener that provides user-specific behavior.



There are a number of reasons that you might want to provide a customized feedback listener. Some of these are:

- To collect request parameters, referral parameters, or cookies. By default, the feedback listener does not collect this data. You must implement a customized feedback listener that enables the collection of this data.
- To prevent private information from being stored. For instance, you could mask the userid or IP address to ensure the privacy of your users.
- To augment the event data. Suppose your event data contains a product id number and you would like to report on products by product name and id. You could perform a custom lookup during event processing and add the product name to the event.

There are a number of reasons that you might want to provide a new custom listener class. Some of these are:

- To store event data in a separate database. Suppose that you want to capture rating data in a preference database. You can do this through your own web application or you could do this as by adding a custom listener and capturing rating events. The custom listener could facilitate real time rating results.
- To generate email when an event occurs. Perhaps you want to send email to customers after they purchase a large order. By processing an action event with the purchase amount included as action data, you could do this with a custom log listener.
- To generate notifications when an event occurs. You can detect the frequency of shopping cart abandons and generate a notification to the site administrator to check site availability and performance.

"Custom listener classes" on page 2363
A custom listener class is a class that implements the LogListener interface. View the steps to implement a custom listener class.

"Customized feedback listeners" on page 2364
A customized feedback listener is a subclassed FeedbackListener object that is registered with the feedback LogManager. View the steps to implement a custom feedback listener.

Custom listener classes:

A custom listener class is a class that implements the LogListener interface. View the steps to implement a custom listener class.

The custom listener class can implement the LogListener interface explicitly and provide implementations for all of the LogListener methods. Alternatively, the custom listener class can extend the LogAdaptor class. Since the LogAdaptor class contains default implementations of all of the LogListener methods, LogAdaptor subclasses only need to implement the LogListener methods of interest. To implement a custom listener class:

1. Implement a class that extends `com.ibm.wcp.analysis.event.LogAdaptor`. Override the handleEvent methods that accept the event type of interest. You can also provide an implementation for startHandlingEvents and stopHandlingEvents if your listener needs to perform initialization or cleanup, respectively.
2. Install the class file for your custom listener in the classpath of the server where the Personalization run-time is installed.
3. Add the class name to the logListeners property in the `FeedbackService.properties` file, located in the *wp_profile_root*`/PortalServer/config/config/services` directory.
4. Restart the Personalization run-time server.

Note that custom listener classes (other than customized feedback listeners) are always enabled when the Personalization run-time enterprise application is running.

The following example illustrates the implementation of a custom listener class. The listener in this example will generate an alert whenever the "MegaPurchase" action is logged.

```
import com.ibm.wcp.analysis.event.*;

public class SimpleCustomListener extends LogAdapter
{
   /**
    * Method to handle action events.
    */
   public void handleEvent( ActionEvent event )
   {
      if (event.getActionName().equals( "MegaPurchase" ))
         generateAlert();
   }

   /**
    * Method to generate an alert.
    */
   private void generateAlert( )
   {
      // Your custom code for generating an alert can go here.
      System.out.println( "We have a big purchase!" );
   }
}
```

Customized feedback listeners:

A customized feedback listener is a subclassed FeedbackListener object that is registered with the feedback LogManager. View the steps to implement a custom feedback listener.

Perform the following steps to implement a custom feedback listener:

1. Implement a class that extends com.ibm.wcp.analysis.event.FeedbackListener. Override the handleEvent methods that accept the event type of interest.
2. Install the class file for your custom feedback listener in the classpath of the server where the Personalization run-time is installed.
3. Add the class name to the **logListeners** property in the `FeedbackService.properties` file, located in the *wp_profile_root*`/PortalServer/config/config/services` directory.
4. Ensure that the **LoggingEnabled** is set to `true`.
5. Restart the Personalization run-time server.

Note that whenever logging is enabled, your customized FeedbackListener is enabled. Conversely, your customized FeedbackListener is disabled whenever logging is disabled. Only the default FeedbackListener or one custom feedback listener can be active at a time. The specification of a custom feedback listener will override the registration of the default FeedbackListener with the LogManager.

The following example illustrates the implementation of a customized feedback listener. The listener in this example will collect cookie data, request query data, and referral query data. Note that this data is not collected by the default FeedbackListener, but can be set in the event data with a customized feedback listener.

```
import com.ibm.wcp.analysis.event.*;

public class ParmCookieListener extends FeedbackListener
{
   /**
    * Method to handle action events.
    */
   public void handleEvent( ActionEvent event )
   {
      enableParmCollection( event );
      super.handleEvent( event );
   }

   /**
    * Method to handle category events.
    */
   public void handleEvent( CategoryEvent event )
   {
      enableParmCollection( event );
      super.handleEvent( event );
   }

   /**
    * Method to handle rule events.
    */
   public void handleEvent( RuleEvent event )
   {
      enableParmCollection( event );
      super.handleEvent( event );
   }

   /**
```

```
     * Method to set switches to collect cookie and
     * query string data.
     */
    private void enableParmCollection( LogEvent event )
    {
       event.enableLogCookies();
       event.enableLogQueryParms();
       event.enableLogReferralParms();
    }
}
```

Classes and APIs for writing custom listeners:

In order to write custom listeners, it is necessary to familiarize yourself with the classes representing logging events and info that is contained in those events. A reference of these classes is provided here.

"LogEvent class"
The LogEvent class is the base class for all run-time logging events. The methods in this class are used to access all basic http request information.

"ResourceInfo class" on page 2371
The ResourceInfo class is a wrapper class for a resource id and collection name tuple.

"RuleInfo class" on page 2372
The RuleInfo class is a wrapper class for a rule name and campaign name tuple.

LogEvent class:

The LogEvent class is the base class for all run-time logging events. The methods in this class are used to access all basic http request information.

All run-time log data is accessible through the log event sub classes. These log events are constructed by either a rule trigger or a logging bean. They are then routed to the registered log listeners.

The direct subclasses of the LogEvent class are ActionEvent, CategoryEvent, CustomLogEvent, PageViewEvent, RatingEvent, and RuleEvent.

```
public class com.ibm.wcp.analysis.event.LogEvent extends com.ibm.wcp.analysis.event.Event
                                        implements Serializable
```

Table 367. Method summary

Method	Explanation
`protected LogEvent( HttpServletRequest request )`	Constructor
`public Cookie[] getCookies( )`	Returns the cookies available with the request for this event.
`public void setCookies( Cookie[] )`	Sets the cookies for this event. Can be used by custom listeners in order to replace the cookie data received with the current JSP request.
`public void enableLogCookies( boolean enable )`	If enable is true, enables the collection of cookies for this event instance; otherwise, disables the collection of cookies for this event instance. If you want to collect cookie information with the FeedbackListener or a subclassed FeedbackListener, use this method.
`public void enableLogCookies( )`	Same as `enableLogCookies( true )`.

Table 367. Method summary (continued)

Method	Explanation
`public boolean logCookies( )`	Returns true if cookie information should be logged to the Feedback schema for this event; otherwise, returns false.
`public String getIPAddress( )`	Returns the Web client IP address.
`public void setIPAddress( String ipAddress )`	Sets the IP address for this event. Can be used by custom listeners in order to replace the IP address for the current JSP request.
`public String getMethod( )`	Returns the HTTP method used in the current JSP request (GET, POST). Note that the method is not stored in the Feedback schema.
`public void setMethod( String method )`	Sets the HTTP method for the current JSP request. Can be used by custom listeners in order to replace the method from the current JSP request. Note that the method is not stored in the Feedback schema.
`public String getProtocol( )`	Returns the protocol for the current JSP request (http or https).
`public void setProtocol( String protocol )`	Sets the protocol for the current JSP request. Can be used by custom listeners in order to replace the protocol from the current JSP request.
`public void enableLogReferralParms( boolean enable )`	If enable is true, enables the collection of referral parameters for this event instance; otherwise, disables the collection of referral parameters for this event instance. If you want to collect the referral query string parameters with the FeedbackListener or a subclassed FeedbackListener, use this method.
`public void enableLogReferralParms( )`	Same as `enableLogReferralParms( true )`.
`public boolean logReferralParms( )`	Returns true if referral parameter information should be logged to the Feedback schema for this event; otherwise, return false.
`public String getRemoteHost( )`	Returns the host name of the client machine that issued this JSP request. Note that the remote host name is not stored in the Feedback schema.
`public void setRemoteHost( String hostName )`	Sets the host name of the client machine that issued this JSP request. Can be used by custom listeners that perform DNS resolution. Note that the remote host name is not stored in the Feedback schema.
`public String getQueryString( )`	Returns the query string parameters for this event.
`public void setQueryString( String queryString )`	Sets the query string parameters for this event. Can be used by custom listeners in order to replace the query string parameters for the current JSP request.
`public void enableLogQueryParms( boolean enable )`	If enable is true, enables the collection of query parameters for this event instance; otherwise, disables the collection of referral parameters for this event instance. If you want to collect the query string parameters with the FeedbackListener or a subclassed FeedbackListener, use this method.
`public void enableLogQueryParms( )`	Same as `enableLogQueryParms( true )`.

Table 367. Method summary (continued)

Method	Explanation
`public boolean logQueryParms( )`	Returns true if query parameter information should be logged to the Feedback schema for this event; otherwise, return false.
`public String getReferrer( )`	Returns the URL of the referral page or null if there was no referrer.
`public void setReferrer( String referrer )`	Sets the referral page for this event. Can be used by custom listeners in order to replace the referrer for the current JSP request.
`public String getServerName( )`	Returns the host name of the server machine that is processing this JSP request. Note that the server host name is not stored in the Feedback schema.
`public void setServerName( String serverName )`	Sets the host name of the server machine that is processing this JSP request. Can be used by custom listeners to set the name of the current server. Note that the server host name is not stored in the Feedback schema.
`public String getSessionId( )`	Returns the id of the session for the current JSP request.
`public void setSessionId( String sessionId )`	Sets the id of the current user session. Can be used by custom listeners in order to replace the id of the current HttpSession object. This can be useful when an alternative session identification mechanism is used.
`public Date getTimestamp( )`	Returns the time that this log event was generated. Note that this timestamp differs slightly from the time the event was received by the IBM WebSphere Application Server. Note that if there are multiple logging beans or content spots in a JSP, the timestamps in the generated log events will be the same.
`public void setTimestamp( Date timestamp )`	Sets the time for this log event. Can be used by custom listeners in order to replace the timestamp used for this event.
`public String getUrl( )`	Returns the URL of the page request encapsulated by this log event.
`public void setUrl( String url )`	Sets the URL of the page request for this event. Can be used by custom listeners in order to replace the URL for the current JSP request.
`public String getUser( )`	Returns the HTTP authenticated user for the current session.
`public void setUser( String user )`	Sets the user for this event. Can be used by custom listeners in order to replace the user for the current JSP request. This can be useful when an alternative authentication mechanism is used.
`public String getUserAgent( )`	Returns the browser engine for the current session.
`public void setUserAgent( String userAgent )`	Sets the user agent for this event. Can be used by custom listeners in order to replace the user agent from the current JSP request.
`public String toString( )`	Returns a String representation of this event.

"RuleEvent class" on page 2368
A RuleEvent class is constructed whenever a rule is executed. It contains

information about the rule that was executed and the resulting resources. It is an implicitly constructed event; a logging bean is not necessary.

"CategoryEvent class" on page 2369
The CategoryEvent class is used to access the data logged with a Category bean.

"ActionEvent class" on page 2369
The ActionEvent class is used to access the data logged with an Action bean.

"CustomLogEvent class" on page 2370
Get an overview of the CustomLogEvent class and its methods.

"RatingEvent class" on page 2370
The RatingEvent class is used to access the data logged with a Rating bean.

"PageViewEvent class" on page 2371
The PageViewEvent class is used to access data logged by a PageView bean.

RuleEvent class:

A RuleEvent class is constructed whenever a rule is executed. It contains information about the rule that was executed and the resulting resources. It is an implicitly constructed event; a logging bean is not necessary.

```
public class com.ibm.wcp.analysis.event.RuleEvent extends com.ibm.wcp.analysis.event.LogEvent
                                                   implements Serializable
```

Get an overview of the methods of the RuleEvent class.

Table 368. Method summary

Method	Explanation
`public RuleEvent( HttpServletRequest request, RuleInfo ruleInfo, ResourceInfo[] resourceInfo )`	Constructor.
`public RuleInfo getRuleInfo( )`	Returns a rule information object containing the campaign and rule name for the rule that was executed in the content spot.
`public void setRuleInfo( RuleInfo ruleInfo )`	Sets the rule information for this event. Can be used by custom listeners in order to replace the rule execution data.
`public ResourceInfo[] getResourceInfo( )`	Returns a resource information array containing the results of the rule for this event. The resource information contains the collection name and resource ids of the results.
`public void setResourceInfo( ResourceInfo[] resourceInfo )`	Sets the resource information for this event. Can be used by custom listeners in order to replace the resource information.
`public String getResourceClass( )`	Returns the class name of the resources returned by the executed rule.
`public void setResourceClass( String className )`	Sets the class name of the resources returned by the executed rule. Can be used by custom listeners in order to replace the class name.
`public String toString( )`	Returns a String representation of this event.

CategoryEvent class:

The CategoryEvent class is used to access the data logged with a Category bean.

```
public class com.ibm.wcp.analysis.event.CategoryEvent extends com.ibm.wcp.analysis.event.LogEvent
                                                    implements Serializable
```

Get an overview of the methods of the CategoryEvent class.

Table 369. Method summary

Method	Explanation
`public CategoryEvent( HttpServletRequest request, String[] topics )`	Constructor.
`public String[] getTopics( )`	Returns the array of topics for this category event.
`public void setTopics( String[] topics )`	Sets the topics for this event. Can be used by custom listeners in order to replace the topics for this event.
`String toString( )`	Returns a String representation of this event.

ActionEvent class:

The ActionEvent class is used to access the data logged with an Action bean.

```
public class com.ibm.wcp.analysis.event.ActionEvent extends com.ibm.wcp.analysis.event.LogEvent
                                                  implements Serializable
```

Get an overview of the methods of the ActionEvent class.

Table 370. Method summary

Method	Explanation
`public ActionEvent( HttpServletRequest request, ResourceInfo resourceInfo, String actionName, Hashtable actionData )`	Constructor.
`public ResourceInfo getResourceInfo( )`	Returns the resource upon which the action in this event was taken.
`public void setResourceInfo( ResourceInfo resourceInfo )`	Sets the resource info for this action event. Can be used by custom listeners to replace the resource information in this event.
`public Hashtable getActionData( )`	Returns the supplemental data associated with this action. The action data is in key value format. Since a single key can have multiple values, the action data values are stored in the hashtable as String arrays.
`public void setActionData( Hashtable actionData )`	Sets the action data for this action event. Can be used by custom listeners to replace the action data in this event.
`public String getActionName( )`	Returns the name given to the current action.
`public void setActionName( String actionName )`	Sets the action name for this event. Can be used by custom listeners to replace the action name in this event.
`public RuleInfo getRuleInfo( )`	Returns the rule associated with this action. The subject rules for this action are determined by all rules in the current session that returned the target resource.

Table 370. Method summary (continued)

Method	Explanation
`public void setRuleInfo( RuleInfo ruleInfo )`	Sets the rule information for this action event. Can be used by custom listeners to replace the rule information in this event.
`public String toString( )`	Returns a String representation of this event.

CustomLogEvent class:

Get an overview of the CustomLogEvent class and its methods.

The CustomLogEvent class is used to access the data logged with a CustomLog bean.

```
public class com.ibm.wcp.analysis.event.CustomLogEvent extends com.ibm.wcp.analysis.event.LogEvent
                                                    implements Serializable
```

Table 371. Method summary

Method	Explanation
`public CustomLogEvent( HttpServletRequest request,` `Hashtable customData )`	Constructor.
`public Hashtable getCustomData( )`	Returns the custom data as key value information. Since a single custom data key can have multiple values, the custom data values are stored in the hashtable as String arrays.
`public void setCustomData( Hashtable customData )`	Sets the custom data for this event. Can be used by custom listeners to replace the data in this custom data event.
`public String toString( )`	Returns a String representation of this event.

RatingEvent class:

The RatingEvent class is used to access the data logged with a Rating bean.

```
public class com.ibm.wcp.analysis.event.RatingEvent extends com.ibm.wcp.analysis.event.LogEvent
                                                  implements Serializable
```

Get an overview of the methods of the RatingEvent class.

Table 372. Method summary

Method	Explanation
`public RatingEvent( HttpServletRequest request,` `ResourceInfo resourceInfo,` `int rating )`	Constructor.
`public ResourceInfo getResourceInfo( )`	Returns the resource that is the target of the current rating. The resource object returned contains the collection name and resource id.
`public void setResourceInfo( ResourceInfo resourceInfo )`	Sets the resource information for this rating event. Can be used by custom listeners to replace the resource information for this rating.

Table 372. Method summary (continued)

Method	Explanation
`public int getRating( )`	Returns the rating as an integer value. The value can be any valid integer as defined by the Web application implementor.
`public void setRating( int rating )`	Sets the rating for this event. Can be used by custom listeners to replace the rating in this event.
`public String toString( )`	Returns a String representation of this event.

PageViewEvent class:

The PageViewEvent class is used to access data logged by a PageView bean.

```
public class com.ibm.wcp.analysis.event.PageViewEvent extends com.ibm.wcp.analysis.event.LogEvent
                                                      implements Serializable
```

Get an overview of the methods of the PageViewEvent class.

Table 373. Method summary

Method	Explanation
`public PageViewEvent( HttpServletRequest request )`	Constructor.
`public String toString( )`	Returns a String representation of this event.

ResourceInfo class:

The ResourceInfo class is a wrapper class for a resource id and collection name tuple.

```
public class com.ibm.wcp.analysis.event.ResourceInfo extends Object
                                                     implements Serializable
```

Get an overview of the methods of the ResourceInfo class.

Table 374. Method summary

Method	Explanation
`public ResourceInfo( String resourceId, String collectionName )`	Constructor.
`public ResourceInfo( )`	Constructor.
`public String getResourceId( )`	Returns the id of the resource.
`public void setResourceId( String resourceId )`	Sets the id of the resource.
`public String getCollectionName( )`	Returns the name of the collection that contains this resource.
`public void setCollectionName( String collectionName )`	Sets the name of the collection that contains this resource.
`public String toString( )`	Returns a String representation of this resource tuple.
`public boolean equals( ResourceInfo resourceInfo )`	Returns true if and only if (1) the objects are the same or (2) the resource id and collection name information is equal.

Table 374. Method summary (continued)

Method	Explanation
`public int hashCode( )`	Returns a hash code enabling objects of this type to be used as hash keys.

RuleInfo class:

The RuleInfo class is a wrapper class for a rule name and campaign name tuple.

```
public class com.ibm.wcp.analysis.event.RuleInfo extends Object
                                                 implements Serializable
```

Get an overview of the methods of the RuleInfo class.

Table 375. Method summary

Method	Explanation
`public RuleInfo( String rule, String collectionName )`	Constructor.
`public RuleInfo( )`	Constructor.
`public String getRule( )`	Returns the name of the rule.
`public void setRule( String rule )`	Sets the name of the rule.
`public String getCampaign( )`	Returns the name of the campaign containing this rule.
`public void setCampaign( String campaign )`	Sets the name of the campaign containing this rule.
`public String toString( )`	Returns a String representation of this rule tuple.
`public boolean equals( RuleInfo ruleInfo )`	Returns true if and only if (1) the objects are the same or (2) if the rule names are equal and the campaign names are equal.

Reports:

Once data has been logged to the Feedback database schema, it is possible to use any reporting tool that can connect to a standard SQL database to generate reports based on this data. Reference the Feedback database schema section of the Information Center when writing such reports.

Related concepts:

"Feedback database schema"
The Feedback schema, within the Feedback database, stores data about your Web site visitors' actions. This schema is closely aligned with the Tivoli Site Analyzer schema.

Feedback database schema:

The Feedback schema, within the Feedback database, stores data about your Web site visitors' actions. This schema is closely aligned with the Tivoli Site Analyzer schema.

Any application that can connect to a standard SQL database can make use of the data that has been logged to the Feedback database schema.

For instance, you can use the data in the Feedback database schema to:

- Generate reports using reporting software.
- Integrate OnLine Analytical Processing (OLAP) tools.
- Create your own data integration tools.

"Feedback schema tables"
Learn about the feedback schema tables and the fields or columns they contain.

"Key value pairs" on page 2384
The additional information passed by rule logging events and certain bean logging events is logged to the Feedback database in the form of key value pairs.

Feedback schema tables:

Learn about the feedback schema tables and the fields or columns they contain.

The following tables are used by the Feedback schema:

Table Name: Browsers

Table 376. Table description: This table contains the client Web browser defined internally by a User Agent mapping.

Column Name	Column description
Browser_ID	The primary key. A unique number automatically generated by the database.
Name	The browser name defined internally by a User Agent mapping.

Table Name: Calendar

Table 377. Table description: Initially, this table is empty. The Feedback component calculates date stamp IDs, assuming a start date of 1/1/1995. The table can be populated with a new configuration task for applications that use custom logging or reports that reference this table.

Column Name	Column description
Date_ID	The primary key. A unique identifier automatically generated by the database.
Month	Month expressed as integer 1-12
Day	Day expressed as integer 1-31
Year	Year expressed as integer 1995-2030
Quarter	Quarter expressed as integer 1-4
Weekday	Weekday expressed as integer 1-7
WeekOfYear	The week number expressed as an integer 1-52
EpochDay	The number of days since the beginning date in this table.
EpochWeek	The number of weeks since the beginning date in this table.

Table 377. Table description: Initially, this table is empty. The Feedback component calculates date stamp IDs, assuming a start date of 1/1/1995. The table can be populated with a new configuration task for applications that use custom logging or reports that reference this table. (continued)

Column Name	Column description
EpochMonth	The number of months since the beginning date in this table.
EpochQuarter	The number of quarters since the beginning date in this table.
AggrWeekID	The identifier of the first day of the week that this day belongs to.
AggrMonthID	The identifier of the first day of the month that this day belongs to.
AggrQuarterID	The identifier of the first day of the quarter that this day belongs to.
AggrYearID	The identifier of the first day of the year that this day belongs to.

Table Name: Domain

Table description: This table is RESERVED for future Feedback component use.

Column Name	Column Description
Domain_ID	The primary key; a unique identifier automatically generated by the database.
Name	The domain name as resolved from the TCP/IP address.

Table Name: Entities

Table description: This table is RESERVED for Feedback component use.

Column Name	Column Description
Entity_ID	The primary key; a unique identifier automatically generated by the database.
Name	The name of the entity.
Type	Indicates the type of entity: 0=entity 1=category 2=key/value pair
ParentEntity_ID	For a category entity, indicates the entity the category is based on.

Table Name: EntityTraversal

Table description: This table is RESERVED for IBM Feedback component use.

Column Name	Column Description
EntityTraversal_ID	The primary key. A unique identifier automatically generated by the database.
Entity_ID	The identifier of the entity we start from.

Column Name	Column Description
Table1	The table this entity is stored in.
Column1	ID column for this entity.
Table2	The table of the parent entity.
Column2	Join column between entity and parent entity table.
PickThis	RESERVED for IBM Feedback component use.

Table Name: Hit_Facts

Table description: This table contains the information processed during data collection. Each row represents a hit to a page of your Web site--if that page contains a rule or logging bean. Not all fields are used on each entry.

Note: The first date stamp (date ID=1) corresponds to 1/1/1995. Time stamp IDs are calculated such that each second of the day has a separate ID.

Column Name	Column Description
JS_ID	A foreign key to the JavaScriptStatus table.
CookiesStatus_ID	A foreign key to the CookiesStatus table.
Hits	The actual number of hits.
Status_ID	A foreign key to the ResetStatus table.
ReturnCode_ID	A foreign key to the ReturnCodes table.
HTTPVersion_ID	A foreign key to the HTTPVersion table.
RecordType	Indicates what type of log file this hit came from. This field is for Feedback component use only.
LastUpdated	Time stamp of when this row was last created / updated.
PageViews	The actual number of page views. If the resource for this hit is a page, this field is set to 1.
TimeTaken	Time taken by the Web server to process this hit. This column is not implemented and is RESERVED for future Feedback component use.
Bytes	The number of bytes sent by the Web server to the client browser for this hit.
CorrelationKey	The key used to correlate information between the various types of logs that can be processed during data collection.
Session_ID	The identifier of the session this hit belongs to. A foreign key to the Session_Facts table.
HitTimestmp	Time stamp of this hit expressed as a Java timeInMillis value.

Column Name	Column Description
LocalDate_ID	The date of this hit. The first date stamp (date ID=1) corresponds to 1/1/1995. See also, Populating CALENDAR and TIMEOFDAY tables.
ImportHistory_ID	Not implemented. This field is RESERVED for future Feedback component use.
Hit_ID	The primary key. A unique identifier automatically generated by the database.
RefProtocol_ID	Protocol that the referrer used to request this hit. A foreign key to the Protocols table.
Referrer_ID	The referrer for this hit. A foreign key to the Referrer table.
Protocol_ID	The protocol the Web server used to process this hit. A foreign key to the Protocols table.
LocalTimeOfDay_ID	The time of this hit. See also, Populating CALENDAR and TIMEOFDAY tables.
GMTDate_ID	The GMT date of this hit. See also, Populating CALENDAR and TIMEOFDAY tables.
Resource_ID	The resource requested by the client browser. A foreign key to the Resources table.
GMTTimeOfDay_ID	The GMT date of this hit. See also, Populating CALENDAR and TIMEOFDAY tables.
Resource_ID	The resource requested by the client browser. A foreign key to the Resources table.
GMTTimeOfDay_ID	The GMT time of this hit. See also, Populating CALENDAR and TIMEOFDAY tables.

Table Name: HitParms

Table description: This table lists the personalization data (such as rules, campaigns, ratings), as well as query strings associated with a given hit.

Column Name	Column Description
Hit_ID	The identifier of the Hit that contains the query string. This is a foreign key to the ID column of the Hit_facts table.
Parms_ID	The identifier for a specific query string. This is a foreign key to the ID column of the Parms table.
Ordering	Ordering is used to group a set of keys during the processing of a Web page.
ParmType	Identifies the type of key value data. For example, personalization rules data, query strings, or referral query status.

Table Name: HTTPVersion

Table description: This table lists all known HTTP versions. It is pre-populated by the Feedback component when the table is created.

Column Name	Column Description
HTTPVersion_ID	1 - 'HTTP 1.0' 2 - 'HTTP 1.1' 99 - 'Unknown'
Name	The name of the HTTP version.

Table Name: ImportHistory

Table description: This table is RESERVED for future Feedback component use

Column Name	Column Description
ImportHistory_ID	The primary key. A unique number automatically generated by the database.
BeginTimeStamp	Start time of the import, expressed as a JAVA timeInMillis value.
EndTimeStamp	Time the import finished, expressed as a JAVA timeInMillis value.
Status	The status of the import.

Table Name: Key

Table description: Lists all Keys (part of Key/Value pairs) encountered during data collection.

Column Name	Column Description
Key_ID	The primary key. A unique identifier automatically generated by the database.
Name	the name of the key.

Table Name: Key_Value_combo

Table description: This table lists all Key/Value pairs that are grouped together.

Column Name	Column Description
Parms_ID	A foreign key to the Parms table.
KeyValuePair_ID	A foreign key to the Key_Value_Pair table.

Table Name: Key_Value_Pair

Table description: This table lists all Key/Value pairs processed during data collection.

Column Name	Column Description
KeyValuePair_ID	The primary key. A unique identifier generated automatically by the database.
Key_ID	A foreign key to the Key table.

Column Name	Column Description
Value_ID	A foreign key to the Value table.

Table Name: Networks

Table description: This table contains all the TCP/IP addresses processed during data collection.

Column Name	Column Description
Network_ID	The primary key; a unique number automatically generated by the database.
IP_Address	TCP/IP address as obtained from the page hit.
Subdomain_ID	The TCP/IP subdomain this address belongs to. A foreign key to the ID column of the Subdomains table.
Domain_ID	The TCP/IP domain this address belongs to. A foreign key to the ID column of the Domain table.

Table Name: Parms

Table description: This table lists all the key/value pairs strings processed during data collection.

Column Name	Column Description
KVCount	Indicates how many key/value pairs are in this query string.
ParmsString	This field is not used.
WebNode_ID	This field is not used.
Parms_ID	A unique identifier automatically generated by the database.

Table Name: Platforms

Table description: This table contains the client operating system defined internally by a User Agent mapping.

Column Name	Column Description
Platform_ID	The primary key. A unique number automatically generated by the database.
Name	The Operating System name as defined via the User Agent global settings.

Table Name: Protocols

Table description: Lists all network protocols processed during data collection.

Column Name	Column Description
Protocol_ID	The primary key. A unique identifier generated automatically by the database.
Name	The name of the network protocol.

Table Name: Referrer

Table description: This table contains all the referrers processed during data collection.

Column Name	Column Description
Referrer_ID	The primary key. A unique number automatically generated by the database.
RefHost_ID	A foreign key to the ID column of the REFERRERHOST table.
ReferrerURL_ID	A foreign key to the ID column of the REFERRERURL table.

Table Name: ReferrerHost

Table description: This table stores all the referrer site host names processed during data collection.

Column Name	Column Description
RefHost_ID	The primary key. A unique number automatically generated by the database.
IsLocal	Indicates whether this referrer is internal or external. 0 - external referrer 1 - internal referrer
Name	Host name part of referrer as parsed from the Web log record.

Table Name: ReferrerURL

Table description: This table contains the referrer pages processed during data collection. Note that the referrer site's host name is stored in the ReferrerHost table.

Column Name	Column Description
ReferrerURL_ID	The primary key. A unique number automatically generated by the database.
Name	The name of the referrer page as parsed from the Web log record.

Table Name: Resources

Table description: This table contains all resources (URLs) processed during data collection.

Column Name	Column Description
Resource_ID	The primary key. A unique number automatically generated by the database. IsPage Indicates whether this resource is a page. 0 = false 1 = true
IsImage	Indicates whether this resource is an image. 0=false 1=true
IsDirectory	Indicates whether this resources is a file directory. This column is not currently implemented and is RESERVED for future Feedback component use.
Name	The resource string as parsed from the Web log record.

Table Name: Session_Facts

Table description: This table contains all the visits calculated from the Web log data. Note: The first date stamp (date ID=1) corresponds to 1/1/1995. Time stamp IDs are calculated such that each second of the day has a separate ID.

Column Name	Column Description
firstHitTimestmp	Timestamp of the first hit in session expressed as a JAVA timeInMillis value.
lastHitTimestmp	Timestamp of the last hit in the session expressed as a JAVA timeInMillis value.
Result_ID	Foreign key to the ID column of the RESULT table. For your use in classifying this session.
User_ID	The visitor to your site. A foreign key to the Users table.
Referrer_ID	The referrer for this session. A foreign key to the Referrer table.
Sessions	The actual number of sessions. This field will always contain the value. It is used during Report Database processing.
LastUpdated	Timestamp of when this row was last created/updated.
PageViews	Number of page views that are part of this session.
Duration	Duration of the session up to the last hit. The Feedback component cannot calculate the full duration of the session because there is no explicit end-of-session signal from the Web log.
Hits	Number of hits that are part of this session.

Column Name	Column Description
SessionIdentifier	The session identifier string from the Web log. This is sometimes referred to as a session cookie. The SessionIdentifier contains information about the user's id and ip address. If this information needs to be protected steps must be taken to enable encryption on the database level for this column.
SessionTimestmp	Beginning of this session expressed as a JAVA timeInMillis value.
LocalDate_ID	This is the starting date of the session in the local time zone of the Web server that handled this session. See also, Populating CALENDAR and TIMEOFDAY tables.
LocalTimeOfDay_ID	This is the start time of the session in the local time zone of the Web server which handled this session. See also, Populating CALENDAR and TIMEOFDAY tables.
ImportHistory_ID	This column is not used.
Session_ID	The primary key; a unique number automatically generated by the database.
UserAgent_ID	The signature of the Web browser used for this session.
EntryResource_ID	The first resource viewed during this session.
Network_ID	Pointer to the Networks table.
GMTDate_ID	This is the start date of the session translated to the GMT time zone. See also, Populating CALENDAR and TIMEOFDAY tables.
ExitResource_ID	The last resource viewed during this session.
GMTTimeOfDay_ID	This is the start time of the session translated to the GMT time zone. See also, Populating CALENDAR and TIMEOFDAY tables.

Table Name: Result

Table description: For your use in classifying sessions.

Column Name	Column Description
Result_ID	The primary key. We recommend that you use numbers automatically generated by the database. In DB2/UDB, this column is defined as IDENTITY GENERATED BY DEFAULT. On ORACLE, the sequence RESULT_ID is created for your use with this table.
Name	For your use.

Table Name: SessionParms

Table description: This table lists all the Key/Value pairs associated with the session referrer.

Column Name	Column Description
Parms_ID	Foreign key to the ID column of the PARMS table.
Session_ID	Foreign key to the ID column of the SESSION_FACT table.
ParmType	Identifies the type of Key/Value data.

Table Name: Subdomains

Table description: This table is RESERVED for future Feedback component use.

Column Name	Column Description
Domain_ID	Foreign key to the ID column of the DOMAIN table. The TCP/IP domain this subdomain belongs to. Name Subdomain name string from a resolved TCP/IP address.
Subdomain_ID	The primary key, a unique number automatically generated by the database.

Table Name: TimeOfDay

Table description: Initially, this table is empty. Table rows are reserved to list all seconds in a day, when the database is populated. The table can be populated with a new configuration task for applications that use custom logging or reports that reference this table.

Column Name	Column Description
Minute	a number in the range 0..59
Hour	a number in the range 0..23
Second	a number in the range 0..59
AggrHourID	For each database row, indicates which hour it belongs to.
TimeOfDay_ID	The primary key. A unique number automatically generated by the database.
SecondsSinceMidnig	The number of seconds elapsed since midnight.
TimeSpan_ID	Foreign key to the ID column of the TIMESPAN table.

Table Name: TimeSpan

Table description: For your use in classifying time of day values.

Column Name	Column Description
TimeSpan_ID	The primary key. We recommend that you use numbers automatically generated by the database. In DB2/UDB, this column is defined as IDENTITY GENERATED BY DEFAULT. On ORACLE, the sequence TIMESPAN_ID is created for your use with this table.
Name	For your use.

Table Name: UserAgents

Table description: This table contains all UserAgents processed during data collection.

Column Name	Column Description
Browser_ID	Foreign key to the ID column of the BROWSERS table.
Name	The UserAgent string as available from the Web page hit.
Platform_ID	Foreign key to the ID column of the PLATFORMS table.
UserAgent_ID	The primary key. A unique number automatically generated by the database.

Table Name: Users

Table description: This table contains all userids processed from data collection.

Column Name	Column Description
FirstVisitDate_ID	Date of first visit to the site by this userid. See also, Populating CALENDAR and TIMEOFDAY tables.
Name	The userid string as parsed from the Web log record.
User_ID	The primary key. A unique number automatically generated by the database.

Table Name: Value

Table description: Lists all values (from Key/Value pairs) encountered during data collection.

Column Name	Column Description
Value_ID	A unique identifier automatically generated by the database.

Column Name	Column Description
Value	Value string of Key/Value pair parsed from a Web log record.

The following tables are included in the Feedback schema, however, the tables are not used and are not populated.

- Aggregate_Content
- AggregateKey
- Aggregates
- AggregateStatus
- Categories
- Category_Patterns
- Category_Sets
- CategoryMap
- CookiesStatus (Note: This table may be pre-populated, however, the table is not used.)
- JavaScriptStatus
- Linkage
- Log_file_status
- Logs
- ResetStatus
- ReturnCodes
- ServerNodes
- Web_Nodes

Key value pairs:

The additional information passed by rule logging events and certain bean logging events is logged to the Feedback database in the form of key value pairs.

Rule logging events and certain bean logging events pass additional information such as rule names, action names, resource collection names, resource identifiers, etc. when they are fired (refer to the individual rule logging and logging bean sections for more information on what information may be passed). This data is logged to the Feedback database in the form of key value pairs. Key strings representing each type of data are stored in the key table of the Feedback schema, while the values that each key references are recorded in the value table of the Feedback schema. Refer to the Feedback schema diagram for more information on how to join these tables to retrieve a mapping of values onto keys.

The following tables describe what each key represents:

Rule related keys:

Table 378. Key descriptions

Key	Description
wcpRule	The name of the rule that was fired
wcpCampaign	The campaign associated with the rule

Table 378. Key descriptions (continued)

Key	Description
wcpCollection	The name of the resource collection associated with the rule
wcpResourceId	An identifier for each individual resource the associated resource collection

Action bean related keys:

Key	Description
wcpAction	The name of the action being logged
wcpActionResId	The resource (if any) that has been acted upon
wcpActionCollection	The name of the resource collection associated with the resource
wcpActionRule	The name of the rule (if any) that surfaced the resource being acted upon
wcpActionCampaign	The campaign (if any) associated with the rule

Category bean related keys:

Key	Description
wcpCategory	A category string being logged

Rating bean related keys:

Key	Description
wcpRating	The rating value being logged
wcpRatingResId	The resource (if any) that is associated with the rating
wcpRatingCollection	The name of the resource collection associated with the resource

Developing a personalized portlet

This exercise demonstrates how to use Personalization features of WebSphere Portal and Rational Application Developer to build your first personalized portlet. Your final result is a working portlet that uses Personalization rules and content spots to display personal news based on user attributes (or profiles).

The demonstration Web site is organized into the following three pages:

1. **Front Page**
   - **Internal News** displays internal YourCo news for the user. This portlet displays the news upon clicking upon one of the links.
   - **General News** displays external worldwide news articles for users. This portlet messages to the GeneralNewsDetails upon clicking upon one of the links.

- **UserInfo** displays the current user's information. This information is used in rules to target content throughout the website to the particular preferences of your users. This user information can be modified using the edit feature.

2. **Partners Page**
   - **Products** displays products for the current user. This portlet messages to the PartnersDetails upon clicking upon one of the links.
   - **Promotions** runs a simple rule targeting the information in the portlet to the user's preferences.

   The promotions portlet also demonstrates running a campaign and the splitting of rules within a campaign. In this case, between March 1 and April 16, 2005 the Tax Season campaign will run. Within this campaign, one content spot is filled with 2 distinct rules, Get Tax Season Promotions and Get 3 Promotions about IRAs. Get Tax Season Promotions will be run 70% of the time and Get 3 Promotions about IRAs the remaining 30%.

   A second campaign is also running in the promotions spot between April 14 and April 15, 2005. This campaign has a higher priority than the Tax Season campaign so it will run at this time.
3. **Services Page**
   - **Services** displays services that are offered to the user. Clicking on one of the services will display the details of the service. If logging is enabled, clicking on one of the services will log the fact that this particular type of service was selected by the user.
   - **Offers** displays current offers for the user. This portlet demonstrates calling an analysis bean from a rule.

Personalization can use database content. This exercise uses the sample database that comes with the Personalization sample. The following tables are used:

- PZN_USER: contains user information, including profile attributes
- PZN_OFFERS: contains text for special offers categorized by customer type

Table 379. Sample data from PZN_USER table (primary key = USERNAME)

FIRST_NAME	LAST_NAME	DEPARTMENT	CUSTOMERTYPE	USERNAME*
Scott	Green	Loans	Gold	scott
Tawana	Streble	Human Resources	Platinum	tawana
Marge	Roorda	Human Resources	Platinum	marge
Andy	McPherson	IT	Titanium	andy

Table 380. Sample data from PZN_OFFERS table (primary key = OFFER_ID)

OFFER_ID*	CUSTOMERTYPE	TITLE	DETAILS
1	Platinum	2nd House Mortgage	Excellent Mortgage rates on your beach house.
2	Gold	Add other Cards	Add other members of your household to your account.
3	Platinum	ARM Mortgage	1/3 5.9% APR Mortgage for 27 years.

Table 380. Sample data from PZN_OFFERS table (primary key = OFFER_ID) (continued)

OFFER_ID*	CUSTOMERTYPE	TITLE	DETAILS
4	Titanium	Free Checking Deluxe	Free Checking with the attainment of a YourCo Financial Credit Card.

Notice the common element in these tables is the column CUSTOMERTYPE. This column is important when you invoke Personalization later in the exercise.

1. "Prerequisites for the Personalization portlet exercise" on page 2388
   This exercise is intended for users with significant WebSphere Portal Express administration experience and strong portlet Java development skills.
2. "Install the Personalization sample" on page 2389
   This exercise installs the Portal Personalization sample and configures your database for the Personalization sample. No additional database requirements are needed.
3. "Create the JSP file in Rational Application Developer" on page 2389
   Create a basic JSR 168 portlet file for the Personalized Offers project and add the welcome text to the portlet.
4. "Create the Personalization content resource classes and content spot" on page 2390
   View the steps to create the Personalization content resource classes and content spot using IBM Rational Application Developer.
5. "Creating the Personalization user resource classes and content spot" on page 2391
   Use the Project Explorer of IBM Rational Application Developer to create the user resource classes and content spot for the Personalization demo that creates the Personalized Offers portlet for different customer profiles.
6. "Coding the portlet JSP" on page 2392
   Use the Rational Application Developer Project Explorer to work with the pers_offers.Pzn_offersSpot.class and the pers_offers.Per_Offers_UserSpot.class to define the context parameters **offersSpot** and the **userSpot**. Code the setRequest calls to pass the user context to personalization.
7. "Export the WAR file and install the portlet" on page 2394
   Export the IBM Rational Application Developer project to a war file and install the portlet on a portal page.
8. "Import Personalization Workspace resource collections" on page 2394
   Use the Personalization Navigator to create Workspace folders for the resource collections. Then import the resource collections into the Workspace of the Personalization Navigator.
9. "Create a simple content rule" on page 2395
   Use the Personalization Editor to create a business rule for a resource collection.
10. "Create a content spot" on page 2395
    Use the Personalization Editor to create a placeholder for the rule that renders the selected content on a Web page. This placeholder is the *content spot*. Specify which rule to place in the content spot; this is called mapping the rule to the content spot or creating a *rule mapping*. In this example, the content is a resource collection.
11. "Enhance the Personalized Portlet" on page 2396
    Introduce enhancements in the Personalized Portlet.

12. “Insert dynamic table html/jsp code” on page 2397
    Use Rational Application Developer to code the dynamic table in the Personalized Offers portlet JSP. Export the project as a web archive (WAR) file. Open the **WebSphere Portal Administration** page for Portlet Management and update the web module that contains the Personalized Offers portlet.
13. “Modify resource collection properties” on page 2398
    Use the Personalization Navigator to specify the Translator Class for the resource collection.
14. “Create the user profiler rule” on page 2399
    Use the Personalization Editor to create a profiler rule for users who qualify as customers for Gold Offers in the Personalized Offers resource collection.
15. “Create additional advanced rules” on page 2399
    For each customer type specified by a profile, add to the business rule (the profiler) by selecting actions to build the syntax of the rule.
16. “Change content spot rule mapping” on page 2400
    Change the default rule mapping to the new binding rule that you created for different customer types who will use the Personalized Offers portlet. Test the portlet for use by all customer types. Verify that the portlet displays the personalized content that is specified by the business rule for each user profile.
17. “Personalized List portlet” on page 2401
    The Personalized List portlet provides a ready-to-use portlet for displaying personalized content from rules, content spots, or resources. In many cases, it eliminates the need to code new portlets and JSP files yourself. You can use this portlet instead of coding the IBM Rational Application Developer portlet.
18. “Uninstall Personalization sample and database” on page 2402
    View the steps to uninstall Personalization sample demo, database, and users.

Prerequisites for the Personalization portlet exercise:

This exercise is intended for users with significant WebSphere Portal Express administration experience and strong portlet Java development skills.

Before you begin

Software requirements:

- WebSphere Portal Express, including IBM Web Content Manager. You can use the default database or another supported database.
- Rational Application Developer Version 7.0.0.6 or 7.5 with the Portal Tools feature. No agent controller is required. No WebSphere Test Environment or integrated Portal environment is used in this example. For additional information about Rational Application Developer, visit the IBM software library.

Related concepts:

Chapter 11, “Administering,” on page 1041
Use the administration tools that are provided with the portal to do various day-to-day administration tasks. There are two methods for editing portal setup: using the administration portlets or the XML configuration interface. The administration portlets are a convenient way to make real-time updates to the portal's configuration. While the XML configuration interface is suited to more advanced administration, including batch processing of updates.

Related tasks:

 IBM software library

Install the Personalization sample:

This exercise installs the Portal Personalization sample and configures your database for the Personalization sample. No additional database requirements are needed.

Before you begin

Ensure you have the basic system requirements listed in the Prerequisites for the Personalization portlet exercise topic.

Procedure

1. Start the IBM WebSphere Portal Express server.
2. From a command prompt, navigate to *wp_profile_root*/ConfigEngine.
3. Enter the following commands to install the Personalization sample and create the users for this sample:
   - Linux:

     ```
     ./ConfigEngine.sh create-pzndemo-users -DPortalAdminPwd=password
     -DWasPassword=password
     ```

     ```
     ./ConfigEngine.sh install-pzndemo -DPortalAdminPwd=password
     -DWasPassword=password
     ```

   - Windows:

     ```
     ConfigEngine.bat create-pzndemo-users -DPortalAdminPwd=password
     -DWasPassword=password
     ```

     ```
     ConfigEngine.bat install-pzndemo -DPortalAdminPwd=password
     -DWasPassword=password
     ```

4. Stop the WebSphere Portal Express server.
5. Restart the WebSphere Portal Express server
6. Confirm that the users were created by logging in as the following users. Use pzndemo as the password for each user.
   - scott
   - marge
   - tawana
   - andy
7. Navigate to **Personalization** > **Demo**, then click through the different pages and portlets for each user. Notice the different information that displays for each user.
8. Log out of WebSphere Portal Express.
9. Stop the WebSphere Portal Express server. This action is necessary to free the single connection to the Derby database, so you can continue the next steps in this exercise.

Results

The sample demo and database configuration is complete. You can now begin coding a basic personalized portlet.

Create the JSP file in Rational Application Developer:

Create a basic JSR 168 portlet file for the Personalized Offers project and add the welcome text to the portlet.

Before you begin

Before you begin, complete the following prerequisites:

- Ensure you have properly installed the demo and databases.
- Ensure that the WebSphere Portal Server is stopped so that you can make a connection to the database.

Procedure

1. Launch Rational Application Developer.
2. Click **File** > **New** > **Project** and select **Portlet Project**.
3. Click **Next**. The Confirm Enablement window appears. Click **OK** to enable Portal Development.
4. Complete the New Portlet Project screen with the following information:
   a. In the **Project Name** field, type `Pers_Offers`.
   b. Use the default project contents.
   c. Select **WebSphere Portal v6.1 stub** from the **Target Runtime** list.
   d. Select **Add project to an EAR** and in the field **EAR Project Name** select *Pers_OffersEAR* from the list.
   e. In the **Portlet API** field, select *JSR 168 Portlet* from the list.
   f. Select **Create a portlet** and specify the following properties:
      - In the **Portlet Name** field, type `Pers__Offers`.
      - In the **Portlet Type** field, select *Basic Portlet* from the list.
5. Click **Next**.
6. Accept the default Portlet Settings and click **Next**.
7. No Actions are necessary. Clear any selected actions and click **Next**.
8. No Advanced Settings are necessary. Click **Finish**.
9. The JSP file opens automatically in Design mode. Edit the text of the portlet to display `Welcome to Personalized Offers!`.
10. Save and close the JSP.

Results

You have created a JSP file using Rational Application Developer.

What to do next

You can now create the Personalization content resource classes and content spot.

Create the Personalization content resource classes and content spot:

View the steps to create the Personalization content resource classes and content spot using IBM Rational Application Developer.

Procedure

1. In the Project Explorer tab in Rational Application Developer, right-click on the Pers_Offers project and choose **New** > **Other**.
2. From the New window, select **Portal** > **Personalization** > **Content or User Resource**.
3. Click **Next**.
4. Select the following options by clicking the appropriate radio button:

a. **SQL**
b. **Web Content**

5. Select **Create a new connection** and click **Next**.
6. Enter the following values:
   a. From the **JDBC driver** drop-down list, select **Derby Embedded JDBC Driver**.
   b. From the **Database location** field, click **Browse**. Navigate to and select *wp_profile_root*/PortalServer/derby/pzndemo_db/
   c. From the **Class location** field, click **Browse**. Navigate to and select *AppServer_root*/derby/lib/derby.jar
7. Click **Next**. The personalization resource wizard opens.
8. Expand PZNDEMO.
9. On the **Tables** tab, select **PZN_OFFERS**, and click the arrow to add the table to the list of selected tables. Click **Primary Table** to mark it as the primary table.
10. Select the **Columns** tab.
11. On the **Columns** tab, move all columns to the selected columns list by clicking the double arrow button. Notice the primary key is the column Offer_ID.
12. Click the **Mappings** tab.
13. On the **Mappings** tab, select **Customertype** and click **Populate**.
14. Click the **Select** buttons and expand **PZNDEMO** > **PZN_OFFERS** to select CUSTOMERTYPE for the **Description** and **Value** fields. Click **OK**.
15. Click the **Deployment** tab.
16. On the **Deployment** tab, change the datasource to jdbc/pzndemo. This datasource is defined in WAS by the Personalization demo program installation.
17. Click **Next**.
18. Set the package name as pers_offers. Select **Generate a Content Spot for this resource**. Select **Include schema names** in the generated Resource Runtime Manager.
19. Click **Finish**.

Results

You can now see the new JAVA classes in your project:

What to do next

You can now see the new JAVA classes in your project, and create the Personalization user resource classes and content spot.

Creating the Personalization user resource classes and content spot:

Use the Project Explorer of IBM Rational Application Developer to create the user resource classes and content spot for the Personalization demo that creates the Personalized Offers portlet for different customer profiles.

Procedure

1. In the **Project Explorer** tab of Rational Application Developer, right-click the **Pers_Offers** project and choose **New** > **Other**.

2. From the **New** window, select **Portal** > **Personalization** > **Content or User Resource**.
3. Click **Next**
4. Select one of the following radio buttons:
   - **SQL**
   - **Web users**
5. Select **Use an existing connection** and select **pzndemo_db** from the list of existing connections.
6. Click **Next**. The personalization resource wizard opens.
7. Expand **PZNDEMO**.
8. On the **Tables** tab, highlight **PZN_USER**. Click the appropriate arrow button to select the table.
9. Right-click **PZN_USER** and select **Edit Table**.
10. Change the display name of **PZN_USER** to **Per_Offers_User** to avoid naming conflicts with the previously installed demo code. Click the Primary Table button to mark it as the primary table.
11. Select the **Columns** tab
12. On the **Columns** tab, move all of the columns to the selected columns area by clicking the double arrow button. Notice the primary key is the column **USERNAME**.
13. Click the Mappings tab.
14. On the Mappings tab, select **Customertype** and click **Populate**.
15. Click the **Select** buttons and expand **PZNDEMO** > **PZN_USER** to select CUSTOMERTYPE for the **Description** and **Value** fields. Click **OK**.
16. Click the **Deployment** tab.
17. On the **Deployment** tab, change the datasource to `jdbc/pzndemo`. This datasource is defined in WAS by the Personalization demo program installation.
18. Click **Next**.
19. Set the package name as `pers_offers`. Select **Generate a Content Spot for this resource**. Select **Include schema names in the generated Resource Runtime Manager**.
20. Click **Finish**.

Results

You can now see the new JAVA classes in your project:

What to do next

You can now finish coding the portlet JSP file.

Coding the portlet JSP:

Use the Rational Application Developer Project Explorer to work with the pers_offers.Pzn_offersSpot.class and the pers_offers.Per_Offers_UserSpot.class to define the context parameters **`offersSpot`** and the **`userSpot`**. Code the setRequest calls to pass the user context to personalization.

Procedure

1. From the Rational Application Developer Project Explorer, open `PersOffers/WebContent/pers_offers/jsp/html/Pers_OffersPortletView.jsp`
2. Drag the `pers_offers.Pzn_offersSpot.class` file from `PersOffers/WebContent/WEB-INF/classes/pers_offers` onto the JSP file. This class is one of the classes you generated in the content resource wizard.
3. In the **Properties** window, select **offersSpot** from the **Id** list.
4. Drag the `pers_offers.Per_Offers_UserSpot.class` file from `PersOffers/WebContent/WEB-INF/classes/pers_offers` onto the JSP file.
5. In the **Id** field, type **userSpot**.
6. Switch to source mode in the JSP file editor.
7. Replace the existing text with the following sample. The `setRequest` calls pass the user context to personalization:

```
<%@ page session="false" contentType="text/html" import="java.util.*, pers_offers.*"%>

<%@ taglib uri="/WEB-INF/tld/portlet.tld" prefix="portletAPI" %>

<portletAPI:init/>

<jsp:useBean class="pers_offers.Pzn_offersSpot" id="offersSpot"></jsp:useBean>

<jsp:useBean class="pers_offers.Per_Offers_UserSpot" id="userSpot"></jsp:useBean>

<%

offersSpot.setRequest(request);

userSpot.setRequest(request);

%>
```

8. Save the file and check for syntax errors.
9. Insert the following code at the end of the JSP file:

```
<DIV style="margin: 6px">

<H3 style="margin-bottom: 3px">Welcome to Personalized Offers!</H3></DIV>

<BR>

Here is a personalized offer:<BR>

<%=offersSpot.getRuleContent()[0].getTitle() %>

<br>

<%=offersSpot.getRuleContent()[0].getDetails() %>
```

10. Save and close the JSP file.

What to do next

You finished the basic coding of the personalized portlet. You can now export the WAR file from Rational Application Developer and install the portlet in WebSphere Portal.

Export the WAR file and install the portlet:

Export the IBM Rational Application Developer project to a war file and install the portlet on a portal page.

Before you begin

Ensure that you have properly followed the steps in Coding the portlet JSP.

Procedure

1. Export the Rational Application Developer project to a war file called `PersOffers.war`.
   a. Right click Pers_Offers and select **Export** > **WAR file**.
   b. In the **Destination** field, type `filepath/PersOffers.war`.
   c. Select **Export source files**.
   d. Click **Finish**.
2. Start WebSphere Portal.
3. Log in as the Portal administrator (`wpsadmin`).
4. Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.
5. Click **Install**.
6. Complete the installation of `PersOffers.war`. Verify that installation was successful.
7. Open **Portlet Management** > **Portlets**.
8. Search for the Pers_Offers portlet and grant **Privileged User** to **All Authenticated Portal Users**.
9. Create a new page called Pers Offers by completing the following steps:
   a. Select **Portal User Interface** > **Manage Pages**.
   b. Select **Content Root** > **Personalization**.
   c. Select **New Page**.
   d. Label the Page Pers Offer.
10. Add the Pers_Offers portlet to the page.
11. Click **Done**.

    Note: The portlet is not ready to run yet. If you try, you get an error.

What to do next

You can now import the Personalization workspace resource collections.

Import Personalization Workspace resource collections:

Use the Personalization Navigator to create Workspace folders for the resource collections. Then import the resource collections into the Workspace of the Personalization Navigator.

Before you begin

Before you can use the content and user resources in the Personalization Navigator, you must place these class files into a directory accessible by that portlet. To do this, export the pers_offers folder in RAD under `Pers_Offers/Java`

Resources/JavaSource as a JAR file. Make the target location *PortalServer_root*/pzn/prereq.pzn/collections/pers_offers.jar. Accept the defaults and click **Finish**, then restart the server.

Ensure you have properly followed the steps in Export the WAR file and install the portlet.

Procedure

1. Click the **Personalization** tab.
2. In the Personalization Navigator portlet, click **New** > **Folder**
3. Enter the name Pers Offers and click **Create**.
4. Change to the Pers Offers folder.
5. Click **Import**.
6. Browse to find the Pzn_offers.hrf file in your installed Pers_Offers directory under Pers_Offers.war/WEB-INF/pzn-resourceCollections/pers_offers.
7. Click **Import**.
8. See the resource collection in the Workspace.
9. Do the same to import the Pers_Offers_User.hrf file.

What to do next

You can now create a simple content rule.

Create a simple content rule:

Use the Personalization Editor to create a business rule for a resource collection.

Before you begin

Before you begin this procedure, ensure you have imported the resource collections into the Personalization Workspace.

Procedure

1. While still in the Pers Offers folder, click **New** > **Rule**.
2. Type Show Gold Offers in the New Rule field.
3. Select **Select Action** from the **Rule Type** drop-down list.
4. Click **content** next to **Select**.
5. Select **Pzn_offers** from the drop-down list.
6. Click **attribute** and select **Customertype** in the drop-down list.
7. Hover over **value** and click the greater than symbol, **>**, then select **Gold** in the drop-down list.
8. Click **Save**.

What to do next

You can now create a content spot for your rule.

Create a content spot:

Use the Personalization Editor to create a placeholder for the rule that renders the selected content on a Web page. This placeholder is the *content spot*. Specify which

rule to place in the content spot; this is called mapping the rule to the content spot or creating a *rule mapping*. In this example, the content is a resource collection.

Before you begin

Before you begin this procedure, ensure you have created the simple content rule *Show Gold Offers* for the *Personalized Offers* resource collection.

About this task

Note: You must use the same name as the original content spot's display name. Do not place the new content spots into a folder, unless your display name already includes slashes. Place them directly into the root Workspace.

Procedure

1. Return to the root directory in the Personalization Navigator.
2. Click **New** > **Content Spot** to display the Personalization Editor.
3. Type `Pzn_offersSpot` in the title field of the content spot.
4. Select **Pzn_offers** from the **Output Type** drop-down list.
5. Click the button in the **Default Mapping** section.
6. Expand the **Pers Offers** folder in the tree, select **Show Gold Offers** and click **OK**.
7. Click **Save**.
8. Test the content spot with the Personalization Editor portlet by selecting it in the Personalization Navigator and clicking the **Preview** tab in the Personalization Editor.

   Note: If the previous values appear on the Preview tab, the rule and content spot work.
9. View the page with your Pers_Offers portlet.

Results

You can now edit the JSP file to contain dynamic code.

Enhance the Personalized Portlet:

Introduce enhancements in the Personalized Portlet.

Before you begin

Ensure you have properly followed the steps in “Create a content spot” on page 2395.

About this task

We need a few more things in this portlet to make it interesting:

- User profiling
- Special userid handling, so we can build the user profiles
- A more complex binding rule
- A dynamic html table, to display any number of special offers

Insert dynamic table html/jsp code:

Use Rational Application Developer to code the dynamic table in the Personalized Offers portlet JSP. Export the project as a web archive (WAR) file. Open the **WebSphere Portal Administration** page for Portlet Management and update the web module that contains the Personalized Offers portlet.

Before you begin

Before you begin this procedure, ensure that you created a content spot.

Procedure

1. Open Rational Application Developer and open `Pers_OffersPortalView.jsp` in edit mode.
2. Insert the following code at the end of the JSP page:

```
<HR>

Here are all your personalized offers:

<br>

<%

try {

pers_offers.Pzn_offers[] items = offersSpot.getRuleContent();

pers_offers.Pzn_offers item = items[0]; // throws an exception if empty. %>

<TABLE WIDTH="100%">

<TBODY>

<%

for (int i = 0, c = 0; ; ) {

if (c == 0) { %>

<TR bgcolor="e7e7e7"><%

}

else { %>

<TR><%

} %>

<TD><%= item.getTitle() %>: <%= item.getDetails() %>

</TD>

</TR><%

c = c == 0 ? 1 : 0;

i++;

try {

item = items[i];
```

```
}

catch (java.lang.ArrayIndexOutOfBoundsException _e0) {

break;

}

} %>

</TBODY>

</TABLE><%

}

catch (java.lang.ArrayIndexOutOfBoundsException _e0) {

%><FONT>There are no current articles to display. </FONT><%

} %>
```

3. Save and close the file. Verify no errors other than exception handling errors.
4. Export the project as a war file. Close Rational Application Developer.
5. Log in to WebSphere Portal as `wpsadmin`. Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.
6. Click the **Update** button to update the web module.
7. Complete the installation process by using the newly created war file.

What to do next

You can now modify the resource collection properties for Pzn_Offers_User.

Modify resource collection properties:

Use the Personalization Navigator to specify the Translator Class for the resource collection.

Before you begin

Before you begin this procedure, ensure that you have inserted the dynamic table code into the Personalized Offers portlet.

Procedure

1. Open the Personalization Navigator.
2. Navigate to the `Pers_Offers` folder.
3. Select the **Per_Offers_User** resource collection.
4. In the Personalization Editor, click **Edit**.
5. Set the Translator Class to `com.ibm.websphere.personalization.security.RegularExpressionSecurityTranslator` and click **Save**.

What to do next

You can now create a user profiler rule.

Create the user profiler rule:

Use the Personalization Editor to create a profiler rule for users who qualify as customers for Gold Offers in the Personalized Offers resource collection.

Before you begin

Before you begin this procedure, ensure that you have modified the resource collection properties to specify the Translator Class.

About this task

In the Personalization Editor, follow these steps:

Procedure

1. Within the Pers Offers folder, click **New** > **Rule**.
2. Enter the following values:
   a. In the **New Rule** field, type `Pers Offers User Profiler`.
   b. Select **Profiler** in the Rule Type menu.
3. Click **Profile**, type **Gold** in the Profile field, and click **Submit**.
4. Click **attribute** and select **Per_Offers_User** in the drop down, then **Customertype** in the expanded drop down.
5. Click the greater than symbol, >, next to value and select **Gold** in the drop down list.
6. Click **add Profile** to add another conditional expression to the profiler rule.
7. Complete the profiler rule by adding profiles that define distinct sets of users. Each profile expresses the conditions of the user type as illustrated in the following example.

   Note: Select **No value** for the **Otherwise** field.
8. Click **Save**.

Results

You can now create some additional advanced rules for your personalized portlet.

Create additional advanced rules:

For each customer type specified by a profile, add to the business rule (the profiler) by selecting actions to build the syntax of the rule.

Before you begin

Ensure you have properly followed the steps in "Create the user profiler rule."

Procedure

1. Within the Pers Offers folder, select **New** > **Rule**
2. Type `Show Platinum Offer` in the **New Rule** field.
3. Select **Select Action** from the **Rule Type** drop-down list.
4. Edit the rule so that its `Customertype is Platnum` and click **Save**.
5. In the Pers Offers folder, create another rule called Show Titanium Offers. Select Pzn offers whose Customertype is titanium.

6. Within the same folder, select **New** > **Rule**
7. Type `Show Offers by Customer Type` in the **New Rule** field.
8. Select **Binding** from the **Rule Type** drop-down list.
9. Click **Profiler** > **Select a Profiler...**.
10. Expand the Pers Offers folder, select **Pers Offers User Profiler** and click **OK**.
11. Click **Profile** and select **Gold** from the drop-down list.
12. Click **do Action** > **Select Actions...**.
13. Select **Show Gold Offers** and click **OK**.

    Tip: To find **Show Gold Offers**, you may reorder the columns to make navigation easier or page through the list of rules.
14. Click **Profile** and choose **Platinum**. Complete the fields as follows:

What to do next

You can now change your content spot mapping.

Change content spot rule mapping:

Change the default rule mapping to the new binding rule that you created for different customer types who will use the Personalized Offers portlet. Test the portlet for use by all customer types. Verify that the portlet displays the personalized content that is specified by the business rule for each user profile.

Before you begin

Before you begin this procedure, ensure you have properly created additional advanced rules.

Procedure

1. In the Personalization Navigator, select the content spot **Pzn_offersSpot**, located in the **Workspace Root**.
2. In the Personalization Editor portlet, click **Edit**.
3. Change the default rule mapping to the new binding rule and click **Save**.
4. Log in to the Portal as `Scott`, with password `pzndemo`, a Gold customer.
5. Run the enhanced Personalized portlet
6. Log out, then log in as `Marge`, with password `pzndemo`, a Platinum customer.
7. Run the portlet.

Results

If you run the portlet as *wpsadmin*, it fails because *wpsadmin* does not exist in the user resource database, and the programmer who coded the JSP did not code the proper error handling.

Congratulations! You have finished building a Personalized portlet.

What to do next

The next topic, *Personalized list portlet*, shows how to use this portlet instead of coding the Rational Application Developer portlet.

Personalized List portlet:

The Personalized List portlet provides a ready-to-use portlet for displaying personalized content from rules, content spots, or resources. In many cases, it eliminates the need to code new portlets and JSP files yourself. You can use this portlet instead of coding the IBM Rational Application Developer portlet.

About this task

Restriction: The Personalized List portlet is not intended to be used with the Web Content resource collection or with rules that involve the Web Content resource collection. To display Web Content rules, use a Portal Personalization Component in IBM Web Content Manager. When the Web Content resource collection is used with the Personalized List portlet, certain attributes like authoring template shows raw values from the repository that cannot be translated to a readable form. The details page of the Personalized List portlet does not show the results of the rendered content. The details page shows some attribute from the content, such as the creator or last modified date, which is not suitable for production use of content from Web Content Manager.

The intended use of the Personalized List portlet is to display personalized lists of documents. The Personalized List can also be used with some generated or custom resource collections.

Procedure

1. Copy the pers_offers folder from the /Pers_Offers.war/WEB-INF/classes directory under your Pers_Offers portlet in the installedApps location into *wp_profile_root*/PortalServer/pzn/collections. You might need to create this classes folder first.
2. Restart IBM WebSphere Portal Express.
3. Log in as the admin user.
4. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
5. Search for the Personalized List portlet.
6. Make a copy of the Personalized List portlet, named **Personalized List Special Offers**.
7. Set **access control** for the new portlet so **All Authenticated Portal Users** are Privileged Users.
8. Add the Personalized List Special Offers portlet to a new page under Personalization called **Pers List Portlet - Rules**.
9. Display the new page with the new portlet. Click the portlet menu on the Personalized List Special Offers portlet, and select **Configure** from the drop-down list.
10. Click the menu icon under **Which Personalization resources are retrieved** and select **Select a Rule, Content Spot or Resource Collection**.
11. Expand the **Pers Offers** folder and select **Pzn_offers** and click **OK**.
12. Click **Display Options**.
13. Select the following options and click **OK**.
14. Click **OK** again to see the portlet.
15. Click one of the title links to see the details of that resource.
16. Click **Back**.
17. Configure the portlet again to show more personalized offers.

18. From the Personalization Picker, select the content spot **Pzn_offersSpot** under the Workspace Root and click **OK**.
19. Click **Display Options**, set the following values, and click **OK**.
20. Set the Title Attribute and Detail Attribute values to **Fixed**. Click **OK**.
21. Complete the configuration and see that the Personalized List Special Offers portlet is empty. This is because the administrator did not enter customer details in the pzndemo database for the user resource that is being used.
22. Log in as Scott and view the Personalized List Special Offers portlet. The portlet displays the personalized offers that are based on the rule, *Show Offers By Customer Type*, which is mapped to the content spot *Pzn_offersSpot*.
23. Test this portlet, logging in as each pzndemo user having a different profile. You must get the same content results that you saw previously by using your own custom-built portlet, *Pers_Offers*, except you do not have to code a portlet or a JSP file.

Uninstall Personalization sample and database:

View the steps to uninstall Personalization sample demo, database, and users.

About this task

Procedure

1. From a command prompt, navigate to *wp_profile_root*/ConfigEngine.
2. From this command prompt, run the following commands:
   - Linux:

     ```
     ./ConfigEngine.sh remove-pzndemo -DPortalAdminPwd=password
     -DWasPassword=password
     ./ConfigEngine.sh remove-pzndemo-users -DPortalAdminPwd=password
     -DWasPassword=password
     ```

   - Windows:

     ```
     ConfigEngine.bat remove-pzndemo -DPortalAdminPwd=password
     -DWasPassword=password
     ConfigEngine.bat remove-pzndemo-users -DPortalAdminPwd=password
     -DWasPassword=password
     ```

Results

The sample demo, database, and users will be removed.

Note: The database connection to the included Apache Derby database may stay open and prevent removal of the database directory. Restart IBM WebSphere Portal Express and run `ConfigEngine.bat/sh remove-pzndemo-database -DPortalAdminPwd=password -DWasPassword=password` if this is a problem. The directory `PznDemo` in the root of the Portal Personalization Workspace may need to be removed manually.

Personalization programming reference

IBM WebSphere Portal Express provides the programming model, processes, and APIs for the Personalization rules and resource engines.

"Preparing your personalized application" on page 2404
Before deploying applications that take advantage of the features of Portal Personalization, certain features must be configured in order to work properly. The Feedback and LikeMinds components of Personalization both communicate

with their databases using Java data sources. Before using either of these components, you must create resource references to the data sources in your project.

"Programming model" on page 2405
Personalization builds on the same programming model used by WebSphere Application Server. Two components of that model are Java Server Pages (JSP) and business logic (JavaBeans and enterprise beans). JSP files enable you to effectively separate HTML coding (presentation) from business logic. You isolate your business logic in beans that the Web page author embeds in the JSP.

"User and content models" on page 2405
The first step in developing a Personalization solution is to analyze your business conditions and events to determine the users and content to be targeted. The business users and administrators are primarily responsible for this task.

"How the rules engine works" on page 2406
The rules engine processes and delivers the results of a rule execution to a content spot contained in a web page. The content spot is marked by a content spot bean, which is placed in either a JSP file or a servlet. The JSP file or servlet is then linked to the web page.

"Workload management" on page 2409
Only one Portal Personalization engine can be installed on an application server. Consequently, there is one Personalization engine for each servlet engine. Personalization supports application server clustering, because each Personalization instance in the cluster shares the same IBM Java Content Repository. Therefore, each Personalization instance accesses the same customer data stores.

"Using the Personalization APIs" on page 2409
Personalization provides open APIs that enable the Personalization run-time environment and Rational Application Developer to access user and content data in customer data stores.

"Generic query framework" on page 2412
The generic query framework enables resource collection developers to convert a property-based query object into a language specific executable query string. It contains query component classes, and builder and callback interfaces.

"Request context interface" on page 2414
This is the interface used to access various attributes for rules. For HTTP contexts, it provides access to the HttpRequest and HttpSession attributes. For non-HTTP contexts, it provides the same interface to a surrogate for the request and session.

"Sample Personalization resources XML file" on page 2415
Use the sample file `ExportFromServlet.xml` as a reference for coding other Personalization actions.

"Content spot exits" on page 2415
Content spot exits provide the ability to alter the default flow of processing of content spots, making it possible in the runtime environment to override the rule to process, the current user, and the results of rule processing. Instances of the same exit class are instantiated for all content spots. The exit class interface name is public interface RuleExit.

"Resource cache" on page 2417
Personalization uses the WebSphere Application Server Dynamic Cache service to cache the results of select rules and to cache the rules themselves in a DistributedMap. When publishing, importing or saving rules, the cache is flushed automatically to ensure that the site is current.

"Programmatically starting rules" on page 2418
All types of rules can be accessed programmatically within a Java application. For example, a profiler can be used to determine the behavior that an application must exhibit depending on the current user, or an action can return content to your application for further processing before the content is displayed. Rules are mapped to content spots, and because a content spot is an implementation of a JavaBeans, it can be programmatically declared and implemented.

"Rule Exception Handling in the run-time environment" on page 2419
The default method of error or exception handling within the Personalization run-time environment is for the engine to print out a trace error to the application server's stdout log. Using an exception handling utility, it is possible to specify the type of output (error message or stacktrace), the output log file to use (stdout or stderr), and whether the exception should be rethrown to the JSP. The additional exception handling capabilities can be set on a per-request basis or globally.

Preparing your personalized application:

Before deploying applications that take advantage of the features of Portal Personalization, certain features must be configured in order to work properly. The Feedback and LikeMinds components of Personalization both communicate with their databases using Java data sources. Before using either of these components, you must create resource references to the data sources in your project.

About this task

If you are using IBM Rational Application Developer to add resource references to the Feedback and LikeMinds data sources, complete the following steps:

Procedure

1. From the WAR application `WEB-INF/` directory, open the `web.xml` file. Click the **References** tab. Under the list of defined references, click **Add**.
2. In the Add Reference panel, select **Resource Reference** and click **Next**.
3. Complete the following fields in the Add Resource Reference panel and click **Finish**.
   - **Name:** `jdbc/feedback`
   - **Type:** `javax.sql.Datasource`
   - **Authentication:** Container
   - **Sharing scope:** Sharable
   - **Description:** This field is optional.
4. In the section marked **WebSphere Bindings**, enter the JNDI name of your Feedback Datasource.
5. Save the file.

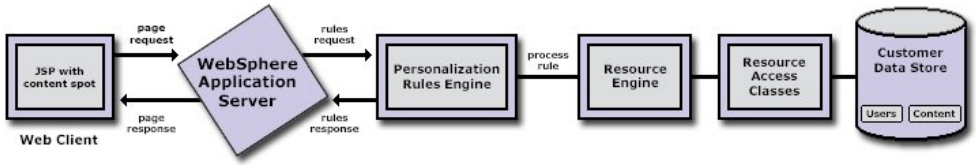
What to do next

Repeat this process for the LikeMinds data source. Change the name of the reference to jdbc/lmdbDS. All other settings remain the same.

Programming model:

Personalization builds on the same programming model used by WebSphere Application Server. Two components of that model are Java Server Pages (JSP) and business logic (JavaBeans and enterprise beans). JSP files enable you to effectively separate HTML coding (presentation) from business logic. You isolate your business logic in beans that the Web page author embeds in the JSP.

The term *developer* could refer to Web page authors or programmers. The developer does not need programming skills to author JSPs that access databases and reusable Java components. The author only needs to know the type of content that the bean, servlet, or other Java component adds to the page. The programmers create the reusable Java components and provide the Web page authors with the component names and properties. The database administrators provide the Web page programmers with the database access and table information.



The model expands three Web team roles:

- The business users

  The business users understand the business goals that the Web site or Web application must achieve. They understand the business conditions and business rules that must be factored into the Personalization solution. For example, the business users know the characteristics by which to categorize users for effective implementation of the business rules.

- The developer

  The developer understands Web site development and can use Rational Application Developer (or similar tools) to create and publish Web pages and sites. The developer works with the business user to determine where personalized content should appear and creates content spots of the appropriate type at the proper locations on the Web pages.

- The administrator

  This team member is the Web content expert and/or server administrator. The administrator knows what content already exists, where it is stored, the people who provide the content, how often the content is updated and other details. This person understands how to categorize content and helps the business users organize and target content for categories of users.

User and content models:

The first step in developing a Personalization solution is to analyze your business conditions and events to determine the users and content to be targeted. The business users and administrators are primarily responsible for this task.

After this analysis is completed, focus on the user, content and other data for your Personalization solution. The subsequent tasks include:

- Developing a user model and a content model

  The user model consists of the properties (attributes) of the user (that is, the typical Web site visitor), such as name and address. Similarly, the content model consists of properties of the Web content, such as title and author. Another term for model is *schema*.

  If you have already stored user data, some level of user model already exists. In such cases, the decision becomes whether to create a new model, or adapt the existing model to meet the requirements for your Personalization solution. You will also need to ensure that the user model and content model facilitate mapping users to content. For example, if you want to display news headlines that are of interest to the site visitor, the user model might include a property called `user_interests` that is a list of the topics in which the user is interested. The content model, for article content, could include a property `topics` that is a list of the subjects covered in the article. To support mapping a user interest to an article topic, you would ensure that there is an understandable relationship between possible values of `user_interests` and values of `topics`.
- Implementing the user and content models

  You must implement the user and content data models. If database tables matching the data models do not exist, implementing the data model involves creating and populating the data store for the user and content data. If the database tables exist, you might need to combine data from multiple tables, or add columns to create a user or content resource that matches the corresponding data model. Reusing existing tables might involve combining data from multiple tables to create a user or content resource.
- Implementing the Personalization APIs for accessing user, content and other resources

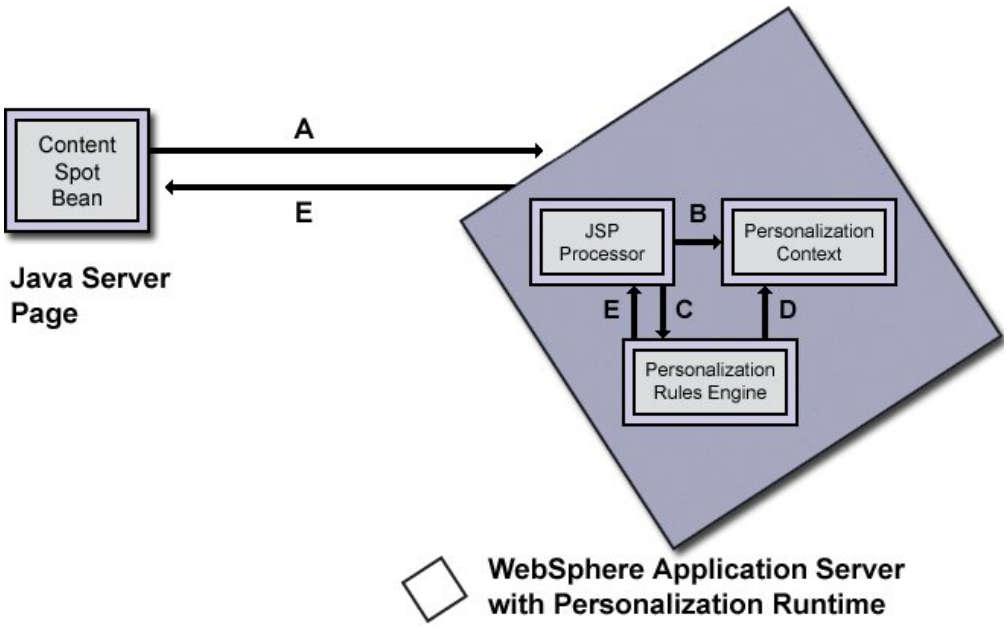
  After you implement the user and content data stores, you must enable the Personalization runtime environment to access the data stores. This task involves creating implementations of the Personalization APIs for accessing resources in the customer data store. You can either implement the `ResourceManager3` and `ResourceDomain3` interfaces manually or you can use the wizards provided with Rational Application Developer to generate resources for LDAP repositories. There are also implementations of the Portal user as a Personalization resource and a resource collection implementation for accessing the DB2 Content Manager.

How the rules engine works:

The rules engine processes and delivers the results of a rule execution to a content spot contained in a web page. The content spot is marked by a content spot bean, which is placed in either a JSP file or a servlet. The JSP file or servlet is then linked to the web page.

At run time, the content spot bean searches for the best rule to fill the spot with personalized data. The best rule to use depends on the campaigns that are set up to run. The rule that is mapped to the content spot in the campaign with the highest priority is run to personalize your web page.

Rule processing results in the return of a set of resources or a profiler. The returned resources or profiler can be used for generating a partial or entire web page. The figure illustrates how a rule is processed.



Step A: The process begins when a user requests a JavaServer Page (JSP) or servlet in which a content spot bean is embedded. The content spot bean contains the code to find and run the rule. When the web server receives the client request for the JSP or servlet, the web server passes the JSP or servlet request to the IBM WebSphere Application Server, which then starts its JSP or servlet processor.

The content spot bean can be embedded in the JSP by using any JSP editor. The following example code demonstrates how to embed and use a content spot bean in a JSP.

Note: IBM Rational Application Developer provides a visual JSP editor (Page Designer) that simplifies the development task and generates the JSP scriptlet coding for you.

The bean is embedded by using the JSP useBean tag. The HTTPServletRequest object is passed to the bean within the body of the useBean tag. The content spot bean properties are retrieved in the same manner as retrieving properties for any JavaBeans. The getRuleContent method of the contactsByLocation content spot bean determines the appropriate rule to run. This action is based on campaigns that have a rule that is mapped to the spot, runs the rule, and returns the results. The bean returns an array of Personnel objects.

Table 381. Example code that demonstrates embedding and by using a content spot bean in a JSP

```
<jsp:useBean id="contactsByLocation" class="GetContactsByLocation">
<% contactsByLocation.setRequest(request); %>
</jsp:useBean>
<%
try {
Personnel[] contentArray = contactsByLocation.getRuleContent();
Personnel theContent = contentArray[0]; // throws an exception if empty
%>
<TABLE border="1">
<TBODY> <TR>
<TD>Last Name</TD>
<TD>First Name</TD>
<TD>Role</TD>
<TD>Site</TD>
</TR>
<% for (int _i0 = 0; ; ) { %>
<TR>
<TD><%= theContent.getLastName() %></TD>
<TD><%= theContent.getFirstName() %></TD>
<TD><%= theContent.getRole() %></TD>
<TD><%= theContent.getSite() %></TD>
</TR>
<% _i0++;
try {
theContent = contentArray[_i0];
}
catch (java.lang.ArrayIndexOutOfBoundsException _e0) {
break;
}
} %>

</TBODY>
</TABLE>
<% }
catch (java.lang.ArrayIndexOutOfBoundsException _e0) {
} %>
```

Note: When you decide to add personalized content to a web page, all that is needed to develop the JSP is the content spot bean. The content spot can display personalized data of a single data type (for example, Personnel in this example). The web developer does not need to know where or how the content is retrieved only that personalized content of type Personnel is returned and it has a set of properties to be displayed.

Step B: When the embedded content spot bean is started, the processor passes the HTTP servlet request object to the content spot bean. The client request is used to initialize the RequestContext. The RequestContext provides access to the resources needed for rule processing. Those resources include collections, application objects, requests, and sessions. The RequestContext is applicable for the life of the HTTP request.

Step C: The Personalization rules engine find the appropriate rules in the IBM Java Content Repository and runs them

Step D: The rules engine processes the rule to obtain the results of the rules execution.

Step E: The rules engine returns the result of the rule execution to the content spot bean. The result can be a list of valid content from which a user can make a selection, a string, a Boolean value, or no results. The JSP scriptlet or servlet uses the rule result to derive specific web content for use in the generated web page. The web server forwards the page to the client.

Workload management:

Only one Portal Personalization engine can be installed on an application server. Consequently, there is one Personalization engine for each servlet engine. Personalization supports application server clustering, because each Personalization instance in the cluster shares the same IBM Java Content Repository. Therefore, each Personalization instance accesses the same customer data stores.

IBM WebSphere Application Server dynamic caching is used to cache resource instance and the results of queries used in rules. The dynamic cache shares expiration notification for the cache across clones in a cluster. Although Personalization uses the dynamic cache internally to cache the results of rules, it is also possible to use the WebSphere Application Server dynamic cache to cache the entire response from a JSP or servlet.

Note: Care must be taken when using Personalization and the dynamic cache of JSPs, servlets, or portlets. When using the dynamic cache to cache JSPs or servlets, the cache key must take into account all the inputs into any rules on that page. If rules on the page use an employee department attribute of a user resource, the cache key must be configured to contain this employee department attribute.

Using the Personalization APIs:

Personalization provides open APIs that enable the Personalization run-time environment and Rational Application Developer to access user and content data in customer data stores.

The Javadoc for Personalization APIs is available from the *PortalServer_root*/doc/Javadoc directory.

"Resource interface" on page 2410
The interface com.ibm.websphere.personalization.resources.Resource enables mapping your user model, content model, or other resource model to data in your customer data store. Get an overview of the methods defined by this interface that you must implement.

"APIs for multivalue properties" on page 2410
Use the com.ibm.websphere.personalization.resources.IMVResource interface to enable mapping multi-value properties. Use the com.ibm.websphere.personalization.resources.IMultiValueUtils interface for retrieving multi-value properties when those resources are in a database.

"General tips" on page 2411
View some general tips related to resource classloading when using the Personalization API.

"Personalization jar files that use public API" on page 2412
Learn about the .jar files that contain public APIs documented in Personalization JavaDoc information. Unless they are included in the JavaDoc documentation, classes are not public API even if they are included in these .jar files. When you use IBM Rational Application Developer and the Portal Personalization tools, these classes are added to your project classpath automatically and no further action is necessary.

Resource interface:

The interface com.ibm.websphere.personalization.resources.Resource enables mapping your user model, content model, or other resource model to data in your customer data store. Get an overview of the methods defined by this interface that you must implement.

Table 382. Explanation of methods used by com.ibm.websphere.personalization.resources.Resource

Method	Explanation
getId()	Returns the primary key or identifier for this resource. The primary key must be a string and unique within the resource collection. This method behaves in coordination with the findById method of the associated resource manager class such that the following method returns true: `manager.findById(resource.getId(), context).getId().equals(resource.getId())`
get(String name)	Returns the value of the specified dynamic property for this resource
keys()	Returns all (an Enumeration) of the dynamic property keys associated with this resource
put(String name, Object value)	Sets the specified dynamic property for this resource
remove(String name)	Removes the specified dynamic property

In addition to the methods listed in this table, your implementation must contain methods for setting and getting each fixed property in the data model. For example, if your user model includes a fixed property userName, you would define the methods getUserName() and setUserName().

Given an implementation of fixed properties, dynamic properties are optional. The get, keys, put, and remove methods may be implemented to perform no operation. If the content schema or resource attributes are known when the Java classes are developed, fixed properties are preferred. If the attributes of a resource are not determined until the resource is instantiated in the application server, dynamic properties are preferred. Dynamic and fixed properties may be used together in a single resource.

Rules support nested method calls. For example, a resource interface implementation could define a `user` object with a fixed property `employer` for which there is a fixed property `name`.

APIs for multivalue properties:

Use the com.ibm.websphere.personalization.resources.IMVResource interface to enable mapping multi-value properties. Use the com.ibm.websphere.personalization.resources.IMultiValueUtils interface for retrieving multi-value properties when those resources are in a database.

The com.ibm.websphere.personalization.resources.IMVResource interface extends the Resource interface and enables mapping multi-value properties. Implementing this interface is only required when an `IMultiValueUtils` implementation is used by the `ResourceManager3`. This is the default case for resources generated with the Portal tools, but may not be necessary for custom resources.

Table 383. Explanation of methods for mapping multi-value properties

Method	Explanation
setMultiValueUtils(IMultiValueUtils instance)	Saves the reference to the instance of MultiValueUtils. That reference is used when invoking the fillinMultiValueProperties method of the MultiValueUtils class. This method does not return output.
addMultiValuePropertyValue(String propertyname, Object propertyvalue)	Enables the `IMVResource` instance to add values for multi-value properties. This method does not return output.

The interface com.ibm.websphere.personalization.resources.IMultiValueUtils is a set of utilities for retrieving multi-value properties when those resources are in a database. This class supports mapping multi-value properties to the corresponding database tables.

Table 384. Explanation of methods for retrieving multi-value properties

Method	Explanation
convertSQLtoMultiValue(String query)	Converts the SQL query string for `ResourceManager3` classes that need to search on single value and multi-value properties. Returns an enumeration that contains the converted where clause followed by one or more elements that contain the table names that are involved in the query.
populateJoinedProperties(`IMVResource` theResource, RequestContext context)	Retrieves the value for all multi-value properties and calls the addMultiValuePropertyValue method of `IMVResource`. This method does not return output.
populateJoinedProperty(IMVResource theResource, String propertyName, RequestContext context)	Retrieves the value for all single value properties and calls the addMultiValuePropertyValue method of `IMVResource`. This method does not return output.
syncJoinedProperty(IMVResource theResource, String propertyName, List values, RequestContext context)	Populates the multi-value property into the resource repository.

General tips:

View some general tips related to resource classloading when using the Personalization API.

Resource classloading

- The recommended location for generated content spot classes and resource collection classes is in a WebSphere Application Server shared library. When a rule is executed, Personalization uses the class loader of the content spot to load any resource collections or application objects required for that rule. If you are using the default `com.ibm.websphere.personalization.ContentSpot` class to execute rules, then that class loader is the Personalization shared library class loader. In this scenario, your resource collections and application objects must be visible to the class loader of the `com.ibm.websphere.personalization.ContentSpot` class. With a generated

content spot class, you have the flexibility to place this class and any associated resource collections directly in a web module or portlet application, but they must also be available to the Personalization portlets. Whichever mechanism you use for content spots, the best way to ensure that your resource collection classes are available is to put them in a shared library on the application server. By default, Personalization is shipped with a shared library that may be used for resource collections. Place your resource collection classes in the *wp_profile_root*/PortalServer/pzn/collections directory and reload the server.

- In previous versions of Personalization, the user interface classes were loaded dynamically out of other web applications, out of databases, and out of other paths entered by the user. In the current version of Personalization, the content spot and resource collections must be on the classpath for the Personalization portlets. The best way to achieve this is through use of a shared library.
- If you use the Personalization resource wizard in Rational Application Developer to create the resource classes in a Web or portlet project, those generated classes will be deployed in the Web module and not be available to the Personalization portlets. You will have to put these classes on a shared library and make that shared library available to the Personalization portlets.
- Classes in a shared library are only reloaded when the application server is reloaded. Classes in a Web module are reloaded when the Web module is reloaded.
- Ensure the global uniqueness of the class names by using package names.
- In a cluster of application servers, be sure to copy your content spot and resource classes to each application server in the cluster.

Personalization jar files that use public API:

Learn about the .jar files that contain public APIs documented in Personalization JavaDoc information. Unless they are included in the JavaDoc documentation, classes are not public API even if they are included in these .jar files. When you use IBM Rational Application Developer and the Portal Personalization tools, these classes are added to your project classpath automatically and no further action is necessary.

If you are compiling your application outside of Rational Application Developer and you are using Personalization APIs, you may need to add the following classes to your classpath when compiling your application. These .jar files are located in *PortalServer_root*/pzn/prereq.pzn/lib:

- pznquery.jar
- pznresources.jar
- pznruntime.jar
- pznwpsruntime.jar

Generic query framework:

The generic query framework enables resource collection developers to convert a property-based query object into a language specific executable query string. It contains query component classes, and builder and callback interfaces.

- Query framework classes, such as the Query class, Predicate class, and Condition class provide an object representation of a query.
- Builder and callback interfaces together facilitate a query string generation mechanism that delegates operations to domain specific callbacks for property-to-attribute resolution and query string syntax conversion.

"Using the Generic Query Framework"
The resource engine constructs a generic query object and passes it to domain developers through the ResourceDomain3 interface method findResourceByQuery(). Get an overview of how this query object can be converted into a meaningful domain query string.

Using the Generic Query Framework:

The resource engine constructs a generic query object and passes it to domain developers through the ResourceDomain3 interface method findResourceByQuery(). Get an overview of how this query object can be converted into a meaningful domain query string.

The developer can take one of the following approaches to convert this query object into a meaningful domain query string.

1. Walk through the query object.

   Note: The com.ibm.websphere.query.base.Query class contains query components that the developer can cover to generate domain specific query string. For detailed information on query hierarchy and components, see the Portal Personalization API documentation.

2. Use a system provided builder callback.

   There are nine builder callbacks:

   a. Microsoft SQL Server Enterprise Edition: (com.ibm.websphere.query.callbacks.SqlSelectQueryCallback)

      Note: Although the generic SQL callback can be used for most SQL Server databases, there are minor differences in SQL syntax and availability of functions which require specific subclasses for some databases.

   b. IBM DB2 Universal Database Enterprise Server Edition: (com.ibm.websphere.query.callbacks.DB2SqlSelectQueryCallback)

   c. IBM DB2 Universal Database for z/OS: (com.ibm.websphere.query.callbacks.DB2390SqlSelectQueryCallback)

   d. IBM DB2 Universal Database for i: (com.ibm.websphere.query.callbacks.DB2400SqlSelectQueryCallback)

   e. Apache Derby: (com.ibm.websphere.query.callbacks.DerbySqlSelectQueryCallback)

   f. Oracle Enterprise Edition: (com.ibm.websphere.query.callbacks.OracleSelectQueryCallback)

   g. LDAP: (com.ibm.websphere.query.callbacks.LdapSelectQueryCallback)

      Note: The LDAP callback supports a set of function common to many LDAP repositories. Users may subclass this callback to support more advanced vendor specific functions.

   Property resolution and query syntax conversion are handled in the callbacks. The developer can prepare a property mapping hash table and use it with one of the previous callbacks to build the executable query string. Here is the sample code for SQL query string generation:

   ```
   String s=q.buildString(new SqlSelectQueryCallback(h));
   ```

   where *q* is a query object, and *h* is a property mapping hash table.

   For detailed information on these builder callbacks, see the Personalization API documentation.

3. Develop and use a domain specific builder callback.

   If the system provided builder callbacks do not satisfy resource domain requirements, a domain specific builder callback can be created and used as long as it implements ISelectQueryCallback. The developer can decide the mechanisms to interpret properties and derive the proper query syntax in their own callbacks. The code would look like:

   ```
   String s=q.buildString(new MySelectQueryCallback(myParameter));
   ```

   where *q* is a query object, and *MySelectQueryCallback* is the custom builder callback that takes *myParameter* as parameter.

Request context interface:

This is the interface used to access various attributes for rules. For HTTP contexts, it provides access to the HttpRequest and HttpSession attributes. For non-HTTP contexts, it provides the same interface to a surrogate for the request and session.

The request context, and any request values accessed via the request context, are only valid for the life of the request.

The Request Context string is used in caching lookups. The lookup is created by using a user-specified string combined with query values as the lookup key. The user-specified string should uniquely represent the current Request Context. This key is stored under ibm.wcp.cache.user.key as a request attribute or as a session attribute with the request attribute taking precedence.

Accessing the Request Context

The Request Context provides the Personalization rules engine with the data and environmental information needed for rules processing. In other words, the Request Context contains all the input to execute Personalization content spots and rules. This includes simple inputs like request and session data, and more advanced input like the user object.

You can access the Request Context from a content spot by first using the setRequest method of the content spot to back the content spot with a request, and then by calling getContext to retrieve the context. You can also use the Request Context to call directly into the ResourceDomain3 and ResourceManager3 APIs.

The Request Context allows you to retrieve session, request, portlet attribute, date, cookie, and other data and environmental information from the resource layer.

The Request Context includes:

- Session

  The session information identifies the HttpSession object that is associated with the current user.
- Request date

  This request date is the date the HTTP request was received. This information supports rules that have date-dependent actions.

Since Personalization uses the Request Context to contain all the rule input, the Request Context must be set onto the content spot prior to rule execution. The code with the content spot's useBean tag must be similar to:

```
<jsp:useBean id="gold_promo_bean"
class="yourco.goldpromo.BannerSpot" />
<% gold_promo_bean.setRequest (request); %>
```

In the previous section, the jsp:useBean tag constructs the yourco.goldpromo.BannerSpot class and stores an instance of that class into the local variable gold_promo_bean. The next line calls setRequest to put the HttpServletRequest or PortletRequest onto the newly constructed content spot bean. The content spot then implicitly constructs a Request Context which is backed by the given HttpServletRequest or PortletRequest. This Request Context then provides access to that request's parameters and attributes and attributes of the session through the com.ibm.websphere.personalization.RequestContext interface.

In some cases, it may be useful to call into a content spot without having access to an HttpServletRequest or PortletRequest. The interface com.ibm.websphere.personalization.PznRequestObjectInterface can be used in these situations. A implementation of this class called com.ibm.websphere.personalization.PznRequestObjectImplementor is provided for convenience.

Sample Personalization resources XML file:

Use the sample file `ExportFromServlet.xml` as a reference for coding other Personalization actions.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE ibm-websphere-personalization>
   <ResourceCollection action="create" name="News">
     <ResourceType>Content</ResourceType>
     <ResourceManagerClass>com.mycompany.personalization.ContentResourceManager</ResourceManagerClass>

     <ResourceDomainClass>com.mycompany.personalization.ContentResourceDomain</ResourceDomainClass>
     <ResourceClass>com.mycompany.personalization.Content</ResourceClass>
  </ResourceCollection>
  <SecurityMappings>
    <collection EnableSecurity="false" name="News"></collection>
  </SecurityMappings>
</ibm-websphere-personalization>
```

Content spot exits:

Content spot exits provide the ability to alter the default flow of processing of content spots, making it possible in the runtime environment to override the rule to process, the current user, and the results of rule processing. Instances of the same exit class are instantiated for all content spots. The exit class interface name is public interface RuleExit.

The content spot exit class can provide the following actions:

1. Access request and session information
2. Set information in the personalization context, including changing the user
3. Get the campaign name
4. Get the rule name to be executed for campaign
5. Override and specify the rule to be executed
6. Bypass rule processing; no rule is processed.

After rule processing, the content spot exit class can provide the following actions:

1. Add result items

2. Remove result items
3. Completely replace result items

RuleExit methods:

void aboutToExecuteRule(RuleTrigger contentSpot, RequestContext requestContext)
Get the results of the rule execution.

Object[] getFilteredResults(RuleTrigger contentSpot, RequestContext requestContext, Object[] originalResults)
Exit to allow for changing the results of the rule execution. originalResults: the original result array is supplied to the exit. filteredResults: the exit should return the original array if no changes are needed

RuleTrigger methods:

String getCampaignName()
Get the campaign name for the content spot.

String getRuleName()
Get the name of the rule to be executed in this spot. Can return null if the name is not yet established.

void setRuleName(String ruleName)
Set the name of the rule to be executed in this spot. If the name is set to null, no rule will be executed.

void setRuleExit(RuleExit ruleExit instance)
Set the rule exit for this particular content spot instance.

The `RuleTrigger` also supports a static method that contains an instance of `RuleExit` that is set up at initialization time. You can implement `setRuleExit(RuleExit)` on a per-content spot basis to override only the content spots that you specify.

The class name of the default `RuleExit` implementor is read from the PersonalizationService.properties file.

Example Usage Scenario

1. Specify a `RuleExit` class in PersonalizationService.properties, as shown:
   ```
   rulesEngine.defaultRuleExit=com.ibm.websphere.personalization.RuleExitSample
    ...
   ```
2. At startup time, the Personalization run-time environment creates an instance of that class (`aRuleExit` in this scenario) and caches it in a private `RuleTrigger` static method
3. As each content spot is triggered, the Personalization rule engine determines the rule name to be used
4. `aRuleExit.aboutToExecuteRule()` is invoked, passing the spot and the request context
5. `aRuleExit` has several options:
   - Access request context information (includes http request and session)
   - Get the campaign and rule names
   - Specify a request user ID
   - Change the rule name to be executed
   - Bypass the rule by setting the rule name to null

6. The rule is executed
7. `aRuleExit.getFilteredResults()` is invoked; the rule exit modifies results as required, then returns the updated set
8. The updated results are stored

Resource cache:

Personalization uses the WebSphere Application Server Dynamic Cache service to cache the results of select rules and to cache the rules themselves in a DistributedMap. When publishing, importing or saving rules, the cache is flushed automatically to ensure that the site is current.

Configuration settings available for caching rules

The `PersonalizationService.properties` file contains cache control settings. The following table summarizes the configuration settings available for caching.

Table 385. PersonalizationService.properties properties and descriptions. Each PersonalizationService property is listed by name and described.

Property	Description
rulesEngine.cache.enabled	Global setting to disable all caching. Setting to *false* will override any collections that are individually set to be cached.
rulesEngine.cache.jndiName	The Dynamic Cache DistributedMap to use, as specified by its JNDI name.
rulesEngine.cache.maxEnumSize	Although the DistributedMap may be configured in the WebSphere Integrated Solutions Console to limit the maximum number of entries in the cache, the collection of resources that is returned for each rule is counted as one entry in the cache. When a rule returns a very large number of results, caching the results may result in extra memory overhead. Therefore, when the result set of a rule exceeds the number specified in this property, it will not be cached.
rulesEngine.cache.timeout	The number of seconds before an entry in the cache expires.
rulesEngine.cache.priority	The priority of a cache entry, relative to other entries in the same DistributedMap.
rulesEngine.cache.enabled.*collectionName*	The same as **rulesEngine.cache.enabled**, except that this property applies to a specific resource collection. The variable *collectionName* is the fully qualified path to the resource collection in Personalization. For instance, the *GeneralNews* resource collection that is included in the sample folder called `PznDemo` has the *collectionName* of `/PznDemo/`*GeneralNews*.
rulesEngine.cache.jndiName.*collectionName*	The same as **rulesEngine.cache.jndiName**, except that this property applies to a specific resource collection.

Table 385. PersonalizationService.properties properties and descriptions (continued). Each PersonalizationService property is listed by name and described.

Property	Description
rulesEngine.cache.maxEnumSize.*collectionName*	The same as **rulesEngine.cache.maxEnumSize**, except that this property applies to a specific resource collection.
rulesEngine.cache.timeout.*collectionName*	The same as **rulesEngine.cache.timeout**, except that this property applies to a specific resource collection.
rulesEngine.cache.priority.*collectionName*	The same as **rulesEngine.cache.priority**, except that this property applies to a specific resource collection.

Caching business rules for resources

You might need to programmatically flush the Personalization cache, for example when a resource is updated outside of Personalization rules through some other application. A programming interface is provided to flush the cache. Since the timeout interval for the cache can be specified in the properties file, in many cases it may be adequate to wait for the cache timeout before updates are seen. The class com.ibm.websphere.personalization.resources.cache.CacheManager can be used to invalidate the cache for a particular resource, a particular resource collection, or the entire cache. Personalization uses this class internally to flush the cache when updates occur.

Flushing the cache for a particular resource may require that all cached queries be flushed. Flushing the cache on a collection may flush the cache for all collections using the same dynamic cache map. When the application frequently flushes the cache for a particular collection, isolating that collection in its own cache map through the use of the **ruleEngine.cache.jndiName**.*resourceCollectionName* property will result in better cache utilization.

Caching occurs before any rule exits are called.

For more information about using the DistributedMap and DistributedObjectCache interfaces for the dynamic cache, refer to the IBM WebSphere Application Server Information Center.

Related tasks:

Using the DistributedMap and DistributedObjectCache interfaces for the dynamic cache

Programmatically starting rules:

All types of rules can be accessed programmatically within a Java application. For example, a profiler can be used to determine the behavior that an application must exhibit depending on the current user, or an action can return content to your application for further processing before the content is displayed. Rules are mapped to content spots, and because a content spot is an implementation of a JavaBeans, it can be programmatically declared and implemented.

To programmatically start a rule, follow these steps:

1. Instantiate the bean. If the class name of your content spot was ProfilerSpot, you would instantiate the bean by using one of the following options:

   ```
   com.ibm.websphere.personalization.ContentSpot contentSpot =
     new com.ibm.websphere.personalization.ContentSpot("ProfilerSpot");
   ```

   or

   ```
   ProfilerSpot contentSpot = new ProfilerSpot();
   ```

2. Call the method `setRequest()` and pass the HttpServletRequest object or an object that implements PznRequestObjectInterface. This action makes the current information that is stored in the request object to be known to the Personalization runtime Engine and the Resource Engine.

   ```
   contentSpot.setRequest(request);
   ```

3. Trigger the rule and, if applicable, get the content from the rule. Use one of the following methods, depending on the type of rule:
   - Select content actions, bindings, and recommendation actions are mapped to content spots and return content from a resource.
     - `getRuleContent()` - returns an array of results
     - `getRuleContent(int which)` - returns the resource at the index
   - Profilers are mapped to empty content spots, which do not declare a return type.
     - `boolean isProfiledAs(string value)` - returns true or false depending on whether the string passed to the method matches a profile that is given to the user
     - `String getProfile(integer value)` - returns the profile in the location that is specified by the integer passed

       A user can have more than one profile. For example, a user might fit profiles that are named "young," "hip," and "sporty"; when the user is looking for the profile at location 0, "young" is returned.
     - `String[] getProfiles()` - returns an array of profiles.

       For example, if a user is in profiles "young," "hip," and "sporty," this method returns an array of the profiles.
     - `boolean isProfiledAsAll(String[] profiles)` - returns True or False depending on whether all the profiles match all the profiles in the list of profiles that are passed to the method
     - `boolean isProfiledAsAny(String[] profiles)` - returns True or False depending on whether the profile is in the list of profiles that are passed to the method
   - Update actions and email actions are mapped to empty content spots.
     a. `trigger()` - runs the rule

Rule Exception Handling in the run-time environment:

The default method of error or exception handling within the Personalization run-time environment is for the engine to print out a trace error to the application server's stdout log. Using an exception handling utility, it is possible to specify the type of output (error message or stacktrace), the output log file to use (stdout or stderr), and whether the exception should be rethrown to the JSP. The additional exception handling capabilities can be set on a per-request basis or globally.

Per-request

To set the scheme on a per-request basis, include the following code within a content spot on a JSP:

```
request.setAttribute(RuntimeUtils.PZN_RUNTIME_EXCEPTION_HANDLING_KEY,
RuntimeUtils.HANDLING_SCHEME);
```

Where HANDLING_SCHEME is one of the options specified for the setRuntimeExceptionHandlingScheme method described in the following section.

This method will only change the exception handling scheme for rules running on that JSP.

Global

To set the same scheme for every rule running on a server, execute the following code:

```
RuntimeUtils.setRuntimeExceptionHandlingScheme(RuntimeUtils.HANDLING_SCHEME);
```

To reset the global exception handling scheme, call:

```
RuntimeUtils.resetRuntimeExceptionHandlingScheme();
```

Note: Restarting the application server will automatically reset the exception handling scheme.

You can also change the global behavior of the server by changing the following value in PersonalizationService.properties:

```
rulesEngine.exceptionHandling=logMessage_stdout
```

Note: To make any changes effective, you must restart the server.

RuntimeUtils methods

public static void setRuntimeExceptionHandlingScheme(String value)

Sets the exceptions handling scheme to the specified value. Options for value include:

- RuntimeUtils.IGNORE
- RuntimeUtils.LOG_MESSAGE_STDOUT
- RuntimeUtils.LOG_MESSAGE_STDERR
- RuntimeUtils.LOG_MESSAGE_STDOUT_AND_RETHROW
- RuntimeUtils.LOG_MESSAGE_STDERR_AND_RETHROW
- RuntimeUtils.LOG_STACKTRACE_STDOUT
- RuntimeUtils.LOG_STACKTRACE_STDERR
- RuntimeUtils.LOG_STACKTRACE_STDOUT_AND_RETHROW
- RuntimeUtils.LOG_STACKTRACE_STDERR_AND_RETHROW
- RuntimeUtils.LOG_MESSAGE_AND_STACKTRACE_STDOUT
- RuntimeUtils.LOG_MESSAGE_AND_STACKTRACE_STDERR
- RuntimeUtils.LOG_MESSAGE_AND_STACKTRACE_STDOUT_AND_RETHROW
- RuntimeUtils.LOG_MESSAGE_AND_STACKTRACE_STDERR_AND_RETHROW
- RuntimeUtils.RETHROW_EXCEPTION

Note: Settings with RETHROW will pass the exception to the screen and are recommended for use within a testing environment only.

public static void resetRuntimeExceptionHandlingScheme()
Resets the current exception handling scheme to LOG_MESSAGE_STDOUT.

public static String getRuntimeExceptionHandlingScheme()
Returns the current exception handling scheme.

Exception Handling Process

When an exception occurs, if the code can continue, it will do so while logging the exception. If not, the exception is wrapped in a PersonalizationException which is passed to RuleTrigger. RuleTrigger looks for a request override for the exception handling scheme, processes the scheme, and returns to the JSP. Any subclasses of Throwable might be wrapped in a PersonalizationException.

Tracing

To trace the runtime classes, enable trace for `com.ibm.websphere.personalization.*=all`. To trace the authoring portlet classes, enable trace for `com.ibm.wps.caf.*=all`.

Social Media Publisher

The Social Media Publisher for Web Content Manager is an extension to Web Content Manager that allows businesses to promote their web content on social networks, and provide some basic statistics about the promoted content.

Requirements

- WebSphere Portal version 8.0.0.1 or later, or Web Content Manager version 8.0.0.1 or later.
- A social media service:
  - IBM Connections version 3.0.2, version 4.0 CF2, version 4.5, or version 5.0.
  - Facebook (API level as at September 2012)
  - LinkedIn (API level as at September 2012)
  - Twitter API level v1.1

"Overview of the Social Media Publisher" on page 2422
The Social Media Publisher for Web Content Manager is used to manage social media posts for published content items and, if configured, draft content items.

"Installing the Social Media Publisher" on page 2423
Follow these steps to install the Social Media Publisher on your authoring server, and then on any servers that subscribe from your authoring server.

"Social network configuration" on page 2425
Your social network configuration settings are stored in separate content items based on the **Social Network Configuration** authoring template that is supplied with the Social Media Publisher.

"The social network information table" on page 2437
When you create a content item by using a content authoring template that is mapped to a social network configuration document, an element that is named **Social Network Information** is displayed on the content item.

"Social Media Workflow Actions" on page 2437
A set of social media workflow actions are supplied to with the Social Media Publisher and are found in the **Social Configuration** library. These actions can be added to workflows to run social media actions as part of a workflow.

Overview of the Social Media Publisher

The Social Media Publisher for Web Content Manager is used to manage social media posts for published content items and, if configured, draft content items.

- The Social Media Publisher supports IBM Connections, Facebook, LinkedIn and Twitter.
- The Social Media Publisher supports both manual and automatic social media posts, and also manages the life-cycle of social media posts.
- Social media posts are only applied to published content and, if configured, draft content items.
- The Social Media Publisher does not include or manage the social media "badges" you can add to websites to allow end-users to link or share web content to their social network followers.

Table 386. Messages supported by each social network

Social Network	Message type	Statistics supported	Message URL addressable	Supports end user tracking	Supports untrack	Supports delete
IBM Connections	Blog post	Like, comment count	Yes	No	Yes	Yes
IBM Connections	Message board post	Comment count	Yes	No	Yes	Yes
IBM Connections	Wiki post	Like, comment count	Yes	No	Yes	Yes
Facebook	Page wall post	Like, comment count	Yes	Yes	Yes	Yes
Facebook	Profile wall post	Like, comment count	Yes	Yes	Yes	Yes
LinkedIn	Network update	None	No	No	Yes	No
LinkedIn	Share	None	No	No	Yes	No

Table 386. Messages supported by each social network (continued)

Social Network	Message type	Statistics supported	Message URL addressable	Supports end user tracking	Supports untrack	Supports delete
Twitter	Tweet	Reshare count	Yes	Yes	Yes	Yes

Note: Page notes have been deprecated by Facebook.

Before you begin

You should become familiar with your social media of choice and be aware of limitations such as:

- throttle limits
- maximum posts per timeframe

Installing the Social Media Publisher

Follow these steps to install the Social Media Publisher on your authoring server, and then on any servers that subscribe from your authoring server.

Before you begin

Note: If you migrated from a WebSphere Portal version 7.0 or Web Content Manager version 7.0 server that was already using the Social Media Publisher, you also need to run these steps on the migrated system to enable the Social Media Publisher. All your data from your version 7.0 system is maintained.

Procedure

1. Ensure that you enable the following options correctly:
   a. That the **WasPassword** and **PortalAdminPwd** passwords are set in the `wkplc.properties` file.
   b. That the **jcr.DbPassword** password is set in `wkplc_dbdomain.properties` file.
   c. That a proxy server is configured if your server is behind a proxy.
2. Edit *wp_profile_root*`/PortalServer/wcm/social/smp.properties` file and to ensure that the configuration is correct for the current server or cluster node.

   Note: The parameter settings in `smp.properties` are case-sensitive.
3. Run the following registration command from the *wp_profile_root*`/ConfigEngine` directory:

   Windows
   ```
   ConfigEngine.bat register-wcm-social
   ```
   Linux
   ```
   ./ConfigEngine.sh register-wcm-social
   ```
   IBM i
   ```
   ConfigEngine.sh register-wcm-social
   ```
4. Run the following deployment command from the *wp_profile_root*`/ConfigEngine` directory:

   Windows
   ```
   ConfigEngine.bat deploy-wcm-social
   ```
   Linux
   ```
   ./ConfigEngine.sh deploy-wcm-social
   ```

IBM i `ConfigEngine.sh deploy-wcm-social`

5. If you are publishing to an IBM Connections server, then import the SSL certificate from the IBM Connections server into the WebSphere Portal server. See the WebSphere Application Server documentation for instructions on importing certificates.

   Note: If your server is located behind a firewall, you might also need to import certificates for Facebook, LinkedIn, and Twitter. For more information, see "Social media certificates" on page 2440 for further information.
6. Restart the server.
7. Add the **Social Configuration** library to all syndication relationships. Repeat these steps for each subscriber server in your environment. The settings that are defined for **Shared Social database properties** in the `smp.properties` file must be the same as the settings defined on the syndicator server.

   Note: The parameter settings in `smp.properties` are case-sensitive.

   When you install on a server other than the authoring server, if your JCR database user name or password is different from the authoring server, then run the following command from the *wp_profile_root*`/ConfigEngine` directory:

   Windows
   ```
   ConfigEngine.bat action-set-wcm-social-datasource-credentials
   -DWcmSocialDSNewUserName=AUTH_DB_USERNAME
   -DWcmSocialDSNewPassword=AUTH_DB_PASSWORD
   ```

   Linux
   ```
   ./ConfigEngine.sh action-set-wcm-social-datasource-credentials
   -DWcmSocialDSNewUserName=AUTH_DB_USERNAME
   -DWcmSocialDSNewPassword=AUTH_DB_PASSWORD
   ```

   IBM i
   ```
   ConfigEngine.sh action-set-wcm-social-datasource-credentials
   -DWcmSocialDSNewUserName=AUTH_DB_USERNAME
   -DWcmSocialDSNewPassword=AUTH_DB_PASSWORD
   ```
8. If your server contains virtual portals, you must also run the following task for each virtual portal on your server:

   Windows
   ```
   ConfigEngine.bat import-wcm-social-data
   -DVirtualPortalHostName=VirtualPortalHostName
   -DVirtualPortalContext=VirtualPortalContext
   ```

   Linux
   ```
   ./ConfigEngine.sh import-wcm-social-data
   -DVirtualPortalHostName=VirtualPortalHostName
   -DVirtualPortalContext=VirtualPortalContext
   ```

   IBM i
   ```
   ConfigEngine.sh import-wcm-social-data
   -DVirtualPortalHostName=VirtualPortalHostName
   -DVirtualPortalContext=VirtualPortalContext
   ```
9. Restart WebSphere Portal.
10. Repeat these steps on every server and cluster node.

Additional installation and configuration

- When you import or migrate a Social Media Publisher library, you must also migrate credential vault data by using the XML configuration interface. See the WebSphere Portal product documentation for further details.
- Two credential vault slots are required for Social Media Publisher configuration:

- A credential vault slot that is called **socialPostUser** is required for post workflow actions. See "Social Media Workflow Actions" on page 2437. The **socialPostUser** slot is not displayed in the list of available vault slots when you create a Social Network Configuration document.
- You must also set up a credential vault for each social network. This action is selected when you create a social network configuration document. See "Creating a social network configuration document."

Both of these credential vault slots must be shared credential vault slots and store the admin user login information of your social network.

- Anonymous access to web content libraries, content items, and images are required for posting to external social networks. Single signon can also be enabled for IBM Connections.
- The Social Media Publisher uses the built-in JMS function of Web Content Manager to monitor and respond to events that are occurring within a system. When the Social Media Publisher is running within a cluster, each server needs to be configured to match the WebSphere Application Server JMS policy type in effect. The `jms.processRemoteMsgs global setting` must be set to either true or false depending on the WebSphere Application Server JMS policy type. For more information, see "Global configuration settings" on page 2433 for further information.
- When you install the Social Media Publisher into a cluster that has a web-server in front of it, add the following Web Content Manager configuration setting. The settings allow the Social Media Publisher to make loop back requests to the current server:

  ```
  wcm.local.host.port=LOCAL_PORTAL_PORT
  ```

  Use the WebSphere Integrated Solutions Console to add this setting to the **WCM WCMConfigService** service. `LOCAL_PORTAL_PORT` is the local WebSphere Application Server port for WebSphere Portal. The default port is 10039.

Social network configuration

Your social network configuration settings are stored in separate content items based on the **Social Network Configuration** authoring template that is supplied with the Social Media Publisher.

"Creating a social network configuration document"
To create a social network configuration document, you create a content item that uses the **Social Network Configuration** authoring template.

"Global configuration settings" on page 2433
Although the Social Media Publisher uses social network configuration documents to specify most of its configuration properties, it also uses a global settings document for configuring server-wide options.

"Adding the social information table to an authoring template" on page 2437
If the **Automatically add social information element** setting on a social network configuration document is disabled, you must manually add the social information element to any authoring template you want to use the social media publisher on.

Creating a social network configuration document:

To create a social network configuration document, you create a content item that uses the **Social Network Configuration** authoring template.

About this task

The configuration settings for each social network you want to post to are stored in separate content items. These content items are never displayed on a website and are only used to store configuration settings. To create a new social network configuration document:

Procedure

1. Create a content item that uses the **Social Network Configuration** authoring template. This template is in the **Social Configuration** library.
2. Type a name and display title.
3. Enter the name of your production domain in the **Site Domain** field. For example: `www.ibm.com`
   - If this site is a virtual portal, then the site domain must be either the virtual portal host name or a public domain name that resolves to the virtual portal host name.
   - If your virtual portal does not define a virtual portal host name, then the site domain field can also be set by using the following format: `host/portal_context/vp_url_context`. For example: `localhost/wps/portal/myvp`
   - When you post content to Facebook, LinkedIn and Twitter, the site domain must be internet accessible, otherwise your social media posts might not function correctly.
   - If a web server is not being used, then the domain must include the portal port. For example: `myserver:10039`.
   - If the domain is not accessible by using port 80, then the domain must also include the HTTP port.
4. In the **Social Network Information** section, select a social network and enter configuration settings for the chosen network.
5. When the authentication settings are specified, click the **Authorize** button.
6. Map the social network configuration document to one or more content authoring templates by clicking **Add** under the **Mapped Authoring Template** section.
   - These templates should be authoring templates that are associated with content types you would like to post to social networks.
   - You can map multiple social network configuration documents to the one authoring template, and multiple authoring templates to the one social network configuration document.
   - Select **Automatically add social information element** to automatically add the **Social Information** element to each new content item created by using a mapped authoring template.
7. Specify extra settings:

   Display social action buttons
   Select which social action buttons are displayed in the social media table.

   Action to perform on document delete
   When an item is deleted, you can choose to either delete the item only, or delete the item and also delete any social media posts related to that item.

   Configuration enabled
   This is enabled by default. If disabled, social media publishing is

stopped for this social media configuration, and this social media configuration is hidden from the social information table in content items, and hidden from selection dialogs in social media workflow actions.

Enable Posting for draft documents
If enabled, social media posts are created for draft items and published items. This setting is disabled by default. If enabled, social media posts can be sent from draft items, either by using the social media table or social media workflow actions, in the same way as published items.

Show enabled social actions in read mode
When enabled, the functions available in the social information table on content forms can be used in both read and edit mode.

Link Mode
This option determines the type of links that are used in social media posts depending on whether your content is published in a portlet, or servlet.

Language
This option is used to select the language that is used to render social media posts.

"Defining social network settings for IBM Connections"
Complete these steps to set up a social network connection for IBM Connections.

"Configuration settings for Facebook" on page 2428
Complete these configuration parameters to setup a social network connection for Facebook.

"Defining social network settings for LinkedIn" on page 2430
Complete these configuration parameters to set up a social network connection for LinkedIn.

"Defining social network settings for Twitter" on page 2432
Complete these configuration parameters to set up a social network connection for Twitter.

Defining social network settings for IBM Connections:

Complete these steps to set up a social network connection for IBM Connections.

Before you begin

Before you begin you must have already created a new credential vault from the WebSphere Portal administration view where:

- Your IBM Connections user name is specified as the shared user ID.
- Your IBM Connections password is specified as the shared password.

About this task

When you create a social network configuration document for IBM Connections:

Procedure

1. Select **IBM Connections** as the social network.
2. Define authentication settings for the social network:
   a. Select the **Credential Vault** that contains your IBM Connections account credentials.

b. Type the name of the Connections server to connect to.
c. Click **Authorize** to bind the IBM Connections account credentials to this configuration.

3. Select a message type:

Blog post:

a. Select the name of the Blog.
b. Enter a default name and message template for Blog posts. A predefined message is included as a guide. For example:

Name: This is posted as text.

```
[Property field="title" context="current" type="content" format="length:100"]
```

Message:
This is posted as HTML.

```
[Element context="current" type="content" key="Message" format="length:100"]
See more: [URLCmpnt context="current" type="content" mode="standalone"
start="<a href='" end="'>Link</a>"]
```

Message board post:

a. Enter a default message template for message board posts. A predefined message is included as a guide. For example:

Message:
This is posted as text.

```
[Element context="current" type="content" key="Message" format="length:100"]
See more: [URLCmpnt context="current" type="content" mode="standalone"]
```

Wiki post:

a. Select the name of the Wiki.
b. Enter a default name, and message template for Wiki posts. A predefined message is included as a guide. For example:

Name: This is posted as text.

```
[Property field="title" context="current" type="content" format="length:100"]
```

Message:
This is posted as HTML.

```
[Element context="current" type="content" key="Message" format="length:100"]
See more: [URLCmpnt context="current" type="content" mode="standalone"
start="<a href='" end="'>Link</a>"]
```

Configuration settings for Facebook:

Complete these configuration parameters to setup a social network connection for Facebook.

Before you begin

Before you begin you must register an application in order to obtain a username and password that grants access to the Facebook API. To register a new application that the WCM Social Media Publisher can use:

1. Go to https://developers.facebook.com/apps
2. Click **Create new App**.
3. A form will open. Enter values for the following parameters:

Display Name:
This is the name of your application that will be displayed at the end of each post. For example, your company name.

Namespace:
This is an optional name that is used to access Facebook Insights information. It is recommended that a unique name is used for each application you setup.

Category:
Select a category that matches your business type. If unsure select **Apps for Pages**.

4. Click **Create App**.
5. A configuration screen for your application is displayed. Select the **Settings** option and enter the following:

   App Domain:
   Enter a comma separated list of domains or server addresses that you want to use to bind this application to individual Facebook accounts. You will only be able to authorize against this application from one of the domains listed here.
6. Click the **Add Platform** button and select **WebSite**.
7. Set the **Site URL** and **Mobile Site URL** fields to your website. For example: http://www.ibm.com
8. Click **Save Changes**.
9. The **App ID/API Key** and **App Secret Key** are now displayed.

You must then create a new credential vault from the WebSphere Portal administration view where:

- The **App ID/API Key** is specified as the shared user ID
- The **App Secret Key** is specified as the shared password.

About this task

When you create a social network configuration document for Facebook:

Procedure

1. Select **Facebook** as the social network.
2. Define authentication settings for the social network:
   a. Select the **Credential Vault** that contains your Facebook application credentials.
   b. Click **Authorize** to bind the credentials to a specific social network account.
3. Select a message type:

   Note: It is not recommended to reference rich text elements or HTML elements in any fields that do not support HTML.

   Page wall post:
   a. Select a page.
   b. Enter a default name, description, image, caption, and message template. Predefined tags for the image, caption and message are included as a guide. For example:

      Name: This is posted as text.

      ```
      [Property field="title" context="current" type="content" format="length:100"]
      ```

      Description:
      This is posted as text.

```
[Property field="description" context="current" type="content"
format="length:100"]
```

Image:
This is posted as a URL.
```

This is posted as text.
```
[Element context="current" type="content" key="Message" format="length:100"]
```

Profile wall post:

a. Select the appropriate visibility option.

   Note: The visibility setting selected here will not override the default visibility setting of your Facebook application if the application has a more secure level of visibility. For example, if the visibility setting of your Facebook application is set to "Friends", you cannot change this to "Public" by selecting "Public" in this option.

b. Enter a default name, description, image, caption, and message template. Predefined tags for the image, caption and message are included as a guide. For example:

   Name: This is posted as text.
   ```
   [Property field="title" context="current" type="content" format="length:100"]
   ```

   Description:
   This is posted as text.
   ```
   [Property field="description" context="current" type="content"
   format="length:100"]
   ```

   Image:
   This is posted as a URL.
   ```
   [Element context="current" type="content" key="Image" format="URL"]
   ```

   Caption:
   This is posted as text.
   ```
   [Element context="current" type="content" key="Caption"]
   ```

   Message:
   This is posted as text.
   ```
   [Element context="current" type="content" key="Message" format="length:100"]
   ```

Note: Page notes have been deprecated by Facebook.

Defining social network settings for LinkedIn:

Complete these configuration parameters to set up a social network connection for LinkedIn.

Before you begin

Before you begin you must register an application to obtain a user name and password that grants access to the LinkedIn API. To register a new application that the WCM Social Media Publisher can use:

1. Go to https://developer.linkedin.com
2. Sign in and click the twistie next to your login name and select **API Keys**.
3. Click **Add New Application**.
4. Under **Company Info** either select an existing company or select **New Company** and enter a company name.
5. Under **Application Info** enter values for the following parameters:

   Application Name:
   This is the name of your application that is displayed at the end of each post. For example, your company name.

   Application Description:
   Enter a short description of the application.

   Website URL:
   This is the URL to your website. For example: http://www.ibm.com

   Application Use:
   Social Aggregation

   Live Status:
   During testing, you can set the application to **Development**. Once ready, modify the status to **Live**.

   Contact Info:
   Add your contact information here.
6. Under **Author User Agreement** select the display language of the user agreement screen. **Browser Locale Setting** is recommended.
7. Click **Add Application**.
8. A success screen is displayed showing your API Key and Secret Key. Record these values and then click **Done**.

You then must create a new credential vault from the WebSphere Portal administration view where:

- The API Key is specified as the shared user ID
- The Secret Key is specified as the shared password.

About this task

When you create a social network configuration document for LinkedIn:

Procedure

1. Select **LinkedIn** as the social network.
2. Define authentication settings for the social network:
   a. Select the **Credential Vault** that contains your LinkedIn application credentials.
   b. Click **Authorize** to bind the credentials to a specific social network account.
3. Select a message type:

   Note: It is not recommended to reference rich text elements or HTML elements in any fields that do not support HTML.

   Network Update:
   a. Enter a default message template. Predefined tags for the message are included as a guide. For example:

Message:
This is posted as HTML.

```
[Element context="current" type="content" key="Message" format="length:200"] See more:
[URLCmpnt context="current" type="content" mode="standalone" start="<a href='" end="'>Link</a>"]
```

Share:

a. Select the appropriate visibility option.

b. Enter a default name, description, image, and message template. Predefined tags for the image, description, and message are included as a guide. For example:

Name: This is posted as text.

```
[Property field="title" context="current" type="content" format="length:100"]
```

Description:
This is posted as text.

```
[Property field="description" context="current" type="content" format="length:100"]
```

Image:
This is posted as a URL.

```
[Element context="current" type="content" key="Image" format="URL"]
```

Note: The URL to the image must be internet accessible.

Message:
This is posted as text.

```
[Element context="current" type="content" key="Message" format="length:200"]
```

Defining social network settings for Twitter:

Complete these configuration parameters to set up a social network connection for Twitter.

Before you begin

Before you begin, you must register a Twitter application to obtain a user name and password that grants access to the Twitter API. To register a new application that the WCM Social Media Publisher can use:

1. Go to https://dev.twitter.com
2. Log in and click **Create an app**.
3. Click **Add New Application**.
4. Under **Application Info** enter values for the following parameters:

Application Name:
This is the name of your application that is displayed at the end of each post. For example, your company name.

Application Description:
Enter a short description of the application.

Website:
This is the URL to your website. For example: http://www.ibm.com

Callback URL:
Set this to `http://domain/wps/wcmsocial/servlet/oAuthCB/twitter` where "domain" is your domain name.

5. Read the terms and conditions and select **I Agree**.
6. Enter the security/captcha information if required.

7. Your Consumer Key and Consumer Secret is displayed. Make a record of these.
8. Click the **Settings** tab.
9. In the **Application Type** section, set the **Access** property to `Read and write`.
10. Click the **Update this Twitter application's settings**.

When you have registered your application, you then create a new Credential Vault from the WebSphere Portal administration view where:

- The Consumer Key is specified as the shared user ID.
- The Consumer Secret is specified as the shared password.

About this task

When you create a social network configuration document for Twitter:

Procedure

1. Select **Twitter** as the social network.
2. Define authentication settings for the social network:
   a. Select the **Credential Vault** that contains your Twitter application credentials.
   b. Click **Authorize** to bind the credentials to a specific social network account.
3. Enter a default message template. This is posted as text. Predefined tags for the message are included as a guide. For example:

```
[Property field="title" context="current" type="content" format="length:100"]
[URLCmpnt context="current" type="content" mode="storable"]
[profilecmpnt type="content" context="current" field="keywords" separator=" #" include="exact" start="#"]
```

   Note: Rich Text is not supported for Twitter posts, so it is not recommended to reference rich text elements in your post message.

   Note: If your posts are exceeding the 140 character limit for Twitter posts, you can adjust length of the title by reducing the length option in the format parameter as shown in this example. Long category names, or a large number of categories, can also lead to exceeding the 140 character limit.

Global configuration settings:

Although the Social Media Publisher uses social network configuration documents to specify most of its configuration properties, it also uses a global settings document for configuring server-wide options.

To use a global setting, you create a text component that is called **Global Settings** within the **Social Configuration** library. Type the settings that you want to configure into the text field, one per line.

Table 387. Global social media settings

Setting	Details
`actions.post.credentialvault=`	This is used to specify the name of the credential vault that contains the user name and password that is used in post workflow actions. The credential vault user requires edit access to all content that is posted.

Table 387. Global social media settings (continued)

Setting	Details
`library.actions.post.credentialvault=`	This is used to specify the name of the credential vault that contains the user name and password that is used in post workflow actions for a specific library, where "library" is the name of the library you want to assign a credential vault to. The credential vault user requires edit access to all content that is posted.
`actions.disableAllSocialWorkflowActionsOnServers=`	You disable all social media actions on specific servers by entering a comma-separated list of servers. You can specify either node-names, host names or cluster-names. It is recommended that this setting is set to the host name or cluster name of all test, preview, and staging servers.
`actions.disablePostSocialWorkflowActionsOnServers=`	You disable all social media post actions on specific servers by entering a comma-separated list of servers. You can specify either node-names, host names or cluster-names. It is recommended that this setting is set to the host name or cluster name of the authoring server or servers.
`actions.disableDeleteSocialWorkflowActionsOnServers=`	You disable all social media delete actions on specific servers by entering a comma-separated list of servers. You can specify either node-names, host names or cluster-names.
`actions.disableUntrackSocialWorkflowActionsOnServers=`	You disable all social media untrack actions on specific servers by entering a comma-separated list of servers. You can specify either node-names, host names or cluster-names.
`disableDeleteHandlerOnServers=`	You disable all social media delete handlers on specific servers by entering a comma-separated list of servers. You can specify either node-names, host names or cluster-names. The delete handler responds to content deletions and untracks or deletes associated social messages that have already been posted to social media. It is recommended that this setting is set to the host name or cluster name of all test, preview, and staging servers.

Table 387. Global social media settings (continued)

Setting	Details
For Facebook: • facebook.endUser.statistics.enabled=true • facebook.endUser.statistics.domain=YOUR_DOMAIN For Twitter: • twitter.endUser.statistics.enabled=true • twitter.endUser.statistics.domain=YOUR_DOMAIN	These settings are used to enable the tracking of end user social activity. Set these parameters to false to disable statistic tracking for a specific social network. These settings can be individually specified per-library by adding the name of the library to the beginning of the parameter. For example: myLibrary.twitter.endUser.statistics.enabled=true When using virtual portals, or not performing servlet-rendering on Web Content Manager V7.0, then the domain' properties must include the virtual portal context. For example: twitter.endUser.statistics.domain=localhost/wps/por
socialTable.showFullRefreshButton=false	If set to true, the social information table displays a **Refresh All** button that will refresh both statistics and table data. If set to false, a **Refresh Table** button is displayed, and only table data is refreshed.
format:network_name.message_type.postfield.default=value to use the default_value	Use this to define the default value for a Post format field. For example: connections.blog_post.message.defaultValue= [Element context="current" type="content" key="Mess format="length:100"] See more: [URLCmpnt context="current" type="content" mode="st start="Link"

Table 387. Global social media settings (continued)

Setting	Details
jms.processRemoteMsgs=	The Social Media Publisher uses the built-in JMS functions of Web Content Manager to monitor and respond to events that are occurring within a system. When the Social Media Publisher is running within a cluster, each server needs to be configured to match the WebSphere Application Server JMS policy type in effect. To determine the current WebSphere Application Server JMS policy type, open the WebSphere Application Server Administration Console and navigate to **Resources > JMS > Topics > IWKTopics_Items > Buses > IWKBus > Bus Members > PortalCluster** **Note:** This is only available if the Social Media Publisher is installed or if Web Content Manager JMS support has been manually enabled. The jms.processRemoteMsgs setting is set to either true or false depending on the WebSphere Application Server JMS policy type: **High Availability (Default)** Set jms.processRemoteMsgs to true. **Scalability** Set jms.processRemoteMsgs to false. **Scalability with high availability** Set jms.processRemoteMsgs to false. **Custom** Set jms.processRemoteMsgs to true if there is a single JMS engine per cluster, or false if there is a JMS engine per node. When this setting is syndicated to all environments, all clusters in your environment will share the same WebSphere Application Server JMS policy type.

Note: These settings are also documented in the **Global Settings Reference** component that is stored in the **Social Configuration** library.

Adding the social information table to an authoring template:

If the **Automatically add social information element** setting on a social network configuration document is disabled, you must manually add the social information element to any authoring template you want to use the social media publisher on.

Procedure

1. Open the authoring template that you want to add the social information element to in edit mode.
2. Add a text element named **SocialNetworkInformation**.
3. Set the **Custom JSP** property of the element to:
   ```
   readMode=/wps/wcmsocial;/jsp/html/ItemField.jsp,editMode=/wps/wcmsocial;/jsp/html/ItemField.js
   ```
4. Save and close the authoring template.

What to do next

To apply the element to all existing content that uses a specific authoring template, open the authoring template in read mode and click **Apply Authoring Template**, ensuring that the **Add new elements** option is selected.

The social network information table

When you create a content item by using a content authoring template that is mapped to a social network configuration document, an element that is named **Social Network Information** is displayed on the content item.

- To post information about the content item to a specific social network, click **Post** and select the social network of choice.
- To post information about the content item to all social networks, click **Post to All**.
- When posted, information about the social media is listed next to each active social media post. You can refresh this list by using the **Refresh Statistics** action.
- You can stop receiving information about the social media post by clicking the **Untrack** action.

  Note: When you stop tracking an item, you cannot go back and track the item from the time it was published. All your old tracking data is lost. You might not be able to post to social media again as the new post can be considered as duplicate content.
- If you have view access to social configuration documents, you use the **View configuration** action to display the configuration document for a social network.
- Click **Delete** to delete a post from the social network altogether.

Social Media Workflow Actions

A set of social media workflow actions are supplied to with the Social Media Publisher and are found in the **Social Configuration** library. These actions can be added to workflows to run social media actions as part of a workflow.

Preinstalled social media workflow actions

These social media workflow actions are included with the Social Media Publisher:

- Post to all registered configurations
- Untrack message from all registered configurations
- Delete message from all registered configurations

Custom social media workflow actions

You can also create the following social media workflow actions for individual configuration documents:

- Post to specific configuration
- Untrack message from specific configuration
- Delete message from specific configuration

To use these actions, you must:

1. Create a custom workflow action:
2. Enter the name of the configuration document you want to use this action with in **Description** field. This description must exactly match the name of the configuration document, not the display title.
3. Select an action from the **Social Custom Workflow Action Factory**.

Post Action Credentials

Post actions require a credential vault slot called **socialPostUser** populated with credentials of a user that has the following access. This is normally an administration user:

- Edit access to all content that will be posted.
- Contributor access to all required social configuration documents.
- User access to the social configuration library. This must be set on both syndicator and subscriber servers.

The name of the credential vault used can be customized via the global setting **actions.post.credentialvault**. You can also specify a library specific vault via the global setting **library.actions.post.credentialvault**, where library is the name of the library the action is saved in.

Using Social Media Workflow Actions In Projects

When using social media workflow actions with projects, you can:

- Add social media workflow actions directly to a project to run them on all content items in the project. This requires IBM Web Content Manager version 8.
- Add social media workflow actions to the publish stage of individual workflows used by content items. The social media workflow actions are automatically executed once the project is published.
- Use both project level and item level social media workflow actions. Project level actions will run before item level actions.

Workflow Scheduling and Syndication

Social media actions are enabled by default on all the servers that subscribe to your authoring server and social media posts will be sent from all the servers in your system when a social media action is run.

It is best practice to disable social media actions on all servers except your rendering server. To do this, update the following parameter in your global settings:

- `actions.disableAllSocialWorkflowActionsOnServers`
- `actions.disablePostSocialWorkflowActionsOnServers`
- `actions.disableDeleteSocialWorkflowActionsOnServers`

- `actions.disableUntrackSocialWorkflowActionsOnServers`

See "Global configuration settings" on page 2433 for further details.

Publishing content directly to a Facebook page

The Social Media Publisher is used to post status updates about your content to Facebook profiles and pages. You can also post content items directly to a Facebook page.

Procedure

1. Go to `https://developers.facebook.com/apps`
2. Click **Create new App**.
3. A form opens. Enter values for the following parameters:

   App Name:
   This is the name of your application that is displayed at the end of each post. For example, your company name.

   App Namespace:
   This is name that is used to access Facebook Insights information. It is recommended that a unique name is used for each application.
4. Click **Continue**.
5. A configuration screen for your application is displayed. Select **Page Tab** under **Select how your app integrates with Facebook** and complete the following parameters:

   Page tab name:
   Enter the name for the page tab.

   Page tab URL:
   This is the URL to the content item you want to add to the Facebook page.

   Secured Page tab URL:
   This is an https version of the Page tab URL.
6. Click **Save Changes**.
7. Click **Authorize** to bind the credentials to a specific social network account.

What to do next

- To post your content to the Facebook page, use the following URL where `APP_ID` is the Application-Id of Facebook Page Tab application:
  `http://www.facebook.com/dialog/pagetab?app_id=APP_ID&next=https%3A%2F%2Fwww.facebook.com%2Fconnect%2Flogin_success.ht`
- Publishing content directly to a Facebook page requires a Secured Page tab URL to be provided. This means that your server must be SSL enabled.

Social media for users

While the current version for the Social Media Publisher focuses on functions for you and your company as website owners, you might also consider adding social features to your rendered website for use by your users.

To enable this feature:

1. Review the documentation for each social network for the markup they require to be added to a page to integrate their social network badges:

   Facebook:
   http://developers.facebook.com/docs/guides/web/

Twitter:
https://dev.twitter.com/docs/twitter-for-websites

2. When you specify the content url to use as an input to the Social badges, use the following tag: `http://YOUR_DOMAIN[URLCmpnt context="current" type="content" mode="static"]`, where `YOUR_DOMAIN` is the production domain of your website.

   For example: `http://www.ibm.com[URLCmpnt context="current" type="content" mode="static"]`

   The domain that is specified in the URL must be the same as the domain specified in the *facebook.endUser.statistics.domain* and *twitter.endUser.statistics.domain* global settings.
3. Enable the tracking of user's social activity within the Social Media Publisher by setting the global settings `Facebook.endUser.statistics.enabled` and `Twitter.endUser.statistics.enabled` to `true`. See "Global configuration settings" on page 2433 for details.

Social media certificates

To communicate to Facebook, LinkedIn and Twitter, your server requires the SSL certificates for these social networks to be installed.

When these certificates expire, you must refresh them on your server by removing then and adding them again.

Viewing certificates

To view a list of current certificates for Facebook, LinkedIn and Twitter, run the following command from the *wp_profile_root*/ConfigEngine directory:

Windows
```
ConfigEngine.bat action-list-wcm-social-certs
```

Linux
```
./ConfigEngine.sh action-list-wcm-social-certs
```

IBM i
```
ConfigEngine.sh action-list-wcm-social-certs
```

Removing certificates

To remove all current certificates for Facebook, LinkedIn and Twitter, run the following command from the *wp_profile_root*/ConfigEngine directory:

Windows
```
ConfigEngine.bat action-remove-wcm-social-certs
```

Linux
```
./ConfigEngine.sh action-remove-wcm-social-certs
```

IBM i
```
ConfigEngine.sh action-remove-wcm-social-certs
```

Installing certificates

To install the certificates for Facebook, LinkedIn and Twitter, run the following command from the *wp_profile_root*/ConfigEngine directory:

Windows
```
ConfigEngine.bat action-install-wcm-social-certs
```

Linux
```
./ConfigEngine.sh action-install-wcm-social-certs
```

IBM i
```
ConfigEngine.sh action-install-wcm-social-certs
```

Note: If your server is located behind a firewall, you might need to manually import these certificates. See the WebSphere Application Server documentation for instructions on importing certificates. The following locations are for each certificate type:

- Facebook: `graph.facebook.com`
- LinkedIn: `api.linkedin.com`
- Twitter: `api.twitter.com`

SSL port 443 is the default SSL port for these certificates.

Uninstalling the Social Media Publisher

The following procedures to uninstall the Social Media Publisher must be run on every server and cluster node.

About this task

Before starting:

- Ensure that the **WasPassword** and **PortalAdminPwd** passwords are set in the `wkplc.properties` file.
- Ensure that the **jcr.DBPassword** password is set in `wkplc_dbdomain.properties` file.

Procedure

1. To remove the Social Media Publisher tracking data tables, run the following command from the *wp_profile_root*/ConfigEngine directory:

   Windows
   ```
   ConfigEngine.bat action-remove-wcm-social-tables
   ```

   Linux
   ```
   ./ConfigEngine.sh action-remove-wcm-social-tables
   ```

   IBM i
   ```
   ConfigEngine.sh action-remove-wcm-social-tables
   ```

2. To completely remove the Social Media Publisher, run the following command on all servers or nodes in your system from the *wp_profile_root*/ConfigEngine directory:

   Windows
   ```
   ConfigEngine.bat remove-wcm-social
   ```

   Linux
   ```
   ./ConfigEngine.sh remove-wcm-social
   ```

   IBM i
   ```
   ConfigEngine.sh remove-wcm-social
   ```

3. Restart all servers to complete the uninstallation.

What to do next

Note: All SSL certificates for Twitter, Facebook and Linkedin are removed when the uninstall script is run.

Known issues with the Social Media Publisher

These are the current known issues with the Social Media Publisher and their solutions.

Hung tread message in SystemOut.log when running SMP traffic with 10 Virtual Users

WebSphere Application Server provides a detection feature that attempts to locate and report on potentially hung threads in the system. Hung threads can be

difficult to diagnose. The WebSphere Application Server thread monitor architecture monitors managed threads and is enabled by default. When a thread is suspected to be hung, a notification message is written to Sysprint. False alarms do occur. When a false alarm occurs, a followup notification is sent to Sysprint.

Symptom

The following warning from WebSphere Application Server may be observed in the System log:

```
[7/19/12 13:26:39:031 EDT] 00000033 ThreadMonitor W   WSVR0605W: Thread "WorkManager.wpsDefaultWorkManager : 72" (000000ee
    has been active for 682689 milliseconds and may be hung.  There is/are 1 thread(s) in total in the server that may be
    at sun.misc.Unsafe.park(Native Method)
    at java.util.concurrent.locks.LockSupport.parkNanos(LockSupport.java:224)
    at java.util.concurrent.locks.AbstractQueuedSynchronizer$ConditionObject.awaitNanos(AbstractQueuedSynchronizer.java:20
    at java.util.concurrent.LinkedBlockingQueue.poll(LinkedBlockingQueue.java:435)
    at com.ibm.workplace.wcm.messaging.data.JMSTopicContext.getNextMessage(JMSTopicContext.java:232)
```

Cause The Social Media Publisher makes use of JMS background threads that are long running by nature. There is no facility for the Social Media Publisher application to pre-warn the WebSphere Portal server, or the WebSphere Application Server. As a result of this limitation, false alarms can be observed relating to JMS threads, which are used by Social Media Publisher.

Solution

Until this design limitation is corrected, warnings about potential hung threads can be observed, but can be ignored. WebSphere Application Server reports on falsely alerted threads that resume normally. It is possible, but not necessary, to adjust these intervals and thresholds. Note the following custom properties and refer to the WebSphere Application Server documentation for more information:

com.ibm.websphere.threadmonitor.interval
Defaults to 180 seconds. This is the interval at which the thread pools are polled for hung threads.

com.ibm.websphere.threadmonitor.threshold
Defaults to 600 seconds. This is the length of time that a thread can be active before being marked as "potentially hung".

com.ibm.websphere.threadmonitor.false.alarm.threashold
Defaults to 100 false alarms. This is the number of false alarms that can occur before automatically increasing the threshold by 50%.

IBM Web Content Manager Multilingual Solution

The Web Content Manager Multilingual Solution is a set of tools that are used to manage translated versions of localized and regionalized websites.

The multilingual solution requires:

- WebSphere Portal version 8.0.0.1 or later, or Web Content Manager version 8.0.0.1 or later.

"Overview of a multilingual site" on page 2443
A multilingual site consists of content that is localized to support multiple audiences with different languages. Your multilingual site consists of a set of localized and regionalized subsites, including a single base site.

"Deployment, installation, and configuration" on page 2443
Before you use the multilingual solution, you must deploy, install and configure the multilingual solution extensions, and the also update and configure your system.

"How to use the multilingual solution" on page 2452
The multilingual solution is used to author, manage, and publish multilingual content.

"Extensions for multilingual sites" on page 2464
The multilingual solution uses a set of extensions that can be used with existing features to author, manage, and publish your multilingual websites.

Overview of a multilingual site

A multilingual site consists of content that is localized to support multiple audiences with different languages. Your multilingual site consists of a set of localized and regionalized subsites, including a single base site.

Types of sites

The base site

- The base site defines the site structure and contains the shared content that is translated.
- Some base sites are continually updated, and fresh translations are made.
- Other base sites are created once, and used as templates for new sites in other languages.

Translated sites

- In most cases, the entire content and structure of a base site are replicated to a translated site.
- In some cases, only a subset of the original base site is reused on the translated site.

Regional sites

- A regional site is similar to a translated site, but involves no translation.
- Regional sites reuse content from a base site, but the content is updated for each region. For example, different states in a single country.

Translated Regional Sites

- These types of sites both reuse and update content from a base site, but also translates the updated content.

No base-locale sites

- In this type of site, content is written separately in different sites for different languages, but then synchronized and translated to all the sites and languages.

Mixed language sites

- This type of site includes content that is written in multiple languages, but stored in a single site.
- Content is grouped by category, not language.

Deployment, installation, and configuration

Before you use the multilingual solution, you must deploy, install and configure the multilingual solution extensions, and the also update and configure your system.

"Multilingual deployment" on page 2444
Deployment of multilingual sites can be centralized, running out of single environment, or decentralized where locales are served from different environments.

Multilingual deployment

Deployment of multilingual sites can be centralized, running out of single environment, or decentralized where locales are served from different environments.

Centralized deployment

In a centralized deployment, all locales are served from the same environment and all of your localized content is syndicated. Web server mappings to each locale home page are created either as domains or as paths. These mappings provide easily remembered URLs for users to link to a localized version of your site.

Using a single domain name

When a single domain name is used, each path is mapped to the home page in a localized library, by using URLs like `http://mydomain/en` or `http://mydomain/es` for different localities.

Using multiple domain names

When multiple domain names are used, each domain is mapped to the home page in a localized library, by using URLs like `http://mydomain.com` or `http://mydomain.com.es` for different localities.

Your localized navigation links change the domain, not just the path, and use a fully qualified path, not a relative path.

Decentralized deployment

In a decentralized deployment, locales are served from separate environments, one per environment, or potentially multiple locales per environment. Multiple domains must be used, where each locale or combination of locales is served from its own domain.

- When you implement a decentralized deployment, users either switch between localized content on an item by item basis, or users select the locale to use and are taken to the home page for that locale.

- To support a decentralized environment, you need to have all content in all locales that are deployed to every locale environment. The navigation code can then check which content is available before links are rendered, and the user can browse to that localized version without losing their session.
- When using an anonymous site, you can redirect to the localized version of a site on another server. This strategy requires fully qualified links to be generated.

Locale home page navigation

If your site requires a link to go to the home page of each locale instead of item-by-item navigation, you can create links to your other servers. The advantage of implementing your site this way is that you do not need to deploy all content to all servers. You only need the content for the locale you intend to serve out of that environment and any shared assets.

The links to your other localized domains need to be hard-coded because these links cannot be automatically generated.

Installing the multilingual extensions

The multilingual solution consists of a set of extensions to Web Content Manager that can be used to manage the authoring, workflow, and configuration of your multilingual system.

Procedure

1. Ensure that the **WasPassword** and **PortalAdminPwd** passwords are set in the `wkplc.properties` file.
2. Run the following registration command from the *wp_profile_root*/`ConfigEngine` directory:

   Windows
   ```
   ConfigEngine.bat register-wcm-mls
   ```

   Linux
   ```
   ./ConfigEngine.sh register-wcm-mls
   ```

   IBM i
   ```
   ConfigEngine.sh register-wcm-mls
   ```
3. Run the following deployment command from the *wp_profile_root*/`ConfigEngine` directory:

   Windows
   ```
   ConfigEngine.bat deploy-wcm-mls
   ```

   Linux
   ```
   ./ConfigEngine.sh deploy-wcm-mls
   ```

   IBM i
   ```
   ConfigEngine.sh deploy-wcm-mls
   ```
4. If your server contains virtual portals, you must also run the following task for each virtual portal on your server:

   Windows
   ```
   ConfigEngine.bat import-wcm-mls-data
   -DVirtualPortalHostName=VirtualPortalHostName
   -DVirtualPortalContext=virtual_portal_context_url
   ```

   Linux
   ```
   ./ConfigEngine.sh import-wcm-mls-data
   -DVirtualPortalHostName=VirtualPortalHostName
   -DVirtualPortalContext=virtual_portal_context_url
   ```

   IBM i
   ```
   ConfigEngine.sh import-wcm-mls-data
   ```

```
-DVirtualPortalHostName=VirtualPortalHostName
-DVirtualPortalContext=virtual_portal_context_url
```

5. Restart WebSphere Portal.
6. Repeat these steps on every server and cluster node.

Configuring a multilingual system

After you install the multilingual extensions, you then must configure your system to support multilingual authoring and rendering.

Procedure

1. Log into WebSphere Portal as an administrator.
2. Create a new group for your locale owners:
   a. Click the **Administration menu** icon. Then, click **Access** > **Users and Groups**.
   b. Create a new group for your locale owners. For example: **Locale Owners**. The base locale owner must belong to this group.
3. Modify the security of the **MLConfiguration_v7** library:
   a. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.
   b. Assign the **Locale Owners** group to the **Editor** role on the library.
   c. Assign the **Locale Owners** group to the **Contributor** role on the library.
   d. This is an optional step. To hide all sections in the authoring portlet, except the content and component views, disable inheritance for all item types except content and components.
   e. Assign the **Administrators** group to the **Administrators** role on the library and all item types.
4. Run the Update Member Fixer tool by running the following command from the *wp_profile_root*/ConfigEngine directory:

   Windows
   ```
   ConfigEngine.bat run-wcm-admin-task-member-fixer
   -DPortalAdminId=username -DPortalAdminPwd=password
   -DWasUserId=username -DWasPassword=password
   -Dlibrary=MLConfiguration_v7 -Dfix=true -DinvalidDn=update
   -DmismatchedId=update -DaltDn=update
   ```

   Linux
   ```
   ./ConfigEngine.sh run-wcm-admin-task-member-fixer
   -DPortalAdminId=username -DPortalAdminPwd=password
   -DWasUserId=username -DWasPassword=password
   -Dlibrary=MLConfiguration_v7 -Dfix=true -DinvalidDn=update
   -DmismatchedId=update -DaltDn=update
   ```

5. Go to the authoring portlet and update the Configuration settings to add the **MLConfiguration_v7** library to the list of selected libraries.
6. Create multilingual configuration file for each set of localized or regionalized libraries.
   a. From the authoring portlet, create a new content item:
      - use the **LocalizedConfigurationFileAT** content template from the **MLConfiguration_v7** library for localized sites.
      - use the **RegionalizedConfigurationFileAT** content template from the **MLConfiguration_v7** library for regionalized sites.
   b. Type a name and display title to represent the set of multilingual sites.
   c. Complete the following fields:

Base Content Library
Type the name of the library that is used to store items from the default locale, or leave the field blank to indicate that no base locale is used.

Content Libraries
Type the names of all the libraries in your multilingual system, including the base content library, separated by commas. This list must not include any shared design libraries. The order that the libraries are entered in this field determines the output of the render-time and edit-time extensions, so it is recommended to place the base content library first then add the remaining libraries in the order that you want them to be displayed.

Has Regionalizations
Used for localized sites only, this setting determines whether any of the localized sites have associated regionalized versions. Change this setting to true if any regionalized sites are associated with the current set of libraries.

Content Library Owners
For each library listed in the **Content Libraries** field, specify the library name and email address of the user who will be the owner for that library, placing each entry on a new line. For example:
`MyLibraryFR=wpsadmin@portal.com`

Table 388. Configuration file examples

Site Type	Language Tree	Libraries	Configuration files
Localized site	• English • Spanish	• English • Spanish	**Localized Configuration file** • Base Content Library: English • Content Libraries: English, Spanish

Table 388. Configuration file examples (continued)

Site Type	Language Tree	Libraries	Configuration files
Regionalized site	• English – English US (Primary) – English Australia • Spanish – Spanish Spain (Primary) – Spanish Mexico	• English • English US • English Australia • Spanish • Spanish Spain • Spanish Mexico	**Localized Configuration file** • Base Content Library: English • Content Libraries: English, Spanish **Regionalized Configuration file 1 (English)** • Base Content Library: English • Content Libraries: English, English US, English Australia **Regionalized Configuration file 2 (Spanish)** • Base Content Library: Spanish • Content Libraries: Spanish, Spanish Spain, Spanish Mexico

7. For each library referenced in each multilingual configuration file, create a link component directly under the Components folder that references the multilingual configuration file:
   - For references to a localized multilingual configuration file, the link component name must be **MLConfFileReference**.
   - For references to a regionalized multilingual configuration file, the link component name must be **RegionalizedMLConfFileReference**.
   - The **ALL_USERS** group must be assigned to the **User** role in the component access controls.
8. This step is optional. Activate email notifications for the workflow synchronization extensions:

a. Open a multilingual configuration file from the **MLConfiguration_v7** library.
b. Update the following settings in the **General Workflow Synchronization Settings** section:

emailServer
Type the name of your email server.

emailFromAddress
The email address that is entered here is used to set the "From" address on all email notifications. This field must be set to a valid email address.

authoringUIURL
Type the URL of your Authoring server. For example, `http://localhost:10045/wps/myportal/wcmAuthoring`

c. Enable email notifications for each multilingual extension:

Localized Sites
Set the **localize.emailNotificationsEnabled** field in the **Localize Workflow Synchronization Settings** section to **true**.

Regionalized Sites
Set the **regionalize.emailNotificationsEnabled** field in the **Regionalize Workflow Synchronization Settings** section to **true**.

Synchronized publishing
Set the **SyncPublish.emailNotificationsEnabled** field in the **SyncPublish Workflow Synchronization Settings** section to **true**.

Synchronized expiration
Set the **SyncExpire.emailNotificationsEnabled** field in the **SyncExpire Workflow Synchronization Settings** section to **true**.

Synchronized deletion
Set the **SyncDelete.emailNotificationsEnabled** field in the **SyncDelete Workflow Synchronization Settings** section to **true**.

9. This step is optional. To enable project integration for synchronized publishing, set the **SyncPublish.useProjects** field in the **SyncPublish Workflow Synchronization Settings** section to **true**.
10. Enable syndication for the **MLConfiguration_v7** library.

Note: The multilingual solution must be installed on both the syndicator and subscriber before syndication can be enabled.

Optimizing the performance of the extensions

How to optimize your system for best performance of the multilingual solution.

Procedure

1. Add the following settings to the **WCM WCMConfigService** service by using the WebSphere Application Server.
   a. Enable the missed path cache by adding `missed_absPath.cache.enable=true`.
   b. Enable the user cache by setting `user.cache.enable=true`.
   c. Restart the server.
2. Update these settings in the WebSphere Application Server to enable "disk-offload" and "flush to disk" for the following caches:

ML Config File
`services/cache/iwk/mlconffile`

Abs Path
`services/cache/iwk/abspath`

Abs Path Reverse
`services/cache/iwk/abspathreverse`

Missed Path
`services/cache/iwk/missed`

Object Summary
`services/cache/iwk/summary`

Strategy
`services/cache/iwk/strategy`

Note: These changes require manual flushing of the cache offload directories whenever an iFix, Cumulative iFix or Fixpack is installed.

3. Periodically run the clear history tool to improve page load and save performance.
4. Disable workflow actions on subscribers to reduce load and reduce the number of versions that are created for each item. See "Disabling Workflow Actions" on page 434 for further information.

Capacity planning for multilingual sites

It is important to consider the additional load that is placed on the authoring server in comparison with single language websites.

The workload that is imposed by each additional language can be considered equivalent to the workload imposed by an extra set of authoring users. So if you have 50 users that support a single language website, then adding four extra languages is equivalent to having 250 users creating and publishing individual content items.

- When synchronized publishing is required, enabling project integration is recommended as this strategy greatly reduces the load that is generated by this function.
- To further reduce the load that the multilingual extensions generate, the following settings can be modified in each configuration file, with higher values reducing the load:

Localize / Regionalize Workflow Synchronization Settings

`localize.processingDelay`
Specifies the delay in milliseconds between processing each item. Defaults to 100 milliseconds.

`regionalize.processingDelay`
Specifies the delay in milliseconds between processing each item. Defaults to 100 milliseconds.

SyncPublish Workflow Synchronization Settings
This is required only for the legacy synchronized publishing implementation where project publishing synchronization is not used.

`syncPublish.processingDelay`
Specifies the delay in milliseconds between processing each item. Defaults to 2000 milliseconds.

syncPublish.rescheduleInterval
Specifies the interval in seconds to reschedule the action if documents are outstanding. Defaults to 300 seconds.

SyncExpire Workflow Synchronization Settings

syncExpire.processingDelay
Specifies the delay in milliseconds between processing each item. Defaults to 2000 milliseconds.

syncExpire.rescheduleInterval
Specifies the interval in seconds to reschedule the action if documents are outstanding. Defaults to 300 seconds.

SyncDelete Workflow Synchronization Settings

syncDelete.processingDelay
Specifies the delay in milliseconds between processing each item. Defaults to 5000 milliseconds.

Changing the multilingual solution context root

The default context root for the multilingual solution application is /wps. With Version 8.5 CF3, you can change this setting to match the WebSphere Portal context root to better suit the requirements of your organization.

Procedure

1. Ensure that the WebSphere®Portal context root is modified as described in "Changing the portal URI after an installation" on page 368.
2. Ensure that the *WasPassword* and *PortalAdminPwd* passwords are set in the **wkplc.properties** file.
3. Run the following registration command from the *wp_profile_root*/ConfigEngine directory:

   Windows
   ```
   ConfigEngine.bat mls-modify-servlet-path
   ```

   Linux
   ```
   ./ConfigEngine.sh mls-modify-servlet-path
   ```

   IBM i
   ```
   ConfigEngine.sh mls-modify-servlet-path
   ```
4. Restart WebSphere Portal.
5. Repeat these steps on every server and cluster node.
6. If the **Edit-Time Navigation/Creation** extension is being used, for each authoring template that uses the extension:
   a. Edit the **ML Translations** text element properties and update the custom JSP field with dynamic context path tokens:

      For the Auto load version:
      ```
      readMode=[wcm.mls.context.path];/jsp/html/MLAuthorTimeRead_AutoLoad.jsp,
      editMode=[wcm.mls.context.path];/jsp/html/MLAuthorTimeEdit_AutoLoad.jsp
      ```

      For the Manual load version:
      ```
      readMode=[wcm.mls.context.path];/jsp/html/MLAuthorTimeRead_ManualLoad.jsp,
      editMode=[wcm.mls.context.path];/jsp/html/MLAuthorTimeEdit_ManualLoad.jsp
      ```

   a. Save the authoring template.
7. If the **Domain Locale Redirection** extension is being used, update the HTTP Server with the new context root. For example, if you are using the IBM HTTP Server with the following configuration settings and the new context root is /abc:

```
RewriteRule ^/$ /wps/wcmml/jsp/html/MLServletHomePageRedirection.jsp [PT]
RewriteRule ^/en$ /wps/wcm/connect/english/Internet.jsp [PT]
```

Should be updated to:

```
RewriteRule ^/$ /abc/wcmml/jsp/html/MLServletHomePageRedirection.jsp [PT]
RewriteRule ^/en$ /abc/wcm/connect/english/Internet.jsp [PT]
```

Uninstalling the multilingual solution extensions

The following steps are required to uninstall the multilingual solution extensions. These must be run on every server on non-clustered systems, or on the primary cluster node.

Procedure

1. Remove all multilingual workflow stages from each of your workflows.
2. If the **Edit-Time Navigation/Creation** extension is being used:
   a. Manually remove the field from each authoring template that uses the extension.
   b. Save and then reapply any updated authoring templates by using the Remove existing elements option.
3. If the **Servlet Render-Time Navigation** extension is used, remove it from your presentation templates.
4. Ensure that the **WasPassword** and **PortalAdminPwd** passwords are set in the `wkplc.properties` file.
5. To completely remove the multilingual solution, run the following command on all servers or nodes in your system from the *wp_profile_root*`/ConfigEngine` directory:

   Windows
   `ConfigEngine.bat remove-wcm-mls`

   Linux `./ConfigEngine.sh remove-wcm-mls`

   IBM i `ConfigEngine.sh remove-wcm-mls`
6. Delete the **MLConfiguration_v7** library on base portal and all virtual portals.
7. Restart the Portal Server.

How to use the multilingual solution

The multilingual solution is used to author, manage, and publish multilingual content.

"Framework for multilingual site management" on page 2453
The framework covers a data model for storing multilingual sites, processes for managing multilingual sites, and a model for delivering multilingual sites to site visitors.

"Multilingual authoring" on page 2454
Nearly all authoring tasks occur in the base site, and are then replicated, if appropriate, to all of the localized sites. Authoring occurs on translated sites for language or region-specific content, or to fix errors in translation.

"Lifecycle and synchronization" on page 2455
Workflow is used to keep the base site and localized sites synchronized. The creation, modification, publishing, expiry, deletion, and moving of site areas and content can be synchronized across locales by using a workflow.

"Multilingual presentation" on page 2457
Localizing the presentation layer in your site involves deciding which parts of the presentation layer need to be localized, and then separating out those pieces into components that can be localized.

Framework for multilingual site management

The framework covers a data model for storing multilingual sites, processes for managing multilingual sites, and a model for delivering multilingual sites to site visitors.

The key elements of this framework are:

Use one library per locale

A library is created for the base site, and one library for each localized site, and another library for shared templates and components. When you create libraries, ensure that the correct locale is specified during the creation process, as this locale is used during search and in the multilingual user interface extensions.

Note: If a language does not exist in the list of languages available when you create a library, you can add that language to the list of supported languages.

Same site structure in each locale

For content to be recognized as being equivalent between sites, they must have the same URL path. This means the names and structure of all the site areas and content items in your site framework must be identical in each site if they are to be equivalent. The display titles can be different, but the names must match.

Use workflow for all modifications

Creating, updating, publishing, expiring, deleting, and moving content and components are made by using workflow. This strategy allows code to be triggered by the workflow to notify localized sites owners, automate parts of the localization process, and synchronize important stages in the workflow.

Workflows can be localized by creating an equivalently named workflow in each locale library. Localizing the workflow allows separate approval processes to be run per locale and is also a requirement for regionalized sites. Localizing the workflow is part of synchronization process, and the provided extension for workflow synchronization has this ability.

When you create new templated portal pages that are associated with site areas and content items, the templated items are published. The items that are created by copying the site areas and content items are also published. In this case, the items need to be copied to all of the localized sites.

Use shared templates and components

Authoring templates, presentation templates, and components are shared across locales as much as possible. Variability can be built in using

workflows or workflow code that differs across locales, and presentation components that are picked up from the current locale.

Authoring templates can be shared across localizes whenever possible with text providers used to provide localized template display titles, element names, and help-text.

Presentation templates can be different across locales by having different mappings in each locale.

Multilingual authoring

Nearly all authoring tasks occur in the base site, and are then replicated, if appropriate, to all of the localized sites. Authoring occurs on translated sites for language or region-specific content, or to fix errors in translation.

Localization of authoring content

While the initial creation of both the base locale item and any localizations can be done manually by using the authoring portlet, it is recommended to use either a custom authoring field or workflow synchronization code to automate the initial creation of localized documents in the base locale language that are then translated by the appropriate team.

Names and display titles

- The **Name** field in the **Identification** section must not be translated. Doing so breaks the link between the translated item and its base copy.
- Translators are free to translate the **Display Title** field. This is recommended so that links are displayed by using the correct translation of the content name.

Other fields

- Other fields can be different between locales, but for the purposes of consistency of availability and access, typically many of the metadata fields would be kept in sync, including: authors, categories, publish date, expiry date, and security.
- The **owner** field may be localized to indicate the owner of the specific localization. This might be used during automated workflow code to notify the appropriate users of updates.
- The multilingual extensions do not resynchronize fields during updates, nor does it use the owner field. This can be done by using extra custom workflow actions added to the **Localize** and **Regionalize** workflow stages.

Authoring Templates

There are multiple ways in which authoring templates can be set up in a multilingual environment. The common authoring template model is recommended.

Common Authoring Templates

Common authoring templates are usually created in the common library and used for all locales. Text providers can then be written to provide localized template display titles, element names, and help-text. The disadvantage of this approach is that the default values of any elements cannot be translated. You can work around this limitation by moving the recommended default value into the element help text.

Localized Authoring Templates

Each locale uses separate authoring templates with manually translated element names. This approach is not recommended for the following reasons.

- Querying of content is more complicated. Each separate authoring template must be selected in queries that are used by menus or personalization rules.
- Content creation is more complicated. Users must choose the appropriate template not just for the type of content, but also for the appropriate language or locale.
- Maintaining localized authoring templates is more complicated than maintaining common authoring templates. Changes to the base authoring template needs to be duplicated in each of the localized authoring templates, although the multilingual workflow extensions can help with coordinating these changes.

If there is a valid reason to translate the default values of the base authoring template, then it is recommended that this is implemented by creating localized authoring templates in each localized site library that all have the same name, and then set the *localize.supportLocalizedAuthoringTemplates* and *regionalize.supportLocalizedAuthoringTemplates* properties of the **Localize Workflow Synchronization Settings** and **Regionalize Workflow Synchronization Settings** sections of each multilingual configuration file to *true*. Setting the *supportLocalizedAuthoringTemplates* property to *true* enables localized authoring template support and automatically associates each created document with its localized authoring template.

Single Authoring Templates

This approach involves the use of a single authoring template with fields for each locale. This approach is not recommended for the following reasons:

- This approach is not scalable. Only a limited number of languages can be supported due to the number of fields on the authoring template.
- You cannot have content authors editing localizations concurrently.
- Localizations cannot be syndicated separately.
- Only a single workflow can be used.
- Localized content cannot be published or expired independently.
- You cannot use non-Unicode character sets.

Previewing

To preview content to see how it will look in a specific locale or language, including the appropriate encoding, preview the content from within the appropriate library.

Lifecycle and synchronization

Workflow is used to keep the base site and localized sites synchronized. The creation, modification, publishing, expiry, deletion, and moving of site areas and content can be synchronized across locales by using a workflow.

Creating, updating, and moving translated content and components

To keep content and components synchronized between locales, a special workflow stage that runs after the approval stage is created in the base library. This stage is

used for the updating, moving, and creation of content. If the current content item has already been published, the action must be an update or move action. Translated content is treated as new content if no published version exists.

Creating

When new content and components are created in the base library, one of the following actions is run against each configured localized library and a notification sent to localized content owners:

- The item is copied into the library for later translation.
- The item is linked into the library if no translation is required. This applies to content items only.
- Nothing happens and the library is ignored.

Updating

When content or components are updated in the base library, draft copies of existing published localized items are created and a notification sent to localized content owners.

Moving

When you move content in the base library, rather than move the published content, a draft copy of the published content must be created first and then the draft moved to the correct location.

When the draft content is detected as moved within the base library, draft copies of the existing published localized content must be created and moved to the corresponding location in the localized library. A notification is then be sent to localized content owners.

Publishing synchronization

- To ensure that the base item and localized items are published at the same time, project integration can be enabled for the *Update Notification* workflow synchronization extension.
- When project integration is enabled, then all associated draft localized documents are added to a temporary project that is automatically published when all documents are approved.
- When the project is published, a notification is sent to all localized content owners. When the project is successfully published, the project is deleted.

Expiry synchronization

- To ensure that the base item and localized items are expired at the same time, another special workflow stage is required. This workflow stage is run after the publish workflow stage.
- If every published localized copy is in the publish workflow stage, and all their expiry dates are in the past, then items are moved to the next stage that contains the expire action.
- A notification is sent to all localized content owners when documents leave this stage.

Deletion synchronization

- If a base item is deleted the localized content must also be deleted. To handle this task, another special workflow stage is required. This stage is placed after the expire stage if content expiration is used, or after the publish stage if content expiration is not used.
- To delete an item, you need to push the item to the final workflow stage. In most systems, only an administrator has access to do this. When processing

documents in this stage, if the base item is detected, or no base item exists, then all draft, published and expired localized copies are removed and a notification sent to all localized content owners to inform them of the deletion.
- If a localized item is detected and the base item is in another stage, then a deletion request notification is sent to the localized content owners to inform them that various localized copies are ready to be deleted.

Multilingual presentation

Localizing the presentation layer in your site involves deciding which parts of the presentation layer need to be localized, and then separating out those pieces into components that can be localized.

Presentation templates

In many cases the same presentation templates are used in all locales, with fragments of the template being varied by using one of these two options:

- Localized elements can be referenced from the current site area.
- Localized components can be referenced by prefixing the name attribute in the component tag with `name="./item"`. By using dot notation in component tags, the library name is not resolved from the current library until the item is rendered. For example:

```
<component name="./my_component" />
```

In other cases however, a locale requires such different presentation that an entirely different template is required. For example, to support locales with languages that read right to left, or for locales with different branding.

These strategies can all be used together, by setting up template mappings in each localized site, and by using site area elements or dot notation where appropriate.

Site area elements

Using site area elements to vary the locale presentation is used for parts of the presentation that are site-specific content.

Reasons to use site area elements:

- A user must be a site manager to edit these elements.
- The site manager has the option to select different components.
- If the site area is workflowed, all of the modified elements can be previewed at once.
- Suitable for multiple sites per locale.

Reasons to not use site area elements:

- Not a good solution for fragments of the presentation template that are under the control of the designer rather than the site manager.
- Using more than 12 elements can cause scalability issues.

Using dot notation to reference components from the current library

The `name="./item"` parameter is used in component tags for locale-specific design variations in a presentation template.

Reasons to use dot notation in tags:

- Changes can be limited to the users that manage presentation.
- Scales better than using site area elements.

Reasons to not use dot notation in tags:

- Changes cannot be easily previewed.
- References cannot be easily tracked.

Localized navigator components

When creating a navigator, if the **Current site area** or **Current content** options are used, you can reuse navigators across multilingual sites.

Navigators that use selected start positions cannot easily be shared across locales. To use these types of navigators, the `name="./item"` parameter must be used to retrieve localized components.

Another way of localizing a navigator is to use a JSP fragment to set a different context before rendering the navigator. The navigator would be set to use the **Current site area** as the starting point, and by changing the context that you can manipulate this start area by using code. Because the code uses a path lookup, the same JSP fragment works in all of your localized sites.

```
<%@ page import="com.ibm.workplace.wcm.api.*" %>
<%@ taglib uri="/WEB-INF/tld/wcm.tld" prefix="wcm" %>
<wcm:initworkspace user="<%= request.getUserPrincipal() %>" />
<%
RenderingContext context = (RenderingContext)request.getAttribute(Workspace.WCM_RENDERINGCONTEXT_KEY);
String currentLibrary = context.getLibrary().getName();
String navStart = currentLibrary+"/mySiteArea";
%>
<wcm:setExplicitContext path="<%=navStart%>"/>
<wcm:libraryComponent name="theNavigator" library="theLibrary" />
```

In this example:

- `./mySiteArea` is the path.
- `theNavigator` refers to the navigator component.
- `theLibrary` refers to the library the navigator is stored in.

Localized menu components

Menus that use the **Current content site area** option can be reused across multilingual sites.

Menus that use selected site areas cannot easily be shared across locales. To use these types of menus, the dot notation parameter must be used to retrieve localized versions.

Another way of localizing a menu is to use a JSP fragment to allow a list of site areas to be specified at render time. Because the path is the same for each locale, the same JSP fragment works in all of your localized sites.

```
<%@ page import="com.ibm.workplace.wcm.api.*, java.util.*"%>
<%@ taglib uri="/WEB-INF/tld/wcm.tld" prefix="wcm" %>
<wcm:initworkspace user="<%= request.getUserPrincipal() %>" />
<%
RenderingContext context = (RenderingContext)request.getAttribute(Workspace.WCM_RENDERINGCONTEXT_KEY);
String currentPath = context.getPath();
String currentLibrary = context.getLibrary().getName();
Map myparams = new HashMap();
myparams.put("SiteAreas", currentLibrary+"/mySite/mySiteArea1,"+currentLibrary+"/mySite/mySiteArea2");
%>
<wcm:setExplicitContext path="<%=currentPath%>" requestParameters="<%=myparams%>"/>
<wcm:libraryComponent name="theMenu" library="theLibrary" />
```

In this example:

- `theMenu` refers to the menu component.
- `theLibrary` refers to the library the navigator is stored in.
- `SiteAreas` contains the list of site areas to specify in the code.

Localized text within common design components

If you have common design components that you want to reference localized text into, then it is recommended to write a Rendering plug-in that wraps a Java Resource Bundle, with the Resource Bundle Key name and the bundle name that is supplied to the plug-in as arguments.

Localized site search

1. Create a search collection for each locale specifying the appropriate language.
2. Create a content source for each site.
3. Create a search component for each locale library selecting the relevant search collection, or use the Search and Browse portlet.

Localized rendering

Localized rendering is provided by either automatically matching the user locale with the content locale, or by providing a navigation option in the site to allow the user to choose the locale for themselves. These two strategies might also be used together in some cases.

Automatic localization

Automatic localization is when there are different versions of a page for each page and a user is automatically redirected to one of them, based on their locale. The locale can be determined by the following methods:

URL The url can contain the locale. For example, ibm.com.au or ibm.co.uk.

Browser preference
Browsers allow you to specify your language preferences. Language preference information is then sent by the browser in the Accept-Language http header. For example: Accept-Language: en-ca,en-us;q=0.7,en;q=0.3

Portal The portal determines the language for rendering portal content by a search process along the following sequence at login time:

1. If the user has logged in, the portal displays the preferred language that is selected by the user.
2. If no preferred user language can be found, the portal looks for the language in the browser. If the portal supports that language, it displays the content in that language. If the browser has more than one language, the portal uses the first language in the list to display the content.
3. If no browser language can be found, for example if the browser used does not send a language, the portal uses its own default language.
4. If the user has a portlet that does not support the language that was determined by the previous steps, that portlet is shown in its own default language.

User-selected localization

User selected localization is when the user selects a language manually from a link or selection list. The selection can then be stored in a cookie for subsequent visits to the website.

Locale selection page
In this scenario, a launch page is shown when a user first comes to the site that shows what locales are available and user then selects the appropriate one.

Equivalent page navigation
In this scenario, navigation is displayed that allows the user to see the same page in a different locale on every page in the site.

Encoding

UTF-8 (Unicode) is recommended as the encoding for your page, since this encoding supports all the characters you need. If you cannot use UTF-8, then you should use escapes to represent characters that are not supported by the encoding of your page. As all content is stored in the JCR database with UTF-8 encoding, character data is preserved.

WebSphere Portal sites should use the encoding that is set up in the administration portlet. A servlet rendered site should use the encoding that is specified within WebSphere Portal. If a site needs to have more than one encoding, multiple servers are required each with the different encoding settings. A gateway is then used to convert the encoding.

Font face considerations

If implementing a multilingual site, it is worth considering what font to use. There are a few font faces in windows that are installed automatically and can show multilingual characters. One of the best font faces is Tahoma. It is easy to read and contains all the Unicode characters.

Related tasks:

"Adding a new language to render localized content" on page 1425
You can add new languages to the portlet to render localized content in different languages and reach a larger audience.

Creating more multilingual sites

In many cases, the number of languages or regions you require for a site is fixed, but there are times when you need to roll out new locales as your organization grows.

Procedure

1. Use the **ML Library Copy** portlet to copy either the base locale site or one of the translated sites that more closely matches the new site, assigning it a new name and locale during the copy.
2. Translate the copied items as required.
3. Update the relevant multilingual configuration file to reference your new library.

What to do next

When the initial translation is complete, you can run user acceptance tests before you deploy your new site and going into the day to day maintenance that is enabled through automated processes.

You can temporarily disable the automated syncing of this new site while it is going through its initial translation and testing phases.

Advanced options

There are more points of extensibility where you can enhance the multilingual solution to suit your specific requirements.

Mixed language site navigation

In a mixed language site, the navigation is structured to make it possible for users to easily discover what content is available for them in their preferred language, while they maintain the structure of the base language.

- For content that is available in complete translations, the localized navigation code can be used to show a link to the translated content.
- For content that is not available, a menu can be built to pull content from the translated site. For example, the menu might display a list of "Translated content in this area".
- The opposite can be done when you view translated content. For example, a menu might display a list of "Content in this area that is not translated".
- A site map can be built for each translation to provide a shortcut for users to find translated content. This action can be built by using a menu or navigator to explicitly pull content in from the translated site.
- The base site navigation is kept consistent on the page by building navigators that are set to the base site. When translated content is being displayed, the presentation template shows the base navigation always.

Side-by-side preview

Side by side previews might be built by using a special preview page with two web Content Viewer portlets.

- Custom rendering code would be required to pick up two contexts at the same time and display both pages, perhaps in a frame.
- A link to start this preview page might be added to the edit-time navigation or creation extension.

Side-by-side editing

Side by side editing might be built by using a special editing page with containing one authoring portlet and one web content viewer portlet.

- A link might be created that combines the URL parameters for displaying content within the web content viewer portlet with the URL parameters for opening another item in read or edit mode in the authoring portlet
- A link to start this preview page might be added to the edit-time navigation or creation extension.

Writing your own context processor

Provide your own processing whenever the web content viewer portlet renders items.

- Create a **ContextProcessor** class, which implements the com. com.ibm.workplace.wcm.api.ContextProcessor interface.
- Compile the **ContextProcessor** class into a new jar and place that jar in the *wp_profile_root*\wcm\shared\app directory.

Customizing the workflow synchronization email notifications

Modify the default email notifications to provide your own wording.

1. Go to *wp_profile_root* \paa\wcm_mls\components\wcm_mls\shared\app\ directory
2. Extract the contents of **wcm.ml.emailnotifications.jar** to *wp_profile_root*\ wcm\ prereq.wcm\wcm\shared\app .
3. Remove the *wp_profile_root*\wcm\prereq.wcm\wcm\shared\app\META-INF directory.
4. Customize the workflow synchronization email notifications:

Table 389. Localize / Regionalize email notifications (syncupdate.properties)

Message Key	Description
NEWDOCCREATED	The notification when a new translation is created.
LINKCREATED	The notification when a link is created within a localized or regionalized library.
DRAFTCREATED	The notification when a draft is created of any existing localized or regionalized item.
DRAFTEXISTS	The notification when a draft exists within a localized or regionalized library.
DRAFTRENAMED	The notification when a draft is renamed within a localized or regionalized library.
DRAFTMOVED	The notification when a draft is moved within a localized or regionalized library.
FAILED_NOPROCESSSETTING	The notification when no processing setting is found for a given localized or regionalized library
FAILED_CREATENEWDOC	The notification when a new translation fails to be created.
FAILED_CREATEDRAFT	The notification when a draft of an existing translation fails to be created.
FAILED_CREATELINK	The notification when a link fails to be created.
FAILED_CALBASELOCALEDOCPATH	The notification when the path to the current base locale path cannot be determined.
FAILED_RENAMEDRAFT	The notification when a draft fails to be renamed.
FAILED_MOVEDRAFT	The notification when a draft fails to be moved.

Table 390. Publishing Synchronization email notifications (syncpublish.properties)

Message Key	Description
ITEM_PUBLISHED	The notification when a translation is published.

Table 391. Expiry Synchronization email notifications (syncexpiry.properties)

Message Key	Description
ITEM_EXPIRED	The notification when a translation is expired.

Table 392. Delete Synchronization email notifications (syncdelete.properties)

Message Key	Description
ITEMDELETED	The notification when a translation is deleted.
SENTFORDELETION	The notification when a translation is sent for background deletion.
DELETEREQUEST	The notification when a localized translation is being requested to be deleted.
REGIONAL_DELETEREQUEST	The notification when a regionalized translation is being requested to be deleted.
DELETEFAILED	The notification when a translation deletion fails.

5. Modify the message by using any of the following multilingual tags:

Table 393. Multilingual tags

Message Key	Description
[LOCALE]	The locale of the current item.
[ITEM_ID]	The API ID of the current item.
[ITEM_LIBRARY]	The name of the library that the current item is in.
[ITEM_PATH]	The path of the current item.
[ITEM_PATH_LINK]	A link to open the current item within the authoring UI by using the path of the item as the link name.
[ITEM_NEW_NAME]	The new name of the current item, if the item was renamed.
[ITEM_OLD_NAME]	The old name of the current item, if the item was renamed.
[ITEM_NEW_PATH]	The new path of the current item, if the item was moved.
[ITEM_OLD_PATH]	The old path of the current item, if the item was moved.
[BASELOCALE_ITEM_ID]	The API ID of the current base locale item.
[BASELOCALE_ITEM_LIBRARY]	The name of the library that the current base locale item is in.
[BASELOCALE_ITEM_PATH]	The path of the current base locale item.

Table 393. Multilingual tags (continued)

Message Key	Description
[BASELOCALE_ITEM_PATH_ LINK]	A link to open the current base locale item within the authoring user interface by using the path of the item as the link name.
[ERRORS]	The current list of errors that are processing the current item.

6. Save your changes.
7. Translate your message and update the localized versions of the properties files.
8. Restart the server.

Extensions for multilingual sites

The multilingual solution uses a set of extensions that can be used with existing features to author, manage, and publish your multilingual websites.

"Edit-time navigation creation extension"
This extension provides a way to change between localizations of the same item and to create new items in localized libraries.

"Update notification extension" on page 2465
This extension uses the settings in the workflow synchronization section of the multilingual configuration file to automate the creation of localized items.

"Publishing synchronization extension" on page 2466
This extension uses projects to ensure that the base item and any draft localized items are published at the same time.

"Expiry synchronization extension" on page 2467
This extension ensures that the base item and any published localized items are expired at the same time.

"Deletion synchronization extension" on page 2467
This extension ensures that the base item and any draft localized items are deleted at the same time.

"Servlet render-time navigation extension" on page 2468
This extension provides navigation between equivalent published content in different locales from within a presentation template at rendering time.

"Portlet Render-time navigation extensions" on page 2468
This extension enables the Web Content Viewer to become locale aware and thus automatically switch to an equivalent object based on the current user's locale.

"Domain locale redirection extension" on page 2469
This extension provides a redirection from the main domain to another locale based on the locale settings of the current user.

"Library copy portlet extension" on page 2470
This extension is used as part of setting up a new locale by copying an existing library, and assigning it a new name and locale.

Edit-time navigation creation extension

This extension provides a way to change between localizations of the same item and to create new items in localized libraries.

The extension has two versions that differ only when the extension itself renders its results. The Auto Load version renders immediately, whereas the Manual Load version requires the user to click **Refresh** before any results are returned.

To use the edit-time navigation creation extension:

1. Add a text element that is named **ML Translations** to an authoring template.

   Note: CF07 This element is displayed in the content item form only if the Multilingual Solution is enabled. Otherwise, this element is hidden in the content item form, but still visible in the **Manage Elements** dialog.

2. Edit the element properties and add the following code to the custom JSP field:

   For the Auto load version before version 8.5 CF3

   ```
   readMode=/wps/wcmml;/jsp/html/MLAuthorTimeRead_AutoLoad.jsp,
   editMode=/wps/wcmml;/jsp/html/MLAuthorTimeEdit_AutoLoad.jsp
   ```

   CF03 **For the Auto load version for version 8.5 CF3 or higher**

   ```
   readMode=[wcm.mls.context.path];/jsp/html/MLAuthorTimeRead_AutoLoad.jsp,
   editMode=[wcm.mls.context.path];/jsp/html/MLAuthorTimeEdit_AutoLoad.jsp
   ```

   For the Manual load version before version 8.5 CF3

   ```
   readMode=/wps/wcmml;/jsp/html/MLAuthorTimeRead_ManualLoad.jsp,
   editMode=/wps/wcmml;/jsp/html/MLAuthorTimeEdit_ManualLoad.jsp
   ```

   CF03 **For the Manual load version for version 8.5 CF3 or higher**

   ```
   readMode=[wcm.mls.context.path];/jsp/html/MLAuthorTimeRead_ManualLoad.jsp,
   editMode=[wcm.mls.context.path];/jsp/html/MLAuthorTimeEdit_ManualLoad.jsp
   ```

3. Save the authoring template and reapply the template to all content that uses it ensuring the **Add new elements** option is selected.

How it works

Every time that you open a content item that uses this extension in the authoring portlet, all libraries that are configured in the current multilingual configuration file are searched for all matching content. To be matching, it must be in the same site area path and have the same name.

If a matching content item is found, then information about the content, item including a link to open that item in read mode, is displayed. If the existing content item is a link, then information about the originating content item is displayed instead.

If no matching content items are found, and you have edit access to the content item, you can either create a copy or link of the content item in each localized library:

Copy Clicking **Copy** creates a draft with the same name as the current item under the equivalent site area in the localized library.

Link Clicking **Link** creates a content link to the current content under the equivalent site area in the localized library.

Note: When performing copy or link operations against an item within the Portal Site library, any pages on the path to the item being copied will be copied as site areas in the destination library.

Update notification extension

This extension uses the settings in the workflow synchronization section of the multilingual configuration file to automate the creation of localized items.

To use the notification extension:

1. Add either the **MLConfiguration_v7 \ Localize** or **MLConfiguration_v7 \ Regionalize** workflow stage to your workflow after the approval stage, which is the first stage after the draft stage.
2. If any of your localized library sets do not have a base locale:
   a. Ensure that **storeOriginalWorkflow** is set to **true** within the **General Settings** of the associated multilingual configuration file.
   b. For each workflow used by translated content, create another workflow that is named ***WorkflowName*_Translation**, where *WorkflowName* is the name of the original workflow. This workflow must contain a draft stage, approval stage, and the **ML Configuration_v7 \ Switch Workflow** stage.
      - If legacy synchronized publishing is to be used, then use the **ML Configuration_v7 \ Pending Published – No Base Locale** stage instead of **ML Configuration_v7 \ Switch Workflow**.
      - If legacy synchronized publishing is not being used, then the **ML Configuration_v7 \ Switch Workflow** stage must also be added to the base workflow after the approval stage.
3. If any of your localized library sets are going to use localized authoring templates, ensure that the **supportLocalizedAuthoringTemplates** property in the **Localize** or **Regionalize** workflow synchronization settings of your multilingual configuration file is set to true.

How it works

When an item reaches the **Localize** or **Regionalize** workflow stage:

- If the base locale item is in the current stage or a later stage, then each configured library that does not already have a draft item is processed according to the **Localize** or **Regionalize** workflow synchronization settings of your multilingual configuration file and a notification is sent to the all relevant locale owners.
  - If the library that is being processed contains an existing published or expired item, then the workflow synchronization settings are ignored and a draft copy of the existing item is created.
  - If the library that is being processed does not contain an existing published or expired item, then it is either ignored, or a new draft or link is created depending on the configuration that is specified in the multilingual configuration file.
- If one or more localized copies of the current item are found that do not have a corresponding draft base locale item in any stage of the workflow, then all copies are moved to the next workflow stage and a notification is sent to the base locale owner to inform them that changes have been made to localized documents without an associated change to the base locale item.
- If the base locale item is in an earlier stage of the workflow, then nothing happens.

Note: If no base locale library is configured, then the current item is deemed to the base item for the current processing cycle only.

Note: If the base item is renamed or moved, then all localized drafts and regionalized drafts are moved or renamed

Publishing synchronization extension

This extension uses projects to ensure that the base item and any draft localized items are published at the same time.

To use the project synchronized publishing extension, set **syncPublish.useProjects=true** in the multilingual configuration file.

Note: Individual workflows can be excluded from using synchronized publishing by specifying their name in the **SyncPublish.workflowsToExcludeFromSyncProjectPublishing** setting in the multilingual configuration file.

Note: The **syncPublish.useProjects** and **SyncPublish.workflowsToExcludeFromSyncProjectPublishing** settings must be the same across all associated multilingual configuration files.

How it works

When an item enters a publish workflow stage the following things happen:

- If any draft localized copies of the current item are not in the pending publish state, then nothing happens.
- If all draft localized copies of the current item are in the pending publish state, then the current item and its copies are moved to the next workflow stage and a notification sent to relevant locale owners.

Expiry synchronization extension

This extension ensures that the base item and any published localized items are expired at the same time.

To use the extension, add the **MLConfiguration_v7 \ Pending Expire** workflow stage to your workflow before the expire stage.

How it works

When an item reaches the pending expire state the following things happen:

- If any published localized copies of the current item are not in the pending expire state, nothing happens.
- If all published localized copies of the current item are in the pending expire state, then the current item and its copies are moved to the next workflow stage and a notification are sent to the relevant locale owners.
- The expiry extension is only applied to individual workflows, not project workflows.

Deletion synchronization extension

This extension ensures that the base item and any draft localized items are deleted at the same time.

- To use the extension, add the **MLConfiguration_v7 \ Delete** workflow stage to the end of your workflow.
- If your workflow is not using expiry, then instead use the **MLConfiguration_v7 \ Delete – For non expiry workflows** workflow stage.

How it works

When an item reaches the delete workflow stage the following things happen:

- If there is a base locale copy of the current item and it is not in the delete workflow stage, then a deletion request email is sent to the base locale owner to inform them that one or more localized copies need to be removed.

- If the base locale copy of the current item exists in the delete workflow stage, then all available draft and published localized copies are removed and a notification sent to relevant localized library owners, regardless of the workflow stage the localized copies are in.
- The delete extension is only applied to individual workflows, not project workflows.

Servlet render-time navigation extension

This extension provides navigation between equivalent published content in different locales from within a presentation template at rendering time.

To add localized rendering links to content items, reference the JSP component that is named **MLConfiguration_v7/JSP - ML Locale Nav** to either the associated presentation template, or as a reference within a component or element that is also referenced in the presentation template.

How it works

- Every time that you render a page that includes the **MLConfiguration_v7/JSP - ML Locale Nav** component, all libraries that are configured in the multilingual configuration file are searched for all items that match the current content item.
- To be matching, the content must be located under an equivalent site path and have the same name.
- A link is created for each matching localized content item that is displayed in the language of the current user.
- While this extension does work for both servlet-rendering and portlet-rendering, in portlet-rendering it add links only for content displayed in the current portlet.

Portlet Render-time navigation extensions

This extension enables the Web Content Viewer to become locale aware and thus automatically switch to an equivalent object based on the current user's locale.

To enable this extension:

1. Update all Web Content Viewer Portlets to reference the multilingual context processor.

   Web Content Viewer
   Edit the portlet settings and select the `com.ibm.workspace.wcm.ml.contextProcessor.MLContextProcessor` from within the **Plugins** section of the **Advanced Options**.

   Legacy Web Content Viewer Portlet
   Add the following property to the configuration of the Web Content Viewer Portlet:

   ```
   ContextProcessorClass=com.ibm.workplace.wcm.contextprocessor.MLContextProcessor
   ```

2. Modify all of the pages in the site to add a web content associations for the localized sites:
   a. Go into edit mode.
   b. Open the toolbar.
   c. Select **Page**.
   d. Select **General**.
   e. Select **Details**.
   f. Select "Default site area".

g. Add the web content associations to the site areas in the localized sites that are equivalent to the existing associated site area in the base locale.
h. Click **OK**.

How it works

- When a Web Content Viewer Portlet is rendered, the multilingual context processor checks whether the locale has changed. If the locale has changed, then an equivalent item in the new locale is displayed.
- If a presentation template is selected in the Web Content Viewer configuration, then a localized presentation template is also searched for and used if available.
- The multilingual portal local switcher can be used to allow the user to select a locale in which to view the site. This selected locale overrides the locale that the user specifies in their browser or in their portal preferences. To enable this extension:
  1. Integrate the **MLPortalLocaleSwitcher.jsp** from the **wcm-multilocale.ear** into your theme.
  2. Place a Web Content Viewer portlet on the page that is configured to display the **JSP - ML Portal Locale Switcher** component from the **MLConfiguration_v7 library**.
     – Select a content item from one of the localized libraries as the content context.
     – Set "**Broadcast links to**" to "**This Page**".

Related concepts:

"Web content associations" on page 2023
Web content associations are used to combine portal pages and associated web content items that are managed by IBM Web Content Manager so they can be managed and rendered consistently. Web content associations map portal pages to the site structure in the IBM Web Content Manager system.

Domain locale redirection extension

This extension provides a redirection from the main domain to another locale based on the locale settings of the current user.

To use this extension:

1. Edit the `MLServletHomePageRedirection.jsp` in the `wcm-multilocale.ear`:
   - Comment out the lines in the **`getAvailableLocalesList`** method.
   - Change **`s_defaultLocale`** to match the default locale.
2. Update your HTTP Server. For example, if you are using IBM HTTP Server edit the following configuration settings:
   - Add the following text to the end of the IBM HTTP Server configuration file:

     Before version 8.5 CF03

     ```
     LoadModule rewrite_module modules/mod_rewrite.so
     RewriteEngine on
     RewriteRule ^/$ /wps/wcmml/jsp/html/MLServletHomePageRedirection.jsp [PT]
     ```

     CF03 Version 8.5 CF03 or higher

     ```
     LoadModule rewrite_module modules/mod_rewrite.so
     RewriteEngine on
     RewriteRule ^/$ /MLS_CONTEXT_ROOT/wcmml/jsp/html/MLServletHomePageRedirection.jsp [PT]
     ```

     Where *MLS_CONTEXT_ROOT* is the context root for the multilingual solution application.
   - For each locale in the **s_availableLocales** list, also add the following text to the end of the IBM HTTP Server configuration file:

Before version 8.5 CF03

```
RewriteRule ^/LOCALE$ /wps/wcm/connect/LIBRARY/SITE [PT]
```

- LOCALE: The string representation of the corresponding Java Locale object. For example,"fi" for Finnish and "pt_BR" for Brazilian Portuguese.
- LIBRARY: The web content library that is associated with the locale
- SITE: The top-level site area for the specified library

For example: `RewriteRule ^/en$ /wps/wcm/connect/english/ Internet [PT]`

Important: Never map any of the locale redirections to the main domain.

CF03 **Version 8.5 CF03 or higher**

```
RewriteRule ^/LOCALE$ /PORTAL_CONTEXT_ROOT/wcm/connect/LIBRARY/SITE [PT]
```

- LOCALE: The string representation of the corresponding Java Locale object. For example: "fi" for Finnish and "pt_BR" for Brazilian Portuguese.
- PORTAL_CONTEXT_ROOT: The context root for WebSphere Portal.
- LIBRARY: The web content library that is associated with the locale
- SITE: The top-level site area for the specified library

For example: `RewriteRule ^/en$ /wps/wcm/connect/english/ Internet [PT]`

Important: Never map any of the locale redirections to the main domain.

How it works

Every time that you request the top-level domain the locale of the current user, or the ordered list of preferred languages set in the browser, is checked against the list of available locales as in the JSP. The JSP then redirects back to the top-level domain plus the available locale, and the web server then redirects to the correct content item based on that locale.

While this extension is designed for servlet-rendering, it can be used with portlet-rendering to render different locales from different servers.

Library copy portlet extension

This extension is used as part of setting up a new locale by copying an existing library, and assigning it a new name and locale.

To use the extension:

1. Click the **Administration menu** icon. Then, click **Portal Content** > **ML Library Copy**.
2. Select a library to copy.
3. Select a new locale.
4. Type a new name for the library.
5. Click **Copy**.

Note: The **Portal Site** library cannot be cloned by using the **ML Library Copy** portlet, therefore if your base locale is the **Portal Site** library you must either:

- Use the "Edit-time navigation creation extension" on page 2464 to manually copy each of your content items in the **Portal Site** library to your localized libraries. This action automatically duplicates the page path as site areas in the destination library.
- Write some Web Content Manager API code to manually copy the **Portal Site** library by traversing the page hierarchy and creating site areas in the destination library with the same name as the page, then copying the content items by using the Web Content Manager API `Workspace.copy` method.

IBM Syndicated Feed Portlet for WebSphere Portal Express

The new IBM Syndicated Feed Portlet for IBM WebSphere Portal Express offers enhanced feed subscription and presentation capabilities.

Using IBM Syndicated Feed Portlet, a user can:

- Integrate, view, and manage RSS and ATOM feeds from portal pages
- Organize the feeds into new and existing feed categories
- Specify authentication options and credentials (private or shared) for password-protected feeds
- Extensively customize the presentation style for feeds
- Export the feeds of IBM Syndicated Feed Portlet to an Outline Processor Markup Language (OPML) compliant xml file and import multiple feeds by specifying an appropriate OPML URL.
- Enable and configure servlet and dynamic caching for caching the portlet user interface and feed data, respectively

Using IBM Syndicated Feed Portlet, an administrator can perform all the functions that a user can. Additionally, the administrator can:

- Regulate a user's ability to customize the portlet
  - Apply locks on a user's ability to perform feed subscription related functions, such as
    - Adding feeds to the portlet
    - Enabling or displaying the feeds in the view mode of the portlet
    - Configuring cache settings
  - Apply locks on a user's ability to customize feed presentation related options, such as
    - Choosing a presentation style for the feeds
    - Displaying or hiding the toolbar. A toolbar enables you to perform all the operations related to feeds and feed categories from within the view mode.
    - Displaying or hiding the channel bar. The channel bar displays the name of the feed category and the name of the feed subscription separated by a forward slash (/).
    - Customizing the portlet window title to be the same as the default portlet title, the title of the first selected feed, or a custom title
    - Displaying or hiding the author of feed items
    - Displaying or hiding the Published date of feed items

You can perform all the listed tasks from within the IBM Syndicated Feed Portlet. Steps for performing the previous tasks are documented in the WebSphere Portal Express help.

The following configuration tasks need to be performed by an Administrator from WebSphere Portal Express, IBM WebSphere Application Server, or the WebSphere Portal Express file system:

- Configure settings for a proxied environment
- Configure a user's ability to customize the portlet window title
- Enable display of SSL-secured feeds
- Configure global cookies for feeds.

"Additional information for using IBM Syndicated Feed Portlet"
When using IBM Syndicated Feed Portlet for WebSphere Portal it is important to consider additional information about authentication methods, feed details, and settings.

"Configuring proxy settings" on page 2473
IBM Syndicated Feed Portlet for IBM WebSphere Portal Express is supported in a proxied environment.

"Customizing the portlet title" on page 2473
With the appropriate configuration settings, you can customize the portlet window title to be the same as the default portlet title, the title of the first selected feed, or a custom title that you specify in the portlet configuration panel.

"Enabling display of SSL-secured feeds" on page 2475
When you use IBM Syndicated Feed Portlet, some feeds that use HTTP over SSL (HTTPS) might not function properly because of missing SSL certificates. You might encounter errors, such as `Missing certificate`, `Unknown certificate`, or `Untrusted certificate` because of missing root signer certificates or missing self-signed certificates in the certificate truststore. In both the cases, you must add the appropriate certificates to the certificate truststore.

"Configuring cookies and active content filtering" on page 2476
You can configure the IBM Syndicated Feed portlet to forward HTTP cookies with outbound requests to feed sources, or restrict the portlet to forward cookies only to specific domain names. You can also enable active content filtering for all feeds to remove active content such as Java script from the feed text.

"Client side aggregation (CSA) rendering in IBM Syndicated Feed Portlet" on page 2477
IBM Syndicated Feed Portlet can be configured to operate in the client side aggregation (CSA) rendering mode. Client side rendering ensures an improved user experience through faster response time. When you enable client side rendering in the portlet, the portal does not re-render the whole page but only the aspects of the portlet that change.

Additional information for using IBM Syndicated Feed Portlet

When using IBM Syndicated Feed Portlet for WebSphere Portal it is important to consider additional information about authentication methods, feed details, and settings.

Consider the following information when using the IBM Syndicated Feed Portlet:

- IBM Syndicated Feed Portlet supports the following authentication methods:
  - Basic authentication

  - Form-based authentication
  - Single Sign-On (SSO) via LTPA and Netegrity SiteMinder
- The xml file from which you export the feed details for one instance of IBM Syndicated Feed Portlet can not be used to import the feed details into another instance of the portlet.
- Initially, you can view portlet feeds in the View mode based on the settings configured by the Administrator. If you modify the settings, they take precedence over the subsequent settings that the Administrator configures.
- If you encounter problems viewing feeds that use international character sets, refer to the technote, "Viewing feeds using international character sets in the IBM Syndicated Feed Portlet for Websphere Portal", for more information.

Related information:

 Viewing feeds using international character sets from the IBM Syndicated Feed Portlet for WebSphere Portal

Configuring proxy settings

IBM Syndicated Feed Portlet for IBM WebSphere Portal Express is supported in a proxied environment.

About this task

To specify the details of proxy server, proceed as follows:

Procedure

1. Click the **Administration menu** icon in the toolbar. Then, click **Portlet Management** > **Portlets**.
2. Search for the Syndicated Feed portlet entry.
3. Click the **Configure portlet** (wrench) icon for the Syndicated Feed Portlet.
4. Add the following configuration parameters to the existing list of configuration parameters for the Syndicated Feed Portlet.

Table 394. Configuration parameters

Parameter	Value
`proxyHost`	Specify the proxy server hostname
`proxyPort`	Specify the proxy server port number

To add these configuration parameters:

a. Type the parameter name in the **New Preference** text field.
b. Type the value of the parameter in the **New value** text field.
c. Click **Add**.

Note: You do not need to restart the portal server after you specify the configuration parameters. The updated configuration becomes effective without restart.

Customizing the portlet title

With the appropriate configuration settings, you can customize the portlet window title to be the same as the default portlet title, the title of the first selected feed, or a custom title that you specify in the portlet configuration panel.

About this task

The IBM Syndicated Feed portlet provides dynamic window title support that implements the request attribute, `com.ibm.portal.portlet.Constants.DYNAMIC_TITLE`. WebSphere Portal Express defines the title bar for portlets in `control.jsp`. To add dynamic title support for the IBM Syndicated Feed portlet, you must deploy the dynamic window title support and update `control.jsp`.

Because the *PortalServer_root* directory is read only, you cannot modify the window title support libraries, `control.jsp`, or other theme files in this directory. You should include these files as part of a custom theme or deploy the files as a separate Web Archive (WAR). See the following topics for more information: *Location of theme resources* and *Creating a new theme*.

Procedure

1. Deploy the dynamic window title support with your custom Web Archive (WAR).
   a. Navigate to the following directory: *PortalServer_root*`/bp/wp.bp.feedspace/installableApps`

      Note: If you downloaded the IBM Syndicated Feed portlet from the IBM Business Solutions Catalog, the required files are available in the root directory of the archive.
   b. Locate and copy the following files to a work directory:
      - `dynamicWindowTitle.jar`
      - `dynamicWindowTitle.tld`
   c. Copy `dynamicWindowTitle.jar` to the following directory in your custom WAR: `WEB-INF/lib`
   d. Copy the file `dynamicWindowTitle.tld` to the following directory in your custom WAR: `WEB-INF/tld`
2. Customize the skin(s) that you plan to use with the IBM Syndicated Feed portlet. Perform the following steps for each skin you plan to use:
   a. Locate `control.jsp` in the `skin` directory of the WAR file.
   b. Locate the last `taglib` definition in the file. For example,
      ```
      <%@ taglib uri="/WEB-INF/tld/dnd.tld" prefix="dnd" %>
      ```
   c. Insert the following string after that tag:
      ```
      <%@ taglib uri="/WEB-INF/tld/dynamicWindowTitle.tld" prefix="dwt" %>
      ```
   d. Locate the following string:
      ```
      <portal-skin:portletTitle>
      ```
      If the file does not contain this string, insert it after the last `taglib` definition.
   e. Insert the following string before this tag:
      ```
      <dwt:renderTitle windowId="<%=myPortletID%>">
      ```
   f. Locate `</portal-skin:portletTitle>`.
   g. Insert the following string after this tag:
      ```
      </dwt:renderTitle>
      ```
   h. Add the following tag to the end:
      ```
      <dwt:setTitle windowId="<%=myPortletID%>"/>
      ```

i. Save and close `Control.jsp`. The changes you make to `Control.jsp` should be similar to the following:

```
<%@ taglib uri="/WEB-INF/tld/dnd.tld" prefix="dnd" %>
<%@ taglib uri="/WEB-INF/tld/dynamicWindowTitle.tld" prefix="dwt" %>
::::::::::::
::::::::::::
<dwt:renderTitle windowId="<%=myPortletID%>">
<portal-skin:portletTitle>
<portal-fmt:problem bundle="nls.problem"/>
</portal-skin:portletTitle>
</dwt:renderTitle>
<img alt="" style="border:0; text-align: <%= bidiAlignRight %>;"
width="1" height="22"
src='<portal-logic:urlFindInSkin file="title_minheight.gif"/>'>
</div></dnd:dragHandle></td>
<td class="wpsPortletIcons">
<%-- Do not include 'Skip to next portlet' link in --%>
<%-- standalone window or solo mode --%>

<%if(isJSAvail){%>
::::::::::::::::::::::
::::::::::::::::::::::

<dwt:setTitle windowId="<%=myPortletID%>" />
```

What to do next

You can now use the dynamic portlet window title customization option with all IBM Syndicated Feed portlet instances inside the skins you customized.

Note: The IBM Syndicated Feed portlet disables the portlet window title customization options in the Personalize/Edit Shared Settings/Configure modes when the portlet detects that it is displayed in a skin that does not support the dynamic window title features. The IBM Syndicated Feed portlet also disables these options if an administrator locks the window title features.

For more information, see *Tip: Changing a portlet title at run time in WebSphere Portal V6*.

Enabling display of SSL-secured feeds

When you use IBM Syndicated Feed Portlet, some feeds that use HTTP over SSL (HTTPS) might not function properly because of missing SSL certificates. You might encounter errors, such as `Missing certificate`, `Unknown certificate`, or `Untrusted certificate` because of missing root signer certificates or missing self-signed certificates in the certificate truststore. In both the cases, you must add the appropriate certificates to the certificate truststore.

Before you begin

To add the appropriate certificates, you must have Administrator access to your IBM WebSphere Portal Express installation.

Procedure

1. Obtain the missing certificates.

There are various mechanisms for doing this depending on the type of certificate that is missing. In general, the quickest way to obtain the missing certificate is to access the feed you are trying to add directly from a web browser. All modern browsers provide the capability to view a certificate and its trust chain. However, the directions for viewing and exporting certificates from a web browser are browser vendor specific and therefore outside the scope of this document (except to say that they should be exported in Base-64 encoded format as a file with the extension .cer or .arm). If you need assistance with this task, contact your IT administrator. There are also many online resources that can help you complete this task.

Note: If you use self-signed certificates, you might be prompted with several warnings about the acceptance or trust of this certificate. In such cases, ensure that you trust the third-party server before you add the certificate to your certificate truststore.

2. Once you export the appropriate root signer or self-signed certificate, refer to the instructions in the Adding a signer certificate to a keystore topic to import the root signer certificate or to import the self-signed certificate as a new trusted signer certificate to the appropriate truststore.
3. Restart the WebSphere_Portal server.

Related information:

Adding a signer certificate to a keystore

Configuring cookies and active content filtering

You can configure the IBM Syndicated Feed portlet to forward HTTP cookies with outbound requests to feed sources, or restrict the portlet to forward cookies only to specific domain names. You can also enable active content filtering for all feeds to remove active content such as Java script from the feed text.

Procedure

1. Log in to WebSphere Portal Express as an administrator.
2. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
3. Locate the Syndicated Feed portlet.
4. Click the **Configure portlet** icon in the **Syndicated Feed Portlet** row.
5. Add the following preference and value pairs as appropriate to configure the portlet:

Table 395. Preference and value pairs for the Syndicated Feed portlet

Preference	Value
`cookiesToForward`	Specify one or more HTTP cookie names. Use a space to separate multiple cookie names. This preference forwards the specified cookies with the outbound portlet request when you connect to the feed source. **Note:** You can specify cookies to forward for a given feed when you add feeds to the portlet. The cookies that you specify as the value for `cookiesToForward` are appended to the list of cookies you specified when you added the feed.

Table 395. Preference and value pairs for the Syndicated Feed portlet (continued)

Preference	Value
`limitCookiesToForward`	Specify one or more domain names to which you want to forward cookies. This preference restricts cookie forwarding to only the domain names that you specify. You can specify a fully qualified domain name or a partially qualified domain name. For example, • Fully qualified domain name: `www.ibm.com` • Partially qualified domain name: `ibm.com`
`useACF`	Specify one of the following values: **`true`** Enables active content filtering for all feeds. This value removes any active content from the feed text; for example, embedded Java scripts. **`false`** Disables active content filtering for all feeds.

6. Click **OK** to save your changes.

Client side aggregation (CSA) rendering in IBM Syndicated Feed Portlet

IBM Syndicated Feed Portlet can be configured to operate in the client side aggregation (CSA) rendering mode. Client side rendering ensures an improved user experience through faster response time. When you enable client side rendering in the portlet, the portal does not re-render the whole page but only the aspects of the portlet that change.

The following feed management and feed presentation capabilities are available when client side rendering has been enabled for IBM Syndicated Feed Portlet:

Feed management capabilities

- Subscribing to feeds by specifying the feed url, feed title, and optionally feed credentials
- Editing a feed to change feed title
- Enabling or displaying the feeds in the view mode of the portlet
- Deleting a feed subscription

Feed presentation capabilities

- Customizing the number of articles to be displayed per feed
- Viewing the feed article content either expanded or collapsed
- Displaying or hiding the author of feed items
- Displaying or hiding the Published date of feed items

"Enabling client side rendering in IBM Syndicated Feed Portlet" on page 2478
To enable client side rendering in the IBM Syndicated Feed Portlet, create a `useClientSideRendering` configuration parameter and set its value to `true`.

"Configuring the profiling parameter on the page with the Syndicated Feed Portlet"
You must configure the full profiling parameter on the page on which you deployed the Syndicated Feed Portlet.

"Configuring the security role mapping for the Syndicated Feed Portlet" on page 2479
You must configure the security role mapping for the Syndicated Feed Portlet.

Enabling client side rendering in IBM Syndicated Feed Portlet

To enable client side rendering in the IBM Syndicated Feed Portlet, create a `useClientSideRendering` configuration parameter and set its value to `true`.

About this task

To enable client side rendering for IBM Syndicated Feed Portlet:

Procedure

1. From the WebSphere Integrated Solutions Console, click **Portlets** under **Portlet Management**.
2. Search for the Syndicated Feed portlet entry.
3. Click the **Configure portlet** (wrench) icon corresponding to the Syndicated Feed Portlet.
4. Add the `useClientSideRendering` configuration parameter to the existing list of configuration parameters for the Syndicated Feed Portlet. Set the value of this configuration parameter to `true`.

   Following are the steps to add a configuration parameter for a portlet:

   a. Enter the parameter name in the **New Preference** text field.
   b. Enter the value of the parameter in the **New value** text field.
   c. Click **Add**.

   Note: You do not need to restart the portal server after you specify the configuration parameters.

Configuring the profiling parameter on the page with the Syndicated Feed Portlet

You must configure the full profiling parameter on the page on which you deployed the Syndicated Feed Portlet.

Procedure

1. Create the page on which you want to deploy the Syndicated Feed Portlet. Make sure that the page inherits the portal default theme.
2. Deploy the Syndicated Feed Portlet on that page.
3. Locate the page in the **Manage pages** portlet.
4. Click **Edit Page Properties** for the page.
5. Click **Advanced options**.
6. Click **I want to set parameters**.
7. Add the new parameter and value as follows:
   - New parameter: `resourceaggregation.profile`
   - New value: Enter the profile override for the page, for example `profiles/profile_full.json`.
8. Click **Add**.

9. Click **OK** to save the new parameter.
10. Click **OK** to save your changes to the page properties.

Configuring the security role mapping for the Syndicated Feed Portlet

You must configure the security role mapping for the Syndicated Feed Portlet.

Procedure

1. Open the WebSphere Integrated Solutions Console.
2. Click **Application** > **Application Types**.
3. Click **WebSphere enterprise applications**.
4. Click the **Show filter function** icon.
5. In the **Search terms** field, type `PA_wp.feedspace`.
6. Click **Go**.
7. From the search result list, click **PA_wp.feedspace**.
8. Under Detail properties, click **Security role to user/group mapping** .
9. Check the check box for **All Role**.
10. From the drop-down list, select **All Authenticated in Application's Realm**.
11. Check and verify that the All Role has `All Authenticated in Application's Realm` listed for Special subjects.
12. Click **OK**.
13. Click **Apply** and **OK** to save your changes.

Chapter 15. Staging to production

During portal solution development, the solution is initially developed, tested, and refined on one server or a limited number of servers. The solution is deployed later on live systems, referred to as the production environment. The process of moving the solution from the development environment to the production environment is called staging.

Staging is required at multiple times during the development cycle of a solution. Each release of the solution is created on one system and then moved to the production system. During the development lifecycle, multiple solution releases are created and brought into production. Multiple solution releases are built on the previous product release.

Staging is only possible between the same product release. In contrast, upgrading from one release to a newer release is called migration.

IBM WebSphere Portal Express and IBM Web Content Manager solutions can consist of many artifacts. These artifacts include portlets, themes and skins, portlet services, page layouts, wires, portlet configurations, portlet data, web content, and personalization rules. Staging helps you move those artifacts to the production environment in a controlled way.

security manager for authorization decisions requires that the same external security manager is used to manage authentication to the portal.

Overview of staging to production

Review the topics in the overview section to understand all the requirements to successfully stage your production environment.

"Staging to production process"
This overview provides information necessary to understand how to stage your portal to production from managing your configuration to team roles and portal solution release configurations.

"Tools for staging to production" on page 2485
You can use several tools to stage your server to a production environment.

"Staging a virtual portal overview" on page 2486
A virtual portal shares several resources with the main portal installation, especially all the code artifacts and the JVM. When you deploy a portal solution release to a virtual portal, these types of artifacts must not be deployed again.

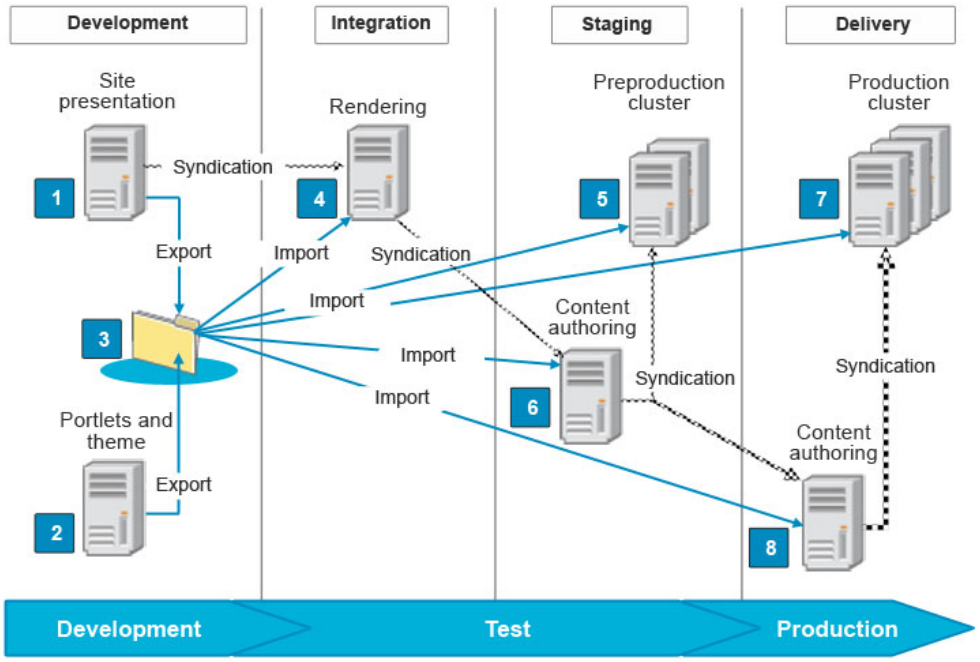
"Staging to production list" on page 2487
The items in the production list can be included in the staging to production Portal Application Archive (PAA) file. However, if you are not using the staging to production PAA file, use this list to determine the tools that are required to move your artifacts from the staging server to the production server. You can also use this list to determine what tool to use for the items not included in the staging to production PAA file.

Staging to production process

This overview provides information necessary to understand how to stage your portal to production from managing your configuration to team roles and portal solution release configurations.

Initial and differential release

The content of a portal solution release is different for the initial staging process and the staging processes that modify the existing content. The following high-level image illustrates the staging to delivery process:



The following information describes the diagram annotation:

1. The web content development environment is where the following information is developed:
   - Presentations
   - Authoring templates
   - Taxonomies
   - Content libraries
   - Content components such as personalization components
   - Personalization rules
2. The Portal development environment is where the following information is developed:
   - Portlets
   - Extensions
   - Themes
   - Applications
3. The export directory is where you store all source artifacts, including Web Content Manager artifacts. You can either compress this directory and import it to your other staging environments or build a Portal Application Archive (PAA) file.
4. Use the rendering environment to test the rendering of the web content and portal development artifacts together. Developers might have access to this environment to test their code.
5. Use the preproduction environment to test everything on a cluster configuration that mirrors the live cluster. Only the administrators have access to this environment.
6. You can use the Content Authoring environment to test the syndication process before you move to the production environment. This environment is the first place where you can test the full content of your site. The full content includes the page structure and the web content. The authoring (6) and rendering (5)

environments are also a good place to run more performance measurements. These measurements ensure that your production environment performs to your expectations. Some teams might also want to use the staging environment for training or demonstration purposes.

7. The production cluster environment is the live website cluster.
8. The authoring environment is where content developers and editors develop new content and content updates for the site.

The initial release

The initial solution release must move all artifacts from the source portal to the staging target, which is assumed to be empty. An empty portal does not hold any application payload. There are procedures in place to allow a clean portal installation and to prepare it as target for an initial staging step. Depending on the set of artifacts that is deployed on the source, multiple tools are required. Use these tools to export the artifacts from the source and import them to the target.

When the initial release is deployed to the production system, users access the system. They can create more user data such as customization and other data. Typically an initial release contains the following data:

- Custom code libraries to the application server that are needed by your applications and extensions
- WAR or EAR files to the application server that might contain custom extensions or themes and skins
- Portlet WAR files
- IBM Web Content Manager libraries
- The initial portal content in an XML file format that is created with the XMLAccess tool
- Personalization rules

The differential release (making updates)

Updates to the portal solution can include creating, modifying, or deleting various artifacts. Artifacts can be pages, portlets, rules, and web content. While the new content can be deployed as a full release, this option would have the following drawbacks:

- Removing of all release data and deploying the new full release is time-consuming. Instead, it would be beneficial to deploy the differences, especially since the differences are only a small part of the solution.
- Customizations can get lost.

To avoid the drawbacks, a differential release can be defined, holding only the changes and not the complete release. A differential release is created by comparing two release exports. Then, you figure out the changes that are required to convert one system into the other one. Release Builder is the tool that helps with this task.

WARNING: If you redeploy your site daily, your JCR size increases because of page versions. Periodically clean up your versions to reduce the JCR size. Go to "Clearing version history" on page 1194 for information.

Use the ReleaseBuilder to manage release configurations independent of user configurations. Release configuration data can be exported into an XMLAccess

configuration file. During staging of follow-on releases, it is possible to stage differences between two releases. Use the XML configuration interface for these differences. Difference means differences between release configurations, including configuration entities that were removed, added, or changed in comparison to the previous release. Go to "Updates using ReleaseBuilder" on page 3624 for information.

Web content updates are done with the Web Content Manager syndication feature. If managed pages are enabled, syndication also ensures that all required page artifacts are transferred along with the content.

Go to "Updates with syndication" on page 2503 for information about managing updates across multiple lines of production.

If your staging server has a different LDAP than the production, go to *Member fixer with syndication* and *Maintaining web content* for information.

Related concepts:

"Web content administration tools" on page 1176
IBM Web Content Manager includes tasks and tools to help maintain your content management system. For example, use the member fixer task to resolve renamed or deleted users and user groups. Use the workflow checker and updater tools to modify workflow security settings, reschedule pending actions, and add workflow to items. Web Content Manager also includes tools to assist with library and item management, and item and version history management.

Related reference:

"Member fixer with syndication" on page 1183
You can configure your system to automatically run the member fixer tool when syndicating. The member fixer is run on the subscriber during syndication. It is run against items that have just been syndicated. Details of the member fixer operations are included in the syndication report.

Tools for staging to production

You can use several tools to stage your server to a production environment.

Portal application archive (PAA)

Each type of artifact can be exported, moved to the target, and imported independently. However, a common archive format does the same tasks. Place all artifacts into the correct location inside the archive file. Copy the PAA file to the target and then use the Solution Installer to deploy it.

For an initial release, the archive file contains all the artifacts that are defined previously. Additional custom components require special handling. The PAA file can be augmented by custom actions that modify the behavior of the Solution Installer as required.

Syndication

Syndication allows your business users to define the content of your Portal Site through an Authoring system. They can then synchronize the content structure, navigation, and web content documents between the authoring system and the production system. Thus syndication is another way to stage changes from the authoring system to the production system. It defines the source and target of the syndication. The artifacts are moved in the direction from source to target only.

Because the business users do the management, the artifacts that can be syndicated are limited to the less critical ones not having the potential to crash the server. Contrary to the PAA process where the release data can be placed on a media that can be moved between the systems, syndication uses an online approach to move changes from one system to another. Thus syndication requires a connection between the systems.

Syndication can be set up between main or virtual portals on different systems or on the same portal system. Because the syndicated pages refer to portlets with the ID of the portlets, an initial staging needs to take place before syndication can be used.

Staging a virtual portal overview

A virtual portal shares several resources with the main portal installation, especially all the code artifacts and the JVM. When you deploy a portal solution release to a virtual portal, these types of artifacts must not be deployed again.

Redeploying can break the references in other virtual portals. Shared resources must be deployed only to the base portal. It is important that the shared resources are deployed to the base portal before they are referenced from the Virtual Portal. Because of these requirements, staging virtual portals needs to be done in the following sequence:

Note: Follow this sequence if the base portal assembly and the Virtual Portal are the same on the source and target server. For example, the staging server has the base portal, VP1, and VP2. Then, you would stage this information to a production server that also contains the base portal, VP1, and VP2.

1. Stage the base portal. This step includes the shared and unique resources for the base portal. You can split the Portal Application Archive (PAA) file for the base portal into two components. One is for the unique components and the other for the shared components. When you build the PAA, use the **exportUniquePortalPAA=false** to export shared artifacts. Or, use **exportSharedPortalPAA=false** to export the unique artifacts. For more information, see *Parameters to customize the release*.
2. Stage the unique artifacts for the Virtual Portal. This step is repeated for all Virtual Portals.

If the source and the target server are not structured the same, then modify the sequence. For example, if the original production server is not capable of carrying the entire base portal load, VP1, and VP2, then you create a new production server that contains only VP2.

1. Stage the shared components of the base portal only.
2. Stage the unique content (for example VP2) of the required Virtual Portal into the base portal of the new server.

This sequence results in a server with only VP2 content.

Note: Before you run the **build-initial-release-paa**, and you have created realms to define the user populations, you must create a super realm. In addition to the realms that you create to define the user populations of the individual virtual portals, you must create a super realm. This super realm spans all other realms and contains all the users of those other realms. It is also known as the default realm. To log in to a virtual portal, the virtual portal administrator and all users must be a member of the realm for that virtual portal. To allow a user access

to more than one virtual portal, that user, and the Virtual Member Manager node to which the user belongs in the hierarchy of the user directory, must be a member of all the realms associated with these virtual portals. This applies to a super administrator who is responsible for all virtual portals within an entire Portal installation. To administer the virtual portals, the master administrator must be a member of the realms of these virtual portals.

Related concepts:

"Parameters to customize the release" on page 2502
You can use these parameters to customize the **build-initial-release-paa** task when you are creating the initial or differential release.

Staging to production list

The items in the production list can be included in the staging to production Portal Application Archive (PAA) file. However, if you are not using the staging to production PAA file, use this list to determine the tools that are required to move your artifacts from the staging server to the production server. You can also use this list to determine what tool to use for the items not included in the staging to production PAA file.

Within the Staging to production documentation, the following directories are the root directories where you place your subdirectories:

- For the base portal: `WebSpherePortal`
- For the Virtual Portals: *`object_id`*

Themes and skins

Choose one of the following static resource options:

Static resources in the WebDAV file store
: Follow the staging to production documentation to export and import your themes and skins. For more information, see "Developing themes for a production portal" on page 2813. To include these resources in your initial or differential release PAA, use the **-DexportWebDavTheme=true** parameter.

  Directory structure
  : Use this method if you are building a custom PAA. Compress the files that contain static theme content and place them in the `content/webdav` directory. This placement allows the themes to be automatically uploaded to the `dav:fs-type1/themes/` directory in the WebDAV file store.

Static resources in an `.ear` file
: Follow the staging to production documentation to export and import your themes and skins. Read "Developing themes for a production portal" on page 2813. To include these resources in your initial or differential release PAA, use the **-DappsToExtract** parameter.

  Directory structure
  : Use this method if you are building a custom PAA. Place the theme `.ear` files in the `InstallableApps/ear` directory.

Portal Server artifacts

The following information is a list of portal server artifacts:

- action
- client

- component
- content-node (pages)
- credential-segment
- device-class
- global-settings
- language
- markup
- resource-type
- skin (definition)
- task
- theme (definition)
- services-settings
- servlet (definition)
- portal
- portlet-app
- portlet
- portletinstance
- proxy-config
- transformation
- transformation-app
- transformationinstance
- url-mapping-context
- virtual-resource
- web-app
- wsrp-producer
- cross-page-wire
- wire

These artifacts are included by default in your initial or differential release PAA. If you are building a custom PAA, use an `XMLAccess.xml` file for installation or uninstallation.

XMLAccess `.xml` files (for installation)
Place these files in the following directory: `content/xmlaccess/install`.

Note: These files might contain the statements to install portlets and transformations out of the `war` directory and to create pages.

XMLAccess `.xml` files (for uninstallation)
Place these files in the following directory: `content/xmlaccess/uninstall`.

Note: These files might contain the statements to remove portlets, transformations, and pages.

References
For information about the portal XML configuration interface and how to work with it, read *Working with the XML configuration interface* and *XML configuration reference*.

WebDAV files

Directory

Use this directory if you are building a custom PAA file. Put these files in the `webdav` directory. This directory and its subtree structure contain artifacts that must be uploaded to the WebDAV file store. There are the following possible subdirectories:

- `themes`
- `skins`
- `layout-templates`
- `common-resources`

References

See "Exporting content from the filestore" on page 2820.

Personalization rules and campaigns

These artifacts are included by default in your initial or differential release PAA. Use these tasks if you are building a custom PAA.

Task Use the **`pznload`** task to export and import the rules and campaigns.

Directory

Place the files in the `content/pzn` directory. Personalization-related artifacts, such as JAR files that contain business rules and personalization `.nodes` files, are in this directory.

References

See "Staging Personalization rules to production" on page 3629.

Web Content Manager data

To include Web Content Manager data in your initial release PAA, use the **`-DexportWcmData=true`** parameter. If you are using a custom PAA, then use the following tasks.

Attention: Run the export task if the data set is less than 10,000 content items and behind a firewall. Syndicate the content if the data set is less than 10,000 content items and not behind a firewall. If the data set is large, clone your database and run the **`sycn-vanityurl-data`** task to synchronize your vanity URL data. Either clone your database or run the export task. Do not do both.

Export task

Use the **`export-wcm-data`** task to export Web Content Manager data.

Import task

Use the **`import-wcm-data`** task to import Web Content Manager data.

Directory

Place the files in the `content/wcm` directory. Each subdirectory represents a separate web content library. These libraries are a specialized form of JCR artifact. Web content libraries are separated into their own directory.

References

Read "Exporting and importing web content libraries" on page 1200.

Portlet WAR files

These artifacts are included by default in your initial or differential release PAA.

If you are building a custom PAA, choose one or more of the following portlet options:

JSR 168 and JSR 286 Portlets (without an `XMLAccess` script to deploy)
Place these portlets in the following directory: `InstallableApps/portlets`.

JSR 168 and JSR 286 Portlets (with an `XMLAccess` script to deploy)
Place these portlets in the following directory: `InstallableApps/war`.

IBM API Portlets
Place these portlets in the following directory: `InstallableApps/war`.

Note: Existing IBM portlets are not handled automatically. These portlets are copied to the archive and must be installed by an accompanied **`XMLAccess`** script.

Transformation `.war` files
Place these portlets in the following directory: `InstallableApps/war`.

Note: These `.war` files are not handled automatically. These files are copied to the archive and must be installed by an accompanied **`XMLAccess`** script.

Shared libraries

To create shared libraries in production, use the **`sharedAppResourcesRootDir`** and **`sharedExtResourcesRootDir`** parameters when you create the initial or differential release PAA. If you are deploying shared libraries manually, be sure that they are included on the production server and that their contents are up to date. Or, if you are manually creating a PAA, put the JAR files into either the `shared/app` or `shared/ext` directories of your custom PAA.

EAR files

To include EAR files in your initial or differential release PAA, use the **`-DappsToExtract`** parameter.

If you are using a custom PAA, place files in the `InstallableApps/ear` directory. This directory contains any EAR files that must be deployed to the application server. It also contains WAR files that do not contain any portlets and must be installed directly to the application server.

More components to stage

The following list contains all portal components that are not handled by the initial import. Use the information in the following list to install the component on each system that is involved in the staging to production process.

Portal Server Performance Tuning parameters
Follow the performance tuning guide: Performance

Active Site Analytics Statistics
There are no applicable tools for exporting or importing Active Site Analytics Statistics. Statistics from staging server are not typically exported or imported. Read “Analyzing portal usage data” on page 1687.

WebSphere Application Server Resource Environment Providers (Portal service settings are stored as Resource Environment Providers)
Run the **`wsadmin`** task to export. Run the following **`ConfigEngine`** task to import: **`update-properties`**.

Read the following documentation:

- http://www.ibm.com/developerworks/websphere/techjournal/0904_chang/0904_chang.html
- "Setting service configuration properties" on page 283

External Security Manager

Follow the staging to production documentation. Read "Staging and external security managers" on page 2506.

Custom components

The following items are custom components:

- Custom login commands
- Custom credential vault adapters
- Custom credentials
- Custom component property files

Custom components are not part of WebSphere Portal Express. Custom components that are developed by the customer must be manually re-created on each system that is involved in the staging to production process.

Vanity URLs

These artifacts are included by default in your initial or differential release PAA. A vanity URL is a portal artifact that is stored with the portal page that it targets. Vanity URLs are managed and stored in the Web Content Manager Portal Site library. Therefore, if you want to stage your portal to production, it is not enough to stage the portal pages by using the portal XML configuration interface (XMLAccess). You must transfer data on both the portal and the Web Content Manager side.

Related concepts:

Staging-server topology for Web Content Manager
If you need to deliver large complex websites with many site users and content creator, implement a staging server configuration. Implementing a staging server provides an environment for checking for accuracy, issues with the design, and performance. With a staging server configuration authoring, staging and delivery are separated onto different servers. The staging environment can be used for testing or to allow changes from the authoring environment to accumulate before you syndicate the changes to the delivery environment in a single batch.

"Web content testing environments" on page 114
Testing environments can be simple or complex. A simple example is a stand-alone server where content and non-content items are tested before they are sent to the live site. A complex environment is a complete replica of your delivery environment. A more complex environment is used to test content, theme, and application changes and the performance of your delivery environment.

"Publishing personalization rules overview" on page 2298
WebSphere Portal Express Personalization sends published rules across HTTP to a servlet which resides on each personalization server. This servlet can receive publishing data or initiate new publishing jobs. When a user begins a publishing job from the personalization authoring environment, the local servlet is provided with the set of information necessary to complete the job. The local servlet contacts the destination endpoint servlet (which could be the same servlet) and sends its data to it. The destination servlet reports success or failure.

Related tasks:

"Exporting and importing a web content library" on page 1203
You can export the contents of a web content library to disk and import this data into another web content server. Use this feature to make a backup copy of a web content library, and to move data between servers. This function cannot be used to send updates, deletes, and moves. It is only suitable for populating new items.

Deleting a web content library
When a web content library is no longer required, you can delete the library.

"Using the XML configuration interface to work with virtual portals" on page 1414
You can export and import the contents of individual virtual portals by using the XML configuration interface. For example, you can use the XML configuration interface to fill a newly created virtual portal with content. As each virtual portal has its own globally unique portal ID, you can determine all resources that are associated with that virtual portal clearly and individually.

Related reference:

"XML configuration reference" on page 1082
Learn more about XML input structure, XML tags for portal resources, attributes for special purposes such as locale data, object IDs, and more. Also find information about action attributes that determine the type of processing that the XML configuration reference applies to the portal resource. There are syntax restrictions that you need to consider as well as information about how to determine the object IDs for portal resources.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

 Configuring a web content staging environment
Configure the staging environment to emulate the web content delivery environment and allow for testing before deployment.

Creating and deploying the initial release

Build the initial Portal Application Archive (PAA) file, prepare the servers for the deployment, and then deploy the initial release to your production servers.

1. "Creating the initial release" on page 2493
   When you want to stage your initial release to another server, you must build the initial release Portal Application Archive (PAA) file from your source server.
2. "Preparing the servers for initial staging" on page 2495
   You must set up your production servers before you move content from the staging server to the production server. The steps remove any release content from these servers to prepare them for the following import of the release data. It is assumed that these servers are fresh installed servers. The servers must not contain any customization data. Complete all database and security configurations.
3. "Deploying the initial release" on page 2496
   After you create and prepare your initial staging and production servers, you must install and deploy the contents of the staging server to the production server. If you have a cluster, install and deploy on the primary and secondary nodes of the cluster. After you stage the initial release to production servers, you can install and deploy your differential release to the production servers.

4. "Deploying the initial release in a multiple cluster" on page 2498
   If you are using a multiple cluster in single cell topology, you must run the **empty-portal** task before you deploy the initial release and before you deploy the PAA file. Use the **-DemptyPortalDuringDeployPAA=false** parameter during the deployment.

Creating the initial release

When you want to stage your initial release to another server, you must build the initial release Portal Application Archive (PAA) file from your source server.

About this task

The initial and differential release PAA file contains all the pertinent items that are related to your release, including the following items:

- Portal Server artifacts
- Web Content Manager Libraries (optional: use the **exportWcmData** parameter)
- Shared Libraries (optional: use the **sharedAppResourcesRootDir** and or the **sharedExtResourcesRootDir** parameters)
- WebDAV files for themes/skins (optional: use the **exportWebDavTheme** parameter)
- Portlet WAR filesEAR files (optional: use the **appsToExtract** parameter)
- WebSphere Application Server Resource Environment Providers (optional: use the **exportREP** parameter)
- Vanity URLs

Procedure

1. Install, configure, and upgrade WebSphere Portal Express on the staging server. This step includes database and security configurations.
2. Develop a release on the staging server. As part of this step, you might have pages, portlets, themes, skins, personalization rules, web content, and other items.
3. Open a command line and change to the *wp_profile_root*/ConfigEngine directory.
4. Run the following command to create a Portal Application Archive (PAA) file for your initial release, including PAA files for all of your virtual portals:
   - Linux :

     ```
     ./ConfigEngine.sh build-initial-release-paa -DdestPAADir=directory_to_store_PAA -DWasPasswor
     ```

   - IBM i:

     ```
     ConfigEngine.sh build-initial-release-paa -DdestPAADir=directory_to_store_PAA -DWasPassword=
     ```

   - Windows:

     ```
     ConfigEngine.bat build-initial-release-paa -DdestPAADir=directory_to_store_PAA -DWasPassword
     ```

   Note: The directory that you enter for the **destPAADir** parameter must be an existing directory.

   You can add the following parameters to customize the **build-initial-release-paa** task:

   sharedAppResourcesRootDir
   The directory for .jar files, classes, and compressed files that are then stored in the shared/app directory.

   sharedExtResourcesRootDir
   The directory for .jar files, classes, and compressed files that are then stored in the shared/ext directory.

appsToExtract
A comma-separated list of applications to extract from the source environment. For example, you might extract the `YourTheme.ear,MyApp.ear,CustWorkflow.ear` files. They are then packaged in the PAA file.

exportWebDavTheme
Enter a value of `true` to download and include the `themes.zip` file from WebDAV.

exportWcmData
Enter a value of `true` to export all Web Content Manager libraries. The **export-wcm-data** task is run when you use **exportWcmData**.

Restriction: Do not use this parameter in place of syndicating the libraries from the target environment.

Related concepts:

"Staging Personalization rules to production" on page 3629
Use the steps in this file to move Personalization rules from a staging system to a production system. There are a number of methods for moving rules between servers, each suitable for different situations.

Related tasks:

"Synchronizing the vanity URL database" on page 2104
Vanity URLs are stored as part of the page in the JCR database in the portal page site area of Web Content Manager. For performance reasons, the data is also stored in the WebSphere Portal Express database. When the data is modified, the portal synchronizes the data between both sides. However, under certain circumstances it can happen that the data is not synchronized. For such cases, the portal provides a configuration task that synchronizes the data.

"Using the XML configuration interface to work with virtual portals" on page 1414
You can export and import the contents of individual virtual portals by using the XML configuration interface. For example, you can use the XML configuration interface to fill a newly created virtual portal with content. As each virtual portal has its own globally unique portal ID, you can determine all resources that are associated with that virtual portal clearly and individually.

"Exporting and importing a web content library" on page 1203
You can export the contents of a web content library to disk and import this data into another web content server. Use this feature to make a backup copy of a web content library, and to move data between servers. This function cannot be used to send updates, deletes, and moves. It is only suitable for populating new items.

"Transferring portal configuration data by using the XML configuration interface" on page 1072
When you use the XML configuration interface to transfer WebSphere Portal Express configuration data, you export or import an XML script file. In most cases, you can use the result file from an XML export for an XML import. Sometimes you can use the export result file directly, sometimes you must modify it.

Related reference:

"XML configuration reference" on page 1082
Learn more about XML input structure, XML tags for portal resources, attributes for special purposes such as locale data, object IDs, and more. Also find information about action attributes that determine the type of processing that the XML configuration reference applies to the portal resource. There are syntax restrictions that you need to consider as well as information about how to determine the object IDs for portal resources.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Preparing the servers for initial staging

You must set up your production servers before you move content from the staging server to the production server. The steps remove any release content from these servers to prepare them for the following import of the release data. It is assumed that these servers are fresh installed servers. The servers must not contain any customization data. Complete all database and security configurations.

Procedure

1. Install and configure WebSphere Portal Express on the production server. This step includes database and security configurations.

   Attention: Ensure that your security configurations and context root URLs match on the staging and production servers. Also, ensure that the production server is configured with the wanted external database.
2. Log on to the production server and delete all existing Web Content Manager Libraries.

   Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**. Click **Delete library** for each library on the system.

   Attention: Edit any libraries that have the option **Prohibit library from being deleted**. Clear that option before you delete them.
3. If you use the web application bridge feature, set the context root for the **wp.vwat.servlet.ear** application:
   a. Log on to the WebSphere Integrated Solutions Console.
   b. Go to **Applications** > **Application Types** > **WebSphere enterprise applications**.
   c. Find and click the **wp.vwat.servlet.ear** application link.
   d. Under the **Web Module Properties** heading, click **Context Root For Web Modules**.
   e. Change the context root to /. This step can create name conflicts. Add a rewrite rule to avoid these conflicts. For more information read *Apache Module mod_rewrite* and *Providing short vanity URLs*.
   f. Click **OK**.
   g. Click **Save** to save your changes to the master configuration.
   h. Stop and restart the **wp.vwat.servlet.ear** application.
4. If you have a clustered environment, turn off automatic node synchronization on all secondary nodes.

Related information:

Exporting and importing web content libraries

IBM Web Content Manager provides two methods for exporting and importing web content libraries: an export or import that operates on one library, and an export or import that creates a separate copy of a library. With either method, you can export the contents of a web content library to disk and import this data into another web content server. If you're working with a copy of a library, you can also import that library into the same web content server multiple times, resulting in a new library after each import without affecting previous copies. Exporting and importing libraries can be used to make a backup copy of a web content library and can also be used to move data between servers. However, this function cannot be used to send updates, deletes, and moves. It is only suitable for populating new items.

Deploying the initial release

After you create and prepare your initial staging and production servers, you must install and deploy the contents of the staging server to the production server. If you have a cluster, install and deploy on the primary and secondary nodes of the cluster. After you stage the initial release to production servers, you can install and deploy your differential release to the production servers.

Procedure

1. Run the following command from the *wp_profile_root*/ConfigEngine directory of the production server to install and deploy the initial PAA file on the production server:
   - Linux :

     ```
     ./ConfigEngine.sh install-paa -DPAALocation=/WebSpherePortal.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlineMode=true
     ./ConfigEngine.sh deploy-paa -DappName=WebSpherePortal -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password
     ```

   - IBM i:

     ```
     ConfigEngine.sh install-paa -DPAALocation=/WebSpherePortal.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlineMode=true
     ConfigEngine.sh deploy-paa -DappName=WebSpherePortal -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password
     ```

   - Windows:

     ```
     ConfigEngine.bat install-paa -DPAALocation=/WebSpherePortal.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlineMode=true
     ConfigEngine.bat deploy-paa -DappName=WebSpherePortal -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password
     ```

2. Run the following commands to install and deploy the virtual portal PAA file on the production server:
   - Linux :

     ```
     ./ConfigEngine.sh install-paa -DPAALocation=/object_id.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlineMode=true
     ./ConfigEngine.sh deploy-paa -DappName=object_id -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password -DVirtualPortalParame
     ```

   - IBM i:

     ```
     ConfigEngine.sh install-paa -DPAALocation=/object_id.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlineMode=true
     ConfigEngine.sh deploy-paa -DappName=object_id -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password -DVirtualPortalParamete
     ```

   - Windows:

     ```
     ConfigEngine.bat install-paa -DPAALocation=/object_id.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlineMode=true
     ConfigEngine.bat deploy-paa -DappName=object_id -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password -DVirtualPortalParamet
     ```

   Tip: Where **VirtualPortalParameter** is one of the following options:

   -DVirtualPortalHostName=*myvirtualportal.mycompany.com*
   Use this parameter if you know the host name of the virtual portal.

   -DVirtualPortalContext=*VirtualPortal1*
   Use this parameter if you know the context root of the virtual portal.

If you are deploying multiple Virtual Portals, run **list-all-virtual-portals** on the source environment, to correctly associate the **VirtualPortalParameter** value with the same Virtual Portal. For more information, see *Portal configuration tasks for administering virtual portals*.

Note: Anything included in the PAA file is included when you run this command, including Web Content Manager and EAR files. If you created the PAA by setting the `exportWcmData` parameter to `true`, then the Web Content Manager libraries are imported during the deployment step.

3. If you cloned your JCR database, extra steps are necessary. You must attach the clone JCR after you do the deployment for the base and virtual portals. The JCR database has objectIDs for the virtual portal that must match the source environment. The **deploy-paa** for the virtual portal does that task, but the **deploy-paa** for the virtual portals must be done before you attach to the cloned database. Run the following task on the target server to synchronize your vanity URL data. The release database and JCR databases share some vanity URLs. If you clone the JCR database, the sharing is broken. This task fixes those errors.
   - Linux :

     ```
     ./ConfigEngine.sh sync-vanityurl-data -DWasPassword=password -DPortalAdminPwd=password
     ```
   - IBM i:

     ```
     ConfigEngine.sh sync-vanityurl-data -DWasPassword=password -DPortalAdminPwd=password
     ```
   - Windows:

     ```
     ConfigEngine.bat sync-vanityurl-data -DWasPassword=password -DPortalAdminPwd=password
     ```
4. Review the checklist. Export or manually re-create any items that cannot be packaged with the PAA file such as Resource Environment Providers and custom content.
5. If you use WSRP, review the configuration of the WSRP web services.
   - If you use your portal as a WSRP producer, manually re-create the web service security configuration of the WSRP service providers. For more information, see the *WSRP services* section.
   - If you use your portal as a WSRP Consumer, verify the web service security configuration and manually re-create the web service security configuration if needed.
     a. If you configured WSRP Producer ports for web service security, for example, by using the Web Services admin portlet or XMLAccess, review the web service security configuration.
     b. If you configured WSRP web service clients, for example, by configuring WSRP service clients through policy sets in the administrative console or by adding service references, you must manually re-create the configuration of the WSRP web service clients. For more information, see the *WSRP services* section.
     c. If you configured web service security by using an LTPA version 1 token, you can enable those tokens. For more information, see the *WSRP services* section.
     d. If you configured HTTP-cookie-based single sign-on, for example, by configuring corresponding client cookie forwarding rules, you must review and re-create the resource environment properties for the cookie forwarding rules. For more information, see the *WSRP services* section.
6. Optional: Export search collections from the staging server and import them into the production server. For more information, see *Exporting and importing search collections*. If you are using alternative context root URLs, go to **Manage Search** portlet. To open the **Manage Search** portlet, click the **Administration**

menu icon. Then, click **Search Administration** > **Manage Search**. Update the search collection URL links on the staging server to point to the alternative root. For example, `http://yourdomain.com:port/your_root/seedlist/myserver?SeedlistId=&Source=com.ibm.workplace.wcm.plugins.seedlist.retriever.WCMRetrieverFactory&Action=Get`

Note: If you installed any additional PAA files on the staging server, they are not included in the initial release PAA. Each additional PAA that was installed and deployed on the staging server must be manually installed and deployed on the production server after the initial release PAA is installed.

7. If you have a clustered environment, enable automatic synchronization for the nodes and synchronize the nodes.
8. Restart the server.

Related concepts:

"WSRP services" on page 1433
IBM WebSphere Portal Express supports the Web Services for Remote Portlets (WSRP) standard. By using this standard, portals can provide portlets, applications, and content as WSRP services. Other portals can then integrate the WSRP services as remote portlets for their users.

Related tasks:

"Exporting and importing search collections" on page 707
View the steps to export search collections from a source portal and import them into a target portal.

"Portal configuration tasks for administering virtual portals" on page 1406
You can use configuration tasks for administering virtual portals.

Deploying the initial release in a multiple cluster

If you are using a multiple cluster in single cell topology, you must run the **empty-portal** task before you deploy the initial release and before you deploy the PAA file. Use the **-DemptyPortalDuringDeployPAA=false** parameter during the deployment.

Before you begin

If you have a single cell with a cluster A and a cluster B, use the following steps after you installed the PAA file on both clusters.

Procedure

1. On cluster B, run the following commands.
   - Linux :

     ./ConfigEngine.sh empty-portal -DWasPassword=*password* -DPortalAdminPwd=*password*
   - IBM i:

     ConfigEngine.sh empty-portal -DWasPassword=*password* -DPortalAdminPwd=*password*
   - Windows:

     ConfigEngine.bat empty-portal -DWasPassword=*password* -DPortalAdminPwd=*password*
2. On cluster A, do a full resynchronization with the WebSphere Integrated Solutions Console.
3. On cluster A, run the following commands:
   - Linux :

     ./ConfigEngine.sh empty-portal -DWasPassword=*password* -DPortalAdminPwd=*password*
   - IBM i:

ConfigEngine.sh empty-portal -DWasPassword=*password* -DPortalAdminPwd=*password*

- Windows:

ConfigEngine.bat empty-portal -DWasPassword=*password* -DPortalAdminPwd=*password*

4. On cluster B, do a full resynchronization with the WebSphere Integrated Solutions Console.
5. On cluster A, run the following commands:
   - Linux :

     ./ConfigEngine.sh deploy-paa -DappName=WebSpherePortal -DforceDeploy=true -DWasPassword=*password* -DPortalAdminPwd=*password* -DemptyPort

   - IBM i:

     ConfigEngine.sh deploy-paa -DappName=WebSpherePortal -DforceDeploy=true -DWasPassword=*password* -DPortalAdminPwd=*password* -DemptyPortal

   - Windows:

     ConfigEngine.bat deploy-paa -DappName=WebSpherePortal -DforceDeploy=true -DWasPassword=*password* -DPortalAdminPwd=*password* -DemptyPorta

6. On cluster B, run the following commands:
   - Linux :

     ./ConfigEngine.sh deploy-paa -DappName=WebSpherePortal -DforceDeploy=true -DWasPassword=*password* -DPortalAdminPwd=*password* -DemptyPort

   - IBM i:

     ConfigEngine.sh deploy-paa -DappName=WebSpherePortal -DforceDeploy=true -DWasPassword=*password* -DPortalAdminPwd=*password* -DemptyPortal

   - Windows:

     ./ConfigEngine.bat deploy-paa -DappName=WebSpherePortal -DforceDeploy=true -DWasPassword=*password* -DPortalAdminPwd=*password* -DemptyPor

Creating and deploying a differential release

Create a differential release of your existing Portal Application Archive (PAA) file. Then, deploy your changes to your production servers. Use Syndication to move IBM Web Content Manager content to your production servers.

1. "Creating the differential release"
   To update your Portal Application Archive (PAA) file, you must create a differential release from your source server.
2. "Deploying the differential release" on page 2500
   After you create the differential release PAA file, you can install and deploy your differential release to the production servers. If you have a cluster, install and deploy on the primary and secondary nodes of the cluster.

Creating the differential release

To update your Portal Application Archive (PAA) file, you must create a differential release from your source server.

Procedure

1. Develop a release on the staging server. As part of this step, you might have non-managed pages, portlets, themes, skins, and other items.

   Tip: Use Syndication to move IBM Web Content Manager content to your production servers.
2. Open a command line and change to the *wp_profile_root*/ConfigEngine directory.
3. Run the following command to create a Portal Application Archive (PAA) file for your differential release, including PAA files for all of your virtual portals. Go to *Parameters to customize the release* for parameters to customize your **build-initial-release-paa** task.
   - Linux :

     ./ConfigEngine.sh build-initial-release-paa -DdestPAADir=*directory_to_store_PAA* -DpreviousPA

   - IBM i:

     ConfigEngine.sh build-initial-release-paa -DdestPAADir=*directory_to_store_PAA* -DpreviousPAA=

- Windows:

```
ConfigEngine.bat build-initial-release-paa -DdestPAADir=directory_to_store_PAA -DpreviousPAA=i
```

Important: The directory that you enter for the **destPAADir** parameter must be an existing directory.

You can add the following parameters to customize the **build-initial-release-paa** task.

javaoption
Add this parameter if you are staging a large set of data. For example, add this string to your command, `-javaoption -Xmx2048M`. Depending on your system and the amount of data, the **-Xmx** value might be higher. Use `2048M` as a starting value.

sharedAppResourcesRootDir
The directory for `.jar` files, classes, and compressed files that are then stored in the `shared/app` directory.

sharedExtResourcesRootDir
The directory for `.jar` files, classes, and compressed files that are then stored in the `shared/ext` directory.

appsToExtract
A comma-separated list of applications to extract from the source environment. For example, you might extract the "`wps_theme,iehs,dojo_resources`" files. They would then be packaged in the PAA file.

exportWebDavTheme
Enter a value of `true` to download and include the `themes.zip` file from WebDAV.

What to do next

Deploy your differential release on the production servers.

Related tasks:

"Parameters to customize the release" on page 2502
You can use these parameters to customize the **build-initial-release-paa** task when you are creating the initial or differential release.

Deploying the differential release

After you create the differential release PAA file, you can install and deploy your differential release to the production servers. If you have a cluster, install and deploy on the primary and secondary nodes of the cluster.

Procedure

1. Run the following command from the *wp_profile_root*`/ConfigEngine` directory of the production server to uninstall and delete any existing differential PAA files:
   - Linux :

```
./ConfigEngine.sh uninstall-paa -DappName=WebSpherePortalUpdate -DWasPassword=password -DPortalAdminPwd=password

./ConfigEngine.sh delete-paa -DdeleteAll=true
```

   - IBM i:

```
ConfigEngine.sh uninstall-paa -DappName=WebSpherePortalUpdate -DWasPassword=password -DPortalAdminPwd=password

ConfigEngine.sh delete-paa -DdeleteAll=true
```

   - Windows:

```
ConfigEngine.bat uninstall-paa -DappName=WebSpherePortalUpdate -DWasPassword=password -DPortalAdminPwd=password

ConfigEngine.bat delete-paa -DdeleteAll=true
```

2. Run the following command to install and deploy the differential PAA file:
   - Linux :

     ```
     ./ConfigEngine.sh install-paa -DPAALocation=/WebSpherePortalUpdate.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlin

     ./ConfigEngine.sh deploy-paa -DappName=WebSpherePortalUpdate -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password
     ```

   - IBM i:

     ```
     ConfigEngine.sh install-paa -DPAALocation=/WebSpherePortalUpdate.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlineM

     ConfigEngine.sh deploy-paa -DappName=WebSpherePortalUpdate -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password
     ```

   - Windows:

     ```
     ConfigEngine.bat install-paa -DPAALocation=/WebSpherePortalUpdate.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offline

     ConfigEngine.bat deploy-paa -DappName=WebSpherePortalUpdate -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password
     ```

3. Run the following command from the *wp_profile_root*/ConfigEngine directory of the production server to uninstall virtual portal updated PAA files:
   - Linux :

     ```
     ./ConfigEngine.sh uninstall-paa -DappName=object_idUpdated.paa -DWasPassword=password -DPortalAdminPwd=password

     ./ConfigEngine.sh delete-paa -DdeleteAll=true
     ```

   - IBM i:

     ```
     ConfigEngine.sh uninstall-paa -DappName=object_idUpdated.paa -DWasPassword=password -DPortalAdminPwd=password

     ConfigEngine.sh delete-paa -DdeleteAll=true
     ```

   - Windows:

     ```
     ConfigEngine.bat uninstall-paa -DappName=object_idUpdated.paa -DWasPassword=password -DPortalAdminPwd=password

     ConfigEngine.bat delete-paa -DdeleteAll=true
     ```

4. Run the following commands to install and deploy the virtual portal PAA file:
   - Linux :

     ```
     ./ConfigEngine.sh install-paa -DPAALocation=/object_idUpdated.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlineMode

     ./ConfigEngine.sh deploy-paa -DappName=object_idUpdated -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password -DVirtualP
     ```

   - IBM i:

     ```
     ConfigEngine.sh install-paa -DPAALocation=/object_idUpdated.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlineMode=t

     ConfigEngine.sh deploy-paa -DappName=object_idUpdated -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password -DVirtualPor
     ```

   - Windows:

     ```
     ConfigEngine.bat install-paa -DPAALocation=/object_idUpdated.paa -DWasPassword=password -DPortalAdminPwd=password -Dwp.si.offlineMode=

     ConfigEngine.bat deploy-paa -DappName=object_idUpdated -DforceDeploy=true -DWasPassword=password -DPortalAdminPwd=password -DVirtualPo
     ```

   Tip: Where **VirtualPortalParameter** is one of the following options:

   -DVirtualPortalHostName=*myvirtualportal.mycompany.com*
   Use this parameter if you know the host name of the virtual portal.

   -DVirtualPortalContext=*VirtualPortal1*
   Use this parameter if you know the context root of the virtual portal.

   If you are deploying multiple Virtual Portals, run **list-all-virtual-portals** on the source environment, to correctly associate the **VirtualPortalParameter** value with the same Virtual Portal. For more information, see *Portal configuration tasks for administering virtual portals*.

   Note: Run syndication for Web Content Manager differential content.

5. If you have a clustered environment, enable automatic synchronization for the nodes and synchronize the nodes.
6. Optional: Complete this step if PAA files include shared libraries. If you included **-DsharedAppResourcesRootDir** and **-DsharedExtResourcesRootDir** when the differential and initial release was created, remove the shared library

that was created during deployment of the initial release. For example, if you included the `sample.jar` file in the initial release PAA, and updated the `sample.jar` file in the differential release PAA, there is a class path conflict with this JAR file that is included in two locations. Find and remove the following JAR files from initial deployment:

- *wp_profile_root*`/paa/WebSpherePortal/components/WebSpherePortal.shared/shared/ext/sample.jar`
- *wp_profile_root*`/paa/WebSpherePortal/components/WebSpherePortal.shared/shared/app/sample.jar`

7. Restart the server.

Related concepts:

"WSRP services" on page 1433
IBM WebSphere Portal Express supports the Web Services for Remote Portlets (WSRP) standard. By using this standard, portals can provide portlets, applications, and content as WSRP services. Other portals can then integrate the WSRP services as remote portlets for their users.

Related tasks:

"Exporting and importing search collections" on page 707
View the steps to export search collections from a source portal and import them into a target portal.

Related reference:

"Portal configuration tasks for administering virtual portals" on page 1406
You can use configuration tasks for administering virtual portals.

Parameters to customize the release

You can use these parameters to customize the **`build-initial-release-paa`** task when you are creating the initial or differential release.

`previousPAA`
Points to a previous PAA file, which is used to create an updated PAA file.

`sharedAppResourcesRootDir`
The directory for shared application resources that are added to the PAA file.

`sharedExtResourcesRootDir`
The directory for the `shared/ext` resources that are added to the PAA file.

`appsToExtract`
A comma-separated list of applications to extract from the IBM WebSphere Application Server and add to the PAA file.

`exportWebDavTheme`
When set to true, this parameter adds WebDAV theme resources to the PAA file.

`exportREP`
When set to true, this parameter adds Resource Environment Provider custom properties to the PAA file. Its default is true.

`versionPAA`
Set to the version number of the PAA file that you created. The default is 1.

`minorVersionPAA`
Set to the minor version number of the PAA file that you created. The default is 0.

destPAADir
Writes PAA files to the directory you specify. The default is the system temporary directory.

exportUniquePortalPAA
Set to true to export the unique portal resource to the base of the virtual portal. The default is true.

exportSharedPortalPAA
Set to true to export the shared resource from the base portal. The default is true.

exportPortalSiteLib
Set to true to export the Portal site library that is used by the managed pages feature. The default is true if managed pages is turned on.

exportManagedPages
Set to true to export managed pages with XMLAccess. The default is false if managed pages is turned on and true if managed pages is turned off.

exportPAAUrlMappings
Set to true to include URL mappings in the PAA file. The default is true.

exportWcmData
Set to true to include IBM Web Content Manager content in the PAA file. The default is false.

Important: Use the **exportWcmData** parameter only for the initial release. Use syndication for your Web Content Manager differential content.

javaoption
Add this parameter if you are staging a large set of data. For example, add this string to your command: **-javaoption -Xmx2048M**. Depending on your system and the amount of data, the **-Xmx** value might be higher. Use 2048 Mb as a starting value.

Updates with syndication

After setting up your initial staging and production servers and deploying the initial release, you can use the syndication feature of IBM Web Content Manager to update content in web content libraries. If managed pages are enabled, syndication also ensures that all required page artifacts are transferred along with the content.

"Syndication and staging"
You can use syndication to update content that was originally created by deploying portal solution releases with either the XML configuration interface or through a Portal Application Archive (PAA) file. You can also set up syndication between virtual portals or primary portals on the same system or between virtual portals on different systems.

"Staging artifacts that are not transferred by syndication" on page 2505
The `ExportManagedPagesRelease.xml` file provides an example that you can use with the XML configuration interface to export all portal artifacts except pages and wires. You can use this file when staging to production with managed pages.

Syndication and staging

You can use syndication to update content that was originally created by deploying portal solution releases with either the XML configuration interface or

through a Portal Application Archive (PAA) file. You can also set up syndication between virtual portals or primary portals on the same system or between virtual portals on different systems.

Important: Successful syndication requires that the object IDs for portlets, themes, and other artifacts are the same on both the syndicator and subscriber. Because the syndication process itself does not manage these artifacts, you must synchronize the two servers by an initial staging process before you syndicate. In addition, each time that you deploy an artifact that is not managed by syndication to the source portal, you must stage the artifact with the appropriate staging tool. However, if the source and target are different virtual portals on the same portal server, this step is unnecessary, because these artifacts are shared between virtual portals.

Limitations:

- Syndication can be set up only between systems that use the same user repository.
- Syndication for managed pages between multiple servers requires that you run an initial staging to all the servers.
- The syndication process runs a prerequisite check on the subscriber to ensure that any required themes, skins, portlets, or iWidgets on a page are present on the target system. If any required objects are missing on the subscriber, syndication is not run for the page. This behavior can result in missing pages and syndication errors for affected pages. Use the XML configuration interface to transfer the missing resources.
- iWidgets and portlets can store data in the WebDAV file store. The syndication process does not verify or transfer WebDAV data. If a portlet on a managed page requires data from the WebDAV file store, you must manually copy the required objects to the target system.

For information about using syndication, see *Syndication*.

Managed pages and syndication

If managed pages are enabled and you are using syndication as part of the staging process, the following considerations apply:

- In addition to web content, syndication includes artifacts like pages and wires.
- When you populate the production server for the first time, you must run a full export with either the XML configuration interface or through a Portal Application Archive (PAA) file. This full export can include pages and wires.
- When you update the production server after the initial staging, do not continue to export pages and wires, but instead use syndication to transfer the updates. If you export pages and wires after the initial staging, you might inadvertently overwrite changes that are already published through syndication.

The `ExportManagedPagesRelease.xml` file or a Portal Application Archive (PAA) file is available for exporting all artifacts except pages and wires. For details on using this file, see *Staging artifacts that are not transferred by syndication* or *Creating a differential release*.

Related concepts:

"Syndication" on page 448
Use syndication to replicate web content library data from one server to another server. Syndication is based on a syndicator and subscriber relationship. The syndicator has the current data. The subscriber received the current data from the syndicator.

"Syndication relationships" on page 449
Syndication is the method that is used by IBM Web Content Manager to replicate data from a web content library on one server to a web content library on another server.

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

Related tasks:

"Staging artifacts that are not transferred by syndication"
The ExportManagedPagesRelease.xml file provides an example that you can use with the XML configuration interface to export all portal artifacts except pages and wires. You can use this file when staging to production with managed pages.

"Creating the differential release" on page 2499
To update your Portal Application Archive (PAA) file, you must create a differential release from your source server.

Staging artifacts that are not transferred by syndication

The ExportManagedPagesRelease.xml file provides an example that you can use with the XML configuration interface to export all portal artifacts except pages and wires. You can use this file when staging to production with managed pages.

Before you begin

Stage artifacts that are not part of the syndication, such as portlet definitions, themes, and personalization rules with the release builder Portal staging tool. It ensures that the artifacts have the same object IDs across the staging systems because they are referenced by this object ID.

About this task

The file is in the *PortalServer_root*/doc/xml-samples directory.

Procedure

1. To export these artifacts with the ExportManagedPagesRelease.xml file, use the **xmlaccess** command.

   Linux
   ```
   ./xmlaccess.sh -in /opt/IBM/WebSphere/PortalServer/doc/xml-
   samples/ExportManagedPagesRelease.xml -out /Sample1/content/
   xmlaccess/install/staging-version1.xml -url "http://
   stagingserver.example.com:port/wps/config" -user wpsadmin_user_ID
   -password wpsadmin_pwd
   ```

   IBM i
   ```
   xmlaccess.sh -in /QIBM/ProdData/WebSphere/PortalServer/V8/
   product_offering/doc/xml-samples/ExportManagedPagesRelease.xml
   -out /Sample1/content/xmlaccess/install/staging-version1.xml -url
   "http://stagingserver.example.com:port/wps/config" -user
   wpsadmin_user_ID -password wpsadmin_pwd
   ```

   Windows
   ```
   xmlaccess.bat -in C:\IBM\WebSphere\PortalServer\doc\xml-samples\
   ExportManagedPagesRelease.xml -out \Sample1\content\xmlaccess\
   install\staging-version1.xml -url "http://
   stagingserver.example.com:port/wps/config" -user wpsadmin_user_ID
   -password wpsadmin_pwd
   ```

   The exported configuration is stored in the staging-version1.xml file.

2. You can use the exported file to import these artifacts. Use the /Sample1/content/xmlaccess/install/staging-version1.xml file and use the **xmlaccess** command.

   Linux `./xmlaccess.sh -in /Sample1/content/xmlaccess/install/staging-version1.xml -out /Sample1/content/xmlaccess/install/staging-version1-Output.xml -url "http://productionserver.example.com:port/wps/config" -user wpsadmin_user_ID -password wpsadmin_pwd`

   IBM i `xmlaccess.sh -in /Sample1/content/xmlaccess/install/staging-version1.xml -out /Sample1/content/xmlaccess/install/staging-version1-Output.xml -url "http://productionserver.example.com:port/wps/config" -user wpsadmin_user_ID -password wpsadmin_pwd`

   Windows

   ```
   xmlaccess.bat -in C:\Sample1\content\xmlaccess\install\staging-version1.xml -out C:\Sample1\content\xmlaccess\install\staging-version1-Output.xml -url "http://stagingserver.example.com:port/wps/config" -user wpsadmin_user_ID -password wpsadmin_pwd
   ```

Staging and external security managers

Staging to production where external security managers (ESM) are used is complex and needs special consideration. The following section discusses considerations of the impact of external security managers on the staging process. External security managers can be used to externalize authentication and authorization decisions from the portal. Externalization of authentication decisions to an external security manager has no impact on the staging to production functionality. Management of authorizations by an external security manager has an impact on the staging to production scenario. Using an external security manager for authorization decisions requires that the same external security manager is used to manage authentication to the portal.

Use the security manager to manage entities that the centralized security manager controls. Managing those entities elsewhere violates the principles of centralized security control. This principle does not change in staging-to-production support. For staging-to-production, this principle leads to the inability to modify security definitions of a resource that is externalized. The following sections describe the direct implications in external security manager (ESM) scenarios for staging-to-production.

The XML configuration interface is used for configuration management in the staging-to-production support. The XML configuration interface covers configurations that are managed by the portal. The XML configuration interface configuration files contain a list of all role mappings for all internally managed resources. Using external security managers allows management of entitlements for selected resources outside of the portal.

For IBM WebSphere Portal Express, the XML configuration interface covers security definitions of externalized resources. You can provide a request parameter within an export request through this functionality for the XML configuration interface. This parameter causes the XML configuration interface to include role mappings of all resources in the output file. The exported file contains role

mappings for internally managed resources and externally managed resources. This feature allows for the staging of role mapping of all resources that are not already externalized in the target system.

The following support matrix illustrates staging support of entitlements in scenarios that involve external security managers (ESM). The source system refers to the system from which the configuration is exported (typically the integration system). The target system is the system into which the configuration is going to be imported (for example, staging or production system).

	no-ESM Target	**ESM Target**
no-ESM Source	All role mappings can be fully synchronized.	Resources on the target system are initially managed internally after release staging. Resources can be externalized on the target system. Role mappings of externally managed resources in the target system are reinternalized.
ESM Source	Role mappings of internalized resources can be synchronized. Synchronization of role mappings of externalized resources results in errors during import. (Manual configuration file updates ("change external to internal state") are required to prevent errors.)	Role mappings of internalized resources are fully synchronized. Role mappings of externalized resources can be synchronized only on time of externalization. Role mappings for resources that are externalized on the target system cannot be synchronized.

In summary, role mappings can be synchronized when the resource is managed internally by the WebSphere Portal Express server. When the resource is externalized, role mappings are owned by the external security manager system and cannot be synchronized.

However, it is not possible to modify role mappings for existing externalized resources and synchronize their updated role mappings to a target system.

Staging from system without external security manager to a system with external security manager

This combination is used where the integration system is reduced as much as possible and is configured like a development environment rather than a production environment.

All entitlements for all resources that are staged in this scenario are fully synchronized. All resources in the target system are managed internally. The external security manager is not used for managing authorization decisions.

It is possible to manually externalize resources. You can also manually edit XML configuration interface configuration files. In this step, all role mappings that were defined within the portal before are moved to the external security manager. Managing these resources externally might include updating the role mappings of these resources outside the portal.

During staging of subsequent releases, resources with updated entitlements appear in the XML configuration interface file as internally managed resources. These resources are internalized when this file is imported to the target system. You can manually update the configurations for externally managed resources to prevent this action. However, there is no build-in support for managing these kinds of configurations. Special care must be taken to manually replicate all changes of role mappings of externalized resources on the target system.

Staging from system with external security manager to system without external security manager

In this scenario, entitlements for internalized resources can be staged without any limitations. These configurations appear as if the source system was not configured to use an external security manager.

If entitlements for resources that are externalized on the source system are staged, errors occur on the target system. During import of this configuration, the target system is asked to externalize a resource. The system is not configured to support resource externalization. This option results in an error condition.

These errors can be resolved by manually updating the configuration file to have all resources that are managed internally. If role mappings for externalized resources are contained in the configuration file, entitlements are synchronized between the two systems.

Chapter 16. Developing

Developing for IBM WebSphere Portal Express includes developing portlets, extending the applications that are provided with the portal, and more. WebSphere Portal Express includes IBM Web Experience Factory to help you start developing quickly. You can also use IBM WebSphere Studio Application Developer.

"REST service for Web Content Manager" on page 3306
Application developers can use Representational State Transfer (REST) services to work with Web Content Manager. The REST service for Web Content Manager provides authoring access to content items and elements. The service follows the Atom Publication Protocol, and Atom feeds, and entries are accessible in XML (application/atom+xml) and JSON (application/json) format.

"How to display data from external sources" on page 3399
You display data from external sources by using the same methods as you would when you create a website.

"Instrumenting web content for Active Site Analytics" on page 3399
You can collect information from web content for Active Site Analytics.

"Java messaging services for web content" on page 3401
Web Content Manager supports for the notification of events such as item state changes, or services starting and stopping. These notifications can be delivered as messages to the Java messaging service.

"Developing basic PAA file applications" on page 3402
Solution developers can create their own Portal Application Archive (PAA) files. The developers can then use the configuration wizard to add on their applications to their IBM WebSphere Portal Express environment.

"Developing advanced PAA file applications" on page 3431
Developers can create their own advanced Portal Application Archive (PAA) file. The advanced PAA file contains custom content. The developers can then use the configuration wizard to add on their applications to their IBM WebSphere Portal Express environment.

"IBM UX Screen Flow Manager" on page 3475
The IBM UX Screen Flow Manager helps operators, developers, and dialog modelers develop fine-granular, small split portlets. Portlets provide the functions for the steps that are presented as screens. You can configure the sequence, transitions, and workflow of a set of screens. Screen flows work like wizards and process the screens to complete the task for the user. Screen flows are completed by a single user and have a short lifetime.

Changing to developer mode

Change to the developer mode to develop portals and portlets. Startup performance is improved within a developer mode environment.

Before you begin

Install IBM WebSphere Portal Express.

About this task

Choose one of the following options to change to developer mode immediately after you install WebSphere Portal Express:

"IBM i: Configuring developer mode" on page 2512
Use the developer mode to improve startup performance and to configure IBM WebSphere Portal Express for development. Developer mode is for a development environment only. Do not use the developer mode in a production environment. You can also run the **optimize-derby-database** task to improve the Derby database performance.

"Linux: Configuring developer mode" on page 2513
Use the developer mode to improve startup performance and to configure IBM WebSphere Portal Express for development. Developer mode is for a

development environment only. Do not use the developer mode in a production environment. You can also run the **optimize-derby-database** task to improve the Derby database performance.

"Windows: Configuring developer mode" on page 2514
Use the developer mode to improve startup performance and to configure IBM WebSphere Portal Express for development. Developer mode is for a development environment only. Do not use the developer mode in a production environment. You can also run the **optimize-derby-database** task to improve the Derby database performance.

IBM i: Configuring developer mode

Use the developer mode to improve startup performance and to configure IBM WebSphere Portal Express for development. Developer mode is for a development environment only. Do not use the developer mode in a production environment. You can also run the **optimize-derby-database** task to improve the Derby database performance.

Before you begin

Install WebSphere Portal Express.

About this task

This task modifies the following components:

JVM The JVM is switched to development mode. This setting is a WebSphere Application Server specific setting independent of WebSphere Portal Express. See the *Application server setting topic* in the related information section for exact changes that are made with this setting. The initial heap size is set to 768 MB to reduce the amount of garbage collection during startup.

Portlets
Portlets and web applications are activated on first access and not at the startup. However, some of the portlets and applications are required at startup. Create a white list, which contains the list of applications, that are required at startup.

Note: To add applications to the white list, modify the *wp_profile_root*/PortalServer/config/StartupPerformance/wp.base_TargetMapExclList.properties file. Add a line such as *App_name*, where *App_name* is the name of the application. Log on to the WebSphere Integrated Solutions Console and go to **Applications** > **Application Types** > **WebSphere enterprise applications** to get a list of available applications.

Procedure

1. Open a command prompt.
2. Stop the WebSphere_Portal server. Go to "Starting and stopping servers, deployment managers, and node agents" on page 1216 for information.
3. Change to the *wp_profile_root*/ConfigEngine directory.
4. Run the ConfigEngine.sh optimize-derby-database task to improve the performance of your Derby database.

Important: This task is appropriate only in a demonstration or development environment that is not configured to use Web Content Manager. You can also run the **optimize-derby-database** task after large data changes in the database.

5. Start the WebSphere_Portal server.
6. Run the `ConfigEngine.sh enable-develop-mode-startup-performance -DWasPassword=`*`password`* tasks. Then, stop and restart the WebSphere_Portal server to propagate your change.
7. Prepare the remote web server for your developer mode.

What to do next

Run the `ConfigEngine.sh disable-develop-mode-startup-performance -DWasPassword=`*`password`* task to revert to a production server. Then, stop and restart the WebSphere_Portal server to propagate your change.

Note: You can run the **disable-develop-mode-startup-performance** task for the following scenarios:

- When you are done developing your portal and portlets.
- If the development settings are not adequate for a special development situation.
- When you cannot re-create a problem on the development server.

Application server settings

Dojo and WebSphere Portal Express

WebSphere Portal Express contains an instance of the IBM Dojo Toolkit, a JavaScript library that is based on the Dojo Toolkit. When you develop components that use Dojo, you must be aware of how the portal uses Dojo, and the tips and restrictions when you use Dojo.

WebSphere Portal Express Version 8.5 comes with six versions of Dojo:

- **Dojo V1.9.x**. This version is packaged in its own web application named Dojo_Resources. You can manage it in the WebSphere Integrated Solutions Console. By default it is deployed at the context root `wps/portal_dojo`. The path for the Dojo V1.9.x files is *PortalServer_root*`/theme/wp.theme.dojo/installedApps/dojo.ear/dojo.war/V1.9`.
- **Dojo V1.7.x**. This version is packaged in its own web application named `Dojo_Resources`. You can manage it in the WebSphere Integrated Solutions Console. By default it is deployed at the context root `wps/portal_dojo`. The path for the Dojo V1.7.x files is *PortalServer_root*`/theme/wp.theme.dojo/installedApps/dojo.ear/dojo.war/v1.7` .
- **Dojo V1.6.x**. This version is packaged in its own web application named `Dojo_Resources`. You can manage it in the WebSphere Integrated Solutions Console. By default it is deployed at the context root `wps/portal_dojo`. The path for the Dojo V1.6.x files is *PortalServer_root*`/theme/wp.theme.dojo/installedApps/dojo.ear/dojo.war/v1.6` .
- **Dojo V1.4.x**. This version is packaged in its own web application named `Dojo_Resources`. You can manage it in the WebSphere Integrated Solutions Console. By default it is deployed at the context root `/portal_dojo`. The path for the Dojo V1.4.x files is *PortalServer_root*`/theme/wp.theme.dojo/installedApps/dojo.ear/dojo.war/v1.4.3` .
- **Dojo V1.3.x**. This version is packaged in its own web application named `Dojo_Resources`. You can manage it in the WebSphere Integrated Solutions Console. By default it is deployed at the context root `/portal_dojo`. The path for the Dojo V1.3.x files is *PortalServer_root*`/theme/wp.theme.dojo/installedApps/dojo.ear/dojo.war` .
- **Dojo V1.1.1**. This version is packaged in the directory *PortalServer_root*`/installer/wp.ear/installableApps/wps_theme.ear/wps_theme.war/themes/dojo/portal_dojo` .

All Dojo packages can be used by IBM and non-IBM components.

Notes:

1. The Portal 8.5 theme uses Dojo V1.9.x by default in WebSphere Portal Express v8.5. This version is the only supported version of Dojo with the Portal 8.5 theme.
2. The Portal 8.0 theme uses Dojo V1.7.x by default in WebSphere Portal Express v8.0. This version is the only supported version of Dojo with the Portal 8.0 theme.
3. The Portal 7.0.0.2 theme uses Dojo V1.6.x by default in WebSphere Portal Express v7.0.0.2. This version is the only supported version of Dojo with the Portal 7.0.0.2 theme.
4. The Page Builder theme uses Dojo V1.4.x by default in WebSphere Portal Express v7.0. The Page Builder theme is deprecated in Portal 8.5, and will no longer be supported in the next release.

5. The Dojo toolkit that is provided with the portal will be updated as needed over time. This toolkit might include entire new Dojo versions, and specific defect fixes. Compatibility of future Dojo versions is defined by the Dojo project.

Where WebSphere Portal Express uses Dojo

The Portal 8.5 theme uses Dojo V1.9.x to support various portlets and edit-mode user interface components. The portlets and components that use Dojo vary over time. The current set of portlets that uses Dojo includes Managed Pages edit-mode user interface components, Search Center, External Search Results, Tagging and Rating, Tag Cloud, Active Site Analytics, Unified Task List, WidgetWrapper Portlet, WCM Rendering Portlet, Web Content Libraries, Web Content Subscribers, Web Content Syndicators, Feed Schedules, Web2Bookmarks Portlet, and CMIS Picker Dialog.

Note: The portal components that use Dojo are only supported for use with the bundled Dojo.

Dojo is packaged as a module as part of the modular architecture for the Portal 8.5 theme. For performance optimization, the minimal profile does not load Dojo at all. The default deferred profile does not load Dojo initially for view mode, but, rather, only when a page is put into edit mode. When you do not load the Dojo module or any module that is a prerequisite for the Dojo module in the non-deferred part of your profile, then you need not pay any performance price of loading Dojo in view mode and at runtime. If you elect, you are now free to use a different JavaScript library in the view mode for your custom theme and runtime. Create and load your own modules for the library.

Using Dojo in your custom portal themes

For information about how to use Dojo in custom portal themes that you create see the topic about Creating a new theme.

Upgrading your custom portal themes to a later Dojo version supported by the portal: To upgrade your existing custom themes to a later supported version of Dojo, see the following sections:

Portal 7.0.0.2 theme, Dojo V1.6.x -> Portal 8.0 theme, Dojo V1.7.x: see Updating a Portal 7.0.0.2 theme to use Dojo 1.7.

Page Builder theme, Dojo V1.4.x -> Portal 7.0.0.2 theme, Dojo V1.6.x: see Updating a Page Builder theme to use Dojo 1.6.

Dojo V1.3.x -> Dojo v1.4.x: see Dojo and WebSphere Portal Express.wp7

Dojo V1.1.x -> Dojo v1.3.x: see Dojo and WebSphere Portal Express.wp7

Dojo usage best practices

When you are working with Dojo and portal components, be aware of the following best practices:

- Only one instance of Dojo can be loaded in a page, and the current Dojo policy is that the first Dojo included in the page takes precedence. Therefore:
  - Dojo can be loaded only once per namespace. You can load more than one version of Dojo in the page by using the Dojo native support for scopes. For details, see the Dojo documentation. For performance reasons, it is best to load only one version of Dojo in the page. However, applications or the

theme can load more Dojo bundles if they are scoped to different namespaces than the Dojo defaults. You need to make sure that applications and portlets that reference Dojo at a particular namespace scope work correctly with the version of Dojo that is mapped to that scope.

– Different themes in the same portal can use different versions of Dojo. You need to make sure that the portlets that run in these themes can work with both Dojo versions.

Support for multiple versions of Dojo at run time creates a more robust application, which is more stable across migrations and upgrades. But the support can be slightly more complex depending on the added code complexity.

- All portlets that use Dojo widgets must manually call the Dojo parser when they are loading. Setting djConfig.parseOnLoad has no effect. Otherwise, no widgets are parsed in the portlet.

  All portlets must pass a markup element to the parser. The markup element can exist only inside the DOM of the portlet. Otherwise, Dojo parses the entire document body every time the parser is called without a markup element. Other portlets might get parsed two or three times, which causes the Dojo parser to fail every time it hits a widget that is already parsed.

  Here is an example of correct usage:

```
<script> dojo.addOnLoad( function () { dojo.parser.parse( "<%=namespace%>portletWidgetContainer" ); } ); </script>
  <div id="<%=namespace%>portletWidgetContainer">
   <div dojoType="some.Widget"></div>
  </div>
```

- The `lotusui30dojo` class is set on the body element in the modularized themes, and its corresponding CSS files are linked in as well. To use a different theme within a particular portlet, do not change the CSS classes of the body element from within the portlet. Because this action has consequences on all other portlets and theme components that use Dijits on the page. Instead, use a separate node within the portlet to contain all the widgets that are used by that portlet. Then, assign the different theme class name on the container node inside the portlet.
- It is important to note that the placement of the theme class (for example, `lotusui30dojo`, `soria`) is vital for the theme to display correctly in Dijit components. If a Dijit component creates any elements as direct children of the body element, instead of or in addition to the same place in the DOM where the Dijit component was attached, then it is important to explicitly assign the class name. The class name is assigned for the secondary theme to the DOM node that is a direct child of the body, in addition to the containing DOM node of the portlet's widgets. For example:

```
<body class="tundra">
 ...
 <!-- Portlet A -->
 <div class="wpsPortletBody">
  <!-- Contents of this portlet -->
  <div class="soria">
   <!-- Any Dijits here will use the soria theme instead of tundra -->
   <button class="dijit dijitReset dijitLeft dijitInline dijitDropDownButton">
   ...
   </button>
  </div>
 </div>
 ...
 <!-- Portlet B -->
 <div class="wpsPortletBody">
  <!-- Any Dijits created here will use the tundra theme -->
  ...
 </div>

 <!-- This table node was created for the dijit.Menu component as part of the
     dijit.form.DropDownButton from Portlet A -->
 <table class="dijit dijitMenu dijitReset dijitMenuTable soria">
  <!-- This menu will use the soria theme instead of tundra, but needs to have it explicitly
```

```
      assigned since none of its ancestors have the soria class applied -->
  ...
 </table>
</body>
```

In this example, when Portlet A creates dijit.form.DropDownButton, the code to create that widget also creates a menu component and a new DOM node under the body. But the code does not assign a CSS class to that DOM node. If nothing else is done after the portlet creates the DropDownButton, then the DropDownButton uses the `soria` class. But the menu that pops up when the button is clicked uses the `tundra` class. In cases like this, it is important to explicitly set the `soria` class on the DOM node that contains the menu.

- If possible, load JavaScript code at the end of the theme markup after the rest of the page is rendered, including the page contents themselves. The initial page can then render quickly without blocking requests to serve large JavaScript files, including custom layer files. However, provide core Dojo functions in the head section of the page so that user interface components such as portlets and widgets can have access to these core functions.
- In relation to loading resources at the end of the theme rather than all inside the head section, the best practice for `dojo.require` statements in portlet applications, widgets, or other user interface components is to include them immediately before the objects or code within the modules that they load are used. This means that if the code is not used until after the page is loaded, for example through an onload handler that is registered by using `dojo.addOnLoad`, then the `dojo.require` statement is best served within the onload handler itself. The theme can then load more resources at the end of the page in layer files after all page components are included. As a result, if the theme already provided those modules in layer files at the end of the markup, the `dojo.require` statements can return immediately, when the onload handlers are fired. This also avoids unnecessary requests for modules that the theme loads but that is not loaded at the point in time when the user interface component is included in the markup on the page.

Dojo usage restrictions

Observe the following restrictions when you use Dojo with the portal:

- Only one instance of Dojo can be loaded in a page.
- Do not rely on making your own updates to the bundled Dojo package. WebSphere Portal Express support is likely to update individual files over time, and might even replace the entire package.

Related tasks:

"Updating custom theme Dojo references" on page 893
The default Dojo context root in WebSphere Portal Express is `/WpsContextRoot/portal_dojo`. You can find the value of `WpsContextRoot` in *wp_profile_root*`/ConfigEngine/properties/wkplc.properties`.

Extending WebSphere Portal class path

Custom code must either be added by a PAA or as APP through the administrative console. Adding custom code in shared application or `wp_profile/classes` is critical because it can be overwritten, deleted by updates or migration.

About this task

There are several options to add the general code that is not part of an EAR or WAR files.

Procedure

1. Add the custom code to a shared library.
   a. Use the administrative console to define a shared library, by creating and associating the shared library with an application, module, or server. For more information, see *Managing shared libraries*.

      Documentation resource: Managing shared libraries.
   b. Add the shared library to the custom applications or to the entire WebSphere Portal Express Server.
      - Adding the shared library to the custom application.

        You can associate a shared library with an application or module. Classes that are represented by the shared library are then loaded in the application's class loader, making the classes available to the application. For more information, see *Associating shared libraries with applications or modules*

        Documentation Resource: Adding the shared library to the custom application
      - Adding the shared library to the entire WebSphere Portal Express.

        You can associate shared libraries with the class loader of a server. Classes that are represented by the shared library are then loaded in a server-wide class loader, making the classes available to all applications deployed on the server. For more information, see *Associating shared libraries with servers.*

        Documentation Resource: Add the shared library to the entire WebSphere Portal
2. If you do not want to create a shared library, then you can drop the code into the profile/classes directory `/opt/IBM/WebSphere/wp_profile/classes/MyCustom.jar`. The code is then available to all applications in the server.
3. If you are developing a PAA, include the compressed files in the PAA `components/COMPONENTNAME/shared/app` or `components/COMPONENTNAME/shared/ext` directories. The solution installer handles creating the shared libraries for these files.

Developing themes and skins

You can create themes using modules to contribute to separate areas of pages to provide flexibility, enhance the user experience, and maximize performance. To optimize themes on your website, use the theme optimization module framework. The framework separates feature-specific logic and capabilities from the theme code.

"Understanding the Portal Version 8.5 modularized theme" on page 2521
Modern websites and browsers enable incredible new capabilities that can greatly enhance your user's web experiences. However, these capabilities are not without cost in terms of large page sizes and more processing in the browser when each page is rendered. These capabilities are worth it when you need them, but removing them for an entire site or including them only on pages that take advantage of these capabilities provides for more flexibility.

"The module framework" on page 2526
The module framework allows extensions to contribute to different areas of a page to provide flexibility, enhance the user experience, and maximize performance.

"Customizing the theme" on page 2658
The module framework allows themes to be customized in order to provide flexibility, enhance the user experience, and maximize performance.

"Developing themes for a production portal" on page 2813
Use the theme artifacts to package a theme for staging to production.

"Device classes" on page 2821
Device classes are used in IBM WebSphere Portal Express as an abstraction for common properties for the device of a client. For instance, tablet computers can be grouped into a device class `tablets`, since they share a form factor and possibly other traits such as touch interface, or additional hardware sensors.

"Responsive Web Design" on page 2826
Responsive Web Design provides content parity between mobile devices and desktop channels, which enhances user experience and brand consistency. Seamless changes in screen size, from small to large, are now possible while the order of the content is maintained. Content maintenance is simplified by having one site that is represented by one set of assets.

Understanding the Portal Version 8.5 modularized theme

Modern websites and browsers enable incredible new capabilities that can greatly enhance your user's web experiences. However, these capabilities are not without cost in terms of large page sizes and more processing in the browser when each page is rendered. These capabilities are worth it when you need them, but removing them for an entire site or including them only on pages that take advantage of these capabilities provides for more flexibility.

The new modularized theme provides a flexible framework that:

- Minimizes download size by giving you the control to specify just the capabilities that are needed for a certain scenario or use case.
- Minimizes the number of requests by combining necessary resources.

Previous themes required a monolithic design and that the same content was downloaded for every page. Theme optimization allows the theme to be highly adaptive to the content you are displaying on certain pages. For example, on pages where only simple content is displayed you can define a lightweight profile. A lightweight profile causes the system to download few static resources such as JavaScript and CSS files. However, on pages where more advanced scenarios are required you can choose to switch to a more powerful profile that causes more resources to download than on the other pages. This way you have only the capabilities you need on certain pages, but all other pages do not pay the penalty. As a result the overall system performance increases significantly.

Theme optimization uses modules and profiles to achieve the flexibility that allows you to achieve better performance. Modules are the components of the new theme that define capabilities. Examples are Tagging&Rating, Dojo, or jQuery. Profiles define sets of modules which can be assigned per page. A default profile is used if no page-specific profile is defined.

By applying these concepts it is possible to turn on and off an arbitrary number of features for certain pages, develop modules independent of each other for greater development speed and flexibility, easily add new capabilities later on into an existing theme and build an altogether new theme with the existing one. This building block concept allows the new theme to work side by side through self contained modules without impacting the existing theme.

The Portal Version 8.5 theme contains three types of files: JavaScript, dynamic content (JSP files) and static resources.

"Static resources"
Static resources include the markup that is defined by `.html`, `.css`, and `.js` files that are used by the theme. Some `.json` files are used to define menu options, module definitions, and module profiles.

"Dynamic content (jsp) resources" on page 2525
Dynamic content includes resources that are defined by `jsp` files that are used by the theme.

"Style resources" on page 2526
JavaScript content includes module resources defined by `js` files used by the theme.

Static resources

Static resources include the markup that is defined by `.html`, `.css`, and `.js` files that are used by the theme. Some `.json` files are used to define menu options, module definitions, and module profiles.

For more information about modularization and modules that are provided by the IBM WebSphere Portal Express 8.5 Theme, see *Modules*. Each WebDAV folder has a readme file with additional information about each section.

On WebDAV: `http://host:port/wps/mycontenthandler/dav/fs-type1`.

Theme module definitions

`fs-type1:\themes\Portal8.5\contributions`

`theme.json`: Module definitions for **`wp_theme_portal_85`**.

- **`wp_theme_menus`**
- **`wp_theme_portal_85`**
- **`wp_theme_skin_region`**
- **`wp_theme_high_contrast`**
- CF06 Removed in combined cumulative fix 06
  - **`wp_theme_edit`**

CF06 `theme_edit.json`: Contribution that is loaded when edit mode is turned on. Separates view mode from edit mode. Module definitions for **`wp_theme_portal_edit_85`**

- **`wp_theme_portal_edit_85`**

`dojo19.json`: Module definitions for Dojo, dijit, and dojox from version 1.9.1.

`oneui303.json`: Module definitions for OneUI version 3.0.3.

- **`wp_one_ui`**
- **`wp_one_ui_dijit`**

`contextmenu.json`: Contains component action menu presentation templates.

`simple_contextmenu.json`: Contains simple menu presentation templates.

`worklight61.json`: Contains Worklight mappings.

Style templates

`fs-type1:\themes\Portal8.5\css`

Style templates contain the `css` definitions for the styles that are provided by the theme. The style options are shown in the **Style** tab on the site toolbar when in **Edit Mode**.

Each of the listed directories has a css definitions file for that style and an icon that contains the image that represents the style. For the black style, there is a `black.css` and an `icon.gif` file under the black directory.

The `css` directory contains the following directories and files:

- Directories: `black`, `blue`, `gold`, `green`, `orange`, `purple`, `red`, `white`, `images`, and `default`.
- Files:
  - `master.css`: Includes the `sideNav.css`, and `default.css` files.
    - CF06 Removed in combined cumulative fix 06
      - `contextmenu.css`
      - `contextmenuCommon.css`
  - `masterRTL.css`: Includes the `sideNavRTL.css`, `defaultRTL.css`, and `default.css` files.
    - CF06 Removed in combined cumulative fix 06
      - `contextmenuRTL.css`
      - `contextmenuCommon.css`

  These files contain the compressed (minified) versions of the css definitions.

  Note: Compressing the files makes the files harder to read, so uncompressed versions are provided. It is best to use uncompressed versions when you are editing and debugging your theme CSS. For more information about using uncompressed versions of css files and special instructions on handling the `master.css` file, see *Enabling the uncompressed CSS files*.

The `default` directory includes the base styles for the theme. The `default_view.css` file contains styles for view mode. The `default_edit.css` file contains styles for edit mode. The `default_search.css` file contains styles for search. These styles are applied to the default theme and optimize it for mobile devices. These styles apply to menus, navigation, layout, and footer.

The `images` directory contains the following common images:

- `blank.gif`: A blank gif file that is used for spacing.
- `loading.gif`: The image that is shown when the page or other resource is loading.
- `loadingDark.gif`: A darker version of the `loading.gif` image.
- `master.png`: A sprite file with common images that are used in the theme. Some of the images in the sprite include the IBM and WebSphere Portal Express logos, search icon, the pencil icon for the edit/view mode toggle, and various sized arrow images.

Images

`fs-type1:\themes\Portal8.5\images`

- Directories: `addContent` and `taggingAndRating`
- Files: `favicon.ico`

js

`fs-type1:\themes\Portal8.5\js`

- `head.js`: This file contains JavaScript processing included in the head section.
- `skinRegion.js`: This file contains JavaScript that applies accessible areas to the skins.
- `mobilenav.js`: This file contains JabaScript processing for the mobile areas of the theme.
- CF06 Removed in combined cumulative fix 06
  - `contextmenu.js`: This file contains the JavaScript implementation of the menu.
  - `theme.js`: This file contains JavaScript processing for the edit capabilities in the theme.
  - `highContrast.js`: This file contains JavaScript processing for high contrast enabled systems. This file was moved to a different module in combined cumulative fix 06.

Layout templates

`fs-type1:\themes\Portal8.5\layout-templates`

Each directory contains a layout template. These templates are shown on the **Change Layout** tab of the site toolbar when in edit mode. Each directory contains a `layout.html` file that defines the layout and an `icon.gif` file that is a thumbnail image of the layout.

The `layout.html` file defines the decorations of the content area that are different between pages.

The layout templates are scoped to the Portal 8.5 theme.

Directories: `1Column`, `1Row2ColumnUnequal`, `1Row3ColumnEqual`, `2ColumnEqual`, `2ColumnLeft`, `2ColumnRight`, `2Row`, `3ColumnCenter`, `3ColumnEqual`, `TopColumn2ColumnUnequal`, and `TopColumn3ColumnCenter`.

Menu definitions

`fs-type1:\themes\Portal8.5\menuDefinitions`

Link to menu framework

- `pageAction.json`: Defines the menu items for the **Page Action** menu. Items include the definitions for the Tagging and Rating, Impersonation, and other page-related menu items.
- `skinAction.json`: Defines menu items for the portlet menu. It includes the definitions for the actions that are available for the portlet. Included items are Wiring, Delete, Edit Settings, Minimize, and Maximize.

nls

`fs-type1:\themes\Portal8.5\nls`

This directory contains translated HTML files for the theme.

Profiles

`fs-type1:\themes\Portal8.5\profiles`

These are the several module profiles that define which modules are loaded when a page is loaded. For more information about deferred modules, see *Modules, and Deferred and non-deferred modules*. For more information about profiles, see *Included Profiles*.

Skins

`fs-type1:\themes\Portal8.5\skins`

Directories: `Hidden`, `NoSkin`, and `Standard`.

These directories contain the ready-to-use skins that are available with the WebSphere Portal Express 8.5 theme: Hidden, NoSkin, and Standard. Each directory has a `skin.html` file, which defines the markup for the skin.

Localized files:

- `fs-type1:\themes\Portal8.5\skins\Standard\nls`
- `fs-type1:\themes\Portal8.5\skins\Hidden\nls`
- `fs-type1:\themes\Portal8.5\skins\NoSkin\nls`

Theme markup

`fs-type1:\themes\Portal8.5\`

Localized versions: `fs-type1:\themes\Portal8.5\nls`

- `Plain.html` Defines a markup that has no decorations. This file is used for some basic dialogs in the theme.
- `theme.html`: Defines the markup that is identical for all the pages to which this theme is applied.
- `theme_sidenav.html`: Defines a theme layout that uses a side navigation.

Dynamic content (jsp) resources

Dynamic content includes resources that are defined by `jsp` files that are used by the theme.

The entry point for a theme is either `Default.jsp` or `Plain.jsp`, both of these files are located here:

PortalServer_root`\theme\wp.theme.modules\webapp\installedApps\ThemeModules.ear\ThemeModules.war\themes\html\`

- `Default.jsp`: Is a main entry point for the theme and bootstraps any required infrastructure, and then delegates all markup rendering to the static template file, which is usually `theme.html`.

- `Plain.jsp`: Is an alternative entry point. This jsp is commonly used for helps or rendering a portlet with an iframe skin.
- `includePortalTaglibs.jspf`: Includes the IBM WebSphere Portal Express taglibs.

dynamicSpots

PortalServer_root`\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes\html\dynamicSpots`

- `commonActions.jsp`: Provides the common actions in the banner sections and the **Actions** menu. The **Actions** menu is not available to anonymous users.
- `crumbTrial.jsp`: Provides the crumb trail information for the location.
- `footer.jsp`: Provides the footer information for the page.
- `head.jsp`: Provides the header information for the page.
- `navigation.jsp`: Provides the navigation controls for the page.
- `mobileNavigation.jsp`: Provides the mobile navigation controls for the page.
- `sideNavigation.jsp`: Provides the side navigation controls for the page.
- `status.jsp`: Template for error, warning, and information messages.

Style resources

JavaScript content includes module resources defined by `js` files used by the theme.

OneUI CSS

The common CSS elements used across Lotus products. For the IBM WebSphere Portal Express version 8.5 theme, these styles are only for content. The WebSphere Portal Express version 8.5 theme markup is independent of OneUI.

For more information, see the *ICS UI Developer Guide*.

ICS UI Developer Guide

The module framework

The module framework allows extensions to contribute to different areas of a page to provide flexibility, enhance the user experience, and maximize performance.

The modularization framework decouples feature enablement from the theme code itself. Themes can be developed more easily with little knowledge about the details of how underlying code for a feature works. Logical points are provided where modules can contribute data into a theme at run time and then optimize those contributions by combining them where possible. Multiple disparate remote sources can be combined into one request for greater performance.

The features of a theme can be enabled and disabled by using a profile to configure them. You can then focus your time on the interface design of the theme without being concerned about the details of getting the features to work correctly within their theme. It is easy to turn off features that are not needed in one environment that might be used in another environment. For example, you can disable editing capabilities in a production portal environment, while they are enabled in a development environment. The same theme code can be used across such environments where the only variable is the module inclusion profile.

CF03 You can set dependencies on features in portlets and profiles. The features are automatically loaded onto the page in an aggregated way. Your profile does not need to contain more modules that are required by portlets. Your profile can be focused on theme capabilities. Modules that are only required by portlets can be loaded by the portlets. Portlet dependencies are loaded independently from the profile. If many portlets use the same features across many pages, you can add this feature to the profile for better cache performance. If you created your theme based on WebSphere Portal Express version 8.5 before CF03, then you must enable this feature to use it. Themes that are based on WebSphere Portal Express version 8.5 created in CF03 or after have this feature enabled by default.

Modules are registered extensions that are then used by a module profile. Each module is enumerated by the modules unique identifiers. A module might require other modules to allow the automatic inclusion of necessary code that is required to make a particular feature work. For example, you can use of the Dojo Toolkit within a module. A module can use the Dojo Toolkit to build custom widgets. To separate the code for the module from the Dojo code, the module requires certain Dojo modules to ensure that the code is loaded in the correct sequence. This separation allows greater serviceability by decoupling the packaging of the code for each module.

"Basic artifacts and their relation" on page 2528
The theme modularization framework foresees the following major artifacts and relations to one another.

"Contribution types" on page 2530
Modules can contribute different types of data to the extension points within the page.

"Deferred and nondeferred modules" on page 2533
The module framework allows a profile to specify whether to defer a particular module. By default, a module is loaded when the initial page loads, but modules that are specified as deferred modules are loaded after the page loads.

CF03 "Resource Aggregator overview" on page 2534
When the page renders, the Resource Aggregator processes all of the modules coming from the profile.

"Module dependencies in portlets" on page 2535
When a portlet requires existing client-side capabilities, such as Dojo, loaded on the page, it can define a set of portlet preferences that declare the capabilities it requires.

CF03 "Change the auto-loading of portlet capabilities" on page 2538
You can change if portlets automatically load their dependent capabilities for a theme.

"Response rendering for themes" on page 2540
To decrease the response time of your portal, a template parser resolves which modules are needed and collects all of the modules that are enabled by the current profile. Parts of the content are parsed and displayed as soon as possible.

"Writing modules" on page 2542
You can define global or theme-specific contributions that contain a theme module, which applies to different scopes through theme profiles. A module defines its contributions by using a `plugin.xml` or JSON file.

"Theme Optimization Analyzer" on page 2566
Use the Theme Optimization Analyzer to view, but not edit, all parts of the theme optimization framework inside of WebSphere Portal. With the portlet,

you can easily see which pages have specific profiles that are set or inherited. You can also see which profiles are available and belong to which theme.

"Troubleshooting modular themes" on page 2600
You can debug your modules to improve performance.

"Specify profiles" on page 2605
You can specify the profiles that you want to use two different ways depending on whether you are an administrator or a user. Profiles help define which modules are used to render a page.

"Modules that are provided with the modularized theme" on page 2608
WebSphere Portal Express provides a set of ready-to-use modules.

"Modules that add features to a theme" on page 2652
Theme modules contribute resources, such as JavaScript, CSS and HTML, to a theme or page. The following modules come with the modularized theme and specifically contribute a feature rather than working in the background. The modules can be added to a theme by listing them in the theme's default profile, or to a single page or set of pages.

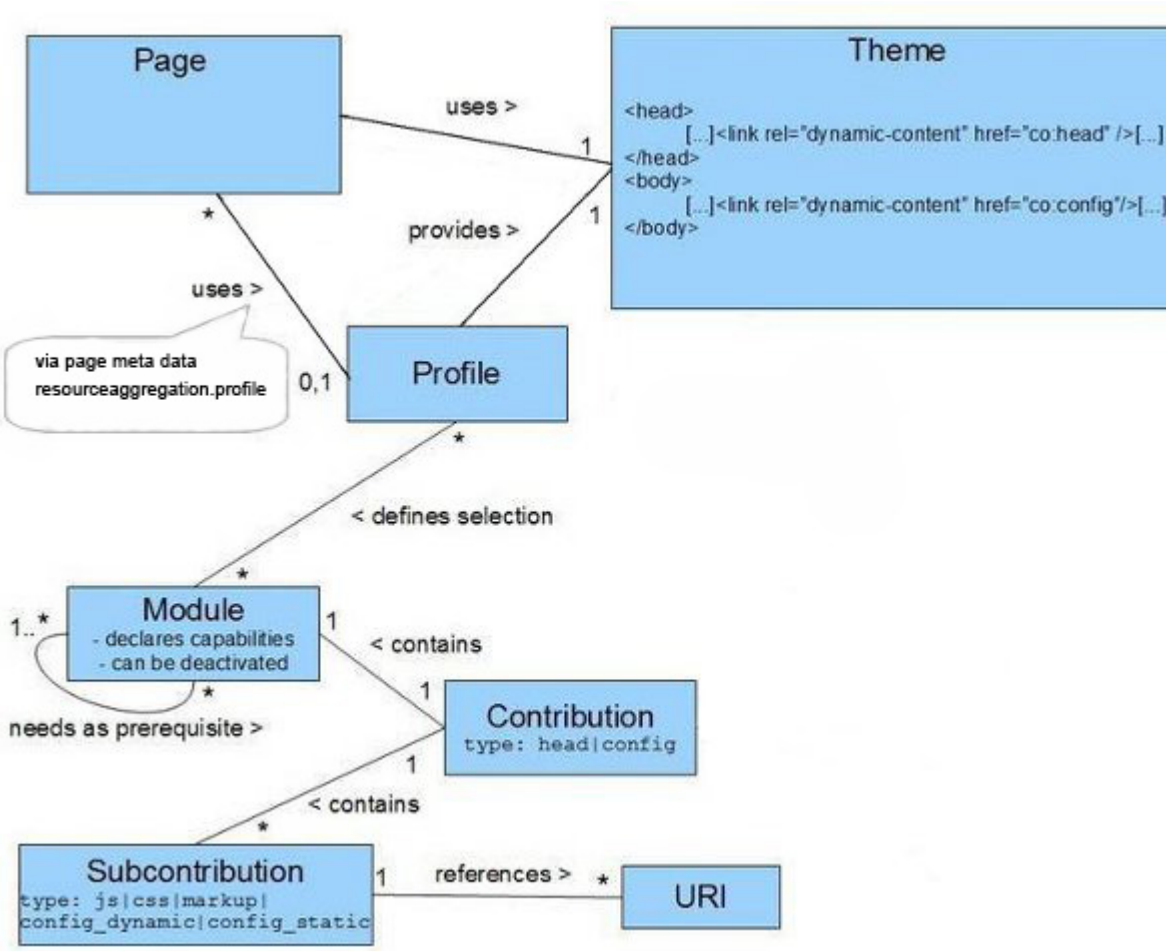
"Adding or removing a module from a profile" on page 2656
To add or remove a module, update the profile that is used to render a page for the theme.

"ConfigEngine tasks for creating a new profile based on a template and an existing profile in the system" on page 2657
You can extend the theme module framework with a new ConfigEngine task.

Basic artifacts and their relation

The theme modularization framework foresees the following major artifacts and relations to one another.

The relations of the major artifacts are depicted in the following figure:



A theme is assigned to a portal page. Dynamic content spots are used to write all of the data for modules that have contributions for a certain type. The module framework provides the dynamic content spots **co:config** and **co:head**. The theme must provide one or more profiles, which declares the set of modules that are used for that profile. One of these profiles is used by each page to which the theme is applied. The profile that is used for the page is the default profile that the theme developer or administrator defines for the theme by setting the theme metadata **resourceaggregation.profile**.

The Page administrator can explicitly overwrite the default by setting the page metadata **resourceaggregation.profile**.

The modules available in the system can either be registered through the extension point **com.ibm.portal.resourceaggregator.module** in a `plugin.xml` file, or using a JSON file that is located within a theme in the folder `<theme-root>/contributions`. This path is not customizable.

For example, the head spot, `<link rel="dynamic-content" href="co:head"></link>`, and aggregates all contributions of type head.

You choose where to place dynamic content spots if the following constraints are fulfilled:

- The head spot must be located inside the <head> element in the page markup. The <head> element must be placed before the <body> element in the page markup.
- The config spot must be located inside the <body> element in the page markup. Make the config spot the last element before the closing tag.

Contributions to the head extension point are best used for data that must be loaded at the beginning of the page. These contributions include producing markup that is only valid inside the <head> element or providing core functions that must be available to other inline code within the page body. For example, <link> elements can show only inside the head element, therefore all CSS must be added to the head contribution. Also, any inline JavaScript that uses a utility function to attach an event handler to the onload event, such as **dojo.addOnLoad**, depends on defining that function earlier in the page markup.

Place the config spot at the end of the page body element. This placement allows the bulk of the JavaScript resources and other enablement code to be written to the markup after the page layout and content area. The perceived responsiveness of the server increases by showing the page content while the browser is still downloading resources that are defined after the content area. However, there is no guarantee that the config spot is placed there, and it is valid for a theme designer to place the config spot inside the <head> element when it fulfills the first constraint.

Because the location of the config spot can vary, any code that displays inside the page content does not assume that the config spot was already generated. The JavaScript code in the content area that depends on other JavaScript modules that are loaded by the config spot are deferred until the onload event is triggered, which guarantees that the code inside a portlet, for example, always works regardless of the position of the config spot. An example is portlet JavaScript that creates client-side widgets on page load. Widget modules that themselves can be loaded by the config spot while the code that creates and uses them is run on load.

Modules can declare dependencies on prerequisite modules. Additionally, they can declare their capabilities, which enable portlets and other code on the page to query the availability of a certain capability.

CF03 Portlets can declare a dependency on capabilities in a way that automatically downloads all resources of a module. You do not need to add this module to the profile, but you must set this behavior in your theme.

Contribution types

Modules can contribute different types of data to the extension points within the page.

By specifying the type of data, a module can optimize how that data is loaded on the page. For instance, all of the JavaScript contributions to the co:config spot from multiple modules can be loaded by a single request to the server. That request generates a single response that contains the data for each contribution.

Contribution type: head

CSS

Contributions of this type must be valid Cascading Style Sheet (CSS) syntax and are always placed inside the `<head>` element. They are only valid in the `co:head` extension point.

Use generated CSS that uses relative URLs when you reference other resources like images or other CSS documents. By using relative URLs, resources can be resolved regardless of the context root in which they are placed.

JavaScript code

Contributions that add static JavaScript code are added it to this type so that it is properly cached and potentially optimized by the framework.

Contributions of this type cannot vary based on the client to further optimize the code. For example, do not use a data source that generates different data for different browsers to eliminate code paths that branch based on the browser type or version. Instead, the data source must generate the same data that works across all supported browsers. Users can then download and save the combined output as a static resource in a separate domain.

Important: It is the responsibility of the contributor to ensure that the content of the contribution does not include malicious code.

Static JavaScript configuration

Contributions to this type must be valid JavaScript code, publicly cacheable, and have no dependencies on the current user, navigation state, or runtime context.

It is common for static JavaScript code to use JavaScript variables that are defined in the global scope to have access to context information that must be provided outside the static script code.

Some of this configuration might be static across pages and can change only when the server is restarted, such as values that are retrieved from Resource Environment Provider custom properties. This data can be loaded as an external script so that it can be cached across users and pages.

Because it is possible to change through configuration changes, this configuration typically has relatively short cache expiration times so that it is still publicly cacheable but can still expire to pick up potential configuration changes.

The link to the URL that creates the aggregated content is part of a script tag.

Important: It is the responsibility of the contributor to ensure that the content of the contribution does not include malicious code. For example, configuration values that are read by a data source must be escaped before serializing the data.

Dynamic JavaScript configuration

Some configuration data that is used by JavaScript code is dynamic and susceptible to changing across pages or users. This configuration includes data, such as the current locale or URLs that are generated dynamically by the server.

Contributions to this type must be valid JavaScript code and are written to the markup inside an inline script element so that they are never cached.

Important: It is the responsibility of the contributor to ensure that the content of the contribution does not include malicious code. For example, configuration values that are read by a data source must be escaped before serializing the data.

Markup

Contributions to this type must be valid HTML in context of the extension point where they contribute to. For instance, contributions to the `co:head` extension point can include markup that is only valid for the <head> section of the page. Alternatively, contributions to the `co:config` extension point can include markup that is only valid inside the <body> tag.

This type is best used for contributions whose markup is not primarily visual but rather semantic, such as resource loading.

Modules that have visual markup must be documented and provided through a **`POC URI`** dynamic content spot. You can place this contribution in a specific place within the theme template relative to the design of the theme. If these unique location-important markup contributions are intended to be configurable or modified by a user, the dynamic content spot mapping data source might be used to map the **`POC URI`** to an alternative **`URI`**. Also, you can associate a dynamic content spot with a module ID so that the rendering of the data can be influenced by the profile that is used for the page.

It is best not to use portal render request-dependent attributes because those attributes sometimes are not available in all cases. For example, when used in deferred mode, the render context is not available.

Contribution type: `config`

- JavaScript code
- Static JavaScript configuration
- Dynamic JavaScript configuration
- Markup

See the head section for details about each of these subcontributions.

Contribution type: `dyn-cs`

Contributions of this type allow you to define dynamic content spots through modules instead of defining them through Resource Environment Providers. This also allows you to overwrite dynamic content spots for different pages by using different modules on the profiles. The only allowed subcontribution is markup. For more information, see *Dynamic content spots*.

Contribution type: `menu`

The only allowed subcontribution is JSON. For more information, see *Menu framework*.

Contribution type: `xslt`

The only allowed subcontribution is `xslt`. You can use `xslt` to gather `xslt` resources along the module hierarchy.

Deferred and nondeferred modules

The module framework allows a profile to specify whether to defer a particular module. By default, a module is loaded when the initial page loads, but modules that are specified as deferred modules are loaded after the page loads.

Nondeferred modules are enabled whenever a request for a page is made to the portal servlet that results in a full page refresh. Use a client-side JavaScript module to load resources that are associated with deferred modules on demand. For example, load deferred modules when entering edit mode for a page. Resources that are not required in view mode can be lazy loaded when the page mode is changed to edit. For more information, see *i$ JavaScript API specification*.

Note: If you enter edit mode while using the deferred profile available out of box, the following error displays when using a JavaScript console: `dojo.back.init() must be called before the DOM has loaded. If using xdomain loading or djConfig.debugAtAllCosts, include dojo.back in a build layer.` This error is thrown by Dojo because the `dojo.back` package is loaded in a deferred way. This code path is used only by older browsers, which are no longer supported. This JavaScript error has no affect on function.

If a nondeferred module requires a deferred module, the server-side combiner framework promotes the deferred module to be nondeferred. The promoted module is then loaded during the initial page rendering process. The module is not deferred, and all of its contributions to each extension point are displayed in view mode. Also, the contributions are not included when any remaining deferred modules are loaded later.

Because deferred modules are loaded distinctly after a page load, the types of resources that can be deferred are necessarily a subset of what can be loaded. CSS, JavaScript code, and markup can be deferred. Therefore, the following rules define when contributions to various places are loaded for deferred modules.

- CSS contributions to the head are deferred and then inserted into the `<head>` element on demand by using the `<link>` element.
- JavaScript configuration, both static and dynamic for both head and config spots, is deferred and loaded as JavaScript.
- Static JavaScript code contributions to the head and config spots are deferred and loaded as JavaScript.
- Markup contributions are lazy loaded by requesting the markup data for all deferred modules that contribute to the config or head markup section. This data is inserted into the page at the appropriate location that is based on where the spot is defined by the theme template.

Note: Because markup contributions can be lazy loaded when a module is deferred, certain limitations apply to the markup inserted dynamically using JavaScript. Script elements, for example, do not run when inserted into the markup as an HTML string. Modules that can be deferred must not generate script elements in their markup contribution to the config spot, unless they are used for another semantic purpose. For example, setting the *type* attribute to some value unknown to the client browser. The framework does not check for or handle any markup that results in side effects or unintended behavior. It is up to the module developer to handle any unintended behavior.

Do not use portal render request-dependent attributes because those attributes are not available in all cases. For example, when used in deferred mode, the render context is not available.

Resource Aggregator overview

When the page renders, the Resource Aggregator processes all of the modules coming from the profile.

The module framework is based on modules that are specified in a profile, and a profile is assigned to a page. It takes all of the resources coming from the modules and aggregates, or combines, them into as few URIs to link on the page as possible to achieve optimal performance. Non-deferred modules are kept separate from deferred modules, so there ends up being two sets of URIs.

Note: You can turn Remote Debugging on to break apart each resource as its own individual, uncompressed request for debugging purposes. For details on how to turn Remote Debugging on and off, see *Theme Optimization Analyzer Utilities*.

For more information on how to create modules and profiles, see *Writing modules*. For more information on how to assign a profile, see *Specifying profiles*.

CF03

Resource aggregation for portlets

In addition to processing the modules coming from the profile, the Resource Aggregator can also process all of the modules coming from the capability dependencies of all of the portlets on a page. The Resource Aggregator processes portlet modules for any theme that has its `metadata resourceaggregation.autoLoadPortletCapabilities` property set to true. For more information about how to set this metadata flag, see *Changing the auto-loading of portlet capabilities*.

For more information about how to specify portlet capability dependencies, see *Module dependencies in portlets*.

With auto-loading of portlet capabilities on, the Resource Aggregator also processes all of the modules coming from all of the capability dependencies of all of the portlets on the page. It processes them while also processing the modules coming from the profile. If the same module or subcontribution is encountered more than once, priority is given in the following order, first-to-last.

1. non-deferred from profile
2. non-deferred from portlets
3. deferred from profile
4. deferred from portlets

For example, if a profile uses Dojo deferred but a portlet uses Dojo non-deferred, Dojo loads non-deferred as part of the combined ResourceAggregator request for the portlets.

When everything is sorted into one of the four buckets, the Resource Aggregator takes all of the resources coming from the modules of each bucket and aggregates, or combines, them into as few URIs to link on the page as possible. There are four sets of URIs, or up to double the number of total URIs, or requests, for the page as compared to when auto-loading of portlet capabilities is off.

CF03

Performance

Auto-loading enhances the ease of use of your system. Users can choose any portlet on a page, if the portlets declare their capabailites, without worrying about the theme or profile. Fewer profiles are needed and the profiles can be smaller.

Auto-loading uses caching on both the client and server level, so the performance of your portal is nearly the same as when it is turned off. You can also mitigate the slight performance drop by adding modules to the theme. The more common or shared a module is, the more it is beneficial to include it in a profile. For example, if a module is used often by portlets on many pages, list that module in the profile so it can be cached as part of the profile URIs. The profile URIs change infrequently and remain cached.

CF03

ResourceCombinerService API

When a portlet must link to its own application-specific resources, it can do that in CF03 with the ResourceCombinerService public API. Previously, you had to link those resources individually. The ResourceCombinerService API can be called to combine resources to into a single optimized URI for optimum performance. For more information, see ResourceCombinerService public API in the *API Javadoc*.

The API has the same flexibility as the Portal module definition syntax to support all the URI possibilities. It has flexibility to support IBM Web Content Manager content URIs, deviceClass classes and equations for mobile, language locales for natural language system, type of debug for the uncompressed version of resources, and type of rtl for bidirectional languages.

The portlet can call the API in the portlet processing, such as in `doHead` for head contributions, or in `doRender` for body contributions. The portlet must manage the dynamic linking of the URIs into the head or body so it can manage the order and grouping of resources. The portlet must manage the cache headers within their datasources. The default cache headers are defined as part of global IBM WebSphere Application Server REP settings. They are `Cache-Control: public, max-age=86400`.

In most case, the returned list from getCombinedURI contains one URI. In a few cases, for example, with CSS size limits in Internet Explorer, it may return multiple URIs. The portlet must code to handle 1 to n.

Note: You must use this API with application-specific resources only. Shared, non-application-specific resources must be defined as modules or capabilities and specified as the portlet module dependencies, using the capability portlet preferences. It optimizes performance. It ensures multiple portlets on a page do not load the same resources. And it controls the order of resources that are loaded, because shared resources must load before application-specific resources.

Module dependencies in portlets

When a portlet requires existing client-side capabilities, such as Dojo, loaded on the page, it can define a set of portlet preferences that declare the capabilities it requires.

Define two preferences for each capability the portlet depends upon. One preference that describes the ID of the capability and one that defines the minimal value or version in the following format, `major.minor.revision`:

ID:

```
Preference Name: capability.<sequence-number>.id
Preference Value : <the capability name>
```

Value:

```
Preference Name: capability.<sequence-number>.minValue
Preference Value: <the capability value>
```

Sample

```
<portlet-preferences>
    <preference>
        <name>capability.1.id</name>
        <value>dojo</value>
        <read-only>true</read-only>
    </preference>
    <preference>
        <name>capability.1.minValue</name>
        <value>1.6</value>
        <read-only>true</read-only>
    </preference>

    <preference>
        <name>capability.2.id</name>
        <value>oneUI</value>
        <read-only>true</read-only>
    </preference>
    <preference>
        <name>capability.2.minValue</name>
        <value>3.0.1</value>
        <read-only>true</read-only>
    </preference>

    <preference>
        <name>capabilities.selfManaged</name>
        <value>false</value>
        <read-only>true</read-only>
    </preference>
</portlet-preferences>
```

CF03 In this version, `capability.`*`sequence-number`*`.minValue` is optional. If you do not know the version numbers or the portlet works with any version of the capability, then do not specify the minValue preference, and the system loads the highest available version of the capability.

CF03 There is not always a capability that is defined for every module. Many modules are not part of any capability. Every module automatically surfaces itself as an implicit capability, or a capability with the same name and version number as the module. If there is no capability or you only know the name of the module, you can specify the module name for the value of `capability.`*`sequence-number`*`.id`.

For the list of available capabilities, see *Modules provided with the WebSphere Portal theme*.

Self managed

In addition to the definition of the capabilities, the portlet must define a `capabilities.selfManaged` preference that describes whether the portlet handles the error case of missing capabilities itself or not. To delegate the handling of the error case to WebSphere Portal Express, the preference `capabilities.selfManaged` must be set to `false`.

Note: A portlet can either handle all capability dependencies or none.

If this preference is not set, the framework expects that the portlet itself manages the handling of the error case of a missing capability dependency.

Non-self managed error handling

When `capabilities.selfManaged` is set to `false`, WebSphere Portal Express handles the error case of missing capability dependencies. It displays error messages. One set of error messages, error codes: `EJPNK0022E`, `EJPNK0023E`, and `EJPNK0024E`, can display at the beginning of the page when you try to add a portlet to a page. The other set of error messages, error codes: `EJPNK0026E`, `EJPNK0027E`, and`EJPNK0028E` can display within the portlet when a portlet is already on a page and the page is rendered. The messages contain detailed information for each portlet about which capabilities are missing entirely or do not meet the minimum version required.

The non-self managed error handling can also be turned off for certain situations, such as for maximum performance on a production system or in the remote rendering use case (WSRP) where the consumer is not of type WebSphere Portal Express. For more information, see *Configuration settings for capability filters*.

Loading the capabilities

While each portlet declares the capabilities the portlet depends on, those capabilities and their modules do not load automatically. The loading of the modules is done through the profile that is assigned to the page, so you must assign a profile that is adequate for the portlets that are to be used on a page.

If the non-self managed error handling messages appear, they mean that the required capabilities are missing from the profile. The errors can be resolved by assigning a different profile to the page.

CF03

Auto-loading the capabilities

All portlets can automatically load their dependent capabilities, independent of which profile is assigned to the page. This feature can be turned on per theme in the theme metadata by setting `resourceaggregation.autoLoadPortletCapabilities` to `true`. For details of how to set this metadata, see *Changing the auto-loading of portlet capabilities*.

The Portal 8.5 theme in CF03 and newer has the auto-loading turned on by default. So, if you create your custom theme from the Portal 8.5 theme on a system at CF03 or beyond, you do not need to manually enable this feature. If your custom theme was created from the Portal 8.5 theme on a system before CF03, you need to manually enable this feature if you want it.

Usage of the auto-loading is recommended, because it makes the system overall simpler and easier to use. Users can use whichever portlets they want on a page (provided the portlets declare their needed capabilities) without having to think about the theme and which profile is assigned to the page. Fewer profiles are needed, and the size of each profile can be smaller.

If auto-loading is turned on, the non-self managed error handling messages appear less frequently, and if they do appear, they mean that the required capabilities are not installed or active anywhere in the system. The errors can be resolved by installing the capabilities and modules or making sure that they are active.

When auto-loading is turned on for a theme, it is not common to turn it off later. If you do, many pages can report missing capability error messages until appropriate profiles are assigned to the pages.

CF03

Deferred Capabilities

A portlet can now also declare a deferred capability dependency.

ID:

```
Preference Name: deferredCapability.<sequence-number>.id
Preference Value : the capability name
```

Value:

```
Preference Name: deferredCapability.<sequence-number>.minValue
Preference Value: the capability minimum version
```

Sample:

```
<portlet-preferences>
    <preference>
        <name>deferredCapability.1.id</name>
        <value>wcm_inplacEdit</value>
        <read-only>true</read-only>
    </preference>
</portlet-preferences>
```

With auto-loading on, a deferred capability does not load until the page is in edit mode or when the `i$.loadDeferred` API is used. With auto-loading off, a deferred capability declaration behaves like a capability declaration in that the loading of the capability's modules is done by the profile and not the portlet.

The `deferredCapability` sequence-number is independent of the `capability` sequence-number. For example, both can start at 1. And, like `capability`, `deferredCapability.`*`sequence-number`*`.minValue` is optional.

Change the auto-loading of portlet capabilities

You can change if portlets automatically load their dependent capabilities for a theme.

The Portal 8.5 theme in combined cumulative fix 03 and newer has the auto-loading turned on by default. So, if you create your custom theme from the Portal 8.5 theme on a system at CF03 or beyond, you do not need to manually enable this feature. If your custom theme was created from the Portal 8.5 theme on a system before CF03, you need to manually enable this feature if you want it.

Usage of the auto-loading is recommended, because it makes the system simpler and easier to use. Users can use whichever portlets they want on a page, provided the portlets declare their needed capabilities, without having to think about the theme and which profile is assigned to the page. Fewer profiles are needed, and the size of each profile can be smaller.

When auto-loading is turned on for a theme, it is not common to turn it off later. If you do, many pages can report missing capability error messages until appropriate profiles are assigned to the pages.

CF03 "Changing the auto-loading of portlet capabilities with WebDAV"
You can change the auto-loading of portlet capabilities with WebDAV

CF03 "Changing the auto-loading of portlet capabilities with XMLAccess"
You can change the auto-loading of portlet capabilities with XMLAccess

Changing the auto-loading of portlet capabilities with WebDAV:

You can change the auto-loading of portlet capabilities with WebDAV

Procedure

1. Connect your WebDAV client to `http://server:port/wps/mycontenthandler/dav/themelist/`.
2. Find the folder for your theme and copy the `metadata.properties` file to your local drive.
3. Edit the local copy of the file and set the auto-loading property to true or false.
   For example:
   ```
   resourceaggregation.autoLoadPortletCapabilities=true
   ```
4. Copy the local copy of the `metadata.properties` file back into the folder for your theme in the `themelist` folder.

Changing the auto-loading of portlet capabilities with XMLAccess:

You can change the auto-loading of portlet capabilities with XMLAccess

Procedure

1. Export the theme. You can export all themes that are defined for WebSphere Portal Express with the following script, or insert the specific theme object ID you want to export.
   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <request
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd" type="export"
   create-oids="true">
       <portal action="locate">
          <theme action="export" objectid="*" />
       </portal>
   </request>
   ```
2. Modify the value of the **`resourceaggregation.autoLoadPortletCapabilities`** parameter to true or false, or add the parameter if it does not exist. For example:
   ```
   <parameter name="resourceaggregation.autoLoadPortletCapabilities" type="string" update="set"><
   ```
3. Import the XML file with the command line or Import XML.
4. Restart WebSphere Portal Express.

Response rendering for themes

To decrease the response time of your portal, a template parser resolves which modules are needed and collects all of the modules that are enabled by the current profile. Parts of the content are parsed and displayed as soon as possible.

When the template parser encounters a dynamic content spot that starts with the prefix `dyn-cs:`, it resolves it by locating and starting the Dynamic Content Spot Mapping DataSource. If the mapping definition from a logical name to a URI includes module information, the spot is rendered only if the module is defined for the current profile.

When the template parser encounters a dynamic content spot for a particular combiner, the combiner service decodes the URI and collects all of the modules that are enabled by the current profile. After all of the defined modules are collected, any modules are added that the defined modules require and that are not already included in the list.

The modules are then processed in order, and contributions to each type are aggregated into sets. All contributions of a particular type at the current extension point are collected into groups by their type.

Important: It is the responsibility of the contributor to ensure that the content of the contribution does not include malicious code. For example, config values that are read by a data source must be escaped before serializing it.

Responses are rendered in this order:

1. CSS
   - CSS is only valid in the head extension point.
   - The framework generates a link element with an `href` attribute whose value is URL that resolves to the combined results of all contributions to CSS at the head extension point.
   - When debug is enabled, separate link elements are generated for each contribution.
2. Static JavaScript configuration
   - The framework writes an external `<script>` tag with a `src` attribute whose value is a URL that resolves to the combined results of all contributions to static JavaScript configuration at the current extension point.
   - When debug is enabled, separate script elements are generated for each contribution.
3. Dynamic JavaScript configuration. The framework generates an inline script tag that loads the combined results of all contributions to dynamic JavaScript configuration at the current extension point.
4. JavaScript code
   - The framework generates an external script tag that loads the combined results of all contributions to JavaScript code at the current extension point.
   - When debug is enabled, separate script elements are generated for each contribution.
5. Markup
   - The framework directly writes the output from each markup contribution at the current extension point to the output stream.

- This framework is intended to be used for markup that always shows in the page when this module is enabled. Use markup for content that is not visual but is semantic.
- Do not use portal render request-dependent attributes, because there is no guarantee that those attributes are available in all cases. For example, when used in deferred mode, the render context is not available.

CF03

Updates for Fix Pack 03

If portlets are on the page and have dependencies that are defined through capabilities, the framework gathers all modules for the provided capabilities from all portlets and downloads those resources. Each is gathered with separate requests for better caching performance. You must set this in your theme.

If a module is already downloaded as part of the profile, the system does not download it again as part of the portlet requests. The order of the responses is identical as depicted previously, with the exception that there are potentially two requests per type.

Profile CSS

Contains all resources from modules within the profile that contribute CSS. This request is skipped if there is no CSS contribution from any module.

Portlet CSS

Contains all resources from modules that are gathered from portlet capabilities that contribute CSS. This request is skipped if there is no CSS contribution from any module.

Profile `Static JavaScript configuration`

Contains all resources from modules within the profile that contribute `Static JavaScript configuration`. This request is skipped if there is no `Static JavaScript configuration` contribution from any module.

Portlet `Static JavaScript configuration`

Contains all resources from modules that are gathered from portlet capabilities that contribute `Static JavaScript configuration`. This request is skipped if there is no `Static JavaScript configurations` contribution from any module.

Profile `Dynamic JavaScript configuration`

Contains all resources from modules within the profile that contribute `Dynamic JavaScript configuration`. This type is written inline into the page and doesn't generate an extra request.

Portlet `Dynamic JavaScript configuration`

Contains all resources from modules that are gathered from portlet capabilities that contribute `Dynamic JavaScript configuration`. This type is written inline into the page and doesn't generate an extra request.

Profile JavaScript

Contains all resources from modules within the profile that contribute JavaScript. This request is skipped if there is no JavaScript contribution from any module.

Portlet JavaScript

Contains all resources from modules that are gathered from portlet capabilities that contribute JavaScript. This request is skipped if there is no JavaScript contribution from any module.

Profile Markup

Contains all resources from modules within the profile that contribute Markup. This request is skipped if there is no Markup contribution from any module.

Portlet Markup

Contains all resources from modules that are gathered from portlet capabilities that contribute Markup. This request is skipped if there is no Markup contribution from any module.

Writing modules

You can define global or theme-specific contributions that contain a theme module, which applies to different scopes through theme profiles. A module defines its contributions by using a `plugin.xml` or JSON file.

System modules

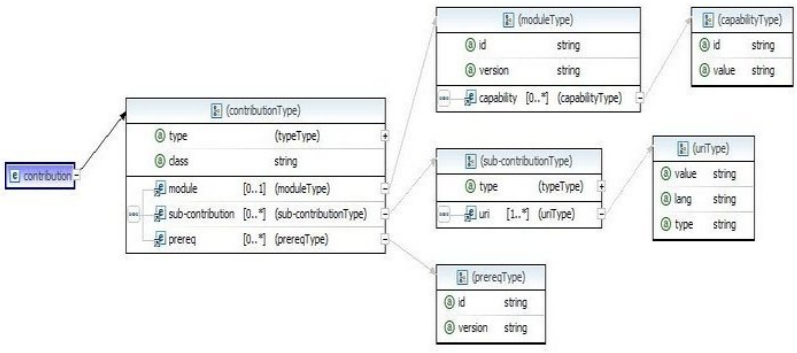
Available to all themes in the system by using a `plugin.xml` file as part of a compressed file in the portal class path, web module, or as a single file in the `WEB-INF` directory of a web module. The theme module must be declared within its extension point: `com.ibm.portal.resourceaggregator.module`.

Theme-specific modules

Can be referenced only by the theme that defines them in a JSON file within its contributions folder. The contributions folder is the default folder, but the location can be changed by setting the `resourceaggregation.contributions.folder` metadata on the theme, as in the case of profiles. These files are automatically scanned by the system and the contributions that are defined are registered for the theme.

XML schema

The following figure depicts the XML schema for this extension point:



The following code is an example of a `plugin.xml` file where the module is deployed within a web application with the context root `res:{war:context-root}/`.

```
<extension point="com.ibm.portal.resourceaggregator.module" id="testModuleExtension1">
       <module id="testModule1" version="1.0">

           <capability id="capabilityA" value="1.0.0"/>
           <capability id="capabilityB" value="1.5"/>

           <prereq id="testModuleA"/>
           <prereq id="testModuleB" minVersion="1.2.3.4"/>
           <prereq id="testModuleC" type="optional"/>
```

```
        <title lang="en" value="en Module"/>
        <title lang="de" value="de Module"/>
        <title lang="es" value="es Module"/>

        <description lang="en" value="one two three"/>
        <description lang="de" value="ein zwei drei"/>
        <description lang="es" value="uno dos tres"/>

        <contribution type="head">
            <sub-contribution type="css">
                <uri value="res:{war:context-root}/css/helloWorld.css" />
                <!-- define alternate styles for right to left -->
                <uri type="rtl" value="res:{war:context-root}/css/helloWorld_rtl.css" />
                <!-- define alternate styles for an iPad -->
                <uri deviceClass="tablet+iOS" value="res:{war:context-root}/css/helloWorld_iPad.css" />
            </sub-contribution>
            <sub-contribution type="js">
                <uri value="res:{war:context-root}/js/helloWorldHead.js" />
            </sub-contribution>
            <sub-contribution type="markup">
                <uri value="res:{war:context-root}/markup/helloWorldHead.html" />
            </sub-contribution>
        </contribution>

        <contribution type="config">
            <sub-contribution type="js">
                <uri value="res:{war:context-root}/js/helloWorldBody_root.js" />
                <!-- define alternate js for when the Portal is using different languages -->
                <uri lang="en" value="res:{war:context-root}/js/helloWorldBody_en.js" />

The following code is an example of a `myModules.json` file that is stored in the contributions folder of a theme. The structure, keys, and values that are used in the `plugin.xml` file are adapted to a JSON format with these rules:

- Keys that allow for multiple child entries on the same level are used in the plural form. For example, prereq becomes prereqs and capability becomes capabilities.

- File paths must start with a forward slash and are resolved relative to the theme root folder.
- JSP files cannot be served out of WebDAV. All resources relative to the theme root must be of a static type, for example, js, CSS, or HTML.

```
{
        "modules":[{
            "id":"testModule1",
            "version":"1.0",

            "capabilities":[{
                    "id":"capabilityA",
                    "value":"1.0.0"
                },
                {
                    "id":"capabilityB",

Contribution URIs for Web Modules

{war:context-root}

This variable fetches the context root of the containing WAR file and inserts it in place. It only works for modules defined as part of a WAR file. This does not work for modules defined in WebDAV or somewhere else in the classloading hierarchy, for example, a shared application.

"Defining theme modules" on page 2547
You can define theme modules in XML or JSON.

"Module schema definition" on page 2554
You can use these elements to define theme modules.

"Profile schema definition" on page 2558
You can write a profile schema with valid JSON.

"Simple modules" on page 2559
Simple modules for the resource aggregator framework are provided in the WebDAV folder. You can define modules quickly with a limited set of features with these simple modules.

"Dynamically extending an existing menu item from a module" on page 2565
You can use a module to add menu items to a menu where the menu item displays only on certain pages,

Defining theme modules:

You can define theme modules in XML or JSON.

About this task

The following samples are a breakdown of the previous examples and cover all available syntax for the `plugin.xml` extension point and JSON module definitions.

Procedure

1. Define the module. An ID is required and version is an optional decimal value.

```
<module id="testModule1" version="1.0" >
```

```
       "modules":[
        // ...  The ellipses indicate place holders for syntax explained in other steps
        {
            "id":"testModule1",
            "version":"1.0",
            // ...
        },
        // ...
        ]
```

2. Optional: Define any number of capabilities in the module with a required ID string and value in dot notation, for example, `1.2.3.4`. This information is added to the overall theme client capabilities map that is carried in the `com.ibm.portal.theme.client.capabilities` request attribute. Portlets can query from the server-side, which client-side capabilities are present, such as JavaScript libraries and CSS style catalogs. Client-side JavaScript code can query the global JSON object `com_ibm_theme_capabilities` for all available capabilities within the scope of the currently rendered page.

```
<capability id="capabilityA" value="1.0.0"/>
       <capability id="capabilityB" value="1.5"/>
```

```
"capabilities":[{
                "id":"capabilityA",
                "value":"1.0.0"
            },
            {
                "id":"capabilityB",
                "value":"1.5"
            }
        ],
```

CF03 In addition to the explicit capabilities defined here, an implicitly defined capability per module was also introduced. This implicitly defined capability has the name and version of the module. If the same name is defined explicitly, the explicit one is used.

3. Optional: Define any number of prereqs inside the module, with a required ID string and optional type string or minVersion in dot notation. If type `optional` is used, no errors are output if the prereq cannot be found on the system.

```
<prereq id="testModuleA"/>
        <prereq id="testModuleB" minVersion="1.2.3.4"/>
        <prereq id="testModuleC" type="optional"/>
```

```
"prereqs":[{
                "id":"testModuleA"
            },
            {
                "id":"testModuleB",
                "minVersion":"1.2.3.4"
            },
            {
                "id":"testModuleC",
                "type":"optional"
            }
        ],
```

4. Optional: Add a title or titles for the module in different languages.

```
<title lang="en" value="en Module"/>
        <title lang="de" value="de Module"/>
        <title lang="es" value="es Module"/>
```

```
 "titles":[{
                "lang":"en",
                "value":"en Module"
            },
            {
                "lang":"de",
                "value":"de Module"
            },
            {
                "lang":"es",
                "value":"es Module"
            }
        ],
```

5. Optional: Add a description or descriptions in different languages.

```
<description lang="en" value="one two three"/>
        <description lang="de" value="ein zwei drei"/>
        <description lang="es" value="uno dos tres"/>
```

```
    "descriptions":[{
            "lang":"en",
            "value":"one two three"
        },
        {
            "lang":"de",
            "value":"ein zwei drei"
        },
        {
            "lang":"es",
            "value":"uno dos tres"
        }
    ],
```

6. Require at least one: Add contributions each with at least one child subcontribution to the module. A contribution must be one of four types, which determines where its subcontributions are returned to the HTML page:

   head These contributions are linked into the head section of the theme at the `co:head` dynamic content spot.

   config These contributions are added to the end of the body section in the theme at the co:config dynamic content spot.

   menu These contributions are available to be called by the theme menu framework.

dyn-cs The outputs of these contributions are added to the theme at the specified dynamic content spot.

See *Working with dynamic content spots*. Each contribution has at least one subcontribution. Each subcontribution has at least one URI to a resource, and exactly one of the URIs is returned from each subcontribution. Subcontributions each has a required type:

css Cascading style sheet files can be added to head contributions only.

js JavaScript files can be linked to head or config contributions.

json JavaScript Object Notation output is used by menu contributions only.

markup
HTML can be served by head, config, or dyn-cs dynamic spots.

config_static
This type is a JavaScript configuration object that is static, global and publicly cacheable, made available in head or config contributions.

config_dynamic
This type is a JavaScript configuration object that can change based on the current page or user, made available in head or config contributions.

See Contribution types. Given these contribution and subcontribution types, one can implement the following use cases in a module. See the sample code at the beginning of this topic to see all the following snippets put together.

a. Optional: Add a CSS file. If you add more than one CSS file of the same type, use a separate subcontribution for each one.

```
<contribution type="head">
                <sub-contribution type="css">
                    <uri value="res:/HelloWorld/css/helloWorld.css" />
                </sub-contribution>
            </contribution>
```

```
"contributions":[{
                "type":"head",
                "sub-contributions":[{
                    "type":"css",
                    "uris":[{
                        "value":"/css/helloWorld.css"
                    }
                }
            }],
```

b. Optional: Define an alternative CSS file for bidirectional styles. These styles are only served up when using a `rtl` language.

```
<contribution type="head">
                <sub-contribution type="css">
                    <uri value="res:/HelloWorld/css/helloWorld.css" />
                    <!-- define alternate styles for right to left -->
                    <uri type="rtl" value="res:/HelloWorld/css/helloWorld_rtl.css" />
                </sub-contribution>
            </contribution>
```

```
"contributions":[{
                "type":"head",
                "sub-contributions":[{
                    "type":"css",
                    "uris":[{
                        "value":"/css/helloWorld.css"
                    },
                    // define alternate styles for right to left
                    {
                        "value":"/css/helloWorld_rtl.css",
```

```
                    "type":"rtl"
                }]
            }
        }],
```

c. Optional: Define a resource for a specific device class. Within the same subcontribution, add URIs with the appropriate device class string or equation identifier. See *Device class equations*.

```
<contribution type="head">
            <sub-contribution type="css">
                <uri value="res:/HelloWorld/css/helloWorld.css" />
                <!-- define alternate styles for an iPad -->
                <uri deviceClass="tablet+iOS" value="res:/HelloWorld/css/helloWorld_iPad.c
            </sub-contribution>
        </contribution>
```

```
"contributions":[{
            "type":"head",
            "sub-contributions":[{
                "type":"css",
                "uris":[{
                    "value":"/css/helloWorld.css"
                },
                // define alternate styles for an iPad
                {
                    "value":"/css/helloWorld_iPad.css",
                    "deviceClass":"tablet+iOS"
                }]
            }
        }],
```

d. Optional: Add a piece of markup to the head section, ensuring that the HTML validates within the head, such as a meta tag. Subcontributions of type markup can also be added to config or dyn-cs contributions.

```
<contribution type="head">
            <sub-contribution type="markup">
                <uri value="res:/HelloWorld/markup/helloWorldHead.html" />
            </sub-contribution>
        </contribution>
```

```
"contributions":[{
            "type":"head",
            "sub-contributions":[{
                "type":"markup",
                "uris":[{
                    "value":"/markup/helloWorldHead.html"
                }]
            }]
        }],
```

e. Optional: Add a JavaScript file to the head section of the theme because it must be available for portlets to use, for example, a js library such as Dojo or jQuery). If you add more than one JavaScript file of the same type, use a separate subcontribution for each one.

```
<contribution type="head">
            <sub-contribution type="js">
                <uri value="res:/HelloWorld/js/helloWorldHead.js" />
            </sub-contribution>
        </contribution>
```

```
"contributions":[{
            "type":"head",
            "sub-contributions":[{
                "type":"js",
                "uris":[{
```

```
                    "value":"/js/helloWorldHead.js"
                }]
            }]
        }]
```

f. Optional: Define a JavaScript file in the config area. It performs better than adding it to the head, but the js is not available until after the portlets have loaded. If you add more than one JavaScript file of the same type, use a separate subcontribution for each one.

```
<contribution type="config">
            <sub-contribution type="js">
                <uri value="res:/HelloWorld/js/helloWorldBody_root.js" />
            </sub-contribution>
        </contribution>
```

```
"contributions":[{
            "type":"config",
            "sub-contributions":[{
                "type":"js",
                "uris":[{
                    "value":"/js/helloWorldBody_root.js"
                }]
            }]
        }]
```

g. Optional: Define an alternative JavaScript file for other locales. Within the same subcontribution, add a second URI with the appropriate locale attribute.

```
<contribution type="config">
            <sub-contribution type="js">
                <uri value="res:/HelloWorld/js/helloWorldBody_root.js" />
                <!-- define alternate js for when the Portal is using different languag
                <uri lang="en" value="res:/HelloWorld/js/helloWorldBody_en.js" />
                <uri lang="de" value="res:/HelloWorld/js/helloWorldBody_de.js" />
                <uri lang="es" value="res:/HelloWorld/js/helloWorldBody_es.js" />
            </sub-contribution>
        </contribution>
```

```
"contributions":[{
            "type":"config",
            "sub-contributions":[{
                "type":"js",
                "uris":[{
                    "value":"/js/helloWorldBody_root.js"
                },
                // define alternate js for when the Portal is using different languages
                {
                    "value":"/js/helloWorldBody_en.js",
                    "lang":"en"
                },
                {
                    "value":"/js/helloWorldBody_de.js",
                    "lang":"de"
                },
                {
                    "value":"/js/helloWorldBody_es.js",
                    "lang":"es"
                }]
            }]
        }],
```

h. Optional: Define an alternative JavaScript file for debugging purposes. To debug the client-side code of a theme, supply a second entry for a debug subcontribution type debug to provide a more readable version of the JavaScript file. For more information, see *Enabling module tracing*.

```
<contribution type="config">
                <sub-contribution type="js">
                    <uri value="res:/HelloWorld/js/helloWorldBody_root.js" />
                    <!-- define alternate js for debugging purposes in LTR and RTL environmen
                    <uri type="debug" value="res:/HelloWorld/js/helloWorldBody_debug.js" />
                    <uri type="debug,rtl" value="res:/HelloWorld/js/helloWorldBody_debug_rtl.
                </sub-contribution>
            </contribution>
```

```
"contributions":[{
                "type":"config",
                "sub-contributions":[{
                    "type":"js",
                    "uris":[{
                        "value":"/js/helloWorldBody_root.js"
                    },
                    // define alternate js for debugging purposes in LTR and RTL environments
                    {
                        "value":"/js/helloWorldBody_debug.js",
                        "type":"debug"
                    },
                    {
                        "value":"/js/helloWorldBody_debug_rtl.js",
                        "type":"debug,rtl"
                    }]
                }]
            }],
```

i. Optional: Add a dynamic JavaScript config object.

```
<contribution type="config">
                <sub-contribution type="config_dynamic">
                    <uri value="res:/HelloWorld/jsp/helloWorldBodyConfig.jsp" />
                </sub-contribution>
            </contribution>
```

```
"contributions":[{
                "type":"config",
                "sub-contributions":[
                {
                    "type":"config_dynamic",
                    "uris":[{
                        "value":"/config/helloWorldBodyConfig.js"
                    }]
                }
            }]
```

j. Optional: Add a static JavaScript config object.

```
<contribution type="config">
                <sub-contribution type="config_static">
                    <uri value="res:/HelloWorld/jsp/helloWorldBodyStatic.jsp" />
                </sub-contribution>
            </contribution>
```

```
"contributions":[{
                "type":"config",
                "sub-contributions":[
                {
                    "type":"config_static",
                    "uris":[{
                        "value":"/config/helloWorldBodyStatic.js"
                    }]
                }]
            }]
```

k. Optional: Define a menu contribution. Create a contribution of type menu with a subcontribution of type json. The subcontribution references a JSON file that defines the individual menu entries. See *Menu framework*.

```
<contribution type="menu">
                <sub-contribution type="json">
                    <uri value="res:/HelloWorld/js/helloWorld.json" />
                </sub-contribution>
            </contribution>
```

```
"contributions":[{
                "type":"menu",
                "sub-contribution":[{
                    "type":"json",
                    "uris":[{
                        "value":"/js/helloWorld.json"
                    }]
                }]
            }]
```

l. Optional: Define a dynamic spot. When the module is turned on, the output of this subcontribution replaces the default contents of the dynamic spot that is identified by the ref-id attribute. See *Dynamic contents spots*.

```
<contribution type="dyn-cs">
                <sub-contribution type="markup" ref-id="some_dynamic_spot_id">
                    <uri value="res:/HelloWorld/jsp/helloWorldDynamicSpot.jsp" />
                </sub-contribution>
            </contribution>
```

```
"contributions":[{
                "type":"dyn-cs",
                 "sub-contribution":[{
                    "type":"markup",
                    "ref-id":"some_dynamic_spot_id",
                    "uris":[{
                        "value":"/html/helloWorldDynamicSpot.html"
                    }]
                }]
            }]
```

7. Optional: Give the module an activation handler. Use either the extensionID, used in these examples, or class attribute to indicate the ModuleActiveChecker implementation; both are supported. By default, all modules that are defined are active. An inactive module is treated the same as a module that is not defined. Therefore, inactive modules are not started during portal run time. Specify a key for activation or deactivation of the module with an entry in a resource environment provider in the application server. See *Adding resource environment provider properties*. Substitute the `RESOURCE_ENV_PROVIDER_NAME` with the name of the resource environment provider, and *KEY_IN_RESOURCE_ENV_PROVIDER* with the key within the resource environment provider. Valid key values are true if the module is active, or false if the module is inactive. For example, if you want to specify the `my.module.is.active` key for module activation in the resource environment provider ConfigService, the entry is:

```
<repentry rep="ConfigService" key="my.module.is.active"/>
```

```
<moduleActivation extensionID="com.ibm.portal.resourceaggregator.util.ResourceEnvironmentProvi
            <parameter name="rep" value="RESOURCE_ENV_PROVIDER_NAME" />
            <parameter name="key" value="KEY_IN_RESOURCE_ENV_PROVIDER"/>
        </moduleActivation>
```

```
"moduleActivation":{
            "extensionID":"com.ibm.portal.resourceaggregator.util.ResourceEnvironmentProviderM
            "parameters":[{
                "name":"rep",
                "value":"RESOURCE_ENV_PROVIDER_NAME"
            },
            {
```

```
            "name":"key",
            "value":"KEY_IN_RESOURCE_ENV_PROVIDER"
        }]
    },
```

8. Optional: Give the module a runtime activation handler with a condition. This allows a module to be turned on or off on a per page basis, which is based on the state of the current page. Currently, the runtime activation handler supports checking device class, which can be a string or an equation. See Device class equations.

```
<runtimeActivation>
            <condition deviceClass="tablet"/>
        </runtimeActivation>{code}
```

```
"runtimeActivation":[{
            "condition":{
                "deviceClass":"tablet"
            }
        }]
```

Module schema definition:

You can use these elements to define theme modules.

Defining a module

You can also define a schema for modules that are independent of their XML or JSON format. For the JSON format, there is a JSON schema definition available at *WebDAV Theme*\themes\Portal8.5\contributions\schema.

In the following examples, use the following syntax.

- 1 means only one is required
- 0..1 means one or zero
- 0..* means that any number is allowed
- 1..* means at least one is required

Element: module

The module that provides contributions.

Attributes:

- ID (1): The system-wide identifier for this module. The ID value is a String that must be unique in the system.
- version (0..1): The version of the module that is provided with this contribution. The version value uses the format major.minor.revision.

Parent

- extension

Child-elements

- 0..* capability
- 0..* prereq
- 0..* title
- 0..* description
- 0..* contribution
- 0..1 moduleActivation
- 0..1 runtimeActivation

Element: capability

The declaration of a capability that this module delivers.

Attributes:

- ID (1): The unique name to be used for this capability.
- value (1): the version of the capability that is provided by this module. The capability value uses a dotted decimal string.

Parent

- module

Element: prereq

A module that is required by another module that defines the requirement.

Attributes:

- ID (1): The ID of the required module.
- minversion (0..1): The minimum version of the prereq module that is required by the module that defines the requirement. The minversion value uses a dotted decimal string.
- type (0..1): Setting the `type="optional"` stops error logging when there is a missing prereq.

Parent

- module

Element: title

A title for the defining module.

Attributes:

- value (1): A title for the module.
- lang (1): The language string for the title, for example, en_US, de_de, or es_es.

Parent

- module

Element: description

A description of the defining module.

Attributes:

- value (1): A string that describes the module.
- lang (1): The language string for the description, for example, en_us, de_de, or es_es.

Parent

- module

Element: contribution

Defines a theme contribution of the module.

Attributes:

- type (1): The type of content spot that this module contributes to. The value is either head, config, menu, or dyn-cs. The valid values for type are:

  head These contributions are added to the head section of the theme. This contribution type can have multiple subcontributions.

config These contributions are added to the end of the body section of the theme. This contribution type can have multiple subcontributions.

dyn-cs This contribution outputs a theme dynamic spot. See *Dynamic content spots*. This contribution type can have one subcontribution.

menu This contribution defines a JSON theme menu. See *Menu framework*. This contribution type can have one subcontribution.

Parent

- module

Child-elements

- 0..* subcontribution

Element: subcontribution

Part of the overall contribution. For example, in the head contribution, subcontributions can add CSS, JavaScript, or head-specific markup.

Attributes

- uri (0..1 or 1..* if there is no URI child): The URI to the subcontribution resource. The URI can also be provided as a child element of the subcontribution node. Use an attribute, or a child, but not both to specify the URI. More than one URI can be supplied, but only one is selected and returned.
- ref-id (0..1): The ID of the dynamic spot to override. Use it only for dyn-cs subcontributions.
- type (1): Declares what type of contribution is provided. The valid values for type are:
  - markup: HTML markup for head, config, or dyn-cs contributions.
  - css: Cascading style sheet files for head contributions only.
  - js: JavaScript libraries, functions, and objects for head and config contributions. These contributions are loaded after contributions with a config_* value.
  - config_static: JavaScript configuration for head and config contributions that are not request-dependent variable definitions. These contributions are collected in a separate file.
  - config_dynamic: JavaScript configuration for head and config contributions that are request-dependent variable definitions. These contributions are injected into the markup.
  - json: JSON definitions for menu contributions only.
- deviceClass (0..1): Controls when the defined subcontribution is aggregated on the page that is based on active device classes. It can be a single device class or logical equation.
- values:
  - markup: HTML markup
  - css: Cascading style sheet statements.
  - js: JavaScript libraries, functions, and objects. These contributions are loaded after contributions with a config_* value.
  - config_static: JavaScript configuration contributions that are not request-dependent variable definitions. These contributions are collected in a separate file.

– config_dynamic: JavaScript configuration contributions that are request-dependent variable definitions. These contributions are injected into the markup.

Parent

- contribution

Child-elements

- 0..1 uri

Element: uri

A URI pointing to a theme module resource. `{war:context-root}` can be used here. For more information, see *Writing modules*.

Attributes:

- value (1): The URI of the resource to be used.
- lang (0..1): The language to which the defined URI applies, for example, en_US.
- type (0..1): The type to which this URI applies. For the subcontribution type of CSS the URI type can be `rtl`, triggered when the Portal is rendering in a right to left language. Or `debug`, triggered when the Portal is in debug mode. For JavaScript, the URI type can be `debug`.
- deviceClass (0..1): The type of device to which the URI applies, such as `smartphone`, `tablet`, or a device class equation.

Parent

- subcontribution

Different schemes can be used within the value attribute.

Use this scheme with caution because it can severely affect performance. The remote file is included on the server and not on the browser. When this scheme is used, remote requests are sent from the virtual machine of the portal during portal page rendering to the remote system in a synchronous manner. Therefore, the response time of the remote system affects portal page rendering time and the number of available threads available for other requests. Use HTTP only for static sources that can be cached in a proxy or HTTP server in front of portal.

The Ajax proxy is used to perform the remote call so that the configuration must be updated for the remote request to occur.

- http: Use HTTP to reference files that are accessible using HTTP.
- res: Use the res scheme to access an arbitrary resource, such as a JSP, a servlet, or a static file, in a web module that is installed on the server.
- dav: Use the dav scheme to access resources in the portal file store. You can also use replacement tokens for the URI value, for example:

```
res:{rep=WP
CommonComponentConfigService;key=cc.theme.context}/themes/html/PageBuilder2/modules/css/markup/head_m.jsp
```

The code

```
{rep=WP CommonComponentConfigService;key=cc.theme.context}
```

is replaced with the value of the custom property **cc.theme.context** in the resource environment provider **WP CommonComponentConfigService**.

Element: moduleActivation

Declaration of a class that controls whether the module is active. Use either the extensionID or class attribute to indicate the activation implementation; both are supported.

Attributes:

- extensionID (0..1 or 0 if class is used): The class name that implements the ModuleActiveChecker interface.
- class (0..1): The class name that implements the ModuleActiveChecker interface.

Parent

- module

Child-elements

- 0..* parameters

Element: parameter

Declaration of a resource environment entry that specifies whether the module is active or not whose values are `true` or `false`. The default value is `true`.

Attributes:

- name (1): The name of the parameter.
- value (1): The value of the parameter.

Parent

- moduleActivation

Element: runtimeActivation

A switch that is triggered during run time to enable or disable a module and its capabilities, depending on a condition of the current page state.

Attributes:

- none

Parent

- module

Child-elements:

- condition (1..*)

Example:

```
<runtimeActivation>
         <condition deviceClass="worklight"/>
</runtimeActivation>"
```

Element: condition

A condition for which the runtimeActivation must be activated.

Attributes:

- deviceClass (1): The type of device to which the URI applies, such as `smartphone`, `tablet`, or a device class equation.

Parent

- runtimeActivation

Profile schema definition:

You can write a profile schema with valid JSON.

Components of a profile file

The JSON schema definition is available in *WebDAV Theme*/themes/Portal8.5/profiles/schema.

The profile definition has five main components.

non-deferred modules
The set of modules that load with the initial page rendering.

deferred modules
The set of modules that render after the initial page rendering.

title (optional)
The title of the profile.

description (optional)
The description of the profile.

metadata (optional)
Here you can define whether this profile is hidden or not.

You can see the properties in the following example.

```
{
 "moduleIDs" : ["moduleID_1", "moduleID_2", "moduleID_3"],
 "deferredModuleIDs" : ["moduleID_4", "moduleID_5", "moduleID_6"],
 "titles": [{ "lang": "en", "value": "title_en" },
              { "lang": "de", "value": "title_de" }],
 "descriptions": [{ "lang": "en", "value": "desc_en" },
                    { "lang": "de", "value": "desc_de" }],
    "metadata":{
 "com.ibm.portal.Hidden": "true"
 }
}
```

Simple modules:

Simple modules for the resource aggregator framework are provided in the WebDAV folder. You can define modules quickly with a limited set of features with these simple modules.

If you need all features of the framework, you must define your modules through a plugin.xml or JSON file in the contributions folder.

Module quick start

Each subdirectory within the modules folder defines one module.

```
WebDAV Root
+ modules
+-- module A
+-- module B
+-- ...
+-- module Z
```

The getting_started_module is pre-defined so you can start quickly. Add your JavaScript, CSS, or markup file to one of the subfolders, and your resources are integrated into WebSphere Portal Express.

You must invalidate the resource aggregator cache before your changes are integrated. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Theme Analyzer**. Then, click **Utilities** > **Control Center** > **Invalidate cache** to

invalidate the cache. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

Module directory

After you create your own module by creating a new directory in the modules directory, you must make sure that the module is integrated with WebSphere Portal Express. Add it to the profile currently set on your page. To verify the profile for any page, you can use the Theme Analyzer Page Explorer. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Theme Analyzer**. Then, click **Examine page profile information**.

Simple contributions can be of three contribution types, `head`, `config`, `menu`.

For more information, on simple modules read the `readme.txt` file in the `getting_started_module` folder.

Simple module directory structure

Simple modules can be customized with the following files and directories.

/module-id
: Each directory in `/modules` defines a new module, but does not support versions.

  /module-id/**prereqs.properties**
  : Optional file that defines the `prereqs` of this module. In the file, there is one `module-id` per new line. Module versions are not supported. For example,

    ```
    module-id
    module-id
    ```

  /module-id/**capabilities.properties**
  : Optional file that defines the capabilities of this module. In the file, there is a property such as **style** with the `name` and `value` that is separated by an equal sign. Add one per line.

    ```
    name=value
    name=value
    ```

  /module-id/**localization.properties**
  : Optional file that defines title and description of this module. In the file, there is a property such as **style**. For example,

    ```
    title.locale=title
    description.locale=description
    ```

    Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`. Replace *title* with the title of the module.

  /module-id/**head**
  : For more information, see *Head contribution*.

  /module-id/**config**
  : For more information, see *Config contribution*.

  /module-id/**menu**
  : Files that are stored in this directory are made available to the menu framework.

/*module-id*/menu/*.json
JSON resources that contain the menu definition are served in alphabetical order.

"Head contribution"
The `head` folder contains files that are served as head contribution through the resource aggregator framework. Those resources appear in the head tag of the markup served to the browser.

"Config contribution" on page 2563
The `config` folder contains files that are served as config contribution through the resource aggregator framework. Those resources are usually before the closing body tag.

Head contribution:

The `head` folder contains files that are served as head contribution through the resource aggregator framework. Those resources appear in the head tag of the markup served to the browser.

Folder: /*module-id*/head

The following section provides a complete list of supported files within the head section.

/*module-id*/head
Files that are stored in this directory are served in the head section.

/head/*.js
JavaScript files are served in alphabetical order. They are grouped by file name and if they have the same name they belong to the same group. Within this group, the following extension variations exist. There are two sets of six resources. The sets cannot be mixed.

***.js** Defines the main compressed JavaScript content.

***.js.uncompressed.js**
Defines the main debug JavaScript content.

***.rtl.js**
Defines the compressed JavaScript to be used for right-to-left languages.

***.rtl.js.uncompressed.js**
Defines the debug JavaScript to be used for right-to-left languages.

***.*locale*.js**
Defines the compressed JavaScript content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

***.*locale*.js.uncompressed.js**
Defines the debug JavaScript content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

The following group is an alternative. You can use either of these variation group, but you cannot mix them.

Alternative

The following group is an alternative. You can use either of these variation group, but you cannot mix them.

***.min.js**
Defines the main compressed JavaScript content.

***.js** Defines the main debug JavaScript content.

***.rtl.min.js**
Defines the compressed JavaScript to be used for right-to-left languages.

***.rtl.js**
Defines the debug JavaScript to be used for right-to-left languages.

***.*locale*.min.js**
Defines the compressed JavaScript content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

***.*locale*.js**
Defines the debug JavaScript content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

/head/*.css
CSS files are served in alphabetical order. They are grouped by file name. If they have the same name, they belong to the same group. Within a group, the following extension variations exist. There are two sets of six resources. The sets cannot be mixed.

***.css** Defines the main compressed CSS content.

***.css.uncompressed.css**
Defines the main debug CSS content.

***.rtl.css**
Defines the compressed CSS to be used for right-to-left languages.

***.rtl.css.uncompressed.css**
Defines the debug CSS to be used for right-to-left languages.

***.*locale*.css**
Defines the compressed CSS content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

***.*locale*.css.uncompressed.css**
Defines the debug CSS content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

Alternative

The following group is an alternative. You can use either of these variation group, but you cannot mix them.

***.min.css**
Defines the main compressed CSS content.

***.css** Defines the main debug CSS content.

***.rtl.min.css**
Defines the compressed CSS to be used for right-to-left languages.

***.rtl.css**
Defines the debug CSS to be used for right-to-left languages.

.locale***.min.css**
Defines the compressed CSS content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

.locale***.css**
Defines the debug CSS content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

/head/*.html
HTML files are served in alphabetical order. They are grouped by file name and if they have the same name they belong to the same group. Within a group, the following extension variations exist.

***.html** Defines the main HTML content.

***.rtl.html**
Defines the HTML to be used for right-to-left languages.

.locale***.html**
Defines the HTML content for a specific language. Replace *locale* with the local representing code for the location. For example, for the United States, use `en_us`.

/head/*device-class-name*
This optional directory scopes the resources by device class. You can use one individual device class, but it has no equation support for the directory or the files in it. You can scope the contribution to a particular device class when the incoming request is recognized as a device class name. This contribution can include JavaScript, HTML, or CSS. See the previous sections for more information.

Config contribution:

The `config` folder contains files that are served as config contribution through the resource aggregator framework. Those resources are usually before the closing body tag.

Folder: /*module-id***/config**

The following section provides a complete list of supported files within the config section.

/*module-id***/config**
Files that are stored in this directory are served in the config section of the resource aggregator.

/config/*.js

JavaScript files are served in alphabetical order. They are grouped by file name and if they have the same name they belong to the same group. Within this group, the following extension variations exist. There are two sets of six resources. The sets cannot be mixed.

***.js** Defines the main compressed JavaScript content.

***.js.uncompressed.js**
Defines the main debug JavaScript content.

***.rtl.js**
Defines the compressed JavaScript to be used for right-to-left languages.

***.rtl.js.uncompressed.js**
Defines the debug JavaScript to be used for right-to-left languages.

***.*locale*.js**
Defines the compressed JavaScript content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

***.*locale*.js.uncompressed.js**
Defines the debug JavaScript content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

The following group is an alternative. You can use either of these variation group, but you cannot mix them.

Alternative
The following group is an alternative. You can use either of these variation group, but you cannot mix them.

***.min.js**
Defines the main compressed JavaScript content.

***.js** Defines the main debug JavaScript content.

***.rtl.min.js**
Defines the compressed JavaScript to be used for right-to-left languages.

***.rtl.js**
Defines the debug JavaScript to be used for right-to-left languages.

***.*locale*.min.js**
Defines the compressed JavaScript content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

***.*locale*.js**
Defines the debug JavaScript content for a specific language. Replace *locale* and with the local representing code for the location. For example, for the United States, use `en_us`.

/config/*.html
HTML files are served in alphabetical order. They are grouped by file name and if they have the same name they belong to the same group. Within a group, the following extension variations exist.

***.html** Defines the main HTML content.

***.rtl.html**
Defines the HTML to be used for right-to-left languages.

***.*locale*.html**
Defines the HTML content for a specific language. Replace *locale* with the local representing code for the location. For example, for the United States, use `en_us`.

/config/*device-class-name*
This optional directory scopes the resources by device class. You can use one individual device class, but it has no equation support for the directory or the files in it. You can scope the contribution to a particular device class when the incoming request is recognized as a device class name. This contribution can include JavaScript, HTML, or CSS. See the previous sections for more information.

Dynamically extending an existing menu item from a module:

You can use a module to add menu items to a menu where the menu item displays only on certain pages,

About this task

There are three changes that are needed to add menu items with a module.

1. Define a module that includes the menu item you want to add.
2. Include the module in a profile.
3. Apply the profile to a page hierarchy.

Procedure

1. Define the module as a JSON file or as part of a `plugin.xml` file. If you define it as a JSON file, put this file in WebDAV at `fs-type1/themes/`*YourTheme*`/contributions/`. If you define it as a `plugin.xml` system module, put it in the application `.war` file in the `WEB-INF` directory.
   - Define the override module as a JSON file.

```
{
"modules":[{
  "id":"menuModule",
  "contributions":[{
   "type":"menu",
   "sub-contributions":[{
    "type":"json",
    "ref-id":"pageAction",
    "uris":[{
     "value":"/menuTest/menuItem.json"
    }]
   }]
  }]
 }]
}
```

ref-id The reference ID of the menu you want to use - this example uses the Action menu for the page.

value A pointer to the file that includes your menu item specifications - this example points to a path relative to your theme location.

- Define the override module in a `plugin.xml` file.

```
<extension point="com.ibm.portal.resourceaggregator.module" id="staticMenuModule" >
    <module id="staticMenuModule">
        <contribution type="config">
         <sub-contribution type="config_dynamic" ref-id="pageAction">
         <uri value="res://wps/defaultTheme80/themes/html/menuTest/menuAction.jsp" />
         </sub-contribution>
        </contribution>

        <contribution type="menu">
         <sub-contribution type="json" ref-id="pageAction">
         <uri value="res://wps/defaultTheme80/themes/html/menuTest/menuItem.json" />
         </sub-contribution>
        </contribution>
    </module>
</extension>
```

extension id
Any meaningful ID.

module id
Any meaningful ID.

sub-contribution ref-id
The reference ID of the menu you want to use, this example uses the **Action** menu for the page.

uri value
A pointer to the files is required to create your menu or other content. In the previous example, there are two contribution types listed. For the `menu` contribution and its `json` subcontribution, this example shows that the uri points to a JSON format file within the theme that defines one or more menu items in the JSON menu definition file syntax.

2. Create the `menuitem.json` that you defined in step 1. For more information, see *Server-side framework*.
3. Include the override module in a profile. For example, in `profile_menuModule.json`:

```
{
 "moduleIDs": [
  "menuModule",
  ...
```

The `profile_menuModule.json` file must be copied to WebDAV at `fs-type1/themes/`*`YourTheme`*`/profiles/`.

4. Open the desired menu json and add an entry for the module to the menu. Use the following example.

```
{
"type":"ModuleRef",
"id":"menuModule"
}
```

Theme Optimization Analyzer

Use the Theme Optimization Analyzer to view, but not edit, all parts of the theme optimization framework inside of WebSphere Portal. With the portlet, you can easily see which pages have specific profiles that are set or inherited. You can also see which profiles are available and belong to which theme.

Additionally you can browse and explore all aspects of the available modules: You can see what modules are loaded for a specific profile or all modules of the whole system. You can drill down into the dependency hierarchy to understand interdependencies and get different views on it, such as a parent view. The module explorer also features a rich search set so that you can easily find modules that contribute certain resources or capabilities, or browse all exposed data.

If you encounter problems, you can also export your set of data as a compressed file and share it with others. They can then import your data set and examine your profiles and modules.

Home is the welcome screen of the portlet and provides a selection of features that are supported by this portlet.

"Examine page profiles"
Use **Examine page profile information** to explore the whole page hierarchy of the system and display information about the set themes and profiles per page. It also differentiates between inherited and explicitly set themes and profiles, and locates errors such as unknown profiles that might be set. It is a great tool to find errors in your deployment.

"Examine modules" on page 2568
Use the modules sections to explore the modules of a specific profile or all of the modules available with the system, theme, or both.

"Examine contributions" on page 2577
Use the **Contributions** section to explore contributions defined as part of modules. You can view the various types of contributions and subcontributions that are provided and the Reference Identifiers that are provided as part of the subcontributions within a tree.

"Examine capabilities" on page 2583
Use the **Capabilities** section to explore capabilities that are defined as part of modules. You can view the various names and versions in one list, with the modules that exposed them shown.

"Validation reports" on page 2589
Use the validation portlet to verify that your theme contains no errors. The validation report analyzes your theme and theme components for known issues and reports the number of errors, warnings, and informational messages. It also includes a detailed explanation about how to fix the errors that occur.

"Utilities" on page 2599
If you need help with a theme issue, you can export your system data. Support personnel can then import and view your data as a simulated system to troubleshoot problems.

Examine page profiles:

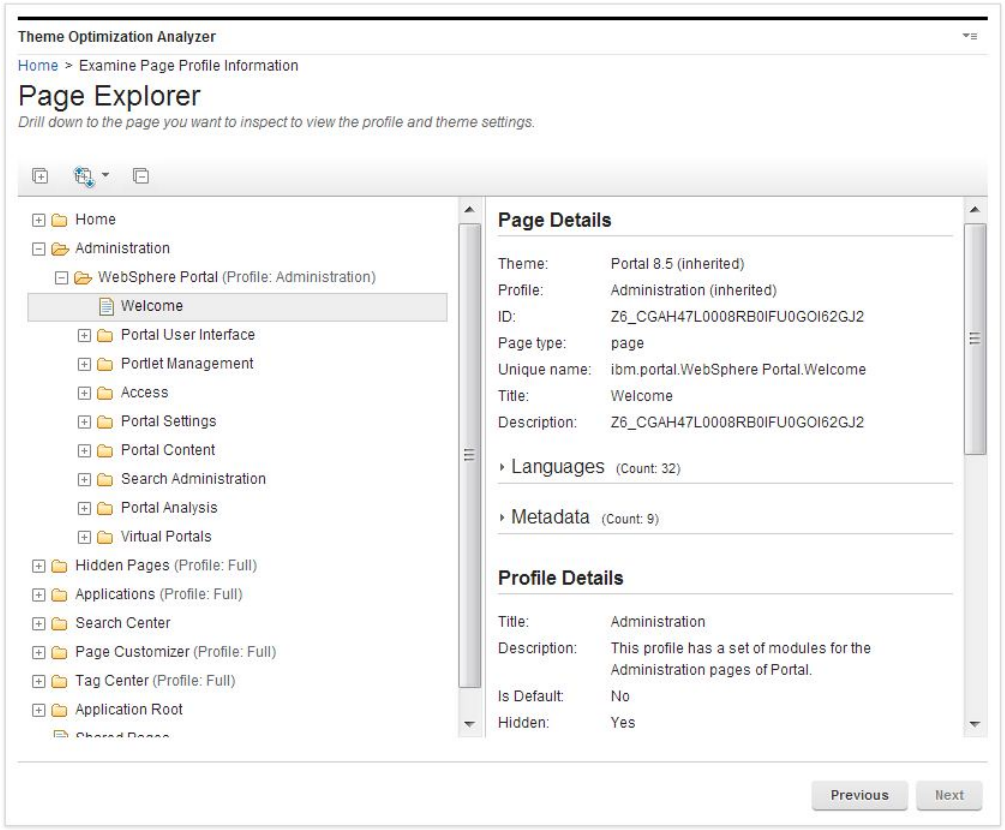
Use **Examine page profile information** to explore the whole page hierarchy of the system and display information about the set themes and profiles per page. It also differentiates between inherited and explicitly set themes and profiles, and locates errors such as unknown profiles that might be set. It is a great tool to find errors in your deployment.

When you select the **Examine page profile information** on the **Home** screen, the Page Explorer screen displays.

Note: In simulation mode, the **Examine page profile information** section is not available and cannot be clicked.

Page explorer

The page explorer displays the page hierarchy of your system in a split view. The tree view shows the page hierarchy and the details view shows information about the branch that is selected in the tree view.



In the tree view, when a page has a specified profile that is not inherited from the parent, the profile name displays in parentheses after the page name.

The details view displays details for the selected page as well as the theme and profile that are used on the page. If a theme or profile is inherited, it is displayed in parentheses after the theme or profile name. When a theme or profile is set specifically, no comment is displayed.

When you expand a tree or branch, if it is large and takes more than 30 seconds to expand, the expansion process is stopped. You must expand those branches individually.

The page explorer provides specialized view of your website pages to shows theme information. It is not intended to provide general information about pages.

Examine modules:

Use the modules sections to explore the modules of a specific profile or all of the modules available with the system, theme, or both.

Reference Identifiers that are provided as part of the subcontributions within a tree.

CF03 You have the option in this screen to continue with **Examine modules by page**, **Examine modules by profile**, or **Examine all modules**.

CF03

Modules by pages

Use the Examine modules by page section to explore modules that are defined on a specific page. Modules can be contributed to a page with its profile or portlets. Select a page in the Select Page screen and then advance to the Module Explorer to explore the modules in that page.

The Select Page screen displays the site's page hierarchy in the tree view and shows details on the selected branch in the details view. You can now learn more about the pages before you select one to examine.

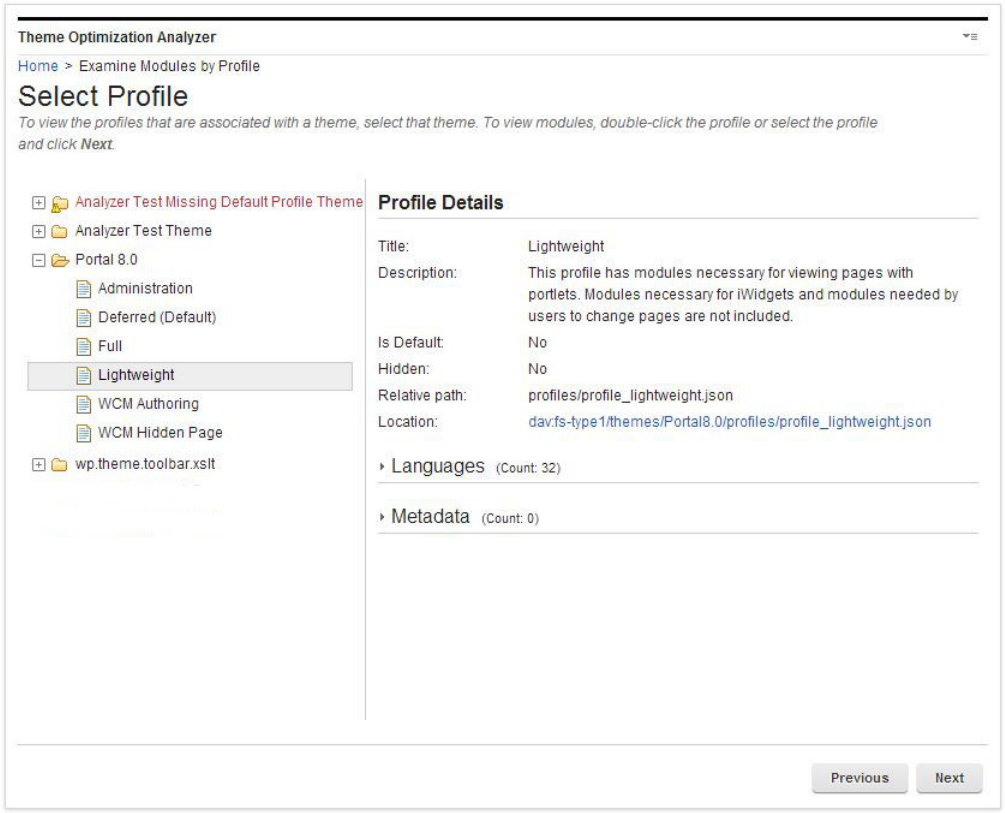
In the tree view, when a page has a specified profile that is not inherited from the parent, the profile name displays in parentheses after the page name. All other information is shown in the details view, such as the page, profile, and theme information.

After you select a page, the Module Explorer displays.

Modules by profile

Use the **Examine modules by profile** section to explore the modules of a specific profile. Select a profile in the **Select Profile** screen and then advance to the Module Explorer to explore the modules in that profile.

The **Select Profile** screen displays the themes and their profiles in the tree view and shows details on the selected branch in the details view. You can now learn more about the various artifacts that are installed in the system before you select a profile to examine.



The tree view also shows in parentheses which theme and profile is the default so this information is easily visible. All other information is shown in the details view, such as the location of the profile JSON file. The profile JSON file is an element that can be clicked and opens a new window and serves the resource in the browser when clicked.

After you select a profile, the Module Explorer screen will display.

All modules

Use the **Examine all modules** section to explore all modules available with the system, theme, or both. Select a theme or the system module branch on the **Select Theme** screen and then advance to the Module Explorer.

The **Select Theme** screen displays a system modules branch and all themes in the tree view. Select a theme to view more information about the various artifacts that are installed in the system before you decide on a theme and continue to the Module Explorer.

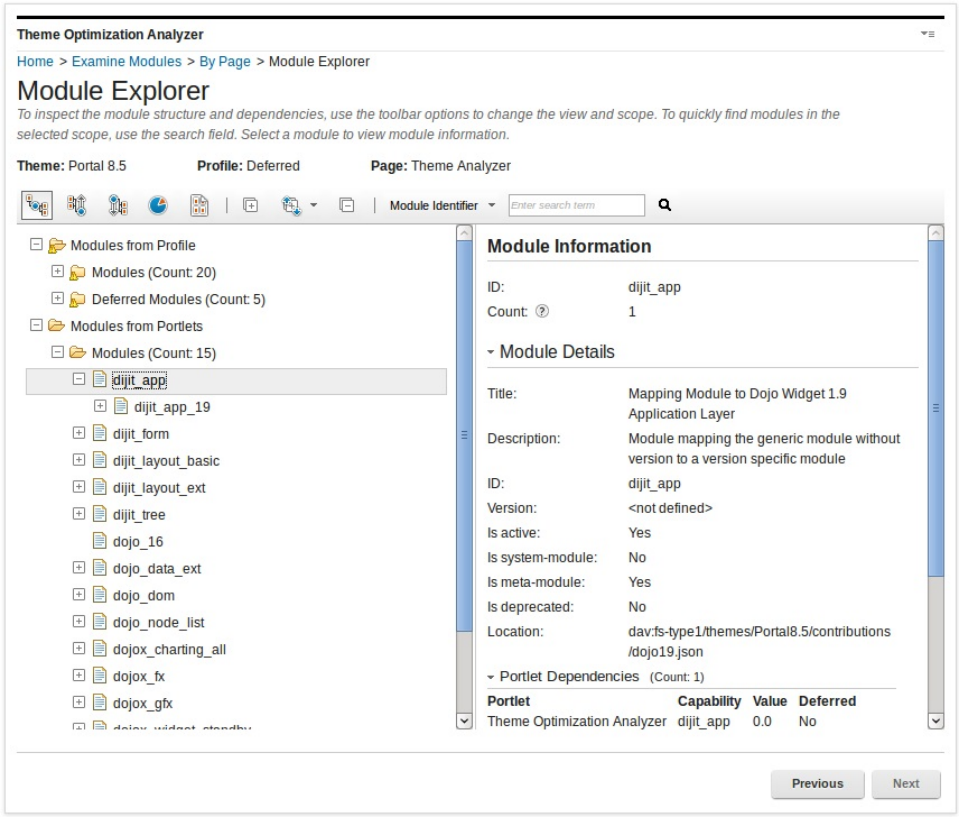
Module explorer

The module explorer displays the module hierarchy of your system in a split view. The tree view shows the module hierarchy, the details view shows details on the selected module from the tree view.

You can get to the module explorer from different paths in the UI.

1. CF03 When you examine the modules that are scoped by page, you have two root branches, each with two childs:

- **Modules from Profile**: The root for all modules in the profile.
  - **Modules**: All modules that are in the non-deferred section of the profile.
  - **Deferred Modules**: All modules that are in the deferred section of the profile.
- **Modules from Portlets**: The root for all modules that are provided by capabilities that are assigned by the page's portlets.
  - **Modules**: All modules that are provided by non-deferred capabilities that are assigned by the page's portlets.
  - **Deferred Modules**: All modules that are provided by deferred capabilities that are assigned by the page's portlets.



2. When you examine modules by profile, you have two root branches:
   - **Modules**: The root for all modules in the none deferred section of the profile.
   - **Deferred Modules**: The root for all modules in the deferred section of the profile.

When you expand a tree or branch, if it is large and takes more than 30 seconds to expand, the expansion process is stopped. You must expand those branches individually.

The module hierarchy has three main views:

Complete hierarchy
This view displays the root and a list of modules underneath as child branches. The child branches for each module then represent the prerequisite dependencies that each module defines. You can drill down until no prerequisites are defined. Therefore, within the tree various modules might display multiple times since they can be defined as a prerequisite for many different modules.

For example: The `wp_toolbar` module, which is referenced in the deferred profile, defines the `dojo` module as a prerequisite. Then, the `dojo` module defines the `dojo_17` module as a prerequisite. When you look at the module explorer, you can drill down into the **Deferred Modules** section, which displays the `wp_toolbar` module. If you drill down further, you can see the `dojo` module is child of `wp_toolbar` and the `dojo_17` module is child of the `dojo` module.

Parent view of a selected branch
This view displays the parents of a module. The parent is a module that has a prerequisite of a child module. Module A has a prerequisite of module B, which means that B 's parent is A. It is useful to figure out who is using a specific module and verify whether the usage is correct.

Note: The parent is displayed as a child branch within the view, the tree is upside down.

For instance: When you look at the `wp_client_main` module in the parent view, it has a child branch in the tree called `wp_status_bar`. Therefore, `wp_status_bar` is the parent of `wp_client_main`.

Child view of a selected branch
This view behaves identically to the complete hierarchy view except that it focused on a single branch as the parent. The dependencies of just this single branch are displayed.

Size explorer

This view shows a pie chart representation of the relative sizes of the modules and size details.

The size details panel shows three representations of a module's size. Each section of the panel computes the size differently.

The first section shows the total download size of the module and its dependencies. Duplicate dependencies are included once in the size calculation.

The middle section shows the total download size for each child of the currently selected module. Dependencies that are shared between siblings are included in the size calculation of each child module.

The last section shows all descendants of the currently selected module and the size of each module, not including the size of the module's prerequisites.

For example, assume that each module size is 1 KB. The hierarchy looks like the following, and `module_0` is the current module.

- module_0
  - module_1
    - module_2
    - module_3
  - module_2
    - module_3
  - module_3

The size of `module_0` in the first section is 4 KB, which includes the size of the module and each of its descendants. `module_2` is a prerequisite for both `module_0` and `module_1` so it is counted only once. The middle section includes `module_1`, `module_2`, and `module_3`. The size of `module_1` is 3 KB. The last section includes all of `module_0`'s descendants or `module_1`, `module_2`, and `module_3` and the size of each of those modules is 1 KB.

You can view sizes as compressed or uncompressed and you can switch between them by clicking the compression icon in the toolbar.

You can browse through the Size Explorer by clicking the segments of the pie chart, or the links in the child section for more details. To return to a higher level, click the module from the Size Explorer breadcrumb trail or click the **Go to Parent** link.

Portlet explorer.
The view displays a list of all portlets on the page. The childs of the portlets are the capabilities depended on by each portlet. Under each capability, are the modules that define the capability. When a portlet is selected, the details view shows its ID, titles, descriptions, capabilities, and preferences.

The details view displays the details for the selected module such as:

- ID: Displays the module ID.
- Version: Displays the module version, if one was defined.
- Is system-module: Yes if the module is globally defined through a `plugin.xml` file.
- Is meta-module: Yes if the module does not contain any contributions, but instead contains only prerequisites.
- Is deprecated: Yes, if the module was deprecated.
- Location: Displays the file path for the module.
- Capabilities: Displays all capabilities for the module.
- Prereqs: Displays all prerequisites for the module.
- Parents: Displays all parent modules for the module
- Contributions: Displays all contributions by contribution and sub contribution. The resources are elements that can be clicked, which open a new window and serves the resource in the browser when clicked.

  Note: In simulation mode, the resources cannot be clicked.

Searching within the module explorer

Use the search bar to search the tree view and the details view for various information. The following search scopes are supported:

- **`Module Identifier`**: Search for a specific module by name. For example, `wp_client_main`.

- **`Resource`**: Search for the module that exposes a certain resource. For example, enter `master.css` to identify the module that exposes this resource. This search is useful if you find an error in a JavaScript file in your browser. You can easily find the module that this resource belongs to.
- **`Capability`**: Search for the modules that are associated with a specific capability. For example, if you want to know which module provides the `dojo` capability. Then, you know which module you must add as a prerequisite for your own module.
- **`Reference Identifiers`**: Search for which dynamic content spot or module reference is exposed by which module.

Enter a term into the search field in the toolbar and press Enter or click the **Find** icon. The found item is then highlighted for a short time with a yellow background. Pressing Enter again or clicking **Find** icon again will find the next item. If no item is found, either a pop-up dialog opens to instruct you to start the search from the beginning or the background of the search field is marked in red.

Examine contributions:

Use the **Contributions** section to explore contributions defined as part of modules. You can view the various types of contributions and subcontributions that are provided and the Reference Identifiers that are provided as part of the subcontributions within a tree.

You have the option in this screen to continue with CF03 **Examine contributions by page, Examine contributions by profiles**, or **Examine all contributions**.

CF03
Contributions by pages

Use the Examine contributions by page section to explore contributions that are defined on a specific page. Modules can be contributed to a page via its profile or portlets. Select a page in the Select Page screen and then advance to the Contribution Explorer to explore the contributions in that page.

The Select Page screen displays the site's page hierarchy in the tree view and shows details on the selected branch in the details view. You can now learn more about the pages before you select one to examine.

In the tree view, when a page has a specified profile that is not inherited from the parent, the profile name displays in parentheses after the page name. All other information is shown in the details view, such as the page, profile and theme information.

After you select a page, the Contribution Explorer screen displays.

Contributions by profiles

Use the **Examine contributions by profiles** section explore contributions that are defined as part of modules for a specific profile. Select a profile in the **Select Profile** screen and then advance to the Contribution Explorer to explore the contributions in that profile.

The **Select Profile** screen displays the themes and their profiles in the tree view and shows details on the selected branch in the details view. You can now learn more about the various artifacts that are installed in the system before you select a profile to examine.

The tree view also shows in parentheses which theme and profile is the default so this information is easily visible. All other information is shown in the details view, such as the location of the profile JSON file. The profile JSON file is an element that can be clicked and opens a new window and serves the resource in the browser when clicked.

After you select a profile, the Contribution Explorer screen will display.

All contributions

Use the **Examine all contributions** section to explore all contributions that are provided by modules available with the system, theme, or both. Select a theme or the system module branch in the **Select Theme** screen and then advance to the Contributions Explorer.

The **Select Theme** screen displays a system modules branch and all themes in the tree view. Select a theme to view more information about the various artifacts that are installed in the system before you decide on a theme and continue to the Contribution Explorer. To view the contributions in a theme, double-click the theme or select the theme and click **Next**.

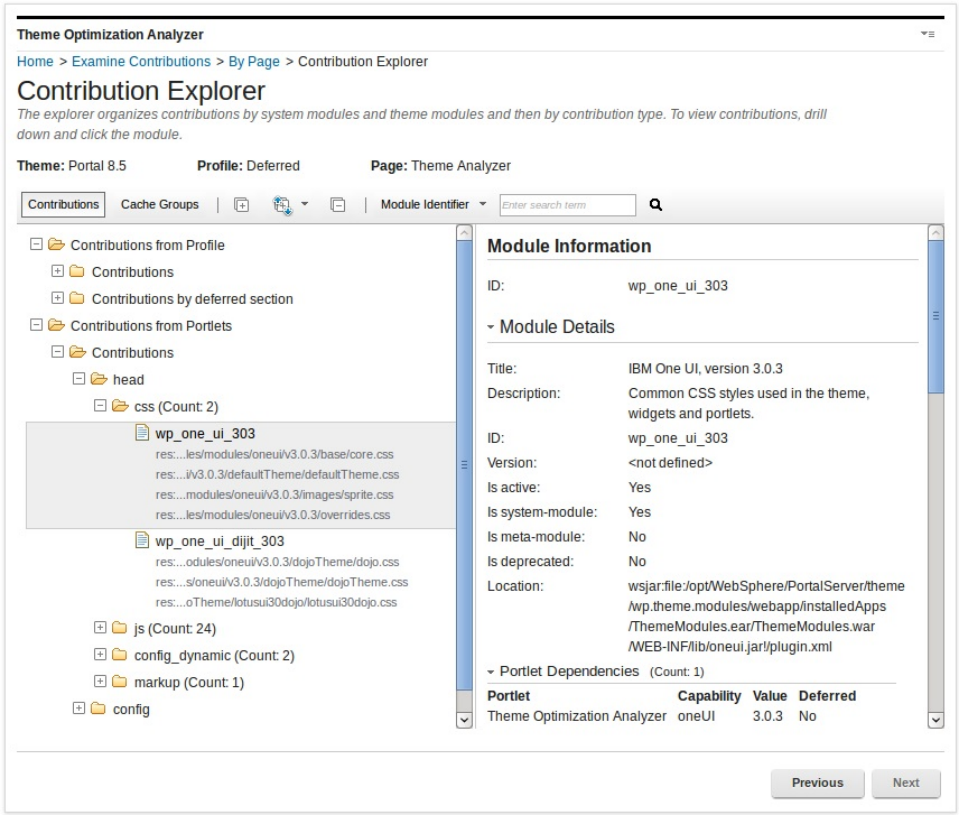
Contribution explorer

The contribution explorer displays the contribution type hierarchy of your system in a split view. The tree view shows the contribution and subcontribution types with modules as the leaf, the details view shows details on the selected module from the tree view.

You can get to the contribution explorer from different paths in the UI.

1. CF03 When you examine the contributions that are scoped by page, you have two root branches, each with two children:
   - **Contributions from Profile**: The root for all contributions that are provided by modules in the profile.
     - **Contributions**: All contributions that are provided by modules in the non-deferred section of the profile.
     - **Contributions by a deferred section**: All contributions that are provided by modules in the deferred section of the profile.
   - **Contributions from Portlets**: The root for all contributions that are provided by capabilities assigned by the page's portlets.
     - **Contributions**: All contributions that are provided by non-deferred capabilities assigned by the page's portlets.
     - **Contributions by a deferred section**: All contributions that are provided by deferred capabilities assigned by the page's portlets.

   CF03



2. When you examine the contributions that are scoped by profile, you have two root branches:
   - **`Contributions`**: The root for all contributions that are provided by modules in the non-deferred section of the profile.
   - **`Contributions by a deferred section`**: The root for all contributions that are provided by modules in the deferred section of the profile.

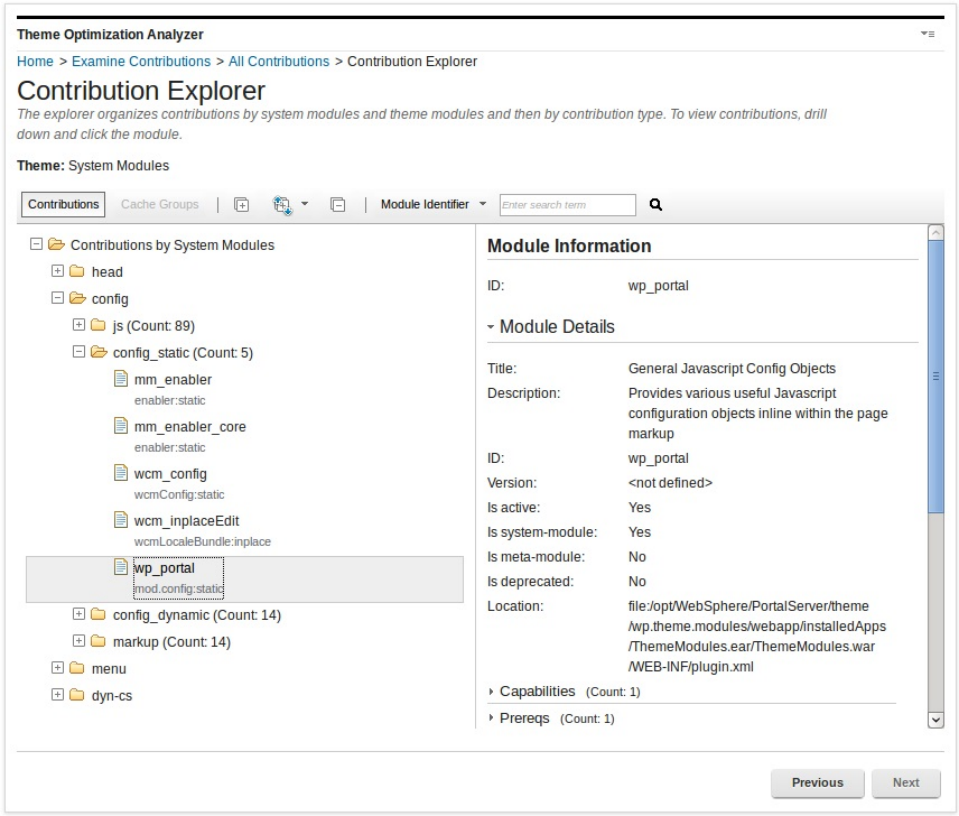
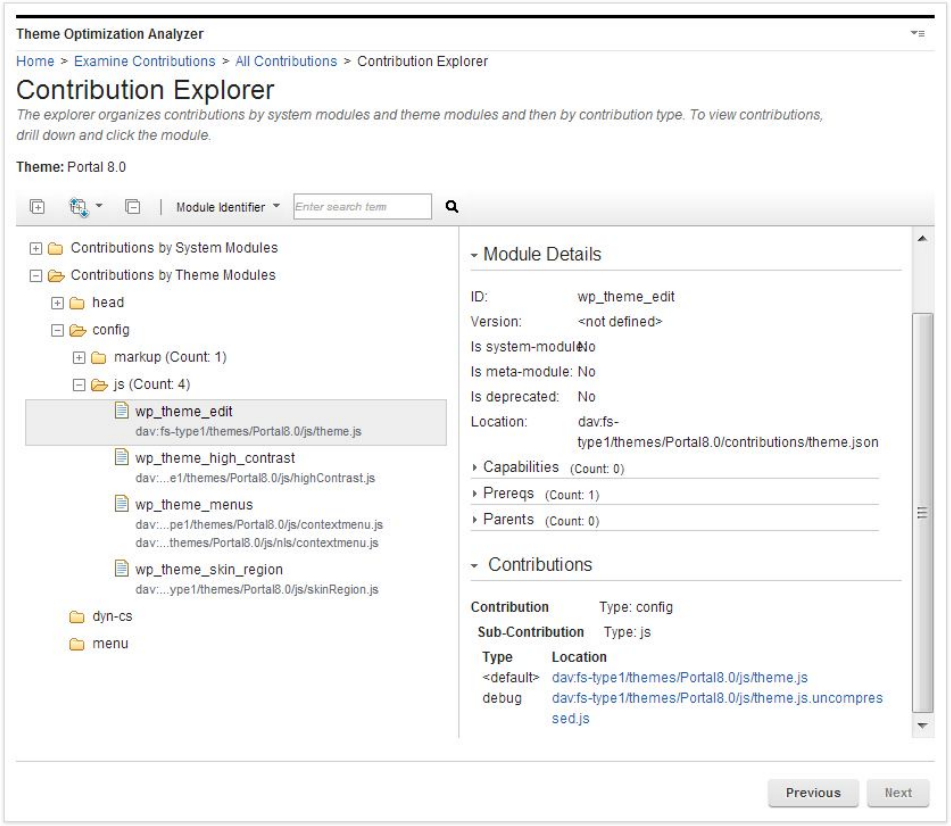
3. When you examine the system and theme contributions, you have one or two branches:
   - **`Contributions by System Modules`**: Contains all contributions that are provided by modules that are defined globally through a `plugin.xml` file.
   - **`Contributions by Theme Modules`**: Contains all contributions that are provided by modules that are defined within the themes contribution folder as part of the JSON files. This branch is only shown when a theme is selected.

CF03





When you expand a tree or branch, if it is large and takes more than 30 seconds to expand, the expansion process is stopped. You must expand those branches individually.

The details view displays the details for the selected module such as:

- ID: Displays the module ID.
- Version: Displays the module version, if one was defined.
- Is system-module: Yes if the module is globally defined through a `plugin.xml` file.
- Is meta-module: Yes if the module does not contain any contributions, but instead contains only prerequisites.
- Is deprecated: Yes, if the module was deprecated.
- Location: Displays the file path for the module.
- Capabilities: Displays all capabilities for the module.
- Prereqs: Displays all prerequisites for the module.
- Parents: Displays all parent modules for the module
- Contributions: Displays all contributions by contribution and sub contribution. The resources are elements that can be clicked, which open a new window and serves the resource in the browser when clicked.

  Note: In simulation mode, the resources cannot be clicked.

Searching within the contribution explorer

Use the search bar to search the tree view and the details view for various information. The following search scopes are supported:

- **`Module Identifier`**: Search for a specific module by name. For example, `wp_client_main`.
- **`Resource`**: Search for the module that exposes a certain resource. For example, enter `master.css` to identify the module that exposes this resource. This search is useful if you find an error in a JavaScript file in your browser. You can easily find the module that this resource belongs to.
- **`Capability`**: Search for the modules that are associated with a specific capability. For example, if you want to know which module provides the `dojo` capability. Then, you know which module you must add as a prerequisite for your own module.
- **`Reference Identifiers`**: Search for which dynamic content spot or module reference is exposed by which module.

Enter a term into the search field in the toolbar and press Enter or click the **Find** icon. The found item is then highlighted for a short time with a yellow background. Pressing Enter again or clicking **Find** icon again will find the next item. If no item is found, either a pop-up dialog opens to instruct you to start the search from the beginning or the background of the search field is marked in red.

Cache groups

For every combined request that the theme optimization framework produces, you can see the overall ability to cache that request and how those caches are calculated. You can select a cache group or resources and examine it.

Examine capabilities:

Use the **Capabilities** section to explore capabilities that are defined as part of modules. You can view the various names and versions in one list, with the modules that exposed them shown.

You have the option in this screen to continue with CF03 **Examine contributions by page, Examine capabilities by profile** or **Examine all capabilities**.

CF03
Capabilities by pages

Use the Examine capabilities by page section to explore capabilities that are defined on a specific page. Capabilities can be contributed to a page via its profile or portlets. Select a page in the Select Page screen and then advance to the Capability Explorer to explore the capabilities on that page.

The Select Page screen displays the site's page hierarchy in the tree view and shows details on the selected branch in the details view. You can now learn more about the pages before you select one to examine.

In the tree view, when a page has a specified profile that is not inherited from the parent, the profile name displays in parentheses after the page name. All other information is shown in the details view, such as the page, profile and theme information.

After you select a page, the Capability Explorer screen displays.

Capabilities by profile

Use the **Examine capabilities by profile** section to explore capabilities that are defined as part of modules for a specific profile. To do that you must first select a profile in the Profile Selection screen and then advance to the Capability Explorer.

The **Select Profile** screen displays the themes and their profiles in the tree view and shows details on the selected branch in the details view. You can now learn more about the various artifacts that are installed in the system before you select a profile to examine.

The tree view also shows in parentheses which theme and profile is the default so this information is easily visible. All other information is shown in the details view, such as the location of the profile JSON file. The profile JSON file is an element that can be clicked and opens a new window and serves the resource in the browser when clicked.

After you select a profile, the Capability Explorer screen will display.

All Capabilities

Use the **Examine all capabilities** section to explore all capabilities that are provided by modules available with the system, theme, or both. Select a theme or the system module branch in the **Select Theme** screen and then advance to the Capability Explorer.

The **Select Theme** screen displays a system modules branch and all themes in the tree view. Select a theme to view more information about the various artifacts that are installed in the system before you decide on a theme and continue to the Capability Explorer. To view the capabilities in a theme, double-click the theme or select the theme and click **Next**.

Capability explorer

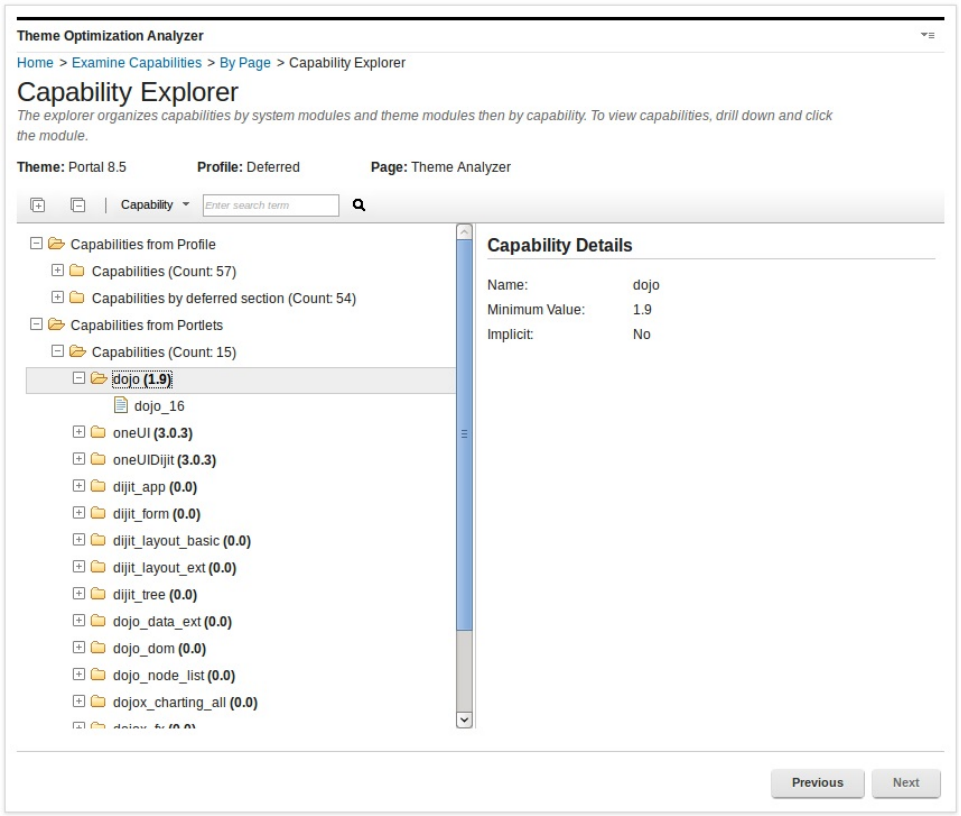
The capability explorer displays the capability names and versions that are provided by a set of modules in a split view. The tree view shows the capabilities and respective module that defines the capability, the details view shows details on the selected module from the tree view.

You can get to the capability explorer from different paths in the UI.

1. When you examine the capabilities that are scoped by page, you have two root branches, each with two children:
   - **`Capabilities from Profile`**: The root for all capabilities that are provided by modules in the profile.
     - **`Capabilities`**: All capabilities that are provided by modules in the non-deferred section of the profile.
     - **`Capabilities by a deferred section`**: All capabilities that are provided by modules in the deferred section of the profile.
   - **`Capabilities from Portlets`**: The root for all capabilities that are assigned by the page's portlets.
     - **`Capabilities`**: All non-deferred capabilities that are provided by the page's portlets.

– **Capabilities by a deferred section**: All deferred capabilities that are provided by the page's portlets.

CF03



2. When you examine the capabilities that are scoped by profile, you have two root branches:
   - **Capabilities**: The root for all capabilities that are provided by modules in the none deferred section of the profile.
   - **Capabilities by a deferred section**: The root for all capabilities that are provided by modules in the deferred section of the profile.

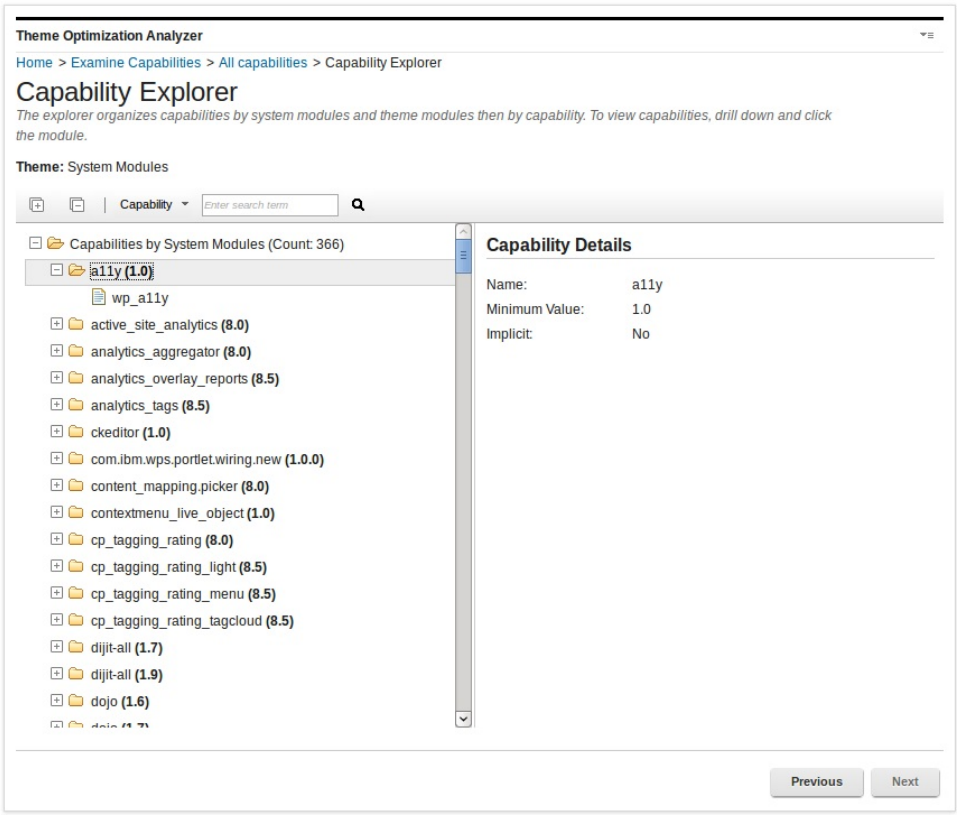
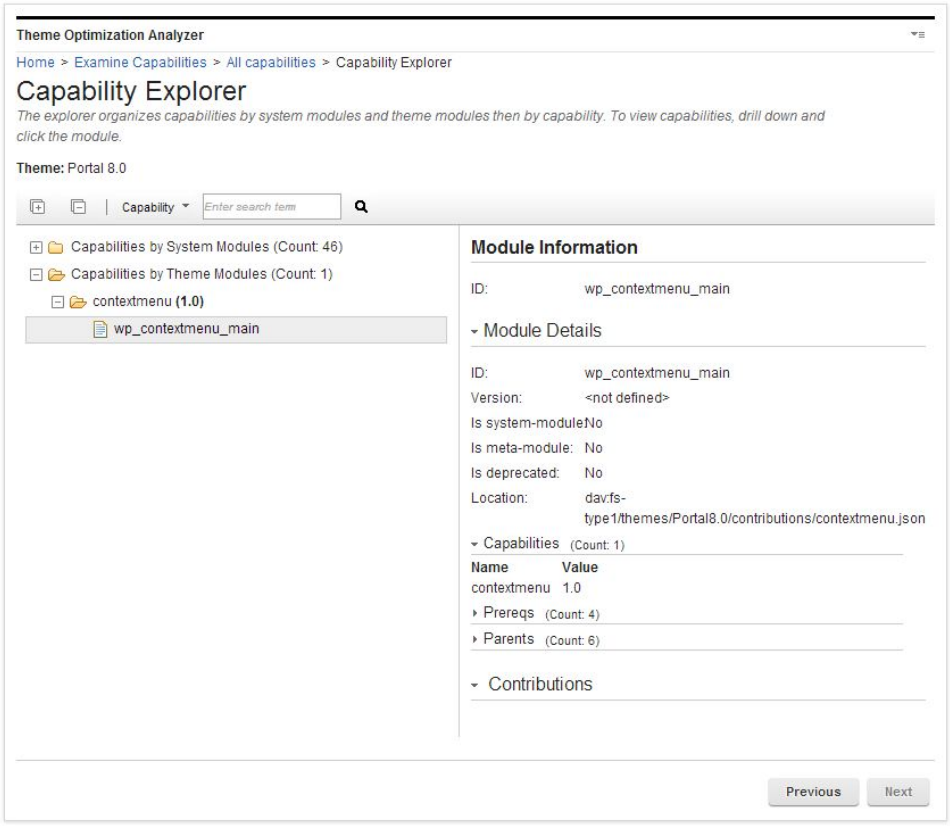
3. When you examine the system and theme capabilities, you have one or two branches:
   - **`Capabilities by System Modules`** Contain all capabilities that are provided by modules that are defined globally through a `plugin.xml`.
   - **`Capabilities by Theme Modules`** Contain all capabilities that are provided by modules that are defined within the themes capabilities folder as part of the JSON files. This branch is only shown when a theme is selected.

CF03





When you expand a tree or branch, if it is large and takes more than 30 seconds to expand, the expansion process is stopped. You must expand those branches individually.

The details view displays the details for the selected module such as:

- ID: Displays the module ID.
- Version: Displays the module version, if one was defined.
- Is system-module: Yes if the module is globally defined through a `plugin.xml` file.
- Is meta-module: Yes if the module does not contain any contributions, but instead contains only prerequisites.
- Is deprecated: Yes, if the module was deprecated.
- Location: Displays the file path for the module.
- Capabilities: Displays all capabilities for the module.
- Prereqs: Displays all prerequisites for the module.
- Parents: Displays all parent modules for the module
- Contributions: Displays all contributions by contribution and sub contribution. The resources are elements that can be clicked, which open a new window and serves the resource in the browser when clicked.

  Note: In simulation mode, the resources cannot be clicked.

Searching within the capability explorer.

Use the search bar to search the tree view and the details view for various information. The following search scopes are supported:

- **`Module Identifier`**: Search for a specific module by name. For example, `wp_client_main`.
- **`Resource`**: Search for the module that exposes a certain resource. For example, enter `master.css` to identify the module that exposes this resource. This search is useful if you find an error in a JavaScript file in your browser. You can easily find the module that this resource belongs to.
- **`Capability`**: Search for the modules that are associated with a specific capability. For example, if you want to know which module provides the `dojo` capability. Then, you know which module you must add as a prerequisite for your own module.
- **`Reference Identifiers`**: Search for which dynamic content spot or module reference is exposed by which module.

Enter a term into the search field in the toolbar and press Enter or click the **Find** icon. The found item is then highlighted for a short time with a yellow background. Pressing Enter again or clicking **Find** icon again will find the next item. If no item is found, either a pop-up dialog opens to instruct you to start the search from the beginning or the background of the search field is marked in red.

Validation reports:

Use the validation portlet to verify that your theme contains no errors. The validation report analyzes your theme and theme components for known issues and reports the number of errors, warnings, and informational messages. It also includes a detailed explanation about how to fix the errors that occur.

Home screen

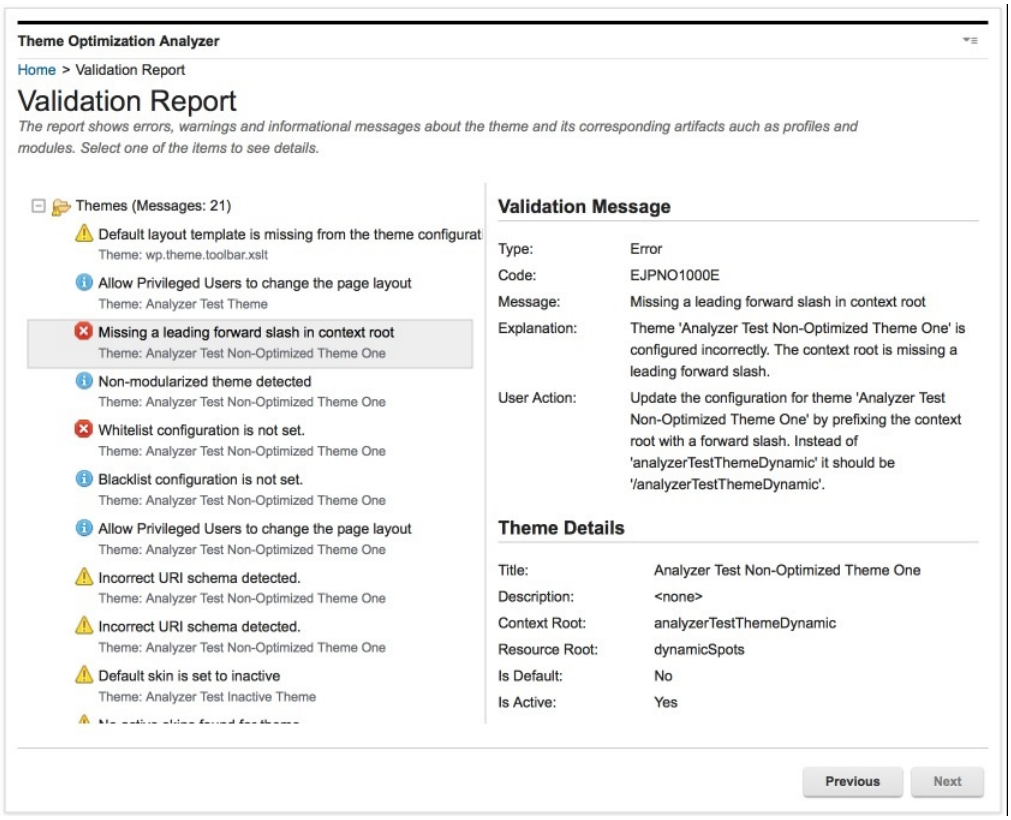
After the validation analyzer runs, the report includes a number badge. The badge shows the total number of messages in the report. The background color indicates the severity within the report. Red means that there is an error. Orange means that there is a warning. Green means that there are informational messages. If no badge is present, no messages were found.

Validation report

The expanded report shows the validation report of your system in a split view. The tree view shows the messages in categories. The details view shows information about the message that is selected in the tree view. The details view also displays related information that is important for the message. These can be theme, profile, module, or skin details.

A check mark by a category means that there are no errors or warnings in that category. In the following screen capture, the Theme Optimization Analyzer portlet Validation Report includes 21 messages. The selected message, `Missing a leading forward slash in context root`, is described in the details section. The error code is `EJPNO1000E`. The explanation is `Theme 'Analyzer Test Non-Optimized Theme One'`

is configured incorrectly. The context root is missing a leading forward slash. It also includes a User Action that tells the user how to fix the error. In this case, it is Update the configuration for theme 'Analyzer Test Non-Optimized Theme One' by prefixing the context root with a forward slash. Instead of 'analyzerTestThemeDynamic', it should be '/analyzerTestThemeDynamic'.



Possible messages

The following topics describe all of the possible messages.

"EJPNO1000E" on page 2591
Missing a leading slash in context root.

"EJPNO1001E" on page 2592
WebDAV directory names must not contain spaces.

"EJPNO1002E" on page 2592
Missing default profile.

"EJPNO1003W" on page 2592
Missing module referenced in profile.

"EJPNO1004I" on page 2592
Duplicate modules found in profile.

"EJPNO1005E" on page 2593
Circular dependency detected.

"EJPNO1007W" on page 2593
Incorrect URI schema detected.

"EJPNO1008W" on page 2593
Incorrect URI schema detected.

EJPNO1000E:

Missing a leading slash in context root.

Explanation

Your theme is configured incorrectly. The context root is missing a leading forward slash.

User action

Update the configuration for your theme by prefixing the context root with a forward slash.

EJPNO1001E:

WebDAV directory names must not contain spaces.

Explanation

Theme metadata with a key you're using for your theme indicates that there are spaces in the WebDAV directory names.

User action

Update the WebDAV directory name and remove all spaces. Update the theme metadata with the key to match the modified WebDAV directory name.

EJPNO1002E:

Missing default profile.

Explanation

The referenced profile in the theme is missing and cannot be accessed.

User action

Update your theme metadata with the key `'resourceaggregation.profile'` to point to a valid profile file.

Related tasks:

"Changing theme metadata" on page 2722
The first step of theme configuration is through theme metadata properties. Changes to the metadata are specific to a single theme, and the entries and values, therefore, can vary from theme to theme.

EJPNO1003W:

Missing module referenced in profile.

Explanation

A module you are using is referenced in the module list of your profile but does not exist within the system.

User action

Update your profile to point to the correct module instead or remove the missing module reference.

EJPNO1004I:

Duplicate modules found in profile.

Explanation

A module you are using is referenced multiple times in the module list of another profile.

User action

Update your profile and remove the duplicate entries of the module.

EJPNO1005E:

Circular dependency detected.

Explanation

A module dependency chain has been detected in a module you are using that contains a circular dependency. To prevent an endless loop the module hierarchy processing has been interrupted and your modules will potentially not work correctly.

User action

Update your module prereqs to resolve the circular dependency. The erroneous module hierarchy is named in this section.

EJPNO1007W:

Incorrect URI schema detected.

Explanation

An unsupported URI schema was detected in your theme. The theme metadata key is using a RES schema. Recommended schemas are WAR and DAV, RES is not supported.

User action

Update your theme metadata with the key to a supported schema.

Related tasks:

"Adapt the scripts that register the custom theme and skins" on page 2818
You must adapt the scripts that register the custom theme and skins that were moved from the file store.

EJPNO1008W:

Incorrect URI schema detected.

Explanation

An unsupported URI schema was detected in a skin you are using. The skin metadata key is using a RES schema. Recommended schemas are WAR and DAV, RES is not supported.

User action

Update your skin metadata with the key the tool suggests to a supported schema.

Related tasks:

"Adapt the scripts that register the custom theme and skins" on page 2818
You must adapt the scripts that register the custom theme and skins that were moved from the file store.

EJPNO1009W:

Incorrect URI detected.

Explanation

An incorrect URI was detected in your theme. This URI is using the WAR schema but contains a leading forward slash.

User action

Update your theme metadata with the correct key.

EJPNO1010W:

Incorrect URI detected.

Explanation

An incorrect URI was detected in a skin you are using. This URI is using the WAR schema but contains a leading forward slash.

User action

Update your skin metadata with the correct key.

EJPNO1011I:

Allow Privileged Users to change the page layout.

Explanation

The theme contains static content deployed in a WAR. It was detected that a value set for parameter **refreshPageLayout.template.regexp** does not match the theme. With the current setting users must have the Markup Editor role that is assigned to be able to change a layout.

User action

Open the WebSphere Integrated Solutions Console. **Open Resources** > **Resource Environment** > **Resource Environment Providers** > **WP ConfigService** > **Custom Properties**. Create or adapt a regular expression for the **refreshPageLayout.template.regexp** parameter.

Related tasks:

"Adapt the scripts that register the custom theme and skins" on page 2818
You must adapt the scripts that register the custom theme and skins that were moved from the file store.

EJPNO1012W:

Default layout template is missing from the theme configuration.

Explanation

The theme does not have a default layout template defined. This can cause pages to be created with the incorrect type.

User action

Create a theme metadata with the key **com.ibm.portal.layout.template.ref**.
xmlAccess Snippet:

```
<div class="themeOptAnalyzerFixedText"><parameter name="com.ibm.portal.layout.template.href" type=
```

Related tasks:

"Changing theme metadata" on page 2722
The first step of theme configuration is through theme metadata properties. Changes to the metadata are specific to a single theme, and the entries and values, therefore, can vary from theme to theme.

EJPNO1013E:

Whitelist configuration is not set.

Explanation

The theme contains static content deployed in a WAR. For security reasons, the WAR data source does not serve content until a special context parameter is set. This context parameter defines which files from your web module WebSphere Portal is able to serve. You must define a whitelist using a regular expression that matches the files that you want to make available.

User action

The parameters are set in the `web.xml` file of the web module that contains the static theme content. For example, serve all files that are not part of the WEB-INF folder.

```
<div class="themeOptAnalyzerFixedText"><web-app><br/>...<br/><context-param><br/>  <para
```

Related tasks:

"Add static content to your custom theme" on page 2817
Add static content for you custom theme that you created based on one of the ready-to-use themes.

EJPNO1014I:

Blacklist configuration is not set.

Explanation

The theme contains static content deployed in a WAR. With a blacklist you can remove certain entries from the set of files that are available in the whitelist. A blacklist is helpful if you want to serve a folder but not a certain file within that folder.

User action

The parameters are set in the `web.xml` file of the web module that contains the static theme content. For example, serve all files that are not part of the WEB-INF folder.

```
<div class="themeOptAnalyzerFixedText"><web-app><br/>...<br/><context-param><br/>  <para
```

Related tasks:

"Add static content to your custom theme" on page 2817
Add static content for you custom theme that you created based on one of the

ready-to-use themes.

EJPNO1015E:

Missing prereq detected.

Explanation

A missing module dependency has been detected in a module which defines a prereq that doesn't exist. The missing module dependency check has been performed within the scope of your theme and your profile.

User action

Update your module dependencies, either remove the referenced module or make the missing module available.

EJPNO1016I:

Non-modularized theme detected.

Explanation

A theme was detected as a non-modularized theme as it is missing the `resourceaggregation.profile` theme metadata key.

User action

If the theme is a non-modularized style theme it is strongly encouraged to upgrade to the modularized theme.

EJPNO1017W:

Default skins is set to inactive.

Explanation

The default skin for your theme is set to inactive. This may result in portlets not displaying until an active skin is applied.

User action

Update your skin to active or change the default skin for the theme to an active skin from the allowed-skin list.

EJPNO1018W:

No active skins found for theme.

Explanation

No active skins were detected from the list of allowed skin for your theme.

User action

Either update the list of allowed skins to include an active skin or set one of your allowed skins to active.

EJPNO1019W:

Invalid URI detected.

Explanation

An invalid URI was detected in your theme. The value of this metadata key cannot be parsed as a URI reference.

User action

Update your theme metadata with the incorrect key to a proper URI.

EJPNO1020W:

Invalid URI detected.

Explanation

An invalid URI was detected in your skin. The value of this metadata key cannot be parsed as a URI reference.

User action

Update your skin metadata with the key to a proper URI.

EJPNO1021W:

Undefined contribution hierarchy in profile.

Explanation

The profile has multiple modules defining the same dynamic content spot ID without a hierarchy or order between them.

User action

A hierarchy or order should be defined between the modules that define the same dynamic content spot ID. To define the dynamic content spot overlay, the module with the dynamic content spot ID definition that should be used needs to list all other modules with the same dynamic content spot ID definition as prereqs.

EJPNO1022E:

System plug-in collision

Explanation

A plug-in ID was detected in more than one `plugin.xml` file.

User action

Update your plug-in definitions by using unique plug-in IDs for each plug-in to avoid duplicate IDs.

EJPNO1023E:

System module collision

Explanation

A duplicate module id and version was detected.

User action

Update your module definitions by using unique module id and version combinations for each module to avoid duplicate module definitions.

EJPNO1024W:

Themelist URL used for rendering

Explanation

The theme metadata key "{1}", which is used when rendering the theme, is set to "{2}". This is a valid URL, but is pointing to the themelist WebDAV entry point. The themelist entry point is intended for performing administrative operations with themes (such as creating a new theme, deleting a theme, or modifying a theme). This themelist URL should not be used for runtime rendering operations, as it adds additional overhead that is unnecessary for non-administrative rendering operations.

User action

Update your theme metadata with the key "{0}" to point to the fs-type1 WebDAV entry point. For example: "{1}".

EJPNO1025W:

Skinlist URL used for rendering

Explanation

The skin metadata key "{1}", which is used when rendering the skin, is set to "{2}". This is a valid URL, but is pointing to the skinlist WebDAV entry point. The skinlist entry point is intended for performing administrative operations with skins (such as creating a new skin, deleting a skin, or modifying a skin). This skinlist URL should not be used for runtime rendering operations, as it adds additional overhead that is unnecessary for non-administrative rendering operations.

User action

Update your skin metadata with the key "{0}" to point to the fs-type1 WebDAV entry point. For example: `dav:fs-type1/themes/`*`custom theme`*`/skins/`*`custom skin`*`/`
.

EJPNO1026E:

Theme context root not found.

Explanation

Theme "{0}" is configured with context-root "{1}". An application with this context root cannot be found.

User action

Verify that the context-root setting of theme "{0}" matches the context root defined for the theme application and that the application is started.

Utilities:

If you need help with a theme issue, you can export your system data. Support personnel can then import and view your data as a simulated system to troubleshoot problems.

The import and export features are compatible with later versions, so if you have a recent version of IBM WebSphere Portal Express you can themes from previous versions. For example, an exported Portal 7002 theme can be viewed on a WebSphere Portal Express 8.0 system.

Export You can export your data to share with IBM support or your local support organization.

Import
You can import data from an external system to create a simulated system to aid in troubleshooting.

Note: When you import display data, the portlet enters a simulation mode. When the portlet is in simulation mode, page browsing is disabled and resource contributions cannot be clicked or viewed.

Control Center
The Control Center provides some short cuts for changing settings, which can help with theme analysis and debugging. These shortcuts are explained in detail on the Control Center page. Tools in the control center affect only the node on which you are currently working.

Invalidate Cache

Allows you to clear theme optimization-related caches so that changes you make locally to a theme's modules and profiles can be made available immediately, without restarting the server. Modify your theme then click the **Click to invalidate** link.

CF06 The framework can recognize updates to module and profile definitions of WebDAV based themes automatically. It significantly reduces the need for you to invalidate the cache manually. However, this feature does not work on `.WAR` file based themes.

For example, updating the file `dav:fs-type1/themes/Portal8.5/contributions/theme.json` through any WebDAV client, is recognized from the default pattern and causes an automatic theme invalidation.

For more information, see Configuration for resource aggregation.

CF07 **Invalidate system modules**
Allows you to invalidate system modules that are defined in `plugin.xml` files during the theme invalidation process. However, this feature skips all `.WAR` files.

For more information, see "Configuration for resource aggregation" on page 2725.

Remote Debugging
Allows you to see each module contribution as an individual request, and if there is a debug uncompressed version of the contribution it uses that resource. This is the same as setting the trace string to `com.ibm.wps.resourceaggregator.CombinerDataSource.RemoteDebug=all`.

Development Mode
Disables all caches of the theme optimization framework. It is equivalent to setting the `resourceaggregation.development.mode` property to true within the IBM WebSphere Portal Express ConfigService resource environment provider.

Reports
Allows you to see further information about the theme optimization framework, which is written to the trace log. There are three types of reports, profiles, modules, and meta-modules. Click the link in each section to turn on the reports, and click again to turn them off.

Client tracing
Client tracing enables traces for JavaScript code. The difference between client tracing and enabling tracing with the administration portlet is that the administration portlet enables Java tracing. You can add multiple strings by adding strings with a pipe. When you click add, the trace is persisted immediately. You can choose to enable the trace scope for the current browser or all users on the server. If you set the trace scope to Server, any client who accesses the server will have JavaScript traces on that server only. If you set it to current browser, you can remotely debug a server. You must have uncompressed Java resources enabled.

Advanced Utilities
Provide an option to export all titles and descriptions of all known modules in the system to a `.CSV` file.

Troubleshooting modular themes

You can debug your modules to improve performance.

A modular theme is a IBM WebSphere Portal Express theme that uses the Resource Aggregator theme optimization framework to allow the encapsulation of function into units that are called modules. You can combine those modules by defining theme profiles, and assign profiles to pages so that only the minimum necessary download data is done for a page. The download of the set of modules for any page is combined to be as efficient as possible.

Theme Optimization Analyzer Portlet

This portlet visualizes all parts of the theme optimization framework. With this portlet, you can see how the profiles are applied to specific themes or pages and see the defined resources for modules. This portlet features a validation report and the ability to export and import profiles to replicate another environment.

The portlet is included with the current version of WebSphere Portal Express. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Theme Analyzer**.

Client console and debugging tools

For debugging errors in the client-side execution of JavaScript or the client-side application of cascading style sheets, use a client-side console and debugging tool. Most browsers have their own development tools that are built in, or available as an add-on. For example, the Firebug add-on can be downloaded and installed into Mozilla Firefox. If there are client-side errors in the JavaScript, they are displayed in the console of these tools. By default, the resources are still being compressed and aggregated so it can be difficult to identify the exact resource that causes the error.

"Turning off aggregation and compression in client-side debug mode"
Turning on debug mode disables compression and makes modules easier to debug.

"Reloading the profile and module in development mode without caching" on page 2602
When you are debugging an issue, sometimes you must actively update the profile or module definitions.

"Debugging your module systematically" on page 2602
Use a pattern to determine an issue within your custom modules. This pattern minimizes the time that is required to investigate and debug.

"Verifying JSON file Syntax" on page 2604
If a JSON file is not formatted correctly it cannot be processed by the server, and is not loaded into your theme.

"Syntax in modules and profile definitions" on page 2605
If your theme is not behaving as it should, it could be because there are syntax problems within the module or profile files.

Theme optimization analyzer on the IBM Solutions Catalog

Turning off aggregation and compression in client-side debug mode:

Turning on debug mode disables compression and makes modules easier to debug.

About this task

In normal operation, the JavaScript and CSS modules in a profile to render a page view are fetched by the ResourceAggregator by building an aggregated request for all the contributions of the same type. It usually includes all the JavaScript, and all the css style definitions. It downloads them together. The JavaScript and CSS is compressed to reduce the size, which makes them difficult to read and debug. By turning on debug mode, the decompressed versions of the resources are loaded if they are defined, and they are loaded individually instead of being aggregated.

Note: If you are using Internet Explorer 7, 8, or 9, the resources continue to be aggregated into one request in debug mode.

To activate debug mode, you can use the Theme Analyzer, or manually enable the feature by turning on a trace string so that debugging is enabled for all users. You can also set a specific cookie so that debugging is only enabled for that user's cookie. In the Theme Analyzer, click **UtilitiesControl Center**. In the Remote

Debugging section, you can turn debugging on and off for all users or just for an individual client.

Procedure

To turn on debug mode for all users, all themes, and all pages, system wide, enable tracing with the following trace string.

```
com.ibm.wps.resourceaggregator.CombinerDataSource.RemoteDebug=all
```

You can set the string in the WebSphere Integrated Solutions Console for the current running instance. Or, you can save it to the persistent server runtime definition. You can also set this trace string with the Enable tracing portlet.

Results

When a user sets a cookie that is named **com.ibm.portal.resourceaggregator.client.debug.mode** to `true`, debug versions of module contributions are loaded if they are defined. Modules are loaded without using separate links and script tags. All resources are downloaded as a combined unit in that case.

Reloading the profile and module in development mode without caching:

When you are debugging an issue, sometimes you must actively update the profile or module definitions.

About this task

You can invalidate the cache using the Theme Analyzer to update the profile or module definitions. Or, you can enable development mode, which disables all caches in the system and refreshes all profile and module information for every request.

Procedure

1. Open the WebSphere Integrated Solutions Console.
2. Select **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Select the **WP ConfigService** resource environment provider.
4. Click **Custom properties**.
5. Change the **resourceaggregation.development.mode** entry to **true**.
6. Save the changes.
7. Restart the WebSphere Portal Express server.

Debugging your module systematically:

Use a pattern to determine an issue within your custom modules. This pattern minimizes the time that is required to investigate and debug.

Procedure

1. Use the console in the client. Most browsers have their own development tools built-in. If there are client-side errors in the JavaScript, they are displayed in the console of these tools. The resources are still being aggregated so it can be difficult to identify the exact resource that causes the error.

2. Turn on tracing. With tracing, you can see the specific resources that are aggregated on the page and you can see the location of where an error in the console originates. You can follow the code flow and track the expected values within the code.
3. Investigate the logs. If the error is not apparent in the client-side console, then investigating the WebSphere Portal Express system logs is another likely place to track down an issue. These logs display any server-side errors and tracing that is enabled.
   a. Open the WebSphere Portal Express logs in the following locations, *wp_profile_root*//logs/WebSphere_Portal/SystemOut.log and *wp_profile_root*/logs/WebSphere_Portal/SystemErr.log.
   b. You can enable more tracing through the Enable Tracing portlet in the Administration section of WebSphere Portal Express. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Enable Tracing**.

   For more information, see *Logging and tracing*.
4. Add logging to your resources. The WebSphere Portal Express code logs throughout the product for serviceability. However, your custom code might need more logging that is inserted to track down an issue. For client-side code, use a console log statement. A typical console log statement for displaying a value with a label is `console.debug("example value: "+value);`. Using this code displays a string value. To display the object in the console to see the values that are stored in the object, you can use

   ```
   console.log("the ibmCfg object:");
   console.debug(ibmCfg);
   ```

   The first line tracks the instance of the object. The second line adds the object to the console. Then, you can use the console to see the attributes and their values.
5. Ensure that the resources are loaded on the page. If a particular feature of the page is not visible or does not seem to function properly, sometimes the resources are not on the page. To verify, you can view the requests on the page and see the individual JavaScript or CSS. Ensure the files that are needed for the function are included on the page. If resources are missing, edit the profile to include the necessary modules.
6. Investigate with the Theme Optimization Analyzer. The theme optimization analyzer portlet can display many attributes of the theme, pages, profiles, and modules. You can investigate a module and view the details for visibility that is based on device class and contributions of resources. Each resource is listed with its path in the server. So, you can use this information to determine whether it is being aggregated on the page or to add more logging.
7. Export XML definition for resources. After you investigate the issue, modifying the resource attributes is the next solution. Resources that would require a change to their XML definition are the theme, page, client, or device class. To export the XML definition of a resource, you can use XMLAccess. This is a command-line tool that is at *wp_profile_root*/PortalServer/bin/xmlaccess.bat in Windows and *wp_profile_root*/PortalServer/bin/xmlaccess.sh in Linux. You can use the following scripts to export a specific resource that is related to the theme framework but more examples are located here *PortalServer_root*/doc/xml-samples/.
8. Export all theme definitions to modify the advanced features such as the metadata, resource root, default layout, or theme template definition. You can also modify other attributes through this definition.

```
<?xml version="1.0" encoding="UTF-8"?>
<request
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLocation="PortalConfi
type="export" create-oids="true">
<portal action="locate">
<theme action="export" active="true" objectid="*"></theme>
</portal>
</request>
```

9. Export page definition to modify features specific to the theme such as theme template override, dynamic content spot overrides, or device class filtering.

```
<?xml version="1.0" encoding="UTF-8"?>
<request
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLocation="PortalConfi
type="export" create-oids="true">
<portal action="locate">
<content-node action="export" uniquename="ibm.portal.SamplePage"/>
</portal>
</request>
```

10. Export all defined clients to modify the device class assigned. You can view this information in the Manage Clients portlets as well.

```
<?xml version="1.0" encoding="UTF-8"?>
<request
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLocation="PortalConfi
type="export" create-oids="true">
<portal action="locate">
<client action="export" uniquename="*"></client>
</portal>
</request>
```

11. Export all defined device classes to view the available groups and change the title or ID.

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="export" create-oids="true"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="PortalConfig_7.0.0_2.xsd">
<portal action="locate">
<device-class action="export" uniquename="*" />
</portal>
</request>
```

Verifying JSON file Syntax:

If a JSON file is not formatted correctly it cannot be processed by the server, and is not loaded into your theme.

A correctly formatted JSON file is both syntactically correct JSON. It also contains only syntactically correct WebSphere Portal Express Theme Optimization Framework Module definitions, theme profile definitions, or JSON menu Framework menu definitions.

To avoid problems, verify both the basic JSON syntax, and the specific WebSphere Portal Express syntax of your JSON file before you deploy it to your WebSphere Portal Express environment.

To validate the basic JSON syntax, use a tool such as JSONLint. For more information, see the JSONLint link.WebSphere Portal Express was extended to allow comments in the JSON file. A strict JSON validator such as JSONLint flags these comments as incorrect syntax. Remove any such comments before you pass the JSON to a validating parser.

To validate the WebSphere Portal Express specific definition syntax, you can use a JSON schema validator, which takes as input two JSON files. It compares the input to be validated, and a schema against which to validate. JSON schema files are available for module definitions, profiles, and menu definitions.

Related information:

JSONLint

Syntax in modules and profile definitions:

If your theme is not behaving as it should, it could be because there are syntax problems within the module or profile files.

Several types of problems could occur, including invalid elements or attributes, invalid element child relationships, invalid attribute values, or invalid attribute value combinations. Some elements and attributes are required, and some must not appear more than once. For more information, see *Theme modules*.

The modules and profiles are validated at runtime when the theme is first loaded. The runtime checks are sometimes able to detect problems that can slip through the schema validations. Perform the schema validations before deploying the JSON files. When syntax errors are encountered at runtime, they are written as warnings in the `SystemOut.log` file. These warnings begin with message identifier prefix `EJPNK` so searching for that string can help you locate them quickly. For example

```
EJPNK0060W: The attribute "version" in module test_analyzer_module_invalidsyntax_1 is not a valid
```

All syntax warnings are also included in the Theme Optimization Analyzer Validation Report.

Specify profiles

You can specify the profiles that you want to use two different ways depending on whether you are an administrator or a user. Profiles help define which modules are used to render a page.

Specify the profile with a module if you have administration access. Otherwise, use the user interface.

Profiles define a set of modules to be loaded by the theme optimization framework during page rendering. An administrator can use the admin portlets or XML access to set a profile. A content author can also set a profile.

CF03 You can set dependencies on features in portlets and profiles. The features are automatically loaded onto the page in an aggregated way. Your profile does not need to contain more modules than are required by the theme. Modules that are only required by a certain portlet can be loaded by that portlet.

"Included profiles" on page 2606
Portal includes profiles that contain modules that change how your portal site is rendered.

"Specify profiles with metadata" on page 2607
If you are an administrator, you can define which modules are used to render a page. Profiles specify which modules are loaded on a page or whether they are deferred to after a page loads.

"Specifying profiles with the user interface" on page 2607
You can change which sets of modules are used to render a page quickly through the user interface.

"Changing the theme default profile" on page 2608
You can change the profile for the theme or a specific page to define the modules loaded.

Included profiles:

Portal includes profiles that contain modules that change how your portal site is rendered.

Portal 8.5 default theme

Basic Content

This profile contains everything that is required for viewing and editing content and capabilities such as tagging and rating, person card, and social rendering.

Basic Content with Dojo

This profile contains everything that is required for viewing and editing content and capabilities such as tagging and rating, person card, and social rendering. This profile includes Dojo.

Deferred with Dojo

This profile has the full set of modules for the theme, but defers loading most of these modules unless needed. This profile includes Dojo. This profile balances function and performance.

Deferred (Default)

This profile has the full set of modules for the theme, but defers loading most of these modules unless needed. This profile balances function and performance.

Lightweight with Dojo

This profile has modules necessary for viewing pages with portlets. Modules necessary for iWidgets and modules that are needed by users to change pages are not included. This profile includes Dojo.

Lightweight

This profile has modules necessary for viewing pages with portlets. Modules necessary for iWidgets and modules that are needed by users to change pages are not included. Assigning the lightweight profile to a page does not imply that the page can be no longer edited. The theme of the page contains modules that are needed for rendering. The lightweight profile contains the `wp_toolbar_host_view` module. The `wp_toolbar_host_view` module does not contain any inline editing artifacts or Drag and Drop artifacts on the main page. However, you can still edit the page using the toolbar, but the toolbar is not loaded into the main page. It is in a different iframe. It is in the view frame, while the toolbar lives in another iframe. If you want make sure the page can no longer be edited, you can assign the user role so the user does not have access, or set the page metadata to disable edit mode for a page. Do set the page metadata, set the `theme.disable.edit.mode = true`.

Web Dock

This profile has the set of modules to be used for the Web Dock applications.

CF03 Web Dock was removed in combined cumulative fix 03. It is not required because the Web Dock capability is automatically downloaded on

demand if you set up the Resource Aggregation for portlet feature in your theme. Then, you must add the module to an existing profile.

Specify profiles with metadata:

If you are an administrator, you can define which modules are used to render a page. Profiles specify which modules are loaded on a page or whether they are deferred to after a page loads.

The list of modules is determined by:

- If a profile path exists, it is obtained from the **resourceaggregation.profile** page metadata.
- If no profile is set on the page, or the theme does not determine the profile, then the default profile is defined by the **resourceaggregation.profiles.default** theme metadata.

The list of available profiles within a theme is determined by loading all files in the folder defined by the **resourceaggregation.profiles.default** theme metadata. If that metadata is not defined, the `profiles/` default folder is scanned for profiles.

Important: Only `profile.json` files are allowed in these folders.

The profile format

The profile files must be valid JSON files. The following sample shows the properties:

```
{
   "moduleIDs" : ["moduleID_1", "moduleID_2", "moduleID_3"],
   "titles": [{
        "value": "title_en",
        "lang": "en"
             },
            {
        "value": "title_de",
        "lang": "de"
             }],

   "descriptions": [{
        "value": "desc_en",
        "lang": "en"
             },
            {
        "value": "desc_de",
        "lang": "de"
             }]
}
```

Specifying profiles with the user interface:

You can change which sets of modules are used to render a page quickly through the user interface.

Procedure

1. Turn on Edit Mode.
2. Click **Page** > **Edit Page Properties**.
3. In the Manage Page Properties window, click the **Advanced** tab.
4. In the Theme settings section, select the profile you want to use in the list of profiles.

5. Select from the visible profiles and click **Save**.

Changing the theme default profile:

You can change the profile for the theme or a specific page to define the modules loaded.

WebDAV:
Procedure

1. Connect your WebDAV client to `http://<server>:<portal>/wps/mycontenthandler/dav/themelist/`.
2. Navigate to the folder for your theme and copy the `metadata.properties` file to your local drive.
3. Edit the local copy of the file and modify it to point to the profile desired. For Example:

   ```
   com.ibm.portal.themetype=CSA2
   resourceaggregation.profile=profiles/profile_lightweight.json
   ```

4. Copy the local copy of the `metadata.properties` file back into the folder for your theme in the `themelist` folder.

XMLAccess:
Procedure

1. Export the theme. You can export all themes defined for WebSphere Portal Express using the following script, or insert the specific theme object ID you want to export:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <request
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd" type="export"
   create-oids="true">
       <portal action="locate">
          <theme action="export" objectid="*" />
       </portal>
   </request>
   ```

2. Modify the parameter **resourceaggregation.profile** to point to the new profile. For Example:

```
<parameter name="resourceaggregation.profile" type="string" update="set"><![CDATA[profiles/profile_lightweight.json]]></parameter>
```

3. Import the XML file using the command line or **Import XML**.
4. Restart WebSphere Portal Express.

Modules that are provided with the modularized theme

WebSphere Portal Express provides a set of ready-to-use modules.

Use these dependency guidelines when you add and remove modules from your profile:

- If you add a module that requires another module that is in not in the profile, the automatic dependency injection adds the required module at run time.
- If you remove a module that is required by another module that is in the profile, the automatic dependency injection adds the module at run time, even if it is not listed in the profile.
- If you remove a module that the theme requires, but is not required by any other modules in the profile, the module is removed and the theme might break.

Theme modules provided with the Portal theme

The following lists describe the modules that are included with the Portal theme. Information about each module includes the module ID and the location in the theme of that module and some details about the module.

85 Theme

These modules are used by the WebSphere Portal Express 8.5 theme. For more information, see the module descriptions.

The `plugin.xml` file location varies and is documented in the module description.

Table 396. List of 85 Theme modules and prerequisites.

Module	Description
wp_theme_portal_85	The Portal 85 theme CSS. Location: `dav:fs-type1:/themes/portal8.5/css`
wp_theme_edit	Adds the ability to go into page edit mode. Location: `dav:fs-type1:/themes/portal8.5/js`
wp_theme_menus	The menu framework that was introduced in 7002. Location: `dav:fs-type1:/themes/portal8.5/js`
wp_portlet_css	Earlier portlet CSS support. Location: `dav:fs-type1:/common-resources/ibm/css/portal`
wp_legacy_layouts	Earlier 7.0 static page layout CSS. Location: `dav:fs-type1:/common-resources/ibm/css/portal`
wp_layout_windowstates	Maximize or Minimize portlet support that is implemented as a server-side data source.
wp_portal	Supplies JavaScript global configuration objects for use by other features; URLs, locale information, and user information. Implemented as a server-side data source.

Table 396. List of 85 Theme modules and prerequisites. (continued)

Module	Description
wp_liveobject_framework	Live object framework provides the feature of adding a special handler to any class selector on a tag. For example, if you have a span tag and its class contains vCard, then this framework makes this markup live. Then, when you hover on the designated text, the following hover text is shown, **click here for person card**. When you click the hover text, it shows the person card. The person card feature is available out-of-box, along with other requirements. Developers can extend this framework and add their own handlers. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/plugin.xml
wp_oob_sample_styles	Styles for default web content samples. Location: *PortalServer_root*/pzn.ext/wp.templating.wcm/shared/app/wp.wcm.templating.jar
wp_theme_skin_region	Provides accessibility support Location: dav:fs-type1:/themes/portal8.5/js
wp_theme_high_contrast	Provides accessibility support when you use high contrast. Location: dav:fs-type1:/themes/portal8.5/js
wp_custom_page_style	The view counterpart of the Edit toolbar shelf that sets the style for a specific page. This module reads the style for a page and makes sure that the corresponding CSS is loaded into the page.
getting_started_module	The getting started module is a pre-defined module that you can use as starting place to quickly inject your own resources into the current theme. For more information, see *Simple modules*. Location: dav:fs-type1:/themes/Portal8.5/modules/getting_started_module
wp_liveobject_framework_core	Live Text Framework core part that provides parsing capability. It parses page for a class selector and returns the retrieved nodes to class handler. Location: *PortalServer_root*/ui/wp.tagging.liveobject/semTagEar/Live_Object_Framework.ear/liveobjects.war/WEB-INF/plugin.xml

Table 396. List of 85 Theme modules and prerequisites. (continued)

Module	Description
wp_openajaxhub	The key feature of OpenAjax Hub 2.0 is its publish/subscribe engine that includes a Managed Hub mechanism that allows a host application to isolate untrusted components into secure sandboxes. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/openajaxhub.jar

Simple menus

These modules are used by the toolbar and theme menus. For more information, see the module descriptions. The `plugin.xml` file location varies and is documented in the module description.

Table 397. List of menu modules and prerequisites

Module	Description
wp_simple_contextmenu_main	Gathers all the modules that are required to make up the simple menus. Location: dav:fs-type1:/themes/Portal8.5/contributions/simple_contextmenu.json
wp_simple_contextmenu_css	Provides CSS styling for the simple menus Location: dav:fs-type1/themes/Portal8.5/contributions/simple_contextmenu.json
wp_simple_contextmenu_js	Provides support to display a simple pop-up menu. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/simple_contextmenu.jar
wp_simple_contextmenu_ext	Provides extensions that plug into the simple menu, such as badge support. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/simple_contextmenu.jar
wp_simple_contextmenu_templates	Provides templates that are used to render the simple menu. Location: dav:fs-type1/themes/Portal8.5/contributions/simple_contextmenu.json

Menus

These modules are used by theme menus in your Portal, such as in place edit. These menus are also called Component Action menus or CAM. For more information, see the module descriptions. The `plugin.xml` file location varies and is documented in the module description.

Table 398. List of menu modules and prerequisites

Module	Description
wp_contextmenu_main	Gathers all the modules that are required to make up the complete **Component Action** menu. Location: `dav:fs-type1:/themes/Portal8.5/contributions/contextmenu.json`
wp_contextmenu_css	Provides CSS styling for the **Component Action** menu. Location: `dav:fs-type1/themes/Portal8.5/contributions/contextmenu.json`
wp_contextmenu_js	Provides support to display an open action menu for page components, for example a portlet or content item. Location: *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/contextmenu.jar`
wp_contextmenu_templates	Provides templates that are used to render the **Component Action** menu in specific contexts, for example, a menu for a component or an inline edit menu. Location: `dav:fs-type1/themes/Portal8.5/contributions/contextmenu.json`
wp_contextmenu_config_lof	Provides the configuration for the Live Object Framework service to handle **Component Action** menu instances on a page. Location: *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/contextmenu.jar`
wp_contextmenu_live_object	Provides Live Object Framework service to handle **Component Action** menu instances on a page. Location: *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/contextmenu.jar`
wp_skin_cam	Allows the Component Action Menu to be opened by clicking an icon in the portlet skin. Location: *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/skincomponentactionmenu.jar`

Dynamic Content Spots

These modules provide mappings for dynamic content spots in the theme.

Table 399. These modules provide mappings for dynamic content spots in the theme.

Module	Description
wp_dynamicContentSpots_85	Defines all dynamic content spots for the 8.5 theme. You can overlay any dynamic content spots through other modules. Location: *PortalServer_root*/theme/wp.theme.themes/default85/installedApps/DefaultTheme85.ear/DefaultTheme85.war/WEB-INF/plugin.xml
wp_dynamicContentSpots_toolbar85	Defines all dynamic content spots for the 8.5 toolbar theme. You can overlay any dynamic content spot through other modules. Location: *PortalServer_root*/toolbar/wp.toolbar.themes/toolbar85/installedApps/ToolbarTheme85.ear/ToolbarTheme85.war/WEB-INF/plugin.xml

Toolbar

These modules provide resources for the toolbar.

Table 400. These modules provide resources for the toolbar.

Module	Description
wp_a11y	Accessibility utility functions APIs. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/a11y.jar
wp_admin_edit	Module providing theme artifacts that are related to the admin area. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/plugin.xml
wp_hiddencontent	Module defining CSS to show or hide the hidden content items in the hidden layout container. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/hiddencontent.jar

Table 400. These modules provide resources for the toolbar. (continued)

Module	Description
wp_movecontrols	This module provides a JavaScript API, which allows for moving layout controls from one layout container to another within a page layout. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/movecontrols.jar
wp_portlet_applications	Support module for Applications portlets. Location: *wp_profile_root*/installedApps/*cell*/PA_Applications.ear/wp.portlet.applic.war/WEB-INF/plugin.xml
wp_portlet_changelayout	Support module for Change Layout portlet. This support module shows the orphaned portlets section. Location: *wp_profile_root*/installedApps/*cell*/PA_Orphaned.ear/wp.portlet.change.war/WEB-INF/plugin.xml
wp_portlet_newcontent	Support module for New Content portlet. Location: *wp_profile_root*/installedApps/*cell*/PA_com.ibm.wps.portle.ear/wp.portlet.conten.war/WEB-INF/plugin.xml
wp_portlet_newpage	Support module for New Page portlet. Location: *wp_profile_root*/installedApps/*cell*/PA_New_Page.ear/wp.portlet.newpag.war/WEB-INF/plugin.xml
wp_portlet_overview	Support module for Overview portlet. Location: *wp_profile_root*/installedApps/*cell*/PA_com.ibm.wps.portle.ear/wp.portlet.conten.war/WEB-INF/plugin.xml
wp_portlet_projects	Support module for Project portlet. Location: *wp_profile_root*/installedApps/*cell*/PA_com.ibm.wps.portle.ear/wp.portlet.conten.war/WEB-INF/plugin.xml
wp_portlet_sitemap	Support module for Sitemap portlet. Location: *wp_profile_root*/installedApps/*cell*/PA_com.ibm.wps.portle.ear/wp.portlet.conten.war/WEB-INF/plugin.xml
wp_portlet_style	Support for mode styles portlet. Location: *wp_profile_root*/installedApps/*cell*/PA_Styles.ear/wp.portlet.styles.war/WEB-INF/plugin.xml

Table 400. These modules provide resources for the toolbar. (continued)

Module	Description
wp_portlet_vanityurl	Support for the Vanity URL portlet. Location: *wp_profile_root*/installedApps/*cell*/PA_VanityUrl.ear/wp.portlet.vanity.war/WEB-INF/plugin.xml
wp_portlet_wiring	Dependencies of the wiring portlet Location: *wp_profile_root*/installedApps/*cell*/PA_Wiring.ear/wp.portlet.wiring.war/WEB-INF/plugin.xml
wp_portlet_wiring_resources	Resources that are provided by the portlet. Location: *wp_profile_root*/installedApps/*cell*/PA_Wiring.ear/wp.portlet.wiring.war/WEB-INF/plugin.xml
wp_state_page	Module that shows the page-specific public render parameters to the client and also provides JavaScript APIs that allow for reading and writing these parameters. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/state.jar!/plugin.xml
wp_state_page_modes	Module that annotates the HTML body element of the DOM with microformats that reflect the page modes that are currently active. The supported page modes are page edit mode, or microformat edit-mode, page information mode, or microformat info-mode," and page help mode or microformat "help-mode". Unlike portlet modes, multiple page modes can be active at the same time. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/state.jar!/plugin.xml
wp_theme_utils	Module providing a set of JavaScript utility APIs, which can be used to work with the DOM of the different page parts, which are potentially running in different iframes. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/themeutils.jar

Table 400. These modules provide resources for the toolbar. (continued)

Module	Description
wp_toolbar85	Module providing a dynamic content spot that allows for embedding the main window of the site toolbar into a theme. The id for the dynamic content spot is `85toolbar`. Location: *PortalServer_root*`/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar`
wp_toolbar85_dynamic	Module that displays the main control panel of the site toolbar without relying on a dynamic content spot. Location: *PortalServer_root*`/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar`
wp_toolbar_actionbar	Module providing a dynamic content spot that renders the main action bar of the site toolbar in the 8.5 theme. The action bar provides access to the site toolbar navigation, project menu, and more menu and also allows for activating page edit mode and page information mode. The id for the dynamic content spot is `85toolbar_actionbar`. Location: *PortalServer_root*`/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/actionbar.jar`
wp_toolbar_changepagelayout	Module providing the Change Page Layout function for menus. Location: *PortalServer_root*`/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar`
wp_toolbar_common	Module providing common resources such as CSS styles, images, and JavaScript for the site toolbar. The resources are supposed to be used in the toolbar theme or by portlets that run in the site toolbar. Location: *PortalServer_root*`/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/common.jar`

Table 400. These modules provide resources for the toolbar. (continued)

Module	Description
wp_toolbar_common_wcm	Module providing common WCM-related resources such as CSS styles, images, and JavaScript for the site toolbar. The resources are supposed to be used in the toolbar theme or by portlets that run in the site toolbar. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/common.jar
wp_toolbar_contextmenu_js	A theme module that defines a simple JavaScript API for creating menus and managing their lifecycle. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/contextmenu.jar
wp_toolbar_controlactions	Module providing the resources that are common to all layout control and portlet-specific menu contributions. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_createpage	Module providing the "Create Page" function for menus. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_deletecontrol	Module providing the "Delete Control" function for portlet menus. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_deletepage	Module providing the Delete Page function for menus. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_editpageproperties	Module providing the "Edit Page Properties" function for menus. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar

Table 400. These modules provide resources for the toolbar. (continued)

Module	Description
wp_toolbar_hiddencontent	Module providing the functions for showing and hiding the layout container that contains the portlets and content items that are currently hidden. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_hidecontrol	Module providing the functions for moving portlets or content items into the hidden layout container of the page. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_host	Meta module that groups all theme modules that are needed to make a page interoperable with the site toolbar. Add this module to the theme profile of your page if you want to edit the page by using the site toolbar. This module contains all contributions for both, view mode and edit mode. This module must be added to the non-deferred section of the theme profile. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar
wp_toolbar_host_dynamic	Meta module that groups all theme modules that are needed to make a page interoperable with the site toolbar. Add this module to the theme profile of your page if you want to edit the page by using the site toolbar. This module contains all contributions for both, view mode and edit mode. This module must be added to the non-deferred section of the theme profile. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar

Table 400. These modules provide resources for the toolbar. (continued)

Module	Description
wp_toolbar_host_dynamic_view	Module that groups all theme modules that are needed to make a page interoperable with the site toolbar. Add this module to the theme profile of your page if you want to edit the page by using the site toolbar. This module contains all contributions that are needed for view mode. This module must be added to the non-deferred section of the theme profile. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar
wp_toolbar_host_edit	Module that groups all theme modules that are needed to make a page interoperable with the site toolbar. Add this module to the theme profile of your page if you want to edit the page by using the site toolbar. This module contains all contributions that are needed for edit mode. This module can be added to the deferred section of the theme profile. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar
wp_toolbar_host_view	Module that groups all theme modules that are needed to make a page interoperable with the site toolbar. Add this module to the theme profile of your page if you want to edit the page by using the site toolbar. This module contains all contributions that are needed for view mode. This module must be added to the non-deferred section of the theme profile. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar
wp_toolbar_logo	Module providing a dynamic content spot to embed the toolbar logo into a theme. The identifier of the dynamic content spot is 85toolbar_logo. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/logo.jar

Table 400. These modules provide resources for the toolbar. (continued)

Module	Description
wp_toolbar_menuactions	Module providing the resources that are common to all toolbar-specific menu contributions. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_moremenu	Module defining the more menu of the toolbar. This module provides a content spot to embed the more menu into a theme. The ID of the dynamic content spot is 85toolbar_moremenu. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/moremenu.jar
wp_toolbar_movecontrol	Module providing the Move Control functions for portlet menus. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_movepage	Module providing the Move Page function for menus. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_pageactions	Module providing the resources that are common to all page-specific menu contributions. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_projectmenu	Module for integrating the project menu into the toolbar. This module provides a content spot to embed the project menu into a theme. The ID of the dynamic content spot is 85toolbar_projectmenu. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/projectmenu.jar

Table 400. These modules provide resources for the toolbar. (continued)

Module	Description
wp_toolbar_sitepreview	Module providing the "Preview as User" and "Preview as Unauthenticated" functions for menus. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_toolbar_sitepreview_contentspot	Module providing the dynamic content spot to embed the site preview function into the theme. The ID of the dynamic content spot is 85toolbar_preview. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/preview.jar
wp_toolbar_tab	Meta module that groups all theme modules that are needed to add a page to the site toolbar. Add this module to the theme profile of your page if your page is to run in the site toolbar. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar
wp_toolbar_utils	Module providing toolbar utility functions for opening or closing the toolbar, engaging edit mode, or opening a toolbar tab. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar
wp_toolbar_validator	Module to validate the state of the toolbar tab frame. This module is needed for handling context switches, such as session timeouts, correctly. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar
wp_toolbar_viewframe_validator	Module to validate the state of the view frame. This module is needed for handling context switches, such as session timeouts, correctly. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar

Table 400. These modules provide resources for the toolbar. (continued)

Module	Description
wp_toolbar_wiring	Module providing the functions for managing communication endpoints and portlet wires. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/menuactions.jar
wp_photon_iframe	XSLT transformation for iFrame transport. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/photon.jar
wp_photon_promisor	A promiser implementation. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/photon.jar
wp_photon_xslt	XML and XLST utility functions Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/photon.jar
wp_toolbar_ghost	Module that groups all theme modules that are needed to make a page interoperable with the site toolbar without rendering it. This module must be added to the non-deferred section of the theme profile. Location: *PortalServer_root*/toolbar/wp.toolbar.modules/webapp/installedApps/ToolbarModules.ear/ToolbarModules.war/WEB-INF/lib/toolbar.jar
wp_draft_page_ribbon	Adds `Draft Page` in text that appears along the sides of a page that has a draft in the current project. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/draftribbon.jar

Drag-and-drop

These modules provide the toolbar drag-and-drop function.

Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/dnd.jar

Table 401. These modules provide the toolbar drag-and-drop function.

Module	Description
wp_dnd_css	This module provides the CSS that is used to show drag sources and drop zones.
wp_dnd_main	This module parses the markup of a page layout to convert the layout containers into valid HTML 5 drop zones.
wp_dnd_util	This module provides JavaScript utility APIs for implementing drag-and-drop features.

IBM Web Content Manager

These modules provide Web Content Manager functions.

Table 402. List of Web Content Manager modules and prerequisites

Module	Description
wcm_config	Web Content Manager Config is a resource that is intended to be used by Web Content Manager theme modules. Location: *PortalServer_root*/wcm/prereq.wcm/wcm/shared/app/ilwwcm-services-impl.jar
wcm_inplaceEdit	In-place editing enables users with edit access to a content item to edit fields of that item from within the web page itself instead of using the authoring portlet. This feature is available when you display content with a web content viewer portlet. Location: *wp_profile_root*/installedApps/*cell*/wcm.ear/wcm-inplaceEdit.war/WEB-INF/plugin.xml

Content Mapping

Description: Provides content mapping support.

PortalServer_root/theme/wp.theme.modules/contentmapping/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/contentmapping.jar

Table 403. List of Content Mapping modules and prerequisites.

Module	Description
wp_content_mapping_picker	Provides the Content Mapping Picker dialog that allows one to select a piece of content from Web Content Manager.
wp_content_targeting_cam	Provides resources that are required for the Content Targeting dialog that is started from the **Component Action** menu. Location: *wp_profile_root*/installedApps/*cell*/PA_wp.pzn.ui.actions.ear/wp.pzn.ui.actions.war/WEB-INF/plugin.xml

Federation

Description: Provides federated document picker support.

PortalServer_root/theme/wp.theme.modules/federation/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/federation.jar

Table 404. List of Federation modules and prerequisites.

Module
wp_federated_documents_picker

Search

These modules provide JavaScript code for the search box widget and provide a JSP to generate the search box markup that can be started as a dynamic content spot.

The plugin.xml file location is *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/search.jar

Table 405. List of Search modules and prerequisites.

Module	Description
wp_search	Search widget
wp_searchbar	Lightweight inline search bar that redirects to the search page to show results. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/search.jar

Analytics

These modules provide Analytics support.

PortalServer_root/theme/wp.theme.modules/asa/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/asa.jar

Table 406. List of Analytics modules and prerequisites.

Module	Description
wp_analytics	Meta module that provides all analytics features. Use this module if you want to enable all analytics features including the aggregator, analytics tags and site promotions, and the overlay reports.
wp_analytics_aggregator	Inserts the reference to the analytics aggregator and its dependencies into the page.
wp_analytics_bootstrap	Internal module that contains the bootstrap code that is needed for analytics. Must not be directly referenced in theme profiles.
wp_analytics_overlay_reports	Public module that provides the analytics overlay reports for portlets and pages.

Table 406. List of Analytics modules and prerequisites. (continued)

Module	Description
wp_analytics_tags	Public module that provides the analytics tag and site promotion functions. This module also provides the dynamic content spots that produce the analytics micro-formats.
wp_analytics_tags_dialog	Public module that provides the dialog for working with analytics tags and site promotions.

Personalization

These modules provide resources for Personalization.

Location: *PortalServer_root*`/pzn/prereq.pzn/installedApps/Personalization_Workspace.ear/pznauthorportlet.war/WEB-INF/plugin.xml`

Table 407. List of modules that provide resources for Personalization.

Module	Description
wp_pzn_geolocation	Provides resources that are required for Geolocation Personalization.

Social lists

Description: The `wp_social_rendering` theme module provides the CSS styles that are used by social lists. It defines the capability with the name `social_rendering` and the version `8.5`.

`PortalServer_root``/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/modules/sr/css/sr.css`

No prerequisites are required to use this theme module.

Web Dock

These modules provide resources to the web dock application.

Location: *wp_profile_root*`installedApps/`*`cell`*`/PA_WebDockPortServlet.ear/WebDockPortlet.war/WEB-INF/plugin.xml`

Table 408. List of modules that provide resources to web Dock.

Module	Description
wp_webdock	This module provides resources that are required by web dock application.

IBM MobileFirst Integration

Description: Provides the modules for MobileFirst application integration.

Location for all wp_worklight_* modules: `dav:fs-type1/themes/Portal8.5/contributions/worklight61.json`

Location for all wl_* modules:*PortalServer_root*/theme/wp.theme.worklight.ext/installableApps/wp.theme.worklight.ext.ear/wp.theme.worklight.ext.war/WEB-INF

Table 409. List of MobileFirst Integration modules and prerequisites.

Module	Description
wp_worklight	Mapping module to MobileFirst integration extension
wp_worklight_android	Mapping module to MobileFirst integration extension for Android
wp_worklight_css	Mapping module to MobileFirst CSS
wp_worklight_css_android	Mapping module to MobileFirst CSS for Android
wp_worklight_css_ios	Mapping module to MobileFirst CSS for iOS
wp_worklight_ios	Mapping module to MobileFirst integration extension for iOS
wp_worklight_jsonstore	Mapping module to MobileFirst client JSONStore
wp_worklight_plugins	Mapping module to MobileFirst integration extension
wp_worklight_plugins_android	Mapping module to MobileFirst integration extension for Android
wp_worklight_plugins_ios	Mapping module to MobileFirst integration extension for iOS
wl_android_6	Provides MobileFirst client and Cordova JavaScript resources for Android devices
wl_android_61	Provides MobileFirst client and Cordova JavaScript resources for Android devices
wl_client_css_android_6	Provides MobileFirst client CSS for Android devices, specifically for the diagnostic window, and modal dialog
wl_client_css_android_61	Provides MobileFirst client CSS for Android devices, specifically for the diagnostic window, and modal dialog
wl_client_css_ios_6	Provides MobileFirst client CSS for iOS devices, specifically for the diagnostic window, and modal dialog
wl_client_css_ios_61	Provides MobileFirst client CSS for iOS devices, specifically for the diagnostic window, and modal dialog
wl_client_jsonstore_android_6	Provides MobileFirst client JSONStore for Android devices
wl_client_jsonstore_android_61	Provides MobileFirst client JSONStore for Android devices
wl_client_jsonstore_ios_6	Provides MobileFirst client JSONStore for iOS devices
wl_client_jsonstore_ios_61	Provides MobileFirst client JSONStore for iOS devices
wl_config	Data source that injects the initialization for client and Cordova API

Table 409. List of MobileFirst Integration modules and prerequisites. (continued)

Module	Description
wl_cordova_css_android_6	Provides Cordova client CSS, specifically for the tab bar component
wl_ios_6	Provides MobileFirst client and Cordova JavaScript resources for iOS devices
wl_ios_61	Provides MobileFirst client and Cordova JavaScript resources for iOS devices
wl_plugins_android_61	Provides MobileFirst plug-in JavaScript resources for Android devices
wl_plugins_ios_61	Provides MobileFirst plug-in JavaScript resources for iOS devices

Sametime

These modules provide the code for integrating with IBM Sametime `stlinks` support and new proxy support.

The `plugin.xml` file location is *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/sametime.jar`

Table 410. List of Sametime modules and prerequisites.

Module	Description
wp_sametime_links	Earlier STlinks support.
wp_sametime_proxy	New Sametime proxy support.

Web Application Integrator

These modules provide the Web Application Integrator.

Location: *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/ic4_wai.jar!/plugin.xml`

Table 411. These modules provide the Web Application Integrator.

Module	Description
wp_ic4_wai_resources	Provides resources to enable Connections integration with WAI.

Client Utils

These modules provide JavaScript utility code with no dependencies on the Dojo Toolkit in the i$ global namespace. These modules are useful for light-weight themes with no framework dependencies. The code includes type checks, configuration that merges, IO utilities, JSON parsing, DOM helpers, Promises, and eventing.

The `plugin.xml` file location is *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/ibmc.jar`

Table 412. List of Client Utils modules and prerequisites.

Module	Description
wp_client_main	Contains basic utilities.
wp_client_ext	Contains advanced utilities like Promises, IO, DOM helpers, events, and the deferred module loading code.
wp_client_dnd	Contains drag-and-drop capabilities. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/ibmc.jar
wp_client_logging	Contains logging capabilities for error, warning, and information messages. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/ibmc.jar
wp_client_selector	Contains a JavaScript CSS selector engine. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/ibmc.jar
wp_client_tracing	Contains tracing capabilities. Location: *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/ibmc.jar

Portal Client

These modules provide utilities and base code for other modules, including Tagging and Rating.

The plugin.xml file location is *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/portalclient.jar

Table 413. List of Portal Client modules and prerequisites.

Module	Description
wp_portlet_client_model	Public client programming model. Includes REST service and state handling. Used as a base prerequisite to other functional modules.
wp_portal_client_utils	Common utilities for other modules to use (XML handling, authentication), used as base prerequisite to other functional modules.
wp_portal_client_rest_utils	Client-side data stores used by other Portal features, such as Tagging and Rating, to access the Portal REST modules on the server.

Table 413. List of Portal Client modules and prerequisites. (continued)

Module	Description
wp_portal_ui_utils	Common UI elements. Used as a base prerequisite for some theme dialogs, such as the Content Mapping Picker and Tagging and Rating
wp_tagging_rating	Tagging and Rating widgets
wp_tagging_rating_opensearch	Open Search plug-in for Tagging and Rating
wp_tagging_rating_light	Provides all lightweight inline tagging and rating widgets.
wp_tagging_rating_menu	Provides tagging and rating menu items in the actions menu.
wp_tagging_rating_tagcloud	Provides tag cloud in Tag center page.
wp_template_select_dialog	A dialog that is started from the New Page dialog that allows a user to pick on a page template, which to base their newly created page.

Dialog API

These modules provide the theme dialog function.

Location: *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/dialog.jar`

Table 414. These modules provide the theme dialog function

Module	Description
wp_dialog_css	Provides the CSS styling for dialogs that are displayed by the dialog API.
wp_dialog_draggable	Provides support to allow dialogs that are created with the dialog API to create dialogs to display page content.
wp_dialog_main	Provides an API to create dialogs to display page content
wp_dialog_util	Provides utilities to support the dialog API.

OneUI

These modules provide the CSS for OneUI.

Meta-Module

- wp_one_ui
- wp_one_ui_dijit

The `plugin.xml` file location is *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/oneui.jar`

Table 415. List of OneUI modules and prerequisites.

Module	Description
wp_one_ui_21	Provides OneUI v2.1 CSS.

Table 415. List of OneUI modules and prerequisites. (continued)

Module	Description
wp_one_ui_30	Provides OneUI v3.0 CSS.
wp_one_ui_dijit_30	Provides dijit support for OneUI.
wp_one_ui_303	Provides OneUI v3.03 CSS.
wp_one_ui_dijit_303	Provides dijit support for OneUI v3.03.

Dojo

These modules are used for separate layers that are built from a Dojo build profile. The `djconfig` object is provided by a Portal data source. The POC URL for Dojo 1.6 is `dojo:config@v1.6`. For Dojo 1.7, it is `dojo:config@v1.7`. For Dojo 1.9, it is `dojo:config@v1.9`. Look in the `/dojo/build.txt` to see which files are in each layer. Each module contributes to the head section.

Dojo Meta-Modules

These Dojo modules are not associated with a specific Dojo release. In WebSphere Portal Express, a meta-module paradigm was added for Dojo support. The user can define which version of Dojo to use, 1.9, 1.7 or 1.6. The meta-modules do not have the Dojo version specified.

The meta module definitions are stored in the following files:

`dojo19.json`
: In *PortalServer_root*`/theme/wp.theme.dojo/installedApps/dojo.ear/dojo.war/v1.9`

`dojo17.json`
: In *PortalServer_root*`/theme/wp.theme.dojo/installedApps/dojo.ear/dojo.war/v1.7`

`dojo16.json`
: In *PortalServer_root*`/theme/wp.theme.dojo/installedApps/dojo.ear/dojo.war/v1.6`

To activate a version, copy the corresponding file into the WebDAV `dav:fs-type1:/themes/portal8.5/contribution` folder. Delete the previous file and restart the server.

Note: You can have only one file in the folder at one time because the `dojo16.json`, `dojo17.json`, and `dojo19.json` files are not supported at the same time. Specific Dojo modules are listed in the Dojo 1.9, Dojo 1.7 and Dojo 1.6 sections. For a list of Dojo classes that are provided by each meta-module, see more information Dojo classes that are provided by the Dojo modules.

The following list shows the meta-modules.

- dojo
- dojo_app
- dojo_data
- dojo_data_ext
- dojo_dnd_basic
- dojo_dnd_ext

- dojo_dom
- dojo_fmt
- dojo_fx
- dojo_node_list
- dojo_promise
- dojo_request
- dojo_selector_lite
- dijit
- dijit_app
- dijit_editor
- dijit_editor_plugins
- dijit_form
- dijit_layout_basic
- dijit_layout_ext
- dijit_menu
- dijit_tree
- dijit_all
- dojox_all
- dojox_app
- dojox_aspect
- dojox_calendar
- dojox_charting
- dojox_charting_all
- dojox_collections
- dojox_data_all
- dojox_data_basic
- dojox_dgauges
- dojox_fx
- dojox_gfx
- dojox_gfx3d
- dojox_grid_all
- dojox_html_basic
- dojox_images
- dojox_io
- dojox_layout_ext
- dojox_layout_basic
- dojox_mobile
- dojox_mobile_app
- dojox_mobile_compat
- dojox_mobile_app_compat
- dojox_string
- dojox_uuid
- dojox_widget_standby
- dojox_xml

Dojo 1.9 modules

The `plugin.xml` file location is *PortalServer_root*`/theme/wp.theme.dojo/installedApps/dojo.ear/dojo.war/v1.9`

Table 416. List of Dojo 1.9 modules and prerequisites.

JQuery

These modules provide jQuery.

Location: *PortalServer_root*`/theme/wp.theme.jquery/installedApps/wp.theme.jquery.ear/wp.theme.jquery.war/WEB-INF/plugin.xml`

Table 419. These modules provide jQuery.

Module	Description
jquery_1_10_2	Provides jQuery v1.10.2 core resources.

Modularized Page Builder

These modules provide support for the modularized Page Builder themes from 7.0.

The plugin.xml file location is *PortalServer_root*/ui/wp.mashup.cc.deploy/installedApps/MashupCommonComponent.ear/mm.builder.v3001.war/WEB-INF

Table 420. List of Modularized Page Builder modules and prerequisites.

Module	Description
mm_template_layout	Widget that handles layout refreshing, this module is only used for Modularized Page Builder themes from 7.0
mm_customize_shelf	Base widget for the site toolbar, this module is only used for Modularized Page Builder themes from 7.0
mm_page_toolbar	Widget for the **Customize**, **Hidden Content**, **Save & Exit**, and **Cancel**. This module is only used for Modularized Page Builder themes from 7.0
mm_content_set_list	Menu framework list widget from 7.0. This module is only used for Modularized Page Builder themes from 7.0
mm_content_set_menu	Menu framework widget from 7.0. This module is only used for Modularized Page Builder themes from 7.0
mm_controlled_nav_widget	Navigation widget from 7.0. This module is only used for Modularized Page Builder themes from 7.0

Theme

These modules provide earlier Portal 7.0 theme skins.

The plugin.xml file location varies and is documented in the module description.

Table 421. List of Theme modules and prerequisites.

Module	Description
wp_pagebuilder_standard_skin_70	Earlier 7.0 standard skin Location: dav:fs-type1/skins/Standard/
wp_pagebuilder_noskin_skin_70	Earlier 7.0 no skin Location: dav:fs-type1/skins/NoSkin/

Mashups Enabler

Provides the modules for Enabler from the Mashups 3.0.0.1 release.

The plugin.xml file location is *PortalServer_root*/ui/wp.mashup.cc.deploy/installedApps/MashupCommonComponent.ear/mm.enabler.war.v3001.war/WEB-INF

Table 422. List of Mashups Enabler modules and prerequisites.

Module	Description
mm_open_ajax_hub	Open Ajax Hub
mm_enabler	Full enabler

Table 422. List of Mashups Enabler modules and prerequisites. (continued)

Module	Description
mm_enabler_core	Enabler core; provides only iWidget container support but no model APIs
mm_enabler_ext	Enabler support is not included in the mm_enabler

Mashups Builder

Provides the modules for Builder from the Mashups 3.0.0.1 release.

The `plugin.xml` file location is *PortalServer_root*`/ui/wp.mashup.cc.deploy/installedApps/MashupCommonComponent.ear/mm.builder.v3001.war/WEB-INF`

Table 423. List of Mashups Builder modules and prerequisites.

Module	Description
mm_builder	Builder base
mm_builder_ext	Builder support
mm_builder_dialogs	Builder dialog base widget
wp_theme_widget	Menu support for iWidgets

User Interface

These modules provide user interface code.

The `plugin.xml` file location is *PortalServer_root*`/ui/wp.mashup.cc.deploy/installedApps/MashupCommonComponent.ear/mm.builder.v3001.war/WEB-INF`

Page handling

Table 424. List of User interface modules and prerequisites for page handling.

Module	Description
mm_move_page	Move Page widget
mm_new_page_dialog	New Page dialog widget
mm_delete_page	Menu contribution for deleting a page

Wiring

Table 425. List of User interface modules and prerequisites for wiring.

Module	Description
mm_builder_wiring	Wiring widget

Portlet handling

Table 426. List of User interface modules and prerequisites for portlet handling.

Module	Description
mm_delete_control	Menu contribution for deleting a portlet

Page Builder

These modules contain code for running Page Builder functions.

The `plugin.xml` file location is *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/WEB-INF/lib/pagebuilder.jar`

Table 427. List of Page Builder modules and prerequisites.

Module	Description
wp_pagebuilder_base	Base code and utilities that are used by the other modules in this section.
wp_pagebuilder_ui	Initialization code and base widgets (such as dialogs) used by other Page Builder modules.
wp_pagebuilder_controls	Code to add the **Move portlet** menu actions (Move Up/Left/Right/Down).
wp_pagebuilder_debug	Client-side debugging and tracing code, this module is turned off by default.
wp_pagebuilder_data	Data stores used by Page Builder editing tools, and that follow the Dojo read/write API.
wp_pagebuilder_dnd	Support for portlet drag-and-drop in the page layout.
wp_pagebuilder_shelf	The site toolbar code, this module is used for modularized Page Builder themes from 7.0 only.
wp_pagebuilder_csa	Earlier CSA-only Page builder code, this module is used for modularized Page Builder themes from 7.0 only.
wp_pagebuilder_widget_css	Earlier CSA widget CSS, this module is used for modularized Page Builder themes from 7.0 only.
wp_pagebuilder_shelf_base	Contains the base code for the tabs in the theme toolbar, used a prerequisite for other modules that implement tabs in the toolbar.
wp_wcm_modal_dialog	Contains a framework that displays a page in an iframe inside a modal dialog Used as a prerequisite to other modules that use this dialog framework.
wp_managed_pages_support	Contains a JavaScript configuration object that is used by all of the managed pages theme modules.
wp_managed_pages_support_edit	Contains base JavaScript code that is shared by the project menu and preview managed pages modules.
wp_toolbar	A managed pages theme module for the toolbar.
wp_status_bar	The theme status bar that relays information, warning, and error messages to the user.
wp_project_menu	A dojo-less managed pages theme module for the view mode display of project menu.
wp_project_menu_edit	A managed pages theme module for the edit mode function of the project menu.

Table 427. List of Page Builder modules and prerequisites. (continued)

Module	Description
wp_preview	CSS for the managed pages Preview controls seen in page view mode.
wp_preview_menu	A managed pages theme module for the Preview function that is seen in the **More** menu
wp_template_select_dialog	A dialog that is started from the **New Page** dialog. A user can pick a page template and base a newly created page on that template.

"Module capabilities"
Module capabilities enable the use of modules in the theme.

"Dojo classes provided by the Dojo modules" on page 2640
A list of Dojo classes that are provided by each version 1.9 Dojo meta-module.

Module capabilities:

Module capabilities enable the use of modules in the theme.

CF03 This table lists explicitly defined capabilities. Implicit capabilities are not listed. Every module automatically surfaces a default capability, or implicit capability, which is the capability with the exact same name and version as the module.

Table 428. List of module capabilities

Capability Name	Capability Value	Modules in the Capability
dojo	1.9	dojo_19
portal.livetext.action	8.0	wp_liveobject_framework
portal.livetext.hcard	8.0	wp_liveobject_framework
portal.livetext.c2a	8.0	wp_liveobject_framework
portal.livetext.adr	8.0	wp_liveobject_framework
mashups.builder	3.0.0.1	mm_enabler
open_ajax_hub	2.0	mm_open_ajax_hub
mashups.enabler	3.0.0.1	mm_enabler mm_enabler_core
widget_container	2.1	mm_enabler
active_site_analytics	8.0	wp_analytics
content_mapping.picker	8.0	wp_content_mapping_picker
federated_documents.picker	8.0	wp_federated_documents_picker
oneUI	2.1	wp_one_ui_21
oneUI	3.0.1	wp_one_ui_30
oneUI	3.0.3	wp_one_ui_303
CF03 oneUIDijit	3.0.1	wp_one_ui_dijit_30
CF03 oneUIDijit	3.0.3	wp_one_ui_dijit_303

Table 428. List of module capabilities (continued)

Capability Name	Capability Value	Modules in the Capability
cp_tagging_rating	8.0	wp_tagging_rating wp_tagging_rating_opensearch
sametime.proxy	8.5.2	wp_sametime_proxy
sametime.links	8.5.2	wp_sametime_links
portal.search	8.0	wp_search

For extra modules and capabilities, see Content Template Catalog theme extensions and Customizing the CSS styles of social lists.

Modules that add features to a theme

Theme modules contribute resources, such as JavaScript, CSS and HTML, to a theme or page. The following modules come with the modularized theme and specifically contribute a feature rather than working in the background. The modules can be added to a theme by listing them in the theme's default profile, or to a single page or set of pages.

Portal 8.5 theme

Table 429. Portal 8.5 theme modules and features

Module name	Feature
wp_status_bar	Adds a status bar for displaying informational, warning, and error messages to the users.
wp_layout_windowstates	Allows portlets to be minimized, maximized, and restored from their menus in the skin.
wp_legacy_layouts	Adds responsive layout support for earlier standard portal pages.

Table 429. Portal 8.5 theme modules and features (continued)

Module name	Feature
wp_liveobject_framework	The Live Text Framework allows portlet applications to display text live names and click to action links.

Site toolbar

Table 430. Site toolbar modules and features

Module name	Feature
wp_toolbar_host	Integrates a theme with the toolbar in both view and edit modes, use either wp_toolbar_host or both wp_toolbar_host_view and wp_toolbar_host_edit to add the toolbar to a theme.
wp_toolbar_host_view	Integrates the toolbar into a theme for viewing purposes only.
wp_toolbar_host_edit	Integrates the toolbar into a theme for editing purposes.
wp_toolbar_ghost	Add this module to pages that do not support edit mode to allow interoperability with the toolbar, so if a user navigates from an editable page to one with this module, the toolbar remains open, and the user is able to continue editing.
wp_draft_page_ribbon	Adds `Draft Page` in text that appears along the sides of a page that has a draft in the current project.

Menus

Table 431. Menu modules and features

Module name	Feature
wp_simple_contextmenu_main	Adds support for simple menus, and added to the default profile to enable **Portlet**, **Actions**, **More**, and **Toolbar** navigation menus.
wp_contextmenu_main	Adds support for the **Component Action** menu, which is used for inline editing of content items.
wp_skin_cam	Allows the Component Action Menu to be opened by clicking an icon in the portlet skin.

Tagging and rating

Table 432. Tagging and rating modules and features

Module name	Feature
wp_tagging_rating_light	Provides all lightweight inline tagging and rating widgets.

Table 432. Tagging and rating modules and features (continued)

Module name	Feature
wp_tagging_rating_menu	Adds the tagging and rating menu items in the Actions and portlet menus.
wp_tagging_rating_tagcloud	Provides the widgets in Tag Cloud portlet.

Analytics

Table 433. Analytics modules and features

Module name	Feature
wp_analytics_aggregator	Adds the analytics aggregator
wp_analytics_tags	Adds the **Sites Promotions...** and **Analytics Tags...** options to the Actions and portlet menus, and inserts the microformats for analytics tags and site promotions into the page.
wp_analytics_overlay_reports	Provides analytics overlay reports for portlets and pages.
wp_analytics	Provides all analytics features: aggregator, the analytics tags and site promotion function, and the overlay reports.

Search

Table 434. Search modules and features

Module name	Feature
wp_searchbar	Adds the inline search bar that redirects to the search page to show results.

Web content management

Table 435. Web content management modules and features

Module name	Feature
wcm_inplaceEdit	Turns on inline editing for content items that are displayed with the Web Content Viewer portlet.
wp_oob_sample_styles	Styles for default web content samples.
wp_federated_documents_picker	Allows the insertion of remote content into Web Content Manager elements that contain a rich text field, by using the Insert Link to **Remote Document** button in the authoring portlet.

Social Rendering

Table 436. Social Rendering modules and features

Module name	Feature
wp_social_rendering_85	Provides the social rendering feature.

Connections

Table 437. Connections modules and features

Module name	Feature
wp_ic4_wai_resources	Resources to enable Connections 4 integration with Web Application Integrator.

IBM Sametime

Table 438. Sametime modules and features

Module name	Feature
wp_sametime_proxy	Enables integration with Sametime using Sametime Proxy Server.

iWidget support

Table 439. iWidget support modules and features

Module name	Feature
wp_theme_widget	Allows for the rendering of iWidgets on pages.

Web Dock Application

Table 440. Web Dock Application modules and features

Module name	Feature
wp_webdock	Provides the web dock application.

Accessibility

Table 441. Accessibility modules and features

Module name	Feature
wp_theme_skin_region	Provides accessibility support to the portlet skins.
wp_theme_high_contrast	Adds support for high contrast mode.

Programming

Table 442. Programming modules and features

Module name	Feature
wp_portal	Provides JavaScript configuration objects that contain information about the Portal state to be used by the themes and portlets.
wp_client_main	Client-side JavaScript APIs for browser detection, event attachment, object manipulation, and type detection.
wp_client_ext	Client-side JavaScript APIs for modules and promises.
wp_client_selector	Client-side JavaScript CSS selection engine API.

Table 442. Programming modules and features (continued)

Module name	Feature
wp_worklight	Adds MobileFirst function.
wp_one_ui	Provides CSS for common elements in Portal. For more information, see the documentation in *PortalServer_root*\theme\wp.theme.modules\webapp\installedApps\ThemeModules.ear\ThemeModules.war\modules\oneui\v2.1\lotusOneUIv2.1_Documentation.zip.
wp_one_ui_dijit	An extension of One UI that provides styling for dijits, it acts as a Dojo theme. For more information, see *Themes and theming*.
wp_portlet_css	Styles for IBM Administrative portlets.
getting_started_module	Adds the default simple module.

Related information:

Themes and theming

Adding or removing a module from a profile

To add or remove a module, update the profile that is used to render a page for the theme.

Before you begin

Read the topics on profiles and modules *Working with profiles* and *Writing modules*.

Procedure

1. Open the profile file in the /profiles directory.
2. Make a copy of the profile file and give your copy a unique name.
3. Edit the .json file by adding or removing the specific module ID.
4. Copy the profile that you created to the /profiles directory.
5. Invalidate the resource aggregator cache to integrate your changes. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Theme Analyzer**. Then, click **Utilities** > **Control Center** > **Invalidate cache**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

   CF03 "Adding or removing a capability from a portlet"
   To add or remove a capability from a portlet, update the portlet.xml for the portlet, or update the portlet preferences sections for the portlet definition or portlet entity with XML access.

Adding or removing a capability from a portlet:

To add or remove a capability from a portlet, update the portlet.xml for the portlet, or update the portlet preferences sections for the portlet definition or portlet entity with XML access.

Before you begin

Read the topics on Module dependencies in portlets and writing modules.

Procedure

1. Open the `portlet.xml` in your portlet archive.
2. Create a portlet preference section. Or add a preference to the existing section. This example shows a preference that you can add to an existing section.

```
<portlet-preferences>
    <preference>
        <name>capability.1.id</name>
        <value>dojo</value>
        <read-only>true</read-only>
    </preference>
    <preference>
        <name>capability.1.minValue</name>
        <value>1.6</value>
        <read-only>true</read-only>
    </preference>
</portlet-preferences>
```

   For more information, see *Module dependencies in portlets*.
3. Package your `.WAR` file.
4. Redeploy the portlet with the Portal Administrator portlet. Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.Install or update your portlet there.

ConfigEngine tasks for creating a new profile based on a template and an existing profile in the system

You can extend the theme module framework with a new ConfigEngine task.

You can create a profile from a profile template and an existing profile. The config task reads the existing profile, takes the deferred and non-deferred theme modules from it, and creates a profile in WebDAV based on the template and the theme modules in the existing profile.

You can use these configuration tasks only for theme profile files that are stored in the WebDAV file store.

For more information about the theme module framework and how you can administer it, see the section about *Managing theme capabilities*.

Use the following parameters with the **`create-profile-based-on-template`** configuration tasks.

WasUserid
: The WebSphere Application Server user ID.

WasPassword
: The WebSphere Application Server user ID.

PortalAdminId
: The WebSphere Portal Express administrator user ID.

PortalAdminPwd
: The WebSphere Portal Express administrator password.

ThemeUniqueName
: The unique name of the theme that contains the profile that you want to update.

TemplateProfileFilePath
: The file path to the local template profile that you want the new profile be based on.

TargetProfileFileName
The name of the target profile file that you want to create.

TemplateModuleListProfileFileName
The name of the existing profile to fetch the list of theme modules from.

OverwriteProfile
Can be true or false. Defines whether the profile in WebDAV should be overwritten if it already exists.

Use the following command to create profile with the name `profile_new_deferred.json` in the theme with the unique name `ibm.portal.85Theme`, which is based on the template that exists on your local hard drive in `/opt/WebSphere/profile_new_template.json`. Once it is created in WebDAV, it has the list of modules from the `profile_deferred.json` profile, which already exists. The example assumes that the WebSphere Application Server and WebSphere Portal Express credentials are defined in the `wkplc.properties` file.

```
./ConfigEngine.sh create-profile-based-on-template -DThemeUniqueName=ibm.portal.85Theme -DTemplatePr
```

Customizing the theme

The module framework allows themes to be customized in order to provide flexibility, enhance the user experience, and maximize performance.

"Create a copy of your theme" on page 2659
You need to create your own custom theme by copying the Portal Version 8.5 theme before you start customization. Creating a copy of the theme ensures that your theme has all the required elements for the theme to function and that changes are not overwritten by a fix pack.

"Dynamic content spots" on page 2666
The static template files use dynamic content spots to reference JSP files or other dynamic resources. The dynamic resources are stored in a WAR file.

"Layouts" on page 2677
You can apply ready-use layouts to your portal pages, modify the existing skins, or add your own custom layout to change how your pages display.

"Skins" on page 2682
You can apply ready-use skins to your portal pages, modify the existing skins, or add your own custom skin to change how your pages display.

"Simple menu framework" on page 2688
You can provide menu feeds in JSON format instead of XML format. The operations can then parse the JSON feed without requiring the XML parsing support in the Dojo toolkit.

"Adding a link to the resource permissions administration portlet in a menu" on page 2705
You can add a link to the resource permissions portlet to see or modify role types or inherited access.

"Theme templates (`theme.html`)" on page 2706
You can use static HTML to write portal themes. The static theme template is named `theme.html`.

"Changing the theme logo" on page 2710
You can change the theme logo to customize your portal site and rebrand it to reflect your business.

"Customizing navigation" on page 2712
Use dynamic content spots to determine what is displayed by Top, Primary, and Secondary navigation. Use the `navigation.jsp` file to map properties to the

dynamic content spot IDs in the `theme.html` files. Rendering of the navigation is done with a single JSP file with `<ul>` and `<li>` tags.

"Styles" on page 2718
The WebSphere Portal Express Version 8.5 provides a selection of ready-use styles that you can be applied to your portal pages. You can also modify the existing theme styles or add your own custom style to achieve the look that you want.

"Configuring the portal theme and modules" on page 2722
Themes and modules are configured through theme metadata properties and resource environment provider custom properties.

"Expression language beans for accessing programming models" on page 2728
Expression language (EL) beans are available for accessing WebSphere Programming models. These beans are accessed through the PortalBean represented in the global namespace by `wp`. The beans provide access to IBM WebSphere Portal Express models and associated classes.

"Drag-and-drop" on page 2779
Drag-and-drop uses HTML5 code to facilitate the layout of content.

"Displaying messages in the status bar module" on page 2782
Displaying messages in the status bar module.

"Updating the content menu to open on click instead of on hover" on page 2783
The content menu opens when a user hovers over a portlet containing IBM Web Content Manager items. In combined Cumulative Fix 05, you can set the content menu to open when a user clicks an icon in the portlet skin instead.

"Displaying the draft page ribbon" on page 2784
The draft page ribbon is a strip of text that appears along both sides of a page that has a draft in the current project.

"Adding jQuery to a theme" on page 2786
The jQuery library is a JavaScript library. IBM WebSphere Portal Express includes a jQuery module for the jQuery core so you can use jQuery in a theme.

"Using Sametime with the WebSphere Portal Version 8.5 theme" on page 2789
You can add modules to your profile to use IBM Sametime with the IBM WebSphere Portal Express Version 8.5 theme.

"Tags used by the portal JSPs" on page 2790
Learn about the most commonly used tags in the portal JSPs. Use these tags to modify the appearance and layout of the portal page.

Create a copy of your theme

You need to create your own custom theme by copying the Portal Version 8.5 theme before you start customization. Creating a copy of the theme ensures that your theme has all the required elements for the theme to function and that changes are not overwritten by a fix pack.

Note: Do not modify the Portal Version 8.5 theme directly, because this theme can be updated by service fix packs and override your changes.

"Copy the static resources for your theme" on page 2660
You need to make a unique copy of the Portal 8.5 theme static resources before you start customizing your custom theme.

"Copy the static resources for your skin" on page 2661
You need to make a unique copy of the static resources for your skin.

"Copying the dynamic resources for your theme" on page 2661
You need to make a unique copy of the dynamic resources for your theme.

Make sure that Eclipse,IBM Rational Application Developer or Rational Team Concert with the Java EE developer tools add-on is installed.

"Link the static resources to the dynamic resources for your theme" on page 2662
The dynamic resources for your theme must be linked to the static resources. You must modify the default IBM WebSphere Portal Express theme references to point to the dynamic resources in your theme. First, you must bind your theme to the web application.

"Make your custom skin the default skin" on page 2665
Add your custom skin to the skins list to set it as the default skin for your theme. If it is the only custom skin, it is automatically set as the default skin for your theme.

Copy the static resources for your theme:

You need to make a unique copy of the Portal 8.5 theme static resources before you start customizing your custom theme.

About this task

Important: Enable development mode before you copy the static resources. Set the `resourceaggregation.development.mode` property to true within the WP ConfigService resource environment provider. If you do not enable development mode, be sure to restart your portal server at the end before you use your copied theme on a page.

Procedure

1. Connect your WebDAV client, such as WebDrive or AnyClient, to `http://host:port/wps/mycontenthandler/dav/themelist/`.
2. Copy the `ibm.portal.85Theme` folder to a local disk.
3. Rename the folder to the name of your theme, such as `customTheme`.
4. In the `metadata` folder, edit the `localized_en.properties` file, or whichever file is your default locale, and change the value of the title key to the display name of your theme, such as `Custom Theme`. Save the file. Repeat this step for any of the other locale files for the languages that you plan to support.
5. Edit the `metadata.properties` file and change the `Portal8.5` part of the **`com.ibm.portal.layout.template.href`** value to `customTheme`. Make sure that you have two properties that look like the following example:

   ```
   com.ibm.portal.layout.template.href=dav\:fs-type1/themes/customTheme/layout-templates/2ColumnEqual/
   resourceaggregation.profile=profiles/profile_deferred.json
   ```

6. Save the file.
7. Delete the skins folder from your `customTheme`, which removes the extra copies of the skins that are shipped with IBM WebSphere Portal Express. Your custom skin is created in a later step.

   ```
   customTheme/skins
   ```

8. Copy the entire `customTheme` folder into the `themelist` folder.
9. Double-check the contents of the `customTheme` folder in the `themelist` to ensure that everything is copied correctly. Compare each subfolder in `customTheme` to the corresponding subfolder in `ibm.portal.85Theme` to ensure that it looks like the correct number of files were copied. Recopy any files or subfolders that are missing. In particular, be sure to:
   a. Double-check the contents of the `metadata.properties` file in the `themelist`.

Note: Ensure that the URI is encoded. If there are spaces or other characters in the URI that are not allowed, the theme does not work.

b. Double-check the contents of the `profiles` folder and ensure all the profile files are there.

Copy the static resources for your skin:

You need to make a unique copy of the static resources for your skin.

Procedure

1. Connect your WebDAV client to http://*host*:*port*/wps/mycontenthandler/dav/skinlist/.
2. Copy the `ibm.portal.85Hidden` folder to a local disk.
3. Rename the folder to the name of your skin, such as `customSkin`.
4. In the metadata folder, edit the `localized_en.properties` file, or whichever file is your default locale, and change the value of the title key to the display name of your skin, such as `Custom Skin`. Save the file. Repeat this step for any of the other locale files for the languages that you support.
5. Copy the entire `customSkin` folder into the `skinlist`.
6. Double-check the contents of the `customSkin` folder in the `skinlist` to ensure that everything copied correctly. Compare each subfolder in `customSkin` to the corresponding folder in `ibm.portal.85Hidden` to ensure that it looks like the correct number of files were copied. Recopy any files or subfolders that are missing.

Copying the dynamic resources for your theme:

You need to make a unique copy of the dynamic resources for your theme. Make sure that Eclipse,IBM Rational Application Developer or Rational Team Concert with the Java EE developer tools add-on is installed.

Procedure

1. Switch to the Java EE perspective, and select **File** > **New** > **Dynamic Web Project**.
2. In the Project name field, enter the name of your theme, such as `CustomTheme`.
3. If it is not already selected, select **2.4** for the Dynamic Web Module version.
4. Select **Add project to an EAR** and click **Next to the Web Module page**.
5. On the Web Module page, change **Context Root** to `customTheme`, or whatever you want your context root to be, and click **Finish**.
6. Expand your new CustomTheme project and find and expand the `WebContent` folder.
7. Find the *PortalServer_root*`\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\skins` folder on file system and drag it onto the `WebContent` folder. This step copies and imports the skins folder into your dynamic web project.
8. Find the *PortalServer_root*`\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes` folder on file system and drag it onto the `WebContent` folder. This step copies and imports the themes folder into your dynamic web project.
9. In your CustomTheme project, find the `WEB-INF` folder inside the `WebContent` folder.

10. Find the *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\WEB-INF\decorations.xml file on file system and drag it onto the WEB-INF folder. This step copies and imports the file into your dynamic web project.
11. Find the *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\WEB-INF\tld folder on file system and drag it onto the WEB-INF folder. This step copies and imports the tld folder into your dynamic web project.
12. If you are developing a theme for a production portal, copy the following plugin.xml file into your dynamic resources. Find the *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\WEB-INF\plugin.xml file on file system and drag it onto the WEB-INF folder.
    a. Follow the steps in the *Modify the dynamic resource references for your theme* before you export the EAR and installing on your portal.

    This step copies and imports the file into your dynamic web project.
13. The previous files and folders are the only ones that you need. Do not copy any others from the DefaultTheme85.war file. Find your CustomThemeEAR project, right-click it and select **Export** > **EAR file** from the menu.
14. Click **Browse**, select a folder to export your EAR file to.
15. Click **Save** and click **Finish**.
16. Log on to the WebSphere Integrated Solutions Console and go to **Applications** > **Application Types** > **WebSphere enterprise applications**.
17. Click the **Install** toolbar button.
18. Click **Browse...**, find, and select the EAR file that you exported and click **Next**.
19. Select **Fast Path**, expand **Choose to generate default bindings and mappings**, select **Generate Default Bindings**, and click **Next**.
20. Change any installation option values that you want, or use the default values, and click **Next**.
21. For **Map Modules to Servers**, select the **Custom Theme module** in the table. Then, select the **...,server=WebSphere_Portal** entry in the list, click **Apply**, and click **Next**.
22. Click **Finish**.
23. When the EAR file is done installing, click **Save** directly to the master configuration.
24. Check your CustomTheme EAR in the table of enterprise applications and click the **Start** toolbar button.
25. On the file system, find and expand the *wp_profile_root*\installedApps\<cell>\CustomThemeEAR.ear\CustomTheme.war folder. The unique copies of the dynamic resources for your theme are in the themes and skins folders. When customizing your theme, always change the files at that location and do not modify the ThemeModules.war file.

Link the static resources to the dynamic resources for your theme:

The dynamic resources for your theme must be linked to the static resources. You must modify the default IBM WebSphere Portal Express theme references to point to the dynamic resources in your theme. First, you must bind your theme to the web application.

"Binding your theme to the context root of the web application"
You must bind your theme to the context root of the web application for your theme.

"Modify the dynamic resource references for your theme" on page 2664
You must modify the dynamic resource references to link to the static resources for your theme.

Binding your theme to the context root of the web application:

You must bind your theme to the context root of the web application for your theme.

Procedure

1. In *PortalServer_root*\bin, create the file input.xml with the following contents:

```
<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
   type="export"
>
<portal action="locate">
<skin action="export" objectid="*" />
<theme action="export" objectid="*" />
</portal>
</request>
```

2. From a command line, change to the *PortalServer_root*\bin directory and run the following **xmlaccess** command to export all skin and theme definitions to a file called output.xml:

```
xmlaccess -user <admin userid> -password <admin password> -url <hostname>:10039/wps/config -in input.xml -out output.xml
```

3. Edit the output.xml file. Search for the title of your theme, such as Custom Theme. Scroll up to the line with the surrounding <theme> tag. It is likely the last <theme> tag in the file. Modify it from:

```
<theme action="update" active="true" context-root="/wps/themeModules" default="false" domain="rel"
  objectid="ZJ_MLSU3F54089F00IP6G7P3F10S5" resourceroot="dynamicSpots">
```

to:

```
<theme action="update" active="true" context-root="/customTheme" default="false" domain="rel"
  objectid="ZJ_MLSU3F54089F00IP6G7P3F10S5" resourceroot="dynamicSpots" uniquename="customTheme">
```

Set the correct context-root and uniquename for your theme.

4. Search for the title of your skin. Scroll up to the line with the surrounding <skin> tag; it is likely the last <skin> tag in the file. Modify it from:

```
<skin action="update" active="true" context-root="/wps/themeModules" default="false" domain="rel"
  objectid="ZK_73OKBB1A088IE0I5O7IP2J0G77" resourceroot="Hidden" type="default">
```

to:

```
<skin action="update" active="true" context-root="/customTheme" default="false" domain="rel"
  objectid="ZK_73OKBB1A088IE0I5O7IP2J0G77" resourceroot="customSkin" type="default" uniquename="customSkin">
```

Set the correct context-root, resourceroot, and uniquename for your skin.

5. Find the <theme> tag for the Portal 8.5 theme. It is likely the first <theme> tag in the file. Find and copy one of the <allowed-skin> tag lines, such as:

```
<allowed-skin skin="ZK_CGAH47L00GJJ40IDC03MS13OS2" update="set"/>
```

Find the <theme> tag for your customTheme theme, it is likely the last <theme> tag in the file. Paste the <allowed-skin> tag line in just before the <parameter> tags. Modify the skin parameter value identifier to be the identifier of your customSkin skin, which can be found in the **objectid** parameter of the <skin> tag of your customSkin skin. It is likely the last <skin> tag in the file, such as:

```
<allowed-skin skin="ZK_N0IEGGC0I08PF0IDQ60O6310N4" update="set"/>
```

6. Find the **com.ibm.portal.layout.template.href** parameter for your customTheme theme. Modify it from:

```
<parameter name="com.ibm.portal.layout.template.href" type="string" update="set"><![CDATA[dav:fs-type1/themes/Portal8.5/layout-templates/2ColumnEqual/]]></parameter>
```

   to:

```
<parameter name="com.ibm.portal.layout.template.href" type="string" update="set"><![CDATA[dav:fs-type1/themes/customTheme/layout-templates/2ColumnEqual/]]></paramete
```

   Set the correct `context-root`, `resourceroot`, and `uniquename` for your layout template.

   Note: Ensure that the URI is encoded. If there are spaces or other characters in the URI that are not allowed, the theme does not work.

7. From the command line, run the following **xmlaccess** command to update the skin and theme definitions according to your change:

```
xmlaccess -user admin userid -password admin password -url hostname:10039/wps/config -in output.xml -out output2.xml
```

8. From the command line, run the following **xmlaccess** command to export all skin and theme definitions again to a file called `output3.xml`.

```
xmlaccess -user admin userid -password admin password -url hostname:10039/wps/config -in input.xml -out output3.xml
```

9. Edit the `output3.xml` file to verify that the result works, and then delete the `input.xml`, `output.xml`, `output2.xml`, and `output3.xml` files.

Modify the dynamic resource references for your theme:

You must modify the dynamic resource references to link to the static resources for your theme.

About this task

Dynamic content spots are defined through a module called `wp_dynamicContentSpots_85`. The module is defined in the `plugin.xml` file, which was copied when you copied your theme.

Procedure

1. Open the `plugin.xml` in the *wp_profile_root*`installedApps\`*cell*`\CustomThemeEAR.ear\CustomTheme.war\WEB-INF\` directory.
2. Edit the IDs and names to have a unique custom name. Use custom plug-in IDs with the prefix of your company name to ensure that your `.WAR` files are invalidated. See *Configuration for resource aggregation* for more information about creating custom plug-in IDs. For example,

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin id="com.yourcompany.customtheme" name="Custom Theme Modules" provider-name="Your Company"

<extension id="wp_dynamicContentSpots_custom" point="com.yourcompany.portal.resourceaggregator.mo
        <module id="wp_dynamicContentSpots_custom">
            <contribution type="dyn-cs">
                <sub-contribution type="markup" ref-id="customtheme_footer">
                    <uri value="res:{war:context-root}/themes/html/dynamicSpots/footer.jsp"/>
                </sub-contribution>
                <sub-contribution type="markup" ref-id="customtheme_crumbTrail">
                    <uri value="mvc:res:{war:context-root}/themes/html/dynamicSpots/crumbTrail.js
                </sub-contribution>
                <sub-contribution type="markup" ref-id="customtheme_topNav">
                    <uri value="mvc:smartphone/tablet@res:{war:context-root}/themes/html/dynamicS
                </sub-contribution>
                <sub-contribution type="markup" ref-id="customtheme_primaryNav">
                    <uri value="mvc:res:{war:context-root}/themes/html/dynamicSpots/navigation.js
                </sub-contribution>
                <sub-contribution type="markup" ref-id="customtheme_secondaryNav">
                    <uri value="mvc:res:{war:context-root}/themes/html/dynamicSpots/navigation.js
                </sub-contribution>
```

```
                    <sub-contribution type="markup" ref-id="customtheme_sideNav">
                        <uri value="mvc:res:{war:context-root}/themes/html/dynamicSpots/sideNaviga
                    </sub-contribution>
                    <sub-contribution type="markup" ref-id="customtheme_mobileNav">
                        <uri value="mvc:smartphone/tablet@res:{war:context-root}/themes/html/dynam
                    </sub-contribution>
                    <sub-contribution type="markup" ref-id="customtheme_commonActions">
                        <uri value="res:{war:context-root}/themes/html/dynamicSpots/commonActions.
                    </sub-contribution>
                    <sub-contribution type="markup" ref-id="customtheme_layout">
                        <uri value="lm:template"/>
                    </sub-contribution>
                    <sub-contribution type="markup" ref-id="85theme_toolbar">
                        <uri value="mc:wp_toolbar85@mvc:dyn-cs%3Aid%3A85toolbar%2Csmartphone%40%2C
                    </sub-contribution>
                    <sub-contribution type="markup" ref-id="customtheme_head">
                        <uri value="res:{war:context-root}/themes/html/dynamicSpots/head.jsp"/>
                    </sub-contribution>
                    <sub-contribution type="markup" ref-id="customtheme_status">
                        <uri value="mc:wp_status_bar@res:{war:context-root}/themes/html/dynamicSpo
                    </sub-contribution>
                </contribution>
            </module>
        </extension>
```

3. Connect your WebDAV client to `http://host:port/wps/mycontenthandler/dav/fs-type1/`.
4. Modify the profiles for your custom theme to include the module in your `plugin.xml`.
   a. From the `themes\customTheme\profiles` folder, copy the profile files.
   b. Remove the `wp_dynamicContentSpots_85` module from the profile.
   c. Add the `wp_dynamicContentSpots_custom` module that you created by modifying the `plugin.xml`.
   d. Copy the profiles back to the profiles folder.
5. From the `themes\customTheme\nls` folder, copy the `theme_en.html` file, or whichever file is your default locale, to the local drive. Repeat for any of the other locale files for the languages that you support.
6. Edit the `theme*.html` files, and find and replace all occurrences of `85theme` with `customTheme`. For example, `dyn-cs:id:85theme_head` becomes `dyn-cs:id:customTheme_head`.
7. Save the files.
8. Copy the files into the `fs-type1` folder.
9. Restart IBM WebSphere Portal Express.

What to do next

Note: You do not need to modify the `theme.html` file in the `themes\customTheme` folder. That file is not used other than to redirect to the appropriate locale file in the `nls` folder. You need to modify it only if you add or remove locales.

Make your custom skin the default skin:

Add your custom skin to the skins list to set it as the default skin for your theme. If it is the only custom skin, it is automatically set as the default skin for your theme.

About this task

Important: If you did not enable development mode before you copied your theme, restart your portal server before you complete the following steps.

Procedure

1. Log on to IBM WebSphere Portal Express.
2. Click the **Administration menu** icon. Then, click **Portal User Interface** > **Themes and Skins**.
3. Select **Custom Theme** in the themes list and click **Edit theme**.
4. Select **Custom Skin** in **Skins for this theme** list and click **Set as Default**.
5. Click **OK**.

What to do next

Your theme is now available for use on your portal. To verify, create a page, edit page properties, and assign your theme to the page.

Note: Your custom theme uses ready-use modules, which are shared across themes and intentionally remain uncopied in the Theme Modules web application. For your theme to operate the Theme Modules web application must remain started in addition to the web application for your theme.

Dynamic content spots

The static template files use dynamic content spots to reference JSP files or other dynamic resources. The dynamic resources are stored in a WAR file.

"Working with dynamic content spots"
You can add dynamic content to your custom theme by using either client-side or server-side logic.

"Creating dynamic content spots" on page 2672
There are two ways you can create dynamic content spots. You can use a module, or a resource environment provider.

"Conditionally disable dynamic content spots" on page 2675
You can control whether a dynamic content spot is rendered into the page or not based on the fact whether a certain module exists on the page or not.

"Modules and dynamic content spots" on page 2675
You can use the modularized framework for dynamic content spots to override spots that were defined through resource environment providers.

"Dynamic content spot debugging" on page 2677
Dynamic Content Spots add dynamic markup into static themes or skins. Sometimes, it is difficult to discern which parts of the page were contributed from which dynamic content spots.

Working with dynamic content spots:

You can add dynamic content to your custom theme by using either client-side or server-side logic.

You can add dynamic content to your custom theme's static content by using dynamic content spots. Dynamic content spots are hook points in your static markup such as the `theme.html` that delegates somewhere else to inject more markup at that spot the page. It can be delegated to any URI known to the system. For instance, it can point to a server-side component such as JSP or servlet.

To abstract the theme from direct links into server-side code, use the `dyn-cs: schema` with a unique identifier for a dynamic content spot. This allows for advanced features such as delegating to different JSPs on different pages. Use the following examples.

Including a named dynamic content spot mapping:

```
<a rel="dynamic-content" href="dyn-cs:id:newDynamicContentSpotName"></a>
```

Including a theme JSP directly:

```
<a rel="dynamic-content"
   href="res:/CustomThemeContext/themes/html/MyTheme/dynamicContent.jsp"></a>
```

Configuring and modifying named dynamic content spots

The dynamic content spot mappings can be defined as part of the module definition by using the `ref-id` attribute on a `dyn-cs` contribution type. Or, they can be defined for the theme and skin templates in a Resource Environment Provider (REP) named WP DynamicContentSpotMappings in the WebSphere Integrated Solutions Console. For more information, see *Creating a dynamic content spot*.

The following tables are an overview of the dynamic content spots that are most frequently used. Use the Theme Analyzer's Contribution Explorer to see all the dynamic content spots provided.

Table 443. Default dynamic content spots for the Portal 8.5 theme template

Name of the content spot	Defined in module	Value	Description
n/a		`co:config`	Starts the combiner data source, which injects the config markup that is identified in the module profile
n/a		`co:head`	Starts the combiner data source, which injects the head markup that is identified in the module profile.

Table 443. Default dynamic content spots for the Portal 8.5 theme template (continued)

Name of the content spot	Defined in module	Value	Description
85theme_asa		`mc:wp_authoring_actionbar@mvc:res:/wps/themeModules`	Provides the site analytics extension
85theme_commonActions	wp_dynamicContentSpots_85	`res:/wps/defaultTheme85/themes/html/dynamicSpots/commonActions.jsp`	Common actions that are on the banner, that is, Actions, Login, Logout
85theme_crumbTrail	wp_dynamicContentSpots_85	`mvc:res:{war:context-root}/themes/html/dynamicSpots/crumbTrail.jsp,smartphone@`	Navigation breadcrumb trail to display the page selection path
85theme_footer	wp_dynamicContentSpots_85	`res:/wps/defaultTheme85/themes/html/dynamicSpots/footer.jsp`	Footer of the page
85theme_head	wp_dynamicContentSpots_85	`res:/wps/defaultTheme85/themes/html/dynamicSpots/head.jsp`	HTML head element that provides the document title, styles, bookmark icon.
85theme_layout	wp_dynamicContentSpots_85	`lm:template`	Layout of the page

Table 443. Default dynamic content spots for the Portal 8.5 theme template (continued)

Name of the content spot	Defined in module	Value	Description
85theme_mobileNav	wp_dynamicContentSpots_85	`mvc:smartphone/tablet@res:/wps/defaultTheme85/th` CF06 `mvc:smartphone/tablet@res:/wps/defaultTheme8`	Navigation used on mobile devices such as smartphones and tablets. CF06 Each level of navigation is lazily loaded as the user clicks.
CF06 85theme_mobileNav_static	wp_dynamicContentSpots_85	`mvc:smartphone/tablet@res:wps/defaultTheme85/themes/html/dynamicSpots/mobileNavigation.jsp`	Navigation that is used on mobile devices such as smartphones and tablets. Each level of navigation is pre-loaded in the page markup.

Table 443. Default dynamic content spots for the Portal 8.5 theme template (continued)

Name of the content spot	Defined in module	Value	Description
85theme_pageModeToggle	wp_dynamicContentSpots_85	zmc:wp_toolbar@res:/wps/defaultTheme85/themes/html/dynamicSpots/pageModeToggle.jsp	Edit Mode and View mode buttons in the theme banner that is seen when the project menu is off.
85theme_primaryNav	wp_dynamicContentSpots_85	mvc:res:{war:context-root}/themes/html/dynamicSpots/navigation.jsp?type=primary&markup=smartphone@,tablet@	Navigation that is in the second level of navigation
85theme_secondaryNav	wp_dynamicContentSpots_85	mvc:res:{war:context-root}/themes/html/dynamicSpots/navigation.jsp?type=secondary&markup=smartphone@,tablet@	Navigation that is in the third level of navigation
85theme_sideNav	wp_dynamicContentSpots_85	mvc:res:/wps/defaultTheme85/themes/html/dynamicSpots/sideNavigation.jsp?startLevel=2&markup=smartphone@,tablet@	Nested side navigation at the third level
85theme_status	wp_dynamicContentSpots_85	mc:wp_status_bar@res:/wps/defaultTheme85/themes/html/dynamicSpots/status.jsp	Area that is located with the page layout that displays status, warning, and error messages to the user

Table 443. Default dynamic content spots for the Portal 8.5 theme template (continued)

Name of the content spot	Defined in module	Value	Description
85theme_topNav	wp_dynamicContentSpots_85	`mvc:smartphone/tablet@res:{war:context-root}/themes/html/dynamicSpots/navigation.jsp?type=top`	Navigation in the theme header, first level of navigation
wp_toolbar_dynspot	wp_toolbar		The tabbed toolbar that is at the beginning of the page while in edit mode
wp_project_menu_dynspot	wp_project_menu		The project drop-down menu in the theme header
wp_search_mobile_dynspot	wp_searchbar		Search input that is displayed on the subbanner
wp_preview_dynspot	wp_preview		**End Preview** button that is at the beginning of the page when you preview the page as a different user
wp_analytics_dynspot	wp_analytics		Provides the site analytics extension

Table 443. Default dynamic content spots for the Portal 8.5 theme template (continued)

Name of the content spot	Defined in module	Value	Description
wp_analytics_head_dynspot	wp_analytics		Provides the site analytics head extension

Table 444. Content spot values available in the skin template

Content spot value	Description
lm:control	Renders the layout control body.
lm:title	Renders the title of the portlet.
lm:description	Renders the description of the portlet.
portlet.link:portlet	Outputs the markup ** to allow page to position itself at a particular portlet markup with a fragment identifier.
wp_analytics_portlet_dynspot Defined in Module: `wp_analytics`.	Provides the site analytics extension for portlets

You can modify the dynamic content spot values two different ways.

- Dynamic content spots that are defined through module `wp_dynamicContentSpots_85` are part of the default theme and is cloned when you create your own theme. Rename the module in your theme, update the reference in the profile, and then you can change the values of the dynamic content spots.
- System dynamic content spots such as `wp_search_dynspot` can be changed by overriding dynamic content spots with the module framework. For example, you can create a module that redefines this dynamic content spot that requires the core module `wp_search`. Your dynamic content spot reference is used as a result.

Creating dynamic content spots:

There are two ways you can create dynamic content spots. You can use a module, or a resource environment provider.

"Creating a dynamic content spot with a module"
In most situations, use the modularized approach to define dynamic content spots. This approach is more flexible than defining them through Resource Environment Providers. You can also switch the dynamic content spot per page and override existing content spot when you define them with a module.

"Creating a dynamic content spot with resource environment providers" on page 2674
You can create a custom dynamic content spot to include in a theme template.

Creating a dynamic content spot with a module:

In most situations, use the modularized approach to define dynamic content spots. This approach is more flexible than defining them through Resource Environment

Providers. You can also switch the dynamic content spot per page and override existing content spot when you define them with a module.

About this task

A dynamic content spot is defined in `theme.html`. You must create a module with the ID `85theme_topNav` and then add that module to a profile. The following example renders the top navigation.

```
<a rel="dynamic-content" href="dyn-cs:id:85theme_topNav"></a>
```

For more information, see *Modules and dynamic content spots*.

Procedure

1. Define the module as a JSON file or as part of a `plugin.xml` file. The dynamic content spot ID is defined within the `ref-id` attribute on the sub contribution.
   - The following example shows the definition of a module by using the JSON format. To define the override module as a JSON file. Add the file in WebDAV at `fs-type1/themes/`*`YourTheme`*`/contributions/`.

     ```
     {
       "modules": [{
         "id" : "topnavoverlay",
         "prereqs": [{
           "id":"wp_dynamicContentSpots_85"
         }],
          "contributions": [{
           "type":"dyn-cs",
           "sub-contributions": [{
             "type":"markup",
             "ref-id":"85theme_topNav",
             "uris": [{
               "value":"res:/your/sample.html"
             }]
           }]
         }]
       }]
     }
     ```

     id This value can be any meaningful ID that is unique to the system.

     ref-id The ID of the dynamic spot to override. In this example, it is `85theme_topNav`.

     value A pointer to the markup for the dynamic spot. In this example, it points to an HTML file relative to the theme location in WebDAV.

     Note: If you want to point to a `.JSP` file, you must define this module within a `plugin.xml` .

     prereqs
     The name of the module that is required or overridden by this module.
   - You can also define the override module in a `plugin.xml` file.

     ```
     <extension point="com.ibm.portal.resourceaggregator.module" id="topnavoverlay" >
        <module id="topnavoverlay">
         <preqreq id="wp_dynamicContentSpots_85"/>
         <contribution type="dyn-cs">
           <sub-contribution type="markup" ref-id="85theme_topNav">
              <uri value="res:/your/sample.jsp" />
     ```

```
      </sub-contribution>
    </contribution>
  </module>
 </extension>
```

extension id
This value can be any meaningful ID that is unique to the system.

module id
This value can be any meaningful ID that is unique to the system.

sub-contribution ref-id
The ID of the dynamic spot to override. In this example, it is `85theme_search`.

uri value
A pointer to the markup for the dynamic spot.

prereqs
The name of the module that is required or overridden by this module.

2. Include the module in a profile. For example, in `newtopnav_profile.json`.

```
{{
  {
   "moduleIDs": [
   "topnavoverlay",
   ...
}}
```

The `newtopnav_profile.json` file must be copied to WebDAV at `fs-type1/themes/`*`YourTheme`*`/profiles/`. For more information, see *Create a module profile*.

3. Apply the profile to a page hierarchy. You can change the profile for the theme or a specific page to define the modules that are loaded. For more information, see *Changing the theme profile*.

Creating a dynamic content spot with resource environment providers:

You can create a custom dynamic content spot to include in a theme template.

Procedure

1. Log on to the WebSphere Integrated Solutions Console.
2. Go to **Resources** > **Resource Environment** > > **Resource environment providers** > **WP DynamicContentSpotMappings**.
3. Select **Custom Properties**.
4. Select **New**.
5. Enter a name to be used as the ID of the mapping. For example `newDynamicContent`.
6. Enter a value that is the URI to the dynamic content to be included by the mapping, similar to the following example:
   `res:/CustomThemeContext/themes/html/MyTheme/dynamicContent.jsp`
7. Select **OK**.
8. Save the changes.
9. Restart the portal.
10. Open the theme template file on WebDAV.

11. Locate where in the template you want to include the dynamic content and add the following line of code:

    ```
    <link rel="dynamic-content" href="dyn-cs:id:<your mappping ID>">
    ```

    Replace <*your mapping ID*> with the name that you gave the mapping, for example **newDynamicContent**.
12. Clear the browser cache and refresh the page that has the theme template that you modified to get the new dynamic content spot to render.

Using parameters

You can pass parameters to a JSP page that is rendering the dynamic content. If the page expects a parameter such as **text**, then you would locate where in the template you want to include the dynamic content and add the following line of code:

```
<link rel="dynamic-content" href="dyn-cs:id:<your mappping ID>+'?text=dynatext'">
```

Conditionally disable dynamic content spots:

You can control whether a dynamic content spot is rendered into the page or not based on the fact whether a certain module exists on the page or not.

When a particular module is turned on, you can choose to have a dynamic content spot display. You can use the mc schema as part of the dynamic content spot URI. The schema is defined in the following example, `mc:module-id@delegate-uri`.

The module-id is the module this URI is tested for. If the module is enabled, the dynamic content spot is rendered. The delegate-uri represents the dynamic content spot URI.

In the Portal 8.5 theme, the status bar component renders error, warning, or informational messages.

In the theme HTML template, the status bar component is rendered with the following dynamic content spot.

```
<a rel="dynamic-content" href="dyn-cs:id:85theme_status"></a>
```

This dynamic content spot maps to the following URI through the system module for the Portal 8.5 theme:

```
'wp_dynamicContentSpots_85': mc:wp_status_bar@res:{war:context-root}/themes/html/dynamicSpots/stat
```

The wp_status_bar module contains the JavaScript resources necessary to display the messages. The markup renders when the module is active.

Modules and dynamic content spots:

You can use the modularized framework for dynamic content spots to override spots that were defined through resource environment providers.

Dynamic content spots and markup contributions are both techniques for adding HTML to a theme, with one important difference. Markup contributions are always placed at the end of the body of the page. But, dynamic content spots render wherever they are placed in the theme HTML template.

When a module requires markup, use a markup contribution if it is not important where the module is in the page, such as with iWidget definitions. If the markup must appear in a particular spot in the theme, then a conditional dynamic spot is used.

Dynamic Content Spots on a page

Portal identifies dynamic content spots after it analyzes the profile of a page and all the modules in the profile that includes its `prereqs`. If any module within the hierarchy contains a dynamic content spot, the spot participates in the page rendering process. If the page's profile does not contain a dynamic content spot's ID that is used within the `theme.html`, nothing is rendered. If Portal identifies a dynamic content spot with a matching ID, it renders the dynamic content spot at the referenced URI.

To use the same dynamic content spot on two different pages, but with different markup, reference different profiles that contain a different module for the dynamic content spot.

In this example, there are two pages, Home and Applications. Home has an inline top navigation, and Applications has a fly-out navigation. The `theme.html` is identical and uses the following dynamic content spot

```
<a rel="dynamic-content" href="dyn-cs:id:85theme_topNav"></a>
```

Create two modules and two profiles to create the two pages with different markup.

Modules:

topNavModule
: Defines a sub contribution with **ref-id** `85theme_topNav` that points to a JSP provided by this module. This JSP renders the inline top navigation.

flyoutNavModule
: Defines a sub contribution with **ref-id** `85theme_topNav` that points to a JSP provided by this module. This JSP renders a fly-out navigation.

Profiles:

HomeProfile, set on Home
: It contains the `topNavModule`. It causes the inline top navigation to be rendered.

ApplicationsProfile, set on Applications
: It contains the `flyoutNavModule`. It causes the inline top navigation to be rendered.

Override dynamic content spots

You can override any dynamic content spot that was defined through resource environment providers. Dynamic content spots in modules overrule the dynamic content spots in resource environment providers. However, you can override dynamic content spots that were defined through modules. To render the dynamic content spots in the correct order, you must create a module that defines a `prereq` on the module that defines the previous dynamic content spot. For more information, see *Writing modules with a plugin.xml file*.

To override the default dynamic content spot for search `wp_search_dynspot`, you must create a module that defines a `prereq` on `wp_searchbar`. This module renders this particular dynamic content spot ID.

Dynamic content spot debugging:

Dynamic Content Spots add dynamic markup into static themes or skins. Sometimes, it is difficult to discern which parts of the page were contributed from which dynamic content spots.

The new Dynamic Content Spot Debugging was introduced to provide a visual indication in the page within your browser. The visual indicator operates two ways.

Default mode

This mode shows the original markup structure and displays the corresponding content sport for markup type when it is in focus. If a user hovers, the markup is highlighted with a background color and a label, which displays the URI of the corresponding spot. If the spot was configured through the `dyn-cs:` scheme the system also resolves the spot to its final URI, which is usually a `.jsp`. The resolved URI is shown as a link. This link does not provide a working URL for you to follow with your browser. You can copy the resolved URI for further use.

Inline mode

With this feature, you can easily spot if you have unnecessary dynamic content spots in your theme or skins. But, it does not preserve the overall design of your page. The advantage of this mode over the default mode is that it displays spots that do not contribute anything visual.

Limitations

The validation report shows errors, warnings, and informational messages about the theme and corresponding artifacts, such as profiles and modules. However, the validation report does not determine whether the profiles that are applied to each page are present in the theme.

When you enable the visualization feature for dynamic content spots, that setting does not persist across a server restart. Also, it applies to the current cluster member. It is not replicated to other cluster members.

Dynamic content spot debugging, development mode, reports, and client tracing do not persist across a cluster or a server restart either.

Layouts

You can apply ready-use layouts to your portal pages, modify the existing skins, or add your own custom layout to change how your pages display.

"Working with layout templates" on page 2678
You can add new layout templates so that they can be assigned to portal pages or update your ready-use layouts to modify the existing skins or change how your pages display.

"Adding a layout to the toolbar" on page 2680
You can add your own custom layout to the theme that can be selected on the site toolbar.

"Default layouts" on page 2681
The IBM WebSphere Portal Express 8.5 theme ships with predefined layouts that can be used as a basis for creating custom layouts.

Working with layout templates:

You can add new layout templates so that they can be assigned to portal pages or update your ready-use layouts to modify the existing skins or change how your pages display.

Layout templates are stored in the WebDAV filestore at the location `/fs-type1/themes/myCustomTheme/layout-templates`. To add a layout template and to assign it to portal pages, create a folder or copy and rename an existing layout template folder in the root folder. Include all CSS files in the theme that are used by the new layout template.

Layout templates control the layout and positioning of the content on a page. The static layout template is called `layout.html`. The author of the layout template defines the HTML fragment markup and CSS for the layout of the page. The HTML fragment uses microformat to specify containers and components, such as portlets and iWidgets to include in the page.

This example defines a two-column layout, with a hidden container for widgets, which participate in the wiring of the page, but are not visible themselves.

```
<div class="hiddenWidgetsDiv">
 <!-- widgets in this container are hidden in the UI by default -->
 <div class="component-container hiddenWidgetsContainer ibmDndRow wpthemeCol12of12 wpthemeFull" name=
 <div style="clear:both"></div>
</div>
<!-- this layout has two equally sized columns -->
<div class="wptheme2Col wpthemeEqual">
 <div class="component-container wpthemeCol wpthemePrimaryContainer ibmDndColumn wpthemeLeft wpthemeC
 <div class="component-container wpthemeCol wpthemeSecondaryContainer ibmDndColumn wpthemeLeft wpther
</div>
```

The meaning of the elements is as follows:

class="component-container"
: The static page parser recognizes the microformat to define containers in the page layout model that can contain components. Components can be portlets or widgets.

name="ibmMainContainer"
: The name attribute on a component container identifies that container uniquely to the page. The static page parser uses the name to correlate containers when it updates the page definition. Using consistent names across layout templates preserves your container contents when you switch between layouts on pages. There must always be a container that is named `ibmMainContainer` for the main content of the page.

name="ibmHiddenWidgets"
: When you create your own layouts, there must always be the one container at the beginning of the page named `ibmHiddenWidgets`.

name="headline"
: If there are containers other than `ibmHiddenWidgets` or `ibmMainContainer`, use `headline` for a header or banner across the page for smooth switching between your layouts and the default layouts.

name="secondary"
Use `secondary` for content that is secondary to the main content, such as a sidebar.

name="tertiary"
Use tertiary for content that supports the secondary content.

name="additional"
Use `additional` for content that supports the tertiary content.

name="footer"
Use `footer` for an item at the end of the page.

class="ibmDndColumn"
class="ibmDndRow"
This class is required for client-side drag-and-drop support. Mark your component container with one of these classes.

class="wpthemeCol"
class="wpthemeRow"
This class provides CSS positioning information. Mark your component container with one of these classes.

class="wpthemeHeadlineContainer"
class="wpthemePrimaryContainer"
class="wpthemeSecondaryContainer"
class="wpthemeTertiaryContainer"
These classes provide CSS sizing information. Mark your component container with one of these classes. These classes are optional. You can use one of your own classes if your container sizing requirements vary from what these provide.

class="wpthemeLeft"
This class provides CSS positioning information. Mark your component container with this class if it is one of multiple containers on the same vertical level and floats to stay on the same level.

class="wpthemeCol1of12"
class="wpthemeCol2of12"
class="wpthemeCol1of5"
class="wpthemeCol3of12"
class="wpthemeCol4of12"
class="wpthemeCol2of5"
class="wpthemeCol5of12"
class="wpthemeCol6of12"
class="wpthemeCol7of12"
class="wpthemeCol3of5"
class="wpthemeCol8of12"
class="wpthemeCol9of12"
class="wpthemeCol4of5"
class="wpthemeCol10of12"
class="wpthemeCol11of12"
class="wpthemeCol5of5"
class="wpthemeCol12of12"
These classes are CSS marker classes. They do not have any styles that are defined for them by default. But, they can be used in CSS selectors to vary the styles of content and portlets that can be dropped in this container. Mark your component container with one of these classes that are based on the width the container has relative to other containers on the same vertical level. These classes are referred to as grid relative width classes.

You can specify that a container takes up any number of width units of the page. See Relative width CSS classes for theme layouts.

class="wpthemeThin"
class="wpthemeNarrow"
class="wpthemeMedium"
class="wpthemeWide"
class="wpthemeFull"

These are CSS marker classes. They do not have any styles that are defined for them by default. But, they can be used in CSS selectors to vary the styles of content and portlets that can be dropped in this container. Mark your component container with one of these classes that are based on the width the container has relative to other containers on the same vertical level. These classes are referred to as semantic relative width classes. See Relative width CSS classes for theme layouts.

If you repeat similar sections in a layout, append 2 through n to the end of any of the names. For example, use `additional2` and `additional3` or use `headline2`, `ibmMainContent2` and `secondary2`. Use this naming convention for better transitions when you switch between layouts.

If you implement a complex layout template that requires its own JavaScript handling, ensure that the required JavaScript components are loaded and initialized by the theme. For best performance, build and minify all JavaScript used into a single, cacheable file that can be loaded one time and cached by the browser.

Adding portlets and iWidgets to layout templates

You can add portlets and iWidgets directly to the layout template definition by using the portlet microformat for static pages, or the iWidget definition specification. You can add portlets or iWidgets inside or outside of containers. The template is applied to the page as a copy. Therefore, every page that uses the template has a new instance of the portlet or iWidget.

Adding a layout to the toolbar:

You can add your own custom layout to the theme that can be selected on the site toolbar.

About this task

To add your own custom layout to the toolbar, first create a folder for your layout in `/fs-type1/themes/myCustomTheme/layout-templates` or copy and rename one of the existing layout folders. In the folder, create or modify your layout template `layout.html` file, and create or modify your `icon.gif` file for the visual representation of your layout as it appears on the toolbar.

These steps add the new layout to the site toolbar.

Procedure

1. Open the `layouts.json` file in WebDAV at `dav:fs-type1/themes/`*`myCustomTheme`*`/system`. If the file does not exist, create the file. The `layouts.json` registers the layout you created in the `layout.html` file with the toolbar and defines it further.
   a. Make sure that the file has the following content:

```
{
localizationPackageName:'com.ibm.bundles',
localizationBundleName:'Shelf', identifier:'label', items:   [
]
}
```

b. For each layout in `dav:fs-type1/themes/myCustomTheme/layout-templates`, add an entry like the following code sample to the JSON array in the file `layouts.json`. For example, here is an entry for a layout that is stored in WebDAV at `dav:fs-type1/themes/myCustomTheme/layout-templates`:

```
{'label':'My Layout','url':'dav:themelist/myCustomTheme/layout-templates/myLayout/','id':'myLayout',
  'thumbnail':ibmCfg.themeConfig.themeRootURI+'/layout-templates/myLayout/icon.gif','help':''}
```

2. Optional: As an alternative to step 1, you can add titles and descriptions of the layout as part of the layout entry.

```
{
    "items": [
    {
        'label': 'Complete',
        'url': ibmCfg.themeConfig.themeWebDAVBaseURI + 'layout-templates/Complete/',
        'id': 'Complete',
        'thumbnail': ibmCfg.themeConfig.themeRootURI + '/layout-templates/Complete/icon.png',
        'help': '',
        "titles": [{
            "value": "Full Page Layout",
            "lang": "en"
        }],
        "descriptions" : [{
            "value": "Full Page Layout Description",
            "lang": "en"
        }]
    },
    ...
    ]
}
```

3. Refresh your browser cache.
4. Reload the page to view the layouts in the **Page** > **Layout** tab of the site toolbar.

Default layouts:

The IBM WebSphere Portal Express 8.5 theme ships with predefined layouts that can be used as a basis for creating custom layouts.

1 column layout
This layout has one main container.

1 row 2 column unequal layout
This layout has one row across the whole page with two unequal columns underneath, one column is larger than the other column.

1 row 3 column equal layout
This layout has one row across the whole page with three equally sized columns underneath.

2 column equal layout
This layout has two equally sized columns.

2 column left layout
This layout has two columns with one column assigned a smaller width.

2 column right layout
This layout has two columns with one column assigned a smaller fixed width.

2 row layout
This layout has two rows that go across the whole page.

3 column center layout
This layout has 3 columns that take up 20%, 60%, and 20% of the space across the page.

3 column equal layout
This layout contains three equally size columns.

Top column 2 column unequal layout
This layout has a column on top with two columns underneath, one column is larger than the other column.

Top column 3 column center layout
This layout has one column on top of three unequal sized columns underneath.

Skins

You can apply ready-use skins to your portal pages, modify the existing skins, or add your own custom skin to change how your pages display.

"Skin templates"
The static skin template `skin.html` is located in the root directory of the skin folder of the WebDAV file store. The `skin.html` file provides the full markup for decoration around a portlet or iWidget. As with theme templates, you can use dynamic content spots to add dynamic elements to the skin template at run time.

"Creating skins" on page 2684
You can create global or theme-based skins to customize a theme. A successful approach to creating custom skins is by copying one of the default skins files, then adding images, JavaScript files, and other custom resources.

"Default skins" on page 2687
The default theme includes these skins that can be used as a basis for creating custom skins: Hidden, Standard, and NoSkin.

Skin templates:

The static skin template `skin.html` is located in the root directory of the skin folder of the WebDAV file store. The `skin.html` file provides the full markup for decoration around a portlet or iWidget. As with theme templates, you can use dynamic content spots to add dynamic elements to the skin template at run time.

The portal provides a base skin template and localized skin templates.

The `skin.html` file is located in the root directory of the skin on WebDAV `\fs-type1\skins\skin-name\`, and there are localized `skin.html` files located within the `nls` directory under the skin `\fs-type1\skins\skin-name\nls\`. Modify the skin template files by using the WebDAV entry point `fs-type1`. When you use this entry point, your changes to the skin template are immediately reflected with a browser refresh.

Root skin template

In a default WebSphere Portal installation, the portal does not render the template file `skin.html` located in the root directory of the theme. Instead, this file links to

the localized templates, and the portal renders the appropriate localized template. The links to the localized templates are at the beginning of the root template. They have the following form:

```
<a rel="alternate" href="nls/skin_locale_code.html" hreflang="locale_code" class="wpthemeDisplayNone"></a>
```

An example of a link to the English template file is as follows:

```
<a rel="alternate" href="nls/skin_en.html" hreflang="en" class="wpthemeDisplayNone"></a>
```

You can place the wpthemeDisplayNone class on these links so that the browser does not expose the anchor element in the user interface. This class makes sure that accessible technologies, such as screen readers, do not encounter these links in the tab order.

If you do not want to use localized skin templates, you can remove these links from the beginning section of the `skin.html` template in the root directory. If you remove the links, the portal renders the root template.

The root skin template also includes Apache Ant scripting in the following form:

```
${bundle_name:bundle_key:character_encoding}
```

The **`character_encoding`** replaces special characters with the escape sequence determined by the specified encoding. The available types of encoding are XML or JSON. You can chain multiple instances of encoding by or as follows:

```
${bundle:key:json:xml} or ${bundle:key:xml:json}
```

You can use the Apache Ant build framework to generate localized templates based on this root template. This framework can be useful if you want to update one template during development and then generate the templates. If you want to use only the root template, replace the Ant scripting with the preferred text that you want to be rendered. You can learn more about the Ant build tool at the Apache Ant Welcome page.

Localized skin templates

In a default portal installation, the theme renders content by using the localized skin templates. These templates are located in the `nls` subdirectory under the skin directory on WebDAV. These files have the locale code appended to the end of the template name, for example `skin_en.html` for English. These templates have translated static text inline within the template.

When you use the localized skin templates and want to view your changes, update the template that the portal renders in the browser. For example, if your preferred language is English, update the `fileskin_en.html` file.

Server-side dynamic content spots

`<a rel="dynamic-content" href="lm:title">`
This inserts the portlet title into the skin.

`<a rel="dynamic-content" href="lm:control">`
This renders the content of the portlet.

Client-side dynamic content spots

Client-side content spots are replaced at page load time or at run time through JavaScript by **`RuntimeSkinModel`** and the live text service.

class='lm-dynamic-icon'

By default, the skins do not contain the lm-dynamic-icon spot. If you want support for a dynamic icon, you need to add an image tag to the titlebar markup in the skin HTML template.

For Example:

```
<img class="lm-dynamic-icon" src=""/>
```

This provides a client-side way for changing the icon for the portlet or iWidget in the skin dynamically. For example, you can add the following code sample to set the icon dynamically. The second parameter sent into the setDynamicContent function is a URL that is the `src` of the icon <img> element.

```
var skinNode = com.ibm.mashups.enabler.runtime.skin.Factory.getRuntimeSkinModel().find("somePortletID");
 skinNode.setDynamicContent(com.ibm.mashups.enabler.runtime.skin.Constants.DYNAMIC_CONTENT_ICON, "http://www.mysite.com/icon.gif");
```

Note: The somePortletID function fetched from the runtime skin model is a string ID of the layout node for which the title or icon is changed. The profile used on the page must include Enabler in view mode as it is required to fetch the skin node and set the dynamic content.

Note: Enabler has been deprecated.

class='lm-dynamic-title'

This content spot changes the title of the skin dynamically at run time.

For example, to set the title, the second parameter is a string that is inserted as the new title.

```
skinNode.setDynamicContent(skinConstants.DYNAMIC_CONTENT_TITLE, "My new title")
```

Where:

`var controlId`: the string ID of the layout node for which the title or icon is changed.

`var runtimeSkinModel`: `com.ibm.mashups.enabler.runtime.skin.Factory.getRuntimeSkinModel()`.

`var skinNode`: `runtimeSkinModel.find(controlId)`.

`var skinConstants`: `com.ibm.mashups.enabler.runtime.skin.Constants`.

Apache Ant Welcome page

Creating skins:

You can create global or theme-based skins to customize a theme. A successful approach to creating custom skins is by copying one of the default skins files, then adding images, JavaScript files, and other custom resources.

Do not modify the default skins directly, because this skin can be updated by service fix packs and override your changes.

You can create skins in the following scopes:

Theme-based

You can scope a skin to one particular theme. Use this scope if the skin relies specifically on code within the theme or has a specific function that

is only useful in that particular theme. These skins are located under the root folder of the theme, and create a specific link between the skin and theme.

This is the recommended approach.

Global
The global scope where the skin is not specific for any theme. Global skins are located in the `skins` folder under the WebDAV root.

All skins created in Portal can be access by the WebDAV `skinlist` entry point.

"Create a theme-scoped skin"
You can create a custom skin that is scoped to a specific theme when you copy an existing ready-use choice to use as the base for your new skin.

"Add static resources to a skin" on page 2687
You can add images, URLs, and other static resources to your skin.

Create a theme-scoped skin:

You can create a custom skin that is scoped to a specific theme when you copy an existing ready-use choice to use as the base for your new skin.

You can define new skin resources manually or by using the Manage properties portlet. After the skin is assigned to the theme, you can define the skin and apply it to specific portlets or use it as the theme default.

"Creating new skin resources"
You can begin to create a custom skin that is scoped to a specific theme by creating new skin resources.

"Defining the skin and assigning it to a theme using **Manage properties**" on page 2686
When you create new skin resources, you can define them so that you can assign them to a theme.

"Defining the skin and assigning it to a theme manually" on page 2686
When you create new skin resources, you can define them so that you can assign them to a theme.

Creating new skin resources:

You can begin to create a custom skin that is scoped to a specific theme by creating new skin resources.

Procedure

1. Mount the `/fs-type1/` WebDAV entry point with your WebDAV client:
   `/wps/mycontenthandler/dav/fs-type1/`

   If you changed the `wps` folder, replace it with your `WpsContextRoot` value.
2. Locate your custom theme under the `themes` folder.
3. Under the theme root folder, find the `skins` folder. If it is not there, then create it.
4. Copy a skin that you want to use as the base to your local system. If the `skins` folder did not exist previously and you created it, go to the `skins` folder in the global scope, `dav:fs-type1/skins`. Copy a skin from that location that you want to use as the base.
5. After you copy the base skin folder to your local system, rename the folder.

6. Copy the new folder to the skins folder under your custom theme, dav:fs-type1/themes/*custom_theme*/skins.

Defining the skin and assigning it to a theme using **Manage properties***:*

When you create new skin resources, you can define them so that you can assign them to a theme.

About this task

You can define the skin and assign it to a theme by using **Manage properties** or manually. Learn more about Defining the skin and assigning it to a theme manually.

Procedure

1. In the Theme Manager, select your custom theme and click **Manage properties**.
2. Click the **Skins** tab. Then, click **Add skin**.
3. Enter a title for your new skin. You can also set and modify other skin properties in the **Localization**, **Metadata**, and **Advanced** tabs.
4. In the **Advanced** pane for the skin, ensure that the static content root matches the path to the directory that contains the skin in WebDAV.
5. Click **Done**.

Defining the skin and assigning it to a theme manually:

When you create new skin resources, you can define them so that you can assign them to a theme.

About this task

You can define the skin and assign it to a theme by using **Manage properties** or manually. Learn more about Defining the skin and assigning it to a theme using **Manage properties**.

Procedure

1. Use the following code snippet as a template for the XMLAccess skin definition to import, where *theme_context*, *skin_folder_name*, *skin_unique_name*, *skin_title*, *theme_folder*, *skin_folder_name*, and *theme_unique_name* are the unique values for your theme and skin.

   Note: This template creates a title in English only, but you can add more locales.

```
<?xml version="1.0" encoding="UTF-8"?>
    <request
     xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" build="wp80" version="8.0"
     xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
     type="update" create-oids="true">
     <portal action="locate">
      <skin action="update" active="true" context-root="theme_context" default="false" domain="re
        resourceroot="skin_folder_name" type="default" objectid="skin_unique_name" uniquename="sk
      <localedata locale="en">
       skin_title
      </localedata>
       <parameter name="com.ibm.portal.skintype" type="string" update="set"><![CDATA[template]]><
       <parameter name="com.ibm.portal.skin.template.file.name.html" type="string" update="set"><
       <parameter name="com.ibm.portal.skin.template.ref"
         type="string" update="set"><![CDATA[dav:fs-type1/themes/theme_folder/skins/skin_folder_n
```

```
  </skin>
  <theme action="update" uniquename="theme_unique_name">
   <allowed-skin skin="skin_unique_name" update="set"/>
  </theme>
 </portal>
</request>
```

2. Import the XMLAccess skin definition by using the command line or the Import XML portlet.

Add static resources to a skin:

You can add images, URLs, and other static resources to your skin.

About this task

When you create a file for the skin on the `/fs-type1/` entry point, there is a link that shows this file through the `/skinlist/` entry point. This link makes it possible to use the path defined to the image as `skinlist` instead of `fs-type1`. You can still use an absolute path to the `/fs-type1/` entry point if you want, such as `<img src="http://server_name:port_number/wps/mycontenthandler/dav/fs-type1/skins/myskin/images/logo.png"/>`.

Procedure

1. Mount the `/fs-type1/` WebDAV entry point with your WebDAV client:
   `/wps/mycontenthandler/dav/fs-type1/`

   If you changed the *wps* folder, replace it with your `WpsContextRoot` value.
2. Add images or other static resources to your skin.
   a. Copy the required static resources, such as images or JavaScript files, into the root directory of your skin in WebDAV.
   b. Organize your files in subdirectories as necessary.
   c. Use server relative or absolute URLs to reference the resources in your `skin.html` file. For example, if you create a folder named `/images` that contains a file named `logo.png`, you can use the following references:

      Server relative URL

      Absolute URL

Default skins:

The default theme includes these skins that can be used as a basis for creating custom skins: Hidden, Standard, and NoSkin.

Hidden skin
Is the default skin. In view mode, this skin does not display the title bar or any decorations. In edit mode, the skin displays the title bar and decorations around the portlet. This skin was created for WCM content that is exposed on external facing websites, where edit mode is not likely to be shown to users so the title bar is hidden. However, when an administrator or user that has access to edit the WCM portlet, they can put a page into edit mode and configure the portlet.

Figure 1. Hidden Skin in view mode. 
Figure 2. Hidden Skin in edit mode. 
Standard skin

Displays the portlet title bar in both edit and view mode. The title bar shows the title of the portlet and the skin action menu. This skin imitates the default skin from past releases.

Figure 3. Standard Skin. 
NoSkin skin

The NoSkin skin does not show the title bar or any decorations around the portlet. This skin is used if you do not need to show the skin actions.

Simple menu framework

You can provide menu feeds in JSON format instead of XML format. The operations can then parse the JSON feed without requiring the XML parsing support in the Dojo toolkit.

"Client-side framework for simple menus"
You can enable simple menus in the client with four modules.

"Server-side framework" on page 2692
A plug-in receives HTTP requests for specific menus from a client and responds with the menu feed in JSON format. The response is marked as content type `application/JSON`.

"Changing menu item visibility" on page 2701
Whether the menu items are visible is controlled in a layered way by client-side JavaScript and markup. The default value for visibility, if not specified, is Boolean true.

"Menu styles" on page 2702
You can vary the appearance of the items in menus that are delivered through the JSON menu framework.

Client-side framework for simple menus:

You can enable simple menus in the client with four modules.

To use the simple menus in your theme, you must add the main module `wp_simple_contextmenu_main` to your theme profile on the current page. All required resources are included on the page.

The simple menu framework includes four modules:

- `wp_simple_contextmenu_main`
  - `wp_simple_contextmenu_js`
  - `wp_simple_contextmenu_css`

- wp_simple_contextmenu_template

Open the menu with the JavaScript function **wptheme.contextMenu.init**. For more information, see the *JsDoc*.

To register a simple menu so that it opens when a user clicks the HTML element, use the following example.

```
<span role="button" aria-haspopup="true" class="wpthemeMenuFocus"
          onclick="if (typeof wptheme != 'undefined') wptheme.contextMenu.init({ 'node': this, mer
          <span class="wpthemeUnderlineText" id="wpContextMenu">My Menu</span>
      </span>
```

This example has the `pageAction` ID, which triggers a request to the server to load a JSON file with the same id. For more information, see Server-side framework.

You can create as many menus as you want in a custom theme.

To force the regeneration of menus, use the JavaScript command:
i$.fireEvent('wptheme/contextMenu/invalidate/all');

When a session timeout occurs, the page refresh returns to the login page.

Module details

The four modules in the simple menu framework provide all the information that you need to render the menus. For flexibility, the modules, except for the JavaScript module, are configured as theme modules. They are included in each theme individually. When you are creating or cloning your own theme, you must copy all the required resources to your theme.

If you copy the default theme, that theme includes all the required resources.

The following list describes all resources that are required in your theme for various modules .

- wp_simple_contextmenu_js (system module)
- wp_simple_contextmenu_main (theme module)
  - meta module, no resources referenced
- wp_simple_contextmenu_css (theme module)
  - theme root directory for static resources/css/wp_simple_contextmenu.css
  - theme root directory for static resources/css/ wp_simple_contextmenu.css.uncompressed.css
  - theme root directory for static resources/css/wp_simple_contextmenuRTL.css
  - theme root directory for static resources/css/ wp_simple_contextmenuRTL.css.uncompressed.css
  - theme root directory for static resources/css/default/contextmenu.css
  - theme root directory for static resources/css/default/ contextmenu.css.uncompressed.css
  - theme root directory for static resources/css/default/ contextmenuCommon.css
  - theme root directory for static resources/css/default/ contextmenuCommon.css.uncompressed.css
  - theme root directory for static resources/css/default/contextmenuRTL.css

  - theme root directory for static resources/css/default/contextmenuRTL.css.uncompressed.css
- wp_simple_contextmenu_template (theme module)
  - theme root directory for static resources/menuDefinitions/templates/simpleMenuTemplate.html

Templates

The menu provides a default template that is embedded into the page markup and contributed through the module `wp_simple_contextmenu_template`. If no inline template or not templateID is passed when initializing the menu, the framework reverts to the default template.

You can define your template with an inline template, which is embedded with the menu markup.

```
<span role="button" aria-haspopup="true" class="wpthemeMenuFocus"
          onclick="if (typeof wptheme != 'undefined') wptheme.contextMenu.init({ 'node': this, menuI
          <span class="wpthemeUnderlineText" id="wpContextMenu">My Menu</span>
          ... <your template markup appears here> ...
      </span>
```

Or, you can use a referenced template through an ID. When calling the init method of the menu, you can pass a templateID as part of the parameters. This ID is resolved as HTML element ID in the DOM and must point to a valid template.

```
<span id="exampleTemplateId" class="wpthemeMenuLeft">
    <div class="wpthemeMenuBorder">
        <div class="wpthemeMenuNotchBorder"></div>
        <!-- define the menu item template inside the "ul" element.  only "css-class", "description"
        <ul class="wpthemeMenuDropDown wpthemeTemplateMenu" role="menu">
            <li class="${css-class}" role="menuitem" tabindex="-1"  ><span class="wpthemeMenuText" >
        </ul>
    </div>
    <!-- Template for loading -->
    <div class="wpthemeMenuLoading wpthemeTemplateLoading">${loading}</div>
    <!-- Template for submenu -->
    <div class="wpthemeAnchorSubmenu wpthemeTemplateSubmenu">
        <div class="wpthemeMenuBorder wpthemeMenuSubmenu">
            <ul id="${submenu-id}" class="wpthemeMenuDropDown" role="menu"><li role="menuitem" tabin
        </div>
    </div>
</span>
```

The template contains 3 sub templates that are identified through classes.

Menu item template
: Defined through the class `wpthemeTemplateMenu`. To generate each individual menu entry, items this DOM node contains are used as a template.

Loading template
: Defined through the class `wpthemeTemplateLoading`. Used to display if the menu content is being loaded.

Submenu template
: Defined through the class `wpthemeTemplateSubmenu`.

The template can also contain a few replacement variables. From within the menu item template, there are three variables.

${css-class}
Replaced with the classes used for this entry.

${description}
Localized description of the menu item.

${title} Localized title of the menu item.

In the loading template, there is one variable.

${loading}
Loading text to be displayed while data is fetched from the server.

In the submenu template, there is one variable.

${submenu-id}
Required to define a unique ID for a newly generated submenu.

Example

This example shows the close handler, another templateId, and alignment.

```
addClass(control.parentNode, VALUE_SELECTED);
            args = {
                "node": control.parentNode,
                "menuId": menuID,
                "jsonQuery": menuQuery,
                "params": {
                    "templateId": "exampleTemplate",
                    "alignment": "right"
                },
                "onClose": function() {
                    removeClass(control.parentNode, VALUE_SELECTED);
                }
            };
            wptheme.contextMenu.init(args);
```

Simple menu extensions

The framework supports extra extensions as part of the module `wp_simple_contextmenu_ext`. The following extensions are available.

actionUrlTarget
You can define the target window within the browser DOM in which a menu action is run. Use this to run a menu action within another iframe of the page for instance. This module is used within the toolbar theme.

badge This extension provides support for displaying badges for each `menuitem` of the `contextmenu`. A badge is a number that is displayed in a graphical box with color. Badges can easily be enabled by setting the metadata `badgeUrl` or `badgeData` on the metadata for the `menuitem`. The feed that is returned from the `badgeUrl` must be of type JSON and must have two JSON elements on the root object.

count The number to be displayed.

level String, which can be either `error`, `warn`, or `info`.

As an alternative to the `badgeURL`, `menuitem` can also contain the `badgeData` element. The `badgeData` element must be a JSON object with the same elements as the feed that is returned from badgeURL. The following is a `badgeURL` example.

```
{
  "type": "StaticMenuitem",
  "id": "myEditFct",
  ...
  "metadata": {
    ...
    "badgeUrl": "?uri=theme-validation:count"
  }
}
```

The following is an example of `badgeData`.

```
{
  "type": "StaticMenuitem",
  "id": "myEditFct",
  ...
  "metadata": {
    ...
    "badgeData": {
      "count": "10",
      "level": "error"
    }
  }
}
```

Server-side framework:

A plug-in receives HTTP requests for specific menus from a client and responds with the menu feed in JSON format. The response is marked as content type `application/JSON`.

The request URL for the menu feed provider is under the `/wps/contenthandler` or `/wps/mycontenthandler` URLs, depending on whether the request is coming from a currently-logged-in user context. The request URL might carry portal URL navigational state, but does require a specific query string to access the menu feed provider. The specific query string to get to the default JSON feed provider is:

```
?uri=menu:<specific menu name>&navID=<navigation node OID or custom unique name>
[&windowID=<portlet window control ID on the page> ]
```

where:

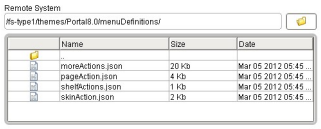
navID This parameter is either the serialized string-format ObjectID or the custom unique name of a portal navigation node (a portal page), which is being displayed when the menu is being requested. This parameter provides a context for the menu feed provider to use when you build the menu, so we know which theme to use, because the theme is tied to the page either explicitly or by inheritance.

windowID
This parameter is optional and is the serialized string-format ObjectID of a portlet window control on the page that is specified by `navID`. This parameter is only necessary for menus that contain portlet-level actions, in other words, `skin menus`. This parameter must be a serialized ObjectID. A custom unique name does not work for the portlet window ID.

WebSphere Portal Express provides three ready-to-use menu definition files with the Portal 8.5 Optimized Theme:

- `pageAction`
- `skinAction`
- `moreActions`

These files exist in WebDAV, under a `menuDefinitions` directory within the root for the theme root. The root is set in theme metadata under the metadata entry name `com.ibm.portal.theme.template.ref`. Other files in that directory are JSON syntax but are not used by the JSON menu framework



New starting in version 8.0.0.1: It is possible to name a menu ID (the *specific menu name* after the `?uri=menu:` in the request) which does not exist. Before 8.0.0.1, this menuID would result in an error message about an invalid or non-existent menu name being requested. In 8.0.0.1 and later, this menuID is treated as though a menu file with that name did exist, with the contents being an empty array ("[ ]"). A menu feed response is then generated that consists only of processing of the dynamic menu contributions or JSON subcontributions for the current theme profile, which are tagged with a `ref-id` matching the menu name on the request.

Important: The order of the items that are dynamically added to a menu is not controlled or guaranteed in any way. Although in testing the order was consistent between server restarts on the same system, it was found to be inconsistent across different operating systems. Especially between IBM JVMs and those not from IBM. If it is necessary to strictly control the order of the menu items, then use the explicit `"type":"ModuleRef"` entry in a menu definition file to explicitly insert the menu item, rather than relying on the dynamic contribution mechanism.

JSON menu definition file syntax

For more information about JSON itself, see the JSON home page.

The JSON syntax of a menu definition file consists of an array of JSON objects, where the array is indicated by outer enclosing opening and closing brackets `[ ]`. Each JSON object is enclosed in braces ({ }) and separated by commas:

```
[
   // optional one-line comment
   {
     JSON object 1 (first menu item)
   },
   /*
     optional multi-line comment
   */
   {
     JSON object 2 (second menu item)
   },
   ...
]
```

You can add comments in this file by using a portal-specific extension to JSON syntax.

Note: The minimum valid JSON menu definition file consists of an opening and closing array bracket ([]). An empty file results in an illegal syntax exception.

The final object in the array does not have a comma between its curly brace and the ending array closing bracket.

The order of the objects in the array within the menu definition file determines the order of appearance of the items in the menu on the client.

Each object within the array is an individual self-contained menu item definition, or a reference to a theme optimization module that can provide more in-line JSON menu definition file markup. This contributed JSON is included in-line as though it was in the menu file itself.

Each object consists of multiple comma-separated JSON members, each of which has a name and a value that are separated by a colon. The member name is always a string in quotation marks. The values can be strings, Booleans, nested objects, or arrays, depending on the member name. Some member names can have only certain values, as defined in the following list.

Each menu item definition must have a `type` entry, which defines that particular menu entry item.

Important: All entry names are case-sensitive.

The following menu item names and values are acceptable values for the type entry.

"type" : "Header"

Defines a label for subsequent entries in the menu. Typically displayed on the client UI as highlighted and outdented, although this menu item is controlled by the style that is applied to the menu items. A header in the menu is typically not clickable.

More title object entries, within the **titles** value, for other languages can be added.

An `itemClass` member can be added for controlling the appearance of the header.

```
{
"type" : "Header",
"titles" : [{"lang":"en","value":"<English text>"}, {"lang":"de", "value" : "German text"},...]
}
```

"type" : "Separator"

Defines a separator between menu items. A separator might show as a space, a line, or other appearance, depending on the style that is applied to the menu.

A separator does not typically need any other members, although an `itemClass` can be added for appearance control.

```
{
"type" : "Separator",
}
```

"type" : "DynamicMenuitem"

Potentially clickable and having an action the `DynamicMenuitem` item has an `id` member whose value is a plug-in name. The menu feed provider uses this ID to retrieve an instance of the named operation, which is then queried for sufficient information to build the menu feed content for this `menuitem`. Several plug-ins are supplied ready-to-use by WebSphere Portal Express for use in the default menu definitions, and these can be reused by custom-written menus and themes.

This plug-in provides its own indicator of whether it is active, including access control permission for the current user, and provides its own

localized title and optionally a description, and an actionHttpMethod value, for the menu feed provider to use when you build the menu for this item. The OperationURI for this operation plug-in becomes the actionUrl in the corresponding menu entry. Other object members are allowed as well, including actionFn, actionHttpMethod, visibilityFn, itemClass, and metadata. A markupID member can be added to create an ID on the html tag for the resulting menu item.

If the isActive() method returns false when called by the menu feed provider code, the menu item is present in the menu feed, but has a `"visibility" : false` boolean member added to the feed. This boolean member indicates to the client-side code to not present this operation to the user, and the client-side code does not include this item in the final rendered menu.

Optionally, a moduleArgs member might also be specified. This member is a string of query parameter-format names and values that are separated by ampersands (&). If present, these arguments are passed to the plug-in when the feed provider accesses the plug-in to build the current menu entry.

```
{
"type" : "DynamicMenuitem",
"id" : "operations.framework.plugin.name"
}
```

"type" : "StaticMenuitem"

Potentially clickable and having an action. This item is typically used to insert a menu item that has a client-side implementation, rather than a server-side implementation.

Allows the menu feed definition file author to completely specify an arbitrary menu item entry. All necessary information must be provided by the menu definition file, because there is no corresponding operation for a `StaticMenuitem`. The **id** parameter is optional and is ignored by the menu feed provider code for a `StaticMenuitem`, although it is not flagged as a syntax error if it is present.

Other optional members might be added as needed.

```
{
"type" : "StaticMenuitem",
 "titles" : [{"lang" : "en", "value" : "My English menu item text"},
        {"lang" : "de", "value" : "Mein menu item text auf Deutsch"},
         ...
        ],
"descriptions" : [{"lang" : "en", "value" : "My English menu item longer description flowing beautiful prose"},
             {"lang" : "de", "value" : "Mein menu item longer description flowing beautiful prose auf Deutsch"},
             ...
             ],
"actionUrl" : "http://www.yourco.com/wps/myportal/some_useful_url",
"actionHttpMethod" : "POST",
"actionFn" : "client_method_to_override_actionUrl",
"metadata" : {
        "navID" : "${navID}",
        "some_name" : "some_value",
        "some_other_name" : "${SubVar_From_Request_Query_Parms}"
        }
"markupId" : "my.item.markupId"
}
```

"type" : "ModuleRef"

A menu definition file has an **id** member whose value is the name of a plug-in. This plug-in must have a contribution of the menu type, and a subcontribution of the JSON type. The menu feed provider uses the value of the **id** member in this JSON object to retrieve a reference to the JSON subcontribution within the menu contribution for that module. This JSON subcontribution must be valid stand-alone JSON menu definition markup,

including the surrounding array opening and closing brackets. The menu feed provider strips the array opening and closing brackets and inserts this contributed markup in-line into the menu feed response as though it is included in the main definition file.

Points by name at a plug-in that provides more JSON format and menu definition file syntax markup, which the feed provider places inline in the menu feed and that replaces the `ModuleRef` entry.

Optionally, a `moduleArgs` member can be added. If present, the value of the `moduleArgs` member is passed as arguments to retrieve the JSON menu definition file markup from the plug-in.

```
{
"type" : "ModuleRef",
"id" : "Theme Optimization Framework module name"
}
```

"type" : "Submenu"

Defines a placeholder in the current menu where a new sublevel menu is attached. This item allows for multiple tiered menus. There is no enforced limit to the nesting level. The submenu is retrieved by an independent additional menu request to the JSON menu feed provider when the submenu entry in the displayed menu is hovered over.

The menu is appended to the one side as screen position dictates. A submenu is fetched in a separate subsequent request by the client.

A submenu names the source of its menu content with either an `id` or a `moduleId` member, and must have a `titles` member to provide the text for the placeholder menu item, and might optionally have a `descriptions` member.

The only difference between these two members is how the next request is processed, when the submenu is expanded and the client code retrieves the expansion menu feed in a new HTTP request:

- For an `id`, the next request is treated as naming a menu definition file where the `id` value is the file name and the extension is `.json`.
- For a `moduleId`, the next request is treated as naming a plug-in that provides the necessary JSON markup. This request is accessed as though a menu definition file specified it.

  ```
  {
  "type" : "ModuleRef",
  "id" : "moduleId_value"
  }
  ```

A `moduleArgs` member might also be added. If present with a `moduleRef` member within a `SubMenu` entry, the value of the `moduleArgs` member is appended to the URL that is built as the ID of the menu item. This value is used as the menu reference from the client for retrieving the menu markup for the cascaded submenu.

```
{
"type" : "SubMenu",
"id" : "name_of_submenu_definition_JSON_file",
 "titles" : [{"lang" : "en", "value" : "My English sub-menu item text"},
      {"lang" : "de", "value" : "Mein sub-menu item text auf Deutsch"},
      ...
      ],
"descriptions" : [{"lang" : "en", "value" : "My English sub-menu item longer description flowing beautiful prose"},
      {"lang" : "de", "value" : "Mein sub-menu item longer description flowing beautiful prose auf Deutsch"},
      ...
      ]
 }
or
 {
```

```
"type" : "SubMenu",
"moduleId" : "name_of_theme_opt_framework_module_which_contributes_submenu_definition_JSON_",
...
}
```

Valid members in a JSON menu definition file

Member name	Value and example syntax	Comments
type	"Header", "Separator", "DynamicMenuitem", "StaticMenuitem", "ModuleRef", Submenu"	Determines the type of menu item that is created by this menu definition file object
`id`	String	For a `DynamicMenuitem` or a `ModuleRef`, the `id` member is required. For a Submenu, either `id` or `moduleId` is required. **DynamicMenuitem** The ID is the name of the plug-in that is accessed by the menu feed provider to get the `actionUrl` (which is the OperationURI of the operation), the localized title and description, and the `isActive` method of the operation, which indicates whether the action is active and also accessible by the current user. The `actionUrl` is sent to the server in a separate request if the user clicks this menu item in the rendered menu. **ModuleRef** The ID is the name of the plug-in that is accessed to retrieve more menu file definition markup. **Submenu** The `id` is present, it is the name of the menu that is requested by the client in an HTTP menu request to create the submenu list of items.
`titles`	Array of objects, each of which has these members: a "lang" defines the language for that title entry, and a "value" contains the string for that language for the title. `"titles" : [ {"lang":"en", "value":"Title in English"}, {"lang":"de", "value":"Title auf Deutsch"}, ... ]`	Used only for header, `StaticMenuitem`, and Submenu entries. The list of languages that are provided covers only the necessary languages that the users of a portal might need. A `DynamicMenuitem` retrieves the title from the corresponding plug-in. The plug-in is required to implement the Localized interface, and provide localized strings for appropriate languages. A Separator has no text that is associated with it. A `ModuleRef` is replaced by other markup.
`descriptions`	Same as titles. `"descriptions" : [ {"lang":"en", "value":"Title in English"}, {"lang":"de", "value":"Title auf Deutsch"}, ... ]`	Optional for all types. If present, this member is interpreted by the default client code as hover help text over the menu item.
`itemClass`	String	Optional for all types. This member is the style class name that is applied to the menu item. If present, this is a class name that is present in the style sheet that is associated with the theme for the menu.

Member name	Value and example syntax	Comments
`enabled`	Boolean true or false	Optional for all types. Defaults to true. This member indicates whether the menu item is clickable on the client side. True equates to active, false equates to not active.
`enableFn`	String	Optional for all types. If present, this member is the name of a JavaScript function to execute on the client to determine whether this menu item is active. The complete menu feed JSON object for this menu item is passed as an argument to the function. The result from this function call overrides the "enabled" setting.
`actionUrl`	String	For a `StaticMenuitem`, either the `actionUrl` or the `actionFn` must be present. If `actionUrl` is present, it might be an absolute URL or a relative URL, or a query string that is appended to the current request URL or tag value. Not required for a `DynamicMenuitem`. Not useful for any other type. Invoking the `actionFn` takes precedence over an `actionUrl` if both are present.
`actionHttpMethod`	String, with normal HTTP values "GET", "POST", "PUT", "DELETE" and other values.	Defaults to "GET". Optional for all object types. If present on a `DynamicMenuitem`, this overrides any action that is provided by the Operation Framework plug-in.
`actionFn`	String	For a `StaticMenuitem`, either the `actionUrl` or the `actionFn` must be present. If `actionFn` is present, this member is the name of a JavaScript function to execute on the client when the menu item is clicked. The complete menu feed JSON object for this menu item is passed as an argument to the function. Invoking the `actionFn` takes precedence over an `actionUrl` if both are present.
`visibilityFn`	String	Optional for all types, but not useful for Separator or `ModuleRef`. For a `DynamicMenuitem` or `StaticMenuitem`, if `visibilityFn` is present, this member is the name of a JavaScript function to execute on the client to determine whether this menu item is active. The complete menu feed JSON object for this menu item is passed as an argument to the function.

Member name	Value and example syntax	Comments
`metadata`	For version 8.0.0.1: Embedded object, where the members can be String values, boolean values, or numeric values, or other nested objects. There is no enforced limit on the nesting level. There are only 2 restrictions on metadata: • No arrays can be used within metadata • No member within a metadata object can have the name "metadata". This results in an IllegalSyntaxException. Prior to version 8.0.0.1, metadata was restricted to only String types with no embedded nesting.	Optional for all types. If present, the members within must observe the restrictions that are listed for the appropriate version. If substitution variables are present in any String value within the metadata object, at any nesting level, in the form `${variableName}`, then these values are substituted from query parameters on the received menu request (`...&variableName=value...`). Multiple replacement variables can be contained in a metadata value string, but only one pass is made through the string. Any replacement variables that are found for which there are no substitutions found in the query parameters from the request, remain unchanged in the metadata that is passed to the client as part of the JSON feed response. For example: `[` `  {` `    ....` `    "metadata" : {` `  "a" : "something",` `  "b" : true,` `  "c" : 123,` `  "thisIsNestedMetadata" : {` `  "a" : "something nested",` `  "d" : "This is a substitution:  ${su` `  }` `    }` `    ...` `  }` `]`
`moduleId`	String	Optional for a Submenu, but only applicable for a Submenu. If present instead of an ID in a Submenu entry, this member is the name of a module like the `id` of a `ModuleRef` that is accessed by the client in a separate direct request if the Submenu item is expanded by the user. The format of the menu item that is built by this is `{"type":"Submenu", "id" : "moduleRef:", ... }`. The client code makes a request to the server by using this ID that is a variation of the normal menu request: `?uri=menu:moduleRef:`. The feed provider code handles this request by starting the named module as though there were a menu feed definition file that contained a `ModuleRef` with that ID.
`moduleArgs`	String, in the format of an HTTP request query parameter set, but without a leading ampersand (the menu feed provider prepends an ampersand). If there are multiple query parameters, insert an ampersand between each parameter after the first. Example: `foo=bar&foo2=bar2&...`	Optional for a Submenu, but only applicable for a Submenu. If present with a moduleId, then the URI built by the menu feed provider for the Submenu entry in the feed looks like `{"type" : "Submenu", "id" : "moduleRef:`*`moduleId_value`*`&`*`moduleArgs_value`*`", ... }`. If present with an ID in the Submenu, the URI looks like the previous example but without the `moduleRef:` prefix for the ID and arguments.

Member name	Value and example syntax	Comments
`markupId`	Arbitrary string, used to create an ID in the html tag that defines the menu item.	Optional. Useful only for `DynamicMenuItem` and `StaticMenuItem` menu entries. Variable substitution is supported for this item, so the `${windowID}` can be used to make unique instances of an ID for each portlet when rendered.

Writing a menu definition file for a modularized theme

You can write a new menu definition file for a new theme by using the server-side feed provider and client-side JavaScript. If the ready-to-use sample theme is copied and altered into a new customized theme, the same JSON menu files can be used, or can be altered as necessary. If any new client-side functions are referenced from menu items, then these new JavaScript features must be created and referenced.

The JSON menu feed provider looks for the JSON menu definition files in a `menuDefinitions` directory in the theme root in WebDAV.

Use the existing menu definitions files as samples, and use tools such as jsonlint to prevalidate the JSON syntax.

The JSON syntax is restrictive for menu definition files except that comments are allowed.

When you are debugging, use the trace string `com.ibm.wps.jsonmenu.*=all` on the server.

Dynamically extended and dynamically constructed menus

Starting with WebSphere Portal 8.0.0.1, it is possible to have menu items added dynamically to a menu definition file. This feature can be used to extend an existing "static" menu definition file, such as the files that exist in the sample theme within the `menuDefinitions` folder in WebDAV. It can also be used to dynamically construct a menu without a static menu file that exists at all.

Recall that in the request URI for a menu, the query parameter starts with `"?uri=menu:`*`menu name`*`"`. This menu name is treated as a file name by the menu framework, and we search for the file in the "base location" for resources for that theme as given by the theme metadata property `com.ibm.portal.theme.template.ref`. Within the menu definition, an entry of `"type":"ModuleRef"` can reference a theme optimization module, which contains a `menu` contribution, and within that a JSON subcontribution. This JSON subcontribution has a URL, which points to the actual JSON code. The JSON retrieved from that subcontribution URL is substituted into the menu feed in place of the `"type":"ModuleRef"` entry from the file.

Starting with WebSphere Portal 8.0.0.1, this JSON subcontribution can also be tagged with a `ref-id` qualifier. The value of this qualifier is a String. At the end of processing the menu definition file, the menu framework adds one more step. It searches through all the JSON subcontributions that are found in theme modules from the profile for the current page, where the page is given by the **`navID`** parameter on the menu request. If any of the `ref-id` tags from those subcontributions match the requested menu name that is being processed, then the

JSON code for those subcontributions is dynamically added to the end of the menu feed, exactly as though there were an entry `"type":"ModuleRef"` that specifically pointed to that module.

This menu framework allows for dynamic extension of the menu contents with new menu items by creating new theme modules, or at least new subcontributions, and updating the profile, rather than having to update the menu definitions files.

In addition, this feature can be used to dynamically construct a menu without creating a menu definition file at all. If the incoming menu request contains a menu name that does not exist, the menu framework now treats that as though it pointed at a menu definition file with only the minimum menu syntax for an empty array, `"[ ]"`. The menu is then created by using only the JSON subcontributions from the modules that are named in the profile for the current page where the `ref-id` qualifier matches the requested menu name, even though it names a file that does not exist.

Important: The order of the items that are dynamically added to a menu is not controlled or guaranteed in any way. Although in testing the order was consistent between server restarts on the same system, it was found to be inconsistent across different operating systems. Especially between IBM JVMs and those not from IBM. If it is necessary to strictly control the order of the menu items, then use the explicit `"type":"ModuleRef"` entry in a menu definition file to explicitly insert the menu item, rather than relying on the dynamic contribution mechanism.

For more information about constructing theme optimization modules that include the JSON subcontribution, see Adding a menu item with a module.

Controlling the cache lifetime of a JSON menu feed

In WebSphere Portal Express version 8.0.0.1 and later, the JSON menu framework accepts one or more WP ConfigService properties of the form `"jsonmenu.cache.time.<menu name>"` where the value is the cache time in seconds. This value must be greater than or equal to 0. A value of `0` indicates that the menu is not cached.

The `<menu name>` values from these WP ConfigService settings are matched against the value from the `"?uri=menu:<menu name>"` query parameter on the incoming request for a menu. The comparison of the menu names from the WP ConfigService to the received request for a menu is case-sensitive.

JSON home page

Changing menu item visibility:

Whether the menu items are visible is controlled in a layered way by client-side JavaScript and markup. The default value for visibility, if not specified, is Boolean true.

Procedure

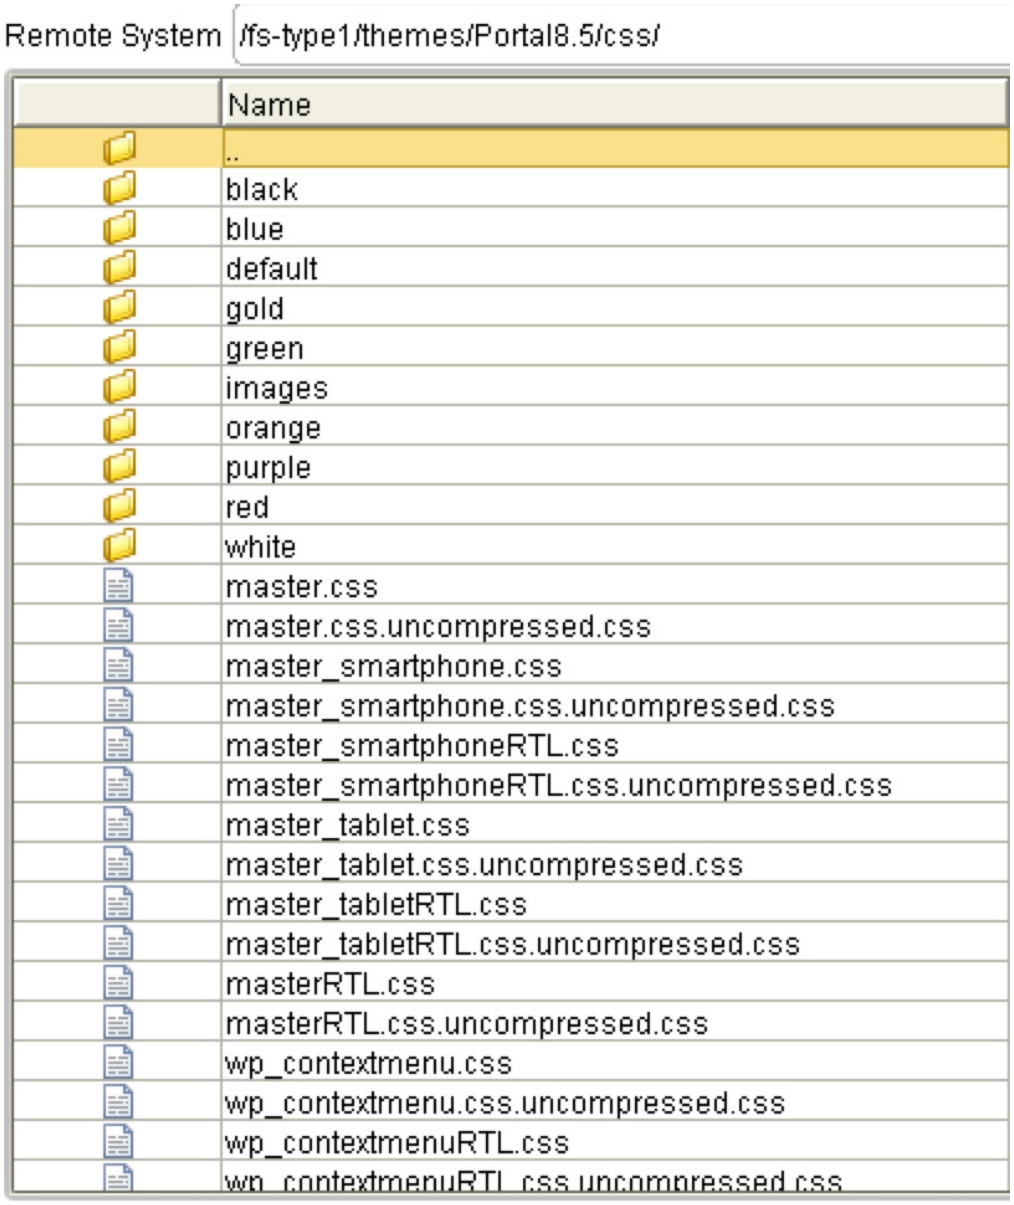
1. In the menu feed from the server is a default value whether a menu item is visible. The client-side code controls whether a menu item is visible in the feed. If a menu item includes a visibilityFn member, that function is invoked client-side to control the visibility.

2. Mark a menu item with a visibility boolean member, in the case where the server-side feed provider code has reached the conclusion that the menu item should not be visible to the client ("visibility" : false). The "visibility" : false member is added to the menu feed when a DynamicMenuitem references a plug-in whose isActive() method returns false when invoked by the menu feed provider code. The isActive() method on a plug-in can return false if, for example, the user does not currently have access control permissions sufficient to invoke the operation on the current page or portlet or other object, or if operation is inconsistent with the current state of the object (if known).

Menu styles:

You can vary the appearance of the items in menus that are delivered through the JSON menu framework.

The appearance of the items in the menus that are rendered by the JSON menu framework are determined by style names that open on the rendered markup for the menu items. These styles are defined in Cascading Style Sheet (CSS) files that are part of the theme. The default theme has these style sheets in WebDAV in the `themes/Portal8.5/css` directory.



There are two ways that the appearance of the menu items can be changed.

- Keep the same style names but change the definition of the named styles in the css files.
- Change the style names that are applied to the menu items and provide definitions and implementations of the new styles.

The first method keeps the same style names on the menu items, but redefine what appearance results from that style. When you creat your custom theme, take copies of the existing default theme css files as samples and alter them to achieve the appearance you want.

For the second approach, the **JSON** menu definition syntax allows the specification of a style name on the menu items, including headers and separators, using the itemClass member in a menu item definition. By adding explicit entries for the style names on the menu items, those overriding style names are used in the resulting menu markup. The itemClass member is only useful on menu items of

type StaticMenuItem, DynamicMenuItem, Header, Separator, and SubMenu. On a SubMenu, the style is applied only to the SubMenu entry `anchor link` itself, and not to the menu items that actually make up that SubMenu.

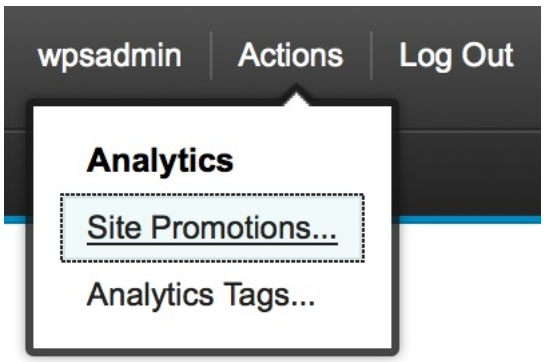
These CSS files define the menus.

`contextmenuCommon.css`
Contains common styles are valid for left-to-right (LTR) and right-to-left (RTL) structured pages.

`contextmenu.css`
The menu styles that are used on LTR structured pages.

`contextmenuRTL.css`
The menu styles that are used on RTL structured pages.

Default menu styles



Style class definitions

wpthemeMenuShow
By default all menus are hidden. This class is used to control visibility. If set on the node the menu is made visible.

wpthemeMenuLeft
Defines a menu that is left-oriented and opens to the right.

wpthemeMenuRight
Defines a menu that is right-oriented and opens to the left.

wpthemeMenuBorder
Defines the main `div` that shows the border and contains all menu items.

wpthemeMenuNotchBorder
Defines the arrow that points to the button that opened the menu.

wpthemeMenuDropDown
Inner element within the menu that contains a list of menu items.

wpthemeMenuitem
Describes a single menu item.

wpthemeMenuDisabled
Describes a disabled menu item.

wpthemeMenuLoading
Describes the text that is displayed when the data is being loaded.

wpthemeAnchorSubmenu
Used to register the submenu within the markup.

wpthemeTemplateMenu
Defines the template for an individual menu item.

wpthemeTemplateLoading
Defines the template for the loading text.

wpthemeTemplateSubmenu
Defines the template for the submenu.

wpthemeMenuError
Used for display when an error occurs.

The menu JavaScript is in `dav:fs-type1/themes/Portal8.5/js/contextmenu.js`.

The `wptheme.contextmenu.css` JSON object defines constants that are used to apply CSS classes. The constants are by default that is set to:

```
contextMenu: {
...
css: {
disabled: "wpthemeMenuDisabled",
show: "wpthemeMenuShow",
error: "wpthemeMenuError",
menuTemplate: "wpthemeTemplateMenu",
submenuTemplate: "wpthemeTemplateSubmenu",
loadingTemplate: "wpthemeTemplateLoading"
},
....
}
```

Adding a link to the resource permissions administration portlet in a menu

You can add a link to the resource permissions portlet to see or modify role types or inherited access.

About this task

To view or modify role types or inherited access, you must use the **Resource Permissions** portlet. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**.

Procedure

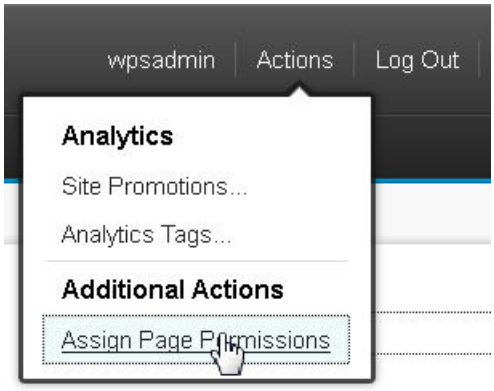
1. Connect your WebDAV client, to `http://`*`host`*`:`*`port`*`/wps/mycontenthandler/dav/fs-type1/`.
2. Go to `/themes/`*`YourCustomTheme`*`/menuDefinitions` and open the menu file to which you want to add the new permissions entry. By default, the `pageAction.json` file corresponds to the **Actions** menu.
3. Add this menu entry to the JSON array: If you make this the last entry, add a comma before the following example.

```
{
   "type":"DynamicMenuitem",
   "id":"ibm.portal.operations.assignPagePermissions",
   "titles": [
      {
         "value":"Assign Page Permissions",
         "lang":"en"
      }
   ]
}
```

4. Restart the server to apply your changes.

Results

The following screen shot shows the modified **Actions** menu. The link in the menu opens a resource page permissions portlet that affects the page that the user is currently viewing.



Theme templates (`theme.html`)

You can use static HTML to write portal themes. The static theme template is named `theme.html`.

A `theme.html` file is in the root directory of the theme on WebDAV `\fs-type1\themes\`*`theme-name`*`\`, and there are `theme.html` files in the `nls` directory under the theme `\fs-type1\themes\`*`theme-name`*`\nls\`. The `theme.html` includes the full HTML structure of the page, including `<html>`, `<head>`, and `<body>` sections. It can include both static and dynamic content.

Notes:

- The folder `nls` contains a file that is named `theme.html` without a locale that is associated with it. This file is not used. You can ignore it.
- Remember to modify the theme template files by using the WebDAV entry point `fs-type1`. When you use this entry point, your changes to the theme template are immediately reflected upon a browser refresh.

Root theme template

In a default WebSphere Portal Express installation, the portal does not render the template file `theme.html` in the root directory of the theme. Instead, this file links to the templates, and the portal renders the appropriate template. The links to the templates are in the `<head>` section of the root template. They have the following form:

```
<link rel="alternate" href="nls/theme_locale_code.html" hreflang="locale_code">
```

An example of a link to the English template file is as follows:

```
<link rel="alternate" href="nls/theme_en.html" hreflang="en">
```

If you do not want to use theme templates, you can remove these links from the `theme.html` template in the root directory. If you do this, the portal renders this root template.

This theme template also includes Apache Ant scripting in the following form:

```
${bundle_name:bundle_key:character_encoding}
```

The `character encoding` replaces special characters with the escape sequence determined by the specified encoding. The available types of encoding are `xml` or `json`. You can chain multiple instances of encoding as follows:

`${bundle:key:json:xml} or ${bundle:key:xml:json}`

You can use the Apache Ant build framework to generate templates that are based on this root template. This can be useful if you want to update one template during development and then generate the templates by using the Ant build process. If you want to use only the root template, replace the Ant scripting with the preferred text that you want to be rendered. You can learn more about the Ant build tool at Apache Ant.

Theme templates

In a default WebSphere Portal Express installation, the theme architecture renders content by using the theme templates. These templates are in the `nls` subdirectory under the theme directory on WebDAV. These files have the locale code that is appended to the end of the template name, for example `theme_en.html` for English. These templates translate static text inline within the template.

When you use the theme templates and want to view your changes, update the template that the portal renders in the browser. For example, if your preferred language is English, update the file `theme_en.html`.

Adding static content to the `theme.html`

You can add static content to the `theme.html` in the following ways:

Adding content directly:
You can add static content, such as HTML markup and images directly to the file `theme.html`.

Adding content from WebDAV:
You can add content that is in WebDAV relative to the `theme.html` file with a relative URL reference.

Adding content by relative URLs:
You can use relative URLs to reference static content in the `/common-resources/` folder in the WebDAV file store. If the relative path does not successfully resolve to a file within the theme folder, the portal uses the folder `/common-resources/` as a fallback location to locate the resource. This way the theme can reference common resources and still preserve the ability to override a file in that folder with a resource of the same name in the theme folder.

Adding server-side dynamic content to the `theme.html`

Dynamic content changes per user, or per page, or per some other server state. Therefore, you cannot define it statically in the theme file. Instead, you insert it into the response at run time. To do this, you edit the `theme.html` and identify these dynamic content spots. Then at run time, a server-side theme parser identifies and resolves dynamic content spots, and streams their output into the final response to the browser.

The format of a dynamic content spot is as follows:

```
<a rel="dynamic-content" href="{path to dynamiccontent}"></a>
```

rel="dynamic-content"
The theme template parser recognizes the element `rel="dynamic-content"`. It resolves the `href` attribute and inserts its output into the response.

href The `href` can point to any URI that is resolved by the resource addressability framework.

Examples:

1. The following example is a special content spot that renders the referenced layout template and content of the current page:
   ```
   <a rel="dynamic-content" href="lm:template"></a>
   ```
2. The following example includes a dynamic content spot from the mapping that is specified through the module `dyn-cs` contribution type, in the `WP_DynamicContentSpotMappings` Resource Environment Provider or theme metadata.
   ```
   <a rel="dynamic-content" href="dyn-cs:customSpot"></a>
   ```
3. The following example includes the output of a theme JSP with a resolver POC URL:
   ```
   <a rel="dynamic-content" href="res:/customContext/themes/html/customTheme/customSpot.jsp"></a>
   ```

Changing the theme template location

You can change the location of the theme template. For this purpose, the theme contains a metadata parameter that stores the location of the theme template `theme.html`. The parameter name is `com.ibm.portal.theme.template.ref`. If required, you can point it to an external location. For example, you can specify a POC URI or the URL to an external server. You do not need to store the theme template on WebDAV. In a default portal installation, the metadata parameter for the theme is as follows:

```
<parameter name="com.ibm.portal.theme.template.ref" type="string" update="set">
<![CDATA[dav:fs-type1/themes/theme_folder/]]>
</parameter>
```

"Setting Inherited Theme Templates"
You can set a theme template to be used on a page and it automatically sets the template for all child pages that are associated with that page. The inherited metadata can be used when you want every page under a specific page to have the same theme template.

"Renaming Theme Templates" on page 2709
You can rename the default filename of the theme template from `theme.html`. In the ready-to-use theme renaming the `theme.html` file is used to provide a different theme view for the administrative pages.

Setting Inherited Theme Templates:

You can set a theme template to be used on a page and it automatically sets the template for all child pages that are associated with that page. The inherited metadata can be used when you want every page under a specific page to have the same theme template.

About this task

This inheritance is introduced through a new metadata key which is added to a page. The new metadata is
`com.ibm.portal.theme.inherited.template.file.name.html=`*`myfile`*`.html`.

Note: The *myfile*.html file, which corresponds to the theme template that you are setting, must already be in WebDAV in the directory /mycontenthandler/fs-type1/themes/Portal8.5/.

You can set the theme template by using WebDAV or managed pages. After your custom theme template is set, you can see it displayed on the page and all child pages corresponding to that parent page.

Procedure

1. Set the theme template through the **Edit Page Properties** dialog from the **Overview** tab.
   a. Go to the page where you would like to set the new metadata.
   b. Click **Edit Mode**.
   c. In the **Overview** section, hover over the name of the page and click the **Edit**.
   d. Click the **Advanced** tab and enter the following information in the **Metadata** section:

      Key com.ibm.portal.theme.inherited.template.file.name.html.

      Value Enter the HTML file name that corresponds to the theme template you are trying to set.
   e. Click **Add** to set the new metadata for the page.
   f. Click **Save**.
2. Set the theme template from the managed pages administrative portlet.
   a. In the IBM WebSphere Portal Express administrative section, click the **Manage Pages** tab and go to the page where you want to set the metadata.
   b. Select the **Edit Page Properties** option for the page you want to edit.
   c. In **Advanced options**, select **I want to set parameters** and enter the following information:

      New parameter
      com.ibm.portal.theme.inherited.template.file.name.html.

      New value
      Enter the HTML file name that corresponds to the theme template you are trying to set.
   d. Click **Add** to set the new metadata for the page.
   e. Click **Save**.

Renaming Theme Templates:

You can rename the default filename of the theme template from theme.html. In the ready-to-use theme renaming the theme.html file is used to provide a different theme view for the administrative pages.

About this task

This change can be done selectively for individual pages by setting a page metadata called com.ibm.portal.theme.template.file.name.html. This setting is not inherited along the navigation hierarchy.

To set the theme template on a page, you must use the XML configuration interface (XMLAccess).

Procedure

1. Export the page by using XMLAccess or by following the instructions in Exporting pages and labels.
2. Edit the resulting XML file and add the following parameter to the content-node, replacing `my_theme.html` with your theme template file name.

   ```
   <parameter name="com.ibm.portal.theme.template.file.name.html" type="string" update="set"><![CDAT
   ```
3. Save the XML file.
4. Import the page using XMLAccess or the Import XML portlet.

Changing the theme logo

You can change the theme logo to customize your portal site and rebrand it to reflect your business.

About this task

The default logo that appears in the banner is a blank placeholder image. The following block of code displays the blank placeholder image:

```
<span class="wpthemeBranding">
     <img alt="IBM Logo" src="/wps/themeModules/themes/html/dynamicSpots/icons/blank.gif">
     <span class="wpthemeAltText">IBM Logo</span>
</span>
```

This logo is provided to the theme with a CSS style class so it can be modified or overridden by packaged styles on the customization shelf. It also updates as new styles are selected. You do not have to modify the theme template.

You can change the theme logo in `.wpthemeLogo in fs-type1:themes\ Your_custom_theme \css\default\default_view.css and fs-type1:themes\ Your_custom_theme \css\default\default_view.css.uncompressed.css`:

Procedure

1. Remove the **display** attribute from the style class.
2. Define a new path to your image for the **background-image** attribute.
3. Modify the height and width.

You can also change your header text to display your logo next to the navigation.

4. Apply the **white** style on the customization shelf.
5. In `fs-type1:themes\Your_custom_theme\nls\theme_locale.html`, enter the following block of code, where *IBM WebSphere Portal* is the name of your portal site:

   ```
   <div class="wpthemeLogo wpthemeLeft">
        <span class="wpthemeAltText">IBM WebSphere Portal</span>
   </div>
   ```

   Note: There is no HTML image element to display the logo. It is provided to the theme through a CSS style class just like the first area of branding. You do not have to modify the theme template.

What to do next

You can also create your own custom style to use with your custom theme defined in `fs-type1:themes\Your_custom_theme\system\styles.json`. If you do that, you can override these styles in the custom style css file, such as `fs-type1:themes\ Your_custom_theme \css\Your_custom_style \Your_custom_style .css`.

"Changing the logo action"
You can change the default action of a logo to take users to different pages in your portal.

Changing the logo action:

You can change the default action of a logo to take users to different pages in your portal.

The default logo action takes users to your portal home page. The logo can complete three other actions:

- The logo can take users to the first child page.
- The logo can take users to another portal page with the unique ID of that page.
- The logo can take users to another portal page with the vanity URL of that page.

Taking users to the first child page

Remove the default code and replace it with the following code :

```
<%-- Logo --%>
 <li>
  <span class="wpthemeBranding">
  <portal-core:lazy-set var="showHiddenPages" elExpression=="wp.publicRenderParam['{http:/
  <portal-logic:if deviceClass="smartphone/tablet">
   <c:set var="isMobile" value="true"/>
  </portal-logic:if>
     <c:set var="homeNodeFound" value="false"/>
  <c:forEach var="node" items="${wp.navigationModel.children[selectionPath[1]]}" varStatus
         <c:set var="isHiddenPage" value="${node.metadata['com.ibm.portal.Hidden'] || (is
         <c:if test="${!homeNodeFound && (!isHiddenPage || showHiddenPages)}">
   <c:set var="nodeID" value="${wp.identification[node]}"/>
           <a class="wpthemeBrandingLink" href="?uri=nm:oid:${nodeID}" alt="<portal-fmt:o
   <img src="
      </a>
      <span class="wpthemeAltText"><portal-fmt:text key="theme.ibmLogo" bundle="nls.commor
         <c:set var="homeNodeFound" value="true"/>
    </c:if>
  </c:forEach>
  </span>
 </li>
```

Taking users to another portal page with its unique ID

Remove the following line of default code:

```
<a class="wpthemeBrandingLink" href="?uri=nm:oid:${nodeID}" alt="<portal-fmt:out>${node.ti
```

Replace it with the following code snippet, where the value of *contentNode* is replaced with the unique name of the page:

```
<portal-navigation:urlGeneration contentNode="ibm.portal.Home.Welcome" >
           <a class="wpthemeBrandingLink" href="<% wpsURL.write(escapeXmlWriter); %>" alt
   </portal-navigation:urlGeneration>
```

Taking users to another portal page with its vanity URL

Remove the following line of default code:

```
<a class="wpthemeBrandingLink" href="?uri=nm:oid:${nodeID}" alt="<portal-fmt:out>${node.ti
```

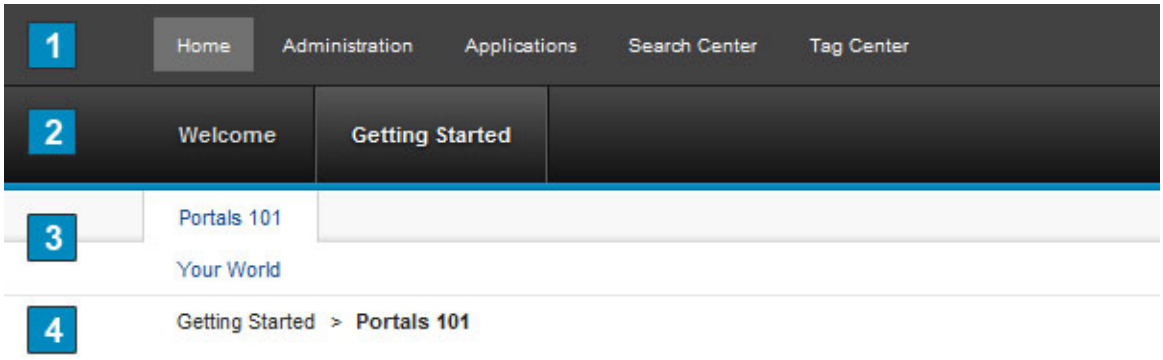
Replace it with the following code snippet, where *host*, *port*, and *contextroot* are substituted with your actual values and where *Home* is replaced with the vanity URL of your page:

```
<a class="wpthemeBrandingLink" href="http://host:port/contextroot/vanityurl/Home" alt="">
```

Customizing navigation

Use dynamic content spots to determine what is displayed by Top, Primary, and Secondary navigation. Use the `navigation.jsp` file to map properties to the dynamic content spot IDs in the `theme.html` files. Rendering of the navigation is done with a single JSP file with `<ul>` and `<li>` tags.

These are the levels of navigation that is provided in a theme:



Top - Item 1

Displays links for the pages directly under Content Root, such as Home, Administration, and Applications. Use the `dyn-cs:id:85theme_topNav` to display Top navigation:

```
<div class="wpthemeHeader">
   ...
   <a rel="dynamic-content" href="dyn-cs:id:85theme_topNav"></a>
   ...
</div>
```

Primary - Item 2

Displays links to the child pages of the currently selected top page, such as Getting Started and Features for Home. Use the `dyn-cs:id:85theme_primaryNav` to display Primary navigation:

```
<div class="wpthemeBanner">
   ...
   <a rel="dynamic-content" href="dyn-cs:id:85theme_primaryNav"></a>
   ...
</div>
```

Secondary - Item 3

Displays links to the child pages of the currently selected primary page. Use the `dyn-cs:id:85theme_secondaryNav` to display Primary navigation:

```
<div class="wpthemeSecondaryBanner">
   ...
   <a rel="dynamic-content" href="dyn-cs:id:85theme_secondaryNav"></a>
   ...
</div>
```

Breadcrumb - Item 4

Displays the position of the current web page within the website and the logical path back to the highest level of the site framework. The breadcrumb trail starts at the content root and goes down to the currently selected static page.

Side Displays links for the child and grandchild pages of the currently selected top page. By default, this template is applied to the Administration section of your portal.

```
<div class="wpthemeSideNavigation wpthemeLeft" role="navigation">
   ...
   <a rel="dynamic-content" href="dyn-cs:id:85theme_sideNav"></a>
   ...
</div>
```

Mobile

Displays links for the child and grandchild pages of the currently selected top page, on mobile devices only, such as smartphones and tablets. CF06 Each level of navigation is lazily loaded onto the page as the user clicks.

```
<div class="wpthemeBanner">
      ...
      <a rel="dynamic-content" href="dyn-cs:id:85theme_mobileNav"></a>
      ...
</div>
```

CF06 To turn off lazy loading of mobile navigation, replace the 85theme_mobileNav dynamic content spot with the 85theme_mobileNav_static dynamic content spot. CF06

```
<div class="wpthemeBanner">      ...
          <a rel="dynamic-content"
    href="dyn-cs:id:85theme_mobileNav_static"></a>            ...
    </div>
```

Navigation content spots

The content spot IDs map to **wp_dynamicContentSpots_85** module subcontributions in the *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\WEB-INF\plugin.xml file.

Table 445. Content spot property names.

Name	Value
85theme_topNav	mvc:smartphone/tablet@res:{war:context-root}/themes/html/dynamicSpots/navigation.jsp?type=top
85theme_primaryNav	mvc:res:{war:context-root}/themes/html/dynamicSpots/navigation.jsp?type=primary,smartphone@,tablet@
85theme_secondaryNav	mvc:res:{war:context-root}/themes/html/dynamicSpots/navigation.jsp?type=secondary,smartphone@,tablet@
85theme_sideNav	mvc:res:{war:context-root}/themes/html/dynamicSpots/sideNavigation.jsp?startLevel=2,smartphone@,tablet@
85theme_mobileNav	mvc:smartphone/tablet@res:{war:context-root}/themes/htm CF06 mvc:smartphone/tablet@res:{war:context-root}/themes

The subcontribution URI value indicates which JSP is loaded in the spot. For the three horizontal navigation spots, the same navigation.jsp file is used with a different parameter passed to the JSP. The navigation.jsp file is in the *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes\html\dynamicSpots folder. The parameter is a key of type with three possible values:

top Causes the navigation JSP to render the top navigation, starting at level 0 in the page navigation, which is the highest level.

primary
Causes the navigation JSP to render the primary navigation, starting at level 1 in the page navigation.

secondary
Causes the navigation JSP to render the secondary navigation, starting at level 2 in the page navigation.

In the `theme.html` files for your theme, you can remove the default navigation dynamic content spots. You can then replace the dynamic content spots with your own mappings that point to your own jsp implementation. For example, you can replace the three top navigation levels with a single top navigation and a single side navigation.

"Creating a dynamic content spot for navigation"
Create a dynamic content spot mapping to customize the theme for Top, Primary, and Secondary navigation. Change the *yourTheme* value to the name of your theme.

"Adding a level of navigation" on page 2715
You can increase levels of navigation by adding a fourth level of navigation.

"Removing a level of navigation" on page 2715
You can reduce your levels of navigation to two levels.

"Side navigation" on page 2715
The Portal 8.5 theme includes a side navigation template that can be applied to render pages at the secondary level in a list with the main content. By default, this template is applied to the Administration section of your portal.

Creating a dynamic content spot for navigation:

Create a dynamic content spot mapping to customize the theme for Top, Primary, and Secondary navigation. Change the *yourTheme* value to the name of your theme.

Procedure

1. Optional: For primary navigation, add a subcontribution to the **wp_dynamicContentSpots_85** module in your theme's `plugin.xml` file. The `plugin.xml` file is in the *wp_profile_root*`\installedApps\`*`cell`*`\`*`YourTheme`*`.ear\`*`YourTheme`*`.war\WEB-INF` folder.
   a. Give your subcontribution the `ref-id` *`yourTheme`*`_primaryNav`, assuming you are changing the primary level.
   b. Enter the URI value `mvc:res:{war:context-root}/themes/html/dynamicSpots/navigation.jsp?type=primary,smartphone@,tablet@`. For example,

```
<sub-contribution type="markup" ref-id="yourTheme_primaryNav">
<uri value="mvc:res:{war:context-root}/themes/html/dynamicSpots/navigation.jsp?type=primary,sm
</sub-contribution>
```

2. Modify the `theme.html` files for your theme and change the dynamic content spot ID for the primary navigation from `85theme_primaryNav` to *`yourTheme`*`_primaryNav`.
3. Define the *`yourTheme`*`PrimaryNav` style class in one of the `.css` files for your theme that gets loaded by one of the modules for your theme.
4. If you are in development mode, restart the application for your theme. Otherwise, restart the portal server.

Adding a level of navigation:

You can increase levels of navigation by adding a fourth level of navigation.

About this task

Note: Change the *yourTheme* value to the actual name of your theme.

Procedure

1. Add a subcontribution to the **wp_dynamicContentSpots_85** module in your theme's `plugin.xml` file. The `plugin.xml` file is in the *wp_profile_root*`\installedApps\`*cell*`\`*YourTheme*`.ear\`*YourTheme*`.war\WEB-INF` folder.
   a. Give your subcontribution the `ref-id` *yourTheme*`_tertiaryNav`.
   b. Enter the URI value `mvc:res:{war:context-root}/themes/html/dynamicSpots/navigation.jsp?type=tertiary,smartphone@,tablet@`.

   ```
   <sub-contribution type="markup" ref-id="yourTheme_tertiaryNav">
   <uri value="mvc:res:{war:context-root}/themes/html/dynamicSpots/navigation.jsp?type=tertiar
   </sub-contribution>
   ```
2. Modify the `theme.html` files for your theme and add a fourth, or tertiary, navigation dynamic content spot under the third, or secondary, navigation dynamic content spot, which is under the secondary banner block:

   ```
   <a rel="dynamic-content" href="dyn-cs:id:yourTheme_tertiaryNav"></a>
   ```
3. Define the *yourTheme*`TertiaryNav` style class in one of the CSS files for your theme that gets loaded by one of the modules for your theme.
4. If you are in development mode, restart the web application for your theme. Otherwise, restart the portal server.

Removing a level of navigation:

You can reduce your levels of navigation to two levels.

Procedure

Modify the `theme.html` files for your theme and delete the tertiary, or secondary, dynamic content spot:

```
<a rel="dynamic-content" href="dyn-cs:id:85theme_secondaryNav"></a>
```

Side navigation:

The Portal 8.5 theme includes a side navigation template that can be applied to render pages at the secondary level in a list with the main content. By default, this template is applied to the Administration section of your portal.

The side navigation is composed of three parts:

Theme template
The theme template includes the markup required to render a dynamic content spot next to the main content and sets a class on the body element that can be used to scope styles to this template.

Location of localized templates: `dav:fs-type1\themes\Portal8.5\nls\sidenav\theme_sidenav.html`

Dynamic Content Spot
The dynamic content spot recursively loops over the navigation hierarchy to render the pages. The dynamic content spot is a JSP that uses expression

logic to access the navigation and provides easy to read code. You can customize the start level parameter of the dynamic content spot to render different sets of pages.

Location: *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes\html\dynamicSpots\sideNavigation.jsp

Styles The CSS is built into the theme master layer and out of box customizations were not included for each style. The default style is applied to the Administration pages.

Location of uncompressed files:

dav:fs-type1\themes\Portal8.5\css\default\sidenav.css

dav:fs-type1\themes\Portal8.5\css\default\sidenavRTL.css

Location of compressed files:

dav:fs-type1\themes\Portal8.5\css\master.css

dav:fs-type1\themes\Portal8.5\css\masterRTL.css

"Set side navigation for a page"
You can set the side navigation template for a specific page.

"Set side navigation as theme default"
You can set the side navigation template as the theme default by changing the ready-to-use template to become the default theme.html.

"Customizing side navigation" on page 2717
You can customize your side navigation by scoping styles specifically to the side navigation template or changing the width of the side navigation area or main content area.

Set side navigation for a page:

You can set the side navigation template for a specific page.

Procedure

1. Log on to your portal.
2. Export the page where you want to apply the side navigation template.

   Note: You can export the page using XMLAccess or by using the Manage Pages portlet.
3. Add the page metadata key com.ibm.portal.theme.template.file.name.html with a value <![CDATA[theme_sidenav.html]]> to the exported XML file. For example:

```
<content-node action="update" content-parentref="wp.example.parent" active="true" objectid="wp.example.id" uniquename="wp.example">
  ...
  <parameter name="com.ibm.portal.theme.template.file.name.html" type="string" update="set"><![CDATA[theme_sidenav.html]]></parameter>
  ...
</content-node>
```

4. Save the new page XML file.
5. Import the XML file using the command line or the Import XML portlet.
6. You can now navigate to the page and it is now rendered as a side navigation.

Set side navigation as theme default:

You can set the side navigation template as the theme default by changing the ready-to-use template to become the default theme.html.

Procedure

1. Connect to the file store WebDAV entry point: http://<server>:<port>/wps/mycontenthandler/dav/fs-type1/
2. Navigate to the theme folder with the current default theme template, for example `dav:fs-type1/themes/Portal8.5/`.
3. You can rename the current `theme.html` to something else or you can delete it.
4. Navigate to the theme folder with the side navigation theme template, most likely the same folder as the old default `theme.html` file.
5. Rename the side navigation template from `theme_sidenav.html` to `theme.html`.

Results

After renaming the template to theme.html, it will now be used as the default template. Inside the `theme.html` file are links to the localized templates, which are named `theme_sidenav_`*`locale`*`.html`. There is no need to rename these templates, but if you want to make the template naming uniform, you can change the link elements as well as the localized template file names.

Customizing side navigation:

You can customize your side navigation by scoping styles specifically to the side navigation template or changing the width of the side navigation area or main content area.

Scoping styles to the side navigation template

You can scope styles specifically to the side navigation template so you do not need to include different styles between templates. By default, the template applies the CSS class wpthemeSplitView to the HTML body element. This class can be used in the CSS to scope styles and is demonstrated in the `sideNav.css`.

Example:

```
.wpthemeSplitView .someStyle { color: #000; }
```

This style demonstrates that it applies only to the element with someStyle class when the side navigation template is applied.

Change the width of the navigation and main content

You can change the width of the side navigation area or main content area by modifying the styles. The applicable styles are:

```
.wpthemeSplitView .wpthemeFrame {
min-width: 1225px;
}

.wpthemeSplitView .wpthemeMainContent > div {
width: 1135px;
}

.wpthemeSplitView .wpthemeLayoutContainers {
width: 850px;
}

.wpthemeSideNavigation {
width: 275px;
margin: 10px 10px 10px 0;
}
```

Change the layout container width

The ready-to-use layout templates have specific side navigation styles applied. If you change the width of the main content, you need to adapt the layouts. These styles are also in the `sideNav.css` file. The applicable styles are:

```
.wpthemeSplitView .wptheme1Col .wpthemeCol {width:850px;}
.wpthemeSplitView .wptheme2Col .wpthemeCol {width:400px;}
.wpthemeSplitView .wptheme3Col .wpthemeCol {width:260px;}
.wpthemeSplitView .wptheme2Col.wpthemeUnequal .wpthemePrimaryContainer {width:545px;}
.wpthemeSplitView .wptheme2Col.wpthemeUnequal .wpthemeSecondaryContainer {width:260px;}
.wpthemeSplitView .wptheme3Col.wpthemeUnequal .wpthemePrimaryContainer {width:434px;}
.wpthemeSplitView .wptheme3Col.wpthemeUnequal .wpthemeSecondaryContainer,
.wpthemeSplitView .wptheme3Col.wpthemeUnequal .wpthemeTertiaryContainer {width:175px;}
.wpthemeSplitView .wpthemeTopCol .wpthemeHeadlineContainer {width: 830px; margin-right: 15px; margin-bottom: 20px;}
.wpthemeSplitView .wpthemeRow {margin: 0 0 20px 20px;}
.wpthemeSplitView #layoutContainers .layoutRow .layoutColumn .component-control { width: 850px; }
```

Styles

The WebSphere Portal Express Version 8.5 provides a selection of ready-use styles that you can be applied to your portal pages. You can also modify the existing theme styles or add your own custom style to achieve the look that you want.

"Creating a theme style"
You can add your own custom style to the theme that can be selected on the site toolbar.

"Updating your custom style" on page 2719
After you create a theme style, use this procedure to apply a customized look and feel to the theme.

"Applying alternate styles" on page 2722
You can apply alternate styles to your portal pages using the IBM WebSphere Portal Express theme that you can apply to your portal pages.

Creating a theme style:

You can add your own custom style to the theme that can be selected on the site toolbar.

About this task

To add your own custom style to the theme, create a Cascading Style Sheet (CSS) file in WebDAV. This new file includes CSS class definitions that override the ones that are provided by the default CSS layer, which is located here: `dav:fs-type1/themes/Portal8.5/css/master.css`.

The ready-use alternate styles can be used as guide while creating your own alternate files in folders as peers to the default CSS layer. The alternate styles can be found at this location: `dav:fs-type1/themes/Portal8.5/css/`.

These steps add a new style to the Styles tab of the site toolbar.

Procedure

1. On your local system, create a folder and place a new CSS file in it that includes the class overrides for the alternate style. For example, `./custom/custom.css`.
2. Connect to the `fs-type1` WebDAV entry point, http://*server:port*/wps/mycontenthandler/dav/fs-type1/.
3. Copy the new folder to this location in WebDAV: `dav:fs-type1/themes/Portal8.5/css/`.

4. Open the file in WebDAV at `dav:fs-type1/themes/Portal8.5/system/styles.json`.
5. Register the style by adding an entry to the items array in the following format:

```
      {'label':'display_name_for_the_style',
   'id':'unique_name_for_style',
'url':'path_to_the_stylesheet_relative_to_theme_folder_in_webdav',
'thumbnail':'path_to_the_thumbnail_image',
'help':'short_description_for_the_style'}
```

   The following code is an example of the items array:

```
      {'label':'change_style_white',
   'id':'white.css',
'url':'css/white/white.css',
'thumbnail':ibmCfg.themeConfig.themeRootURI+'/css/white/icon.gif',
'help':'The white style.'}
```

   The display name shows in the site toolbar. Make the path relative to the folder in WebDAV. The JSON object in the file `styles.json` contains two attributes that are used for globalizing the style display strings `localizationPackageName` and `localizationBundleName`. These objects are used by the `dojo.i18n` file to provide localized strings by creating bundles with `dojo.i18n.getLocalization("localizationPackageName", "localizationBundleName")`. If you choose to globalize the display name of your new style, add a key to the bundle and replace the label value in the JSON with the key name. The site toolbar automatically looks up the display name in the bundle using the key.

Updating your custom style:

After you create a theme style, use this procedure to apply a customized look and feel to the theme.

About this task

Do not edit the IBM WebSphere Portal Express 8.5 theme CSS style sheets directly, because these changes might be lost during a fix pack upgrade. Instead, create the CSS class in a new style sheet belonging to your custom theme.

Procedure

1. Apply the custom style to a page.
   a. On the page that you want to apply the style, turn on **Edit Mode**.
   b. Click the **Page** > **Styles** on the toolbar.
   c. Click the custom style.
2. Write the new styles.
   a. Open a portal page that has your theme and custom style applied.
   b. Use a tool, like Firebug, to select and inspect the style rules that you want to change.
   c. After determining the styles that you want to override in the theme, copy the overrides to the custom style sheet on WebDAV.
3. Apply the custom style sheet to your entire page structure.
   a. Figure out the root page for the area on which you want to apply the custom style. To apply to the entire site, select the **Content Root**.
   b. Add metadata on the root page with a key of `colorPalette` and a value pointing to your custom style sheet in relation to the theme directory on WebDAV. For example: `css/custom/custom.css`.

4. Using Firebug to inspect the CSS file.
   a. Open the Firebug plug-in in a Mozilla Firefox browser.
   b. Click the element selection icon  in the Firebug menu bar.
   c. Click the area on the page that you want to change.
   d. Check that the correct area is selected in the HTML tab. 

   e. Look at the **Style** tab to inspect all the CSS files that are applied to the HTML element. 
   f. Edit the CSS file in the **Style** tab until the HTML element looks how you want it to. To edit an attribute click the text.
   
   g. After you determine that the new value applied has the appearance that you want, copy the CSS file that you changed in the **Style** tab into the custom style sheet.

"Style definitions"
Customize your theme with these definitions.

Related information:

Get Firebug

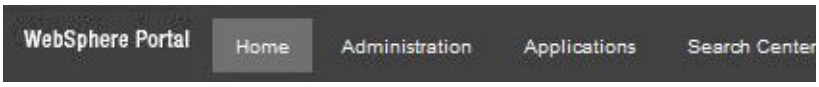
Style definitions:

Customize your theme with these definitions.

.wpthemeHeader
The container element for the theme header that by default displays the top-level navigation and page mode toggle button.

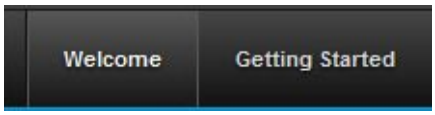
.wpthemeHeaderNav *
This style definition controls the look and feel for the top-level navigation located in the theme header.

.wpthemeLogo
This style definition controls the logo, next to the top-level navigation. By default this style is disabled.

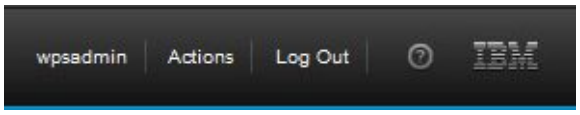


.wpthemeBanner
The container element for the theme banner that by default displays the primary navigation and common actions.

.wpthemePrimaryNav *
The style controls the look and feel for the primary level of navigation located in the theme banner.



.wpthemeCommonActions *
The style controls the look and feel for the common actions that by default displays the profile management link, actions menu, and login and logout links.



.wpthemeBanner.wpthemeBranding *
The logo displayed by default in the common actions.

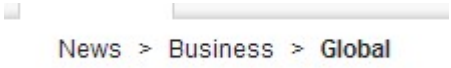
.wpthemeSecondaryBanner
The container element for the secondary banner that, by default,displays the secondary navigation and search form.

.wpthemeSecondaryNav *
The style controls the look and feel for the secondary level of navigation located in the theme banner.

.wpthemeSearch *
The style controls the look and feel for the search form.

. wpthemeMainContent
The container element for the main content of the page. By default, it displays the navigation breadcrumb trail, status bar, and layout.

.wpthemeCrumbTrail *
The style definitions with this scope control the navigation breadcrumb trail displayed before the main content.



.wpthemeFooter
The container element for the footer of the theme.

Applying alternate styles:

You can apply alternate styles to your portal pages using the IBM WebSphere Portal Express theme that you can apply to your portal pages.

Procedure

1. Log on to your portal as an administrator and select the page that you want to change the style.
2. Turn on **Edit mode**.
3. Click **Page** > **Styles** on the toolbar.
4. Select a style for your portal page. When you click a style, that style is applied to the page.

Configuring the portal theme and modules

Themes and modules are configured through theme metadata properties and resource environment provider custom properties.

"Changing theme metadata"
The first step of theme configuration is through theme metadata properties. Changes to the metadata are specific to a single theme, and the entries and values, therefore, can vary from theme to theme.

"Changing resource environment provider custom properties" on page 2723
The second order of theme configuration is through resource environment provider (REP) custom properties in the **WP GlobalThemeConfig** REP. Changes to the REP custom properties apply across all themes, and the values, therefore, cannot vary from theme to theme.

"Adding resource environment provider properties" on page 2724
Resource environment provider (REP) custom properties are global in scope, but you can use a consistent naming convention for a theme or module that applies across multiple themes.

CF06 "Configuration for resource aggregation" on page 2725
Set the following properties in the WP ConfigService Resource Environment Provider to configure the resource aggregator.

"Using your configuration properties" on page 2725
Create a JavaScript object for your theme on the client side. Theme metadata properties must be loaded dynamically. If you must load a property statically, use a resource environment provider custom property instead.

"Configuration settings for capability filters" on page 2727
Set the following properties in the **Wp ConfigService** Resource Environment Provider to enable or disable the various capability filters.

Changing theme metadata:

The first step of theme configuration is through theme metadata properties. Changes to the metadata are specific to a single theme, and the entries and values, therefore, can vary from theme to theme.

About this task

The theme metadata is located in the folder for your theme in `themelist`.

Procedure

1. Connect your WebDAV client to http://*localhost*:*port*/wps/mycontenthandler/dav/themelist/

2. From the folder for your theme, copy the `metadata.properties` file to local drive.
3. Edit the local copy of the file and modify the property values as needed according to the following table.
4. Copy the local copy of the `metadata.properties` file back into the folder for your theme in `themelist`.

Results

Table 446. Metadata properties and values.

Property	Default Value	Description
`com.ibm.portal.layout.template.href`	`dav/:fs-type1/themes/Portal8.5/layout-templates/2ColumnEqual/`	Change this value to say which layout template is used by default on pages in your theme. After initially creating your theme by cloning the IBM WebSphere Portal Express 8.5 theme, be sure to replace `Portal8.5` in the path with the name of the folder for your theme.
`resourceaggregation.profile`	`profiles/profile_deferred.json`	Change this value to say which `profile .json` file (list of modules) to load. The path value is relative to the folder for your theme in `fs-type1`.
`com.ibm.portal.theme.template.ref`	`dav/:fs-type1/themes/Portal8.5/`	Change this value to say in which folder your custom theme's templates are located. Be sure to replace `Portal8.5` with the name of your custom theme folder.

Changing resource environment provider custom properties:

The second order of theme configuration is through resource environment provider (REP) custom properties in the **`WP GlobalThemeConfig`** REP. Changes to the REP custom properties apply across all themes, and the values, therefore, cannot vary from theme to theme.

About this task

The REP custom properties are in the WebSphere Integrated Solutions Console.

Procedure

1. Access the WebSphere Integrated Solutions Console.
2. Go to **Resources** > **Resource Environment** > **Resource Environment Providers** > **WP GlobalThemeConfig**.
3. To view and edit the custom properties for this resource environment provider, click the **Custom properties** link.
4. Modify the property values as needed according to the following table. For each property to modify:
   a. Click the **property name** link.
   b. Modify the value in the **Value** field.
   c. Click **OK**.
5. Save and persist the changes to the master configuration.
6. Restart the portal server.

Results

Resource environment providers use the following properties and values.

`user.displaynameattribute`

Change this value if your identity manager user hierarchy uses a different attribute for the user's full display name. Default value: `cn`

`resources.theme.loadingImage`

The path to the loading image relative to the theme base URI. Default value:`css/images/loading.gif`

Adding resource environment provider properties:

Resource environment provider (REP) custom properties are global in scope, but you can use a consistent naming convention for a theme or module that applies across multiple themes.

About this task

For properties that are used only by a single theme, prefix with *yourTheme*. For those properties that are used only by a single module, prefix with *yourModule*. Modules do not belong to any particular theme and can be used by any theme. It is a good practice to put your modules in one web app and each theme in its own separate web app.

Replace occurrences in italics with the actual names of your items.

Procedure

1. Access the WebSphere Integrated Solutions Console.
2. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Select **Node=<node>, Server=WebSphere_Portal**.
4. Click **New**.
5. Enter *YourPrefix* `ThemesConfig` in the **Name** field.
6. Click **OK**.
7. Find your REP in the table and click ***YourPrefix*** **ThemesConfig**.
8. Click **Custom properties**.
9. Create a global and a theme property:
   a. Click **New**.
   b. Enter `modules.contextRoot` in the **Name** field. Because it is global in scope, it does not use any particular prefix.
   c. Enter the context root of your web application that contains your modules in the **Value** field, such as */*`yourprefix`*/modules*.
   d. Click **OK**.
   e. Click **New**.
   f. Enter *`yourTheme`*`.contextRoot` in the Name field. Because it is scoped to your theme, it uses the *yourTheme*. prefix.
   g. Enter the context root of your web application that contains your theme in the **Value** field, such as */*`yourprefix`*/*`yourtheme`.
   h. Click **OK**.
10. Optional: Create example properties that add REP properties for your theme or module:
    a. Click **New**.
    b. Enter *`yourTheme.yourRepProperty`* in the Name field. Because it is scoped to your theme, use the *yourTheme*. prefix.

c. Enter *yourvalue* in the **Value** field.
d. Click **OK**.
e. Click **New**.
f. Enter *yourModule.yourRepProperty* in the Name field. Because it is scoped to your module, use the *yourModule.* prefix.
g. Enter *yourvalue* in the **Value** field.
h. Click **OK**.

11. Save and persist the changes to the master configuration.
12. Restart the portal server.

Configuration for resource aggregation:

Set the following properties in the WP ConfigService Resource Environment Provider to configure the resource aggregator.

Configure theme invalidation auto recognition

This setting defines a regular expression that is used by the server to recognize updates in WebDAV. When the regular expression finds a match, it invalidates the theme caches automatically. This feature does not work on `.WAR` file-based themes. However, it significantly reduces the need for you to invalidate the cache manually.

In the WP ConfigService Resource Environment Provider, modify the `resourceaggregation.auto.invalidate.regex` property. By default, the property is set to `.*\.json|.*/modules/.*`.

For example, updating the file `dav:fs-type1/themes/Portal8.5/contributions/theme.json` through any WebDAV client, is recognized from the default pattern and causes an automatic theme invalidation.

Configure system module invalidation

This setting defines a regular expression that is used by the server to invalidate system modules that are defined in `plugin.xml` files during the theme invalidation process. The regular expression skips all built-in `.WAR` files. If your`.WAR` file is not invalidated, its plug-in ID might start with `com.ibm` or `wp`. Use custom plug-in IDs with the prefix of your company name to ensure that your `.WAR` files are invalidated.

In the WP ConfigService Resource Environment Provider, modify the `resourceaggregation.cache-refresh.skipPluginRegEx` property. By default, the property is set to `^(com\.ibm|wp\.|wcm\.|jquery).*`.

Using your configuration properties:

Create a JavaScript object for your theme on the client side. Theme metadata properties must be loaded dynamically. If you must load a property statically, use a resource environment provider custom property instead.

About this task

Configuration properties can be loaded either statically, `type="config_static"`, or dynamically, `type="config_dynamic"`. You can use one or the other or both

depending on your needs. Static is intended for property values that do not commonly change after they are loaded initially, and is better for performance because the values are cached. Dynamic is intended for property values that change more frequently.

All configuration properties that your module must reference on the client side are merged together into a single convenient global config object. They are merged whether they are theme metadata properties or resource environment provider custom properties. You can then easily reference any property within the *yourcoCfg*.themesConfig object, such as *yourcoCfg*.themesConfig.*yourTheme_yourRepProperty*.

The theme and the modules that are provided with WebSphere Portal Express merge their configuration properties into the ibmCfg global variable. You can run this variable in a browser console and inspect what the property names and values are. Changes to values in the **WP GlobalThemeConfig** REP are global to all themes. You can override certain values on the client side if you need the values to be different in only your themes that include your module. You can do so with syntax similar to the following example in one of the config*.jsp files for your module:

```
i$.merge({<%--
  --%>ibmCfg: {<%--
  --%>themeConfig: {<%--
  --%>loadingImage: "css/images/yourloading.gif"<%--
  --%>}}});
```

If your module requires the module,**wp_portal** then the portal configuration loads before the configuration for your module, ensuring that your override is merged in last.

Replace occurrences of *your** in italics with the actual names of your items.

Procedure

1. Create an extension point (module definition) in the plugin.xml file for your theme with subcontributions for the configuration of the module.

```
<extension point="com.ibm.portal.resourceaggregator.module" id="yourprefix_yourmodule_config">
 <module id="yourprefix_yourmodule">
  <prereq id="wp_portal"/>
  <contribution type="config">
   <sub-contribution type="config_static">
    <uri value="res:{war:context-root}/yourmodule/markup/config_global.jsp" />
   </sub-contribution>
   <sub-contribution type="config_dynamic">
    <uri value="res:{war:context-root}/yourmodule/markup/config.jsp" />
   </sub-contribution>
  </contribution>
 </module>
</extension>
```

2. Add your **moduleID** to the profile file for your theme so that your module loads.
   a. Connect your WebDAV client to http://*localhost*:*port*/wps/mycontenthandler/dav/fs-type1/.
   b. From the profiles folder within the folder for your theme, copy the profile_deferred.json file to a local drive.
   c. Rename the profile_deferred.json file to create a custom profile.
   d. Modify the local copy of the file and add your **moduleID** at the end of the list:

      ,
      "yourprefix_yourmodule"
   e. Copy your custom profile JSON file into the profiles folder in the folder for your theme in fs-type1 on the portal server.

3. Create the `config_global.jsp` file, `config.jsp` file, or both in your modules web application in the *\yourmodule*\markup folder. The following example of `config.jsp` file loads dynamically. A `config_global.jsp` file (static) would look similar, only without any theme metadata properties in it.

```
<%@ page session="false" contentType="text/javascript;charset=ISO-8859-1" buffer="none" %>
<%@ page trimDirectiveWhitespaces="true" %>
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8.5/portal-fmt" prefix="portal-fmt" %>
i$.merge({<%--
    --%>yourcoCfg: {<%--
     --%>themesConfig: {<%--
      --%>modules_contextRoot: "<portal-fmt:out escape="json">${wp.rep["REP.YourPrefix ThemesConfig"]["modules.contextRoot"]}</portal-fmt:out>",<%--
      --%>yourTheme_contextRoot: "<portal-fmt:out escape="json">${wp.rep["REP.YourPrefix ThemesConfig"]["yourTheme.contextRoot"]}</portal-fmt:out>",<%--
      --%>yourTheme_yourRepProperty: "<portal-fmt:out escape="json">${wp.rep["REP.YourPrefix ThemesConfig"]["yourTheme.yourRepProperty"]}</portal-fmt:out>",<%--
      --%>yourTheme_yourMetadataProperty: "<portal-fmt:out escape="json">${wp.themeConfig["yourTheme.yourMetadataProperty"]}</portal-fmt:out>"<%--
      --%>yourModule_yourRepProperty: "<portal-fmt:out escape="json">${wp.rep["REP.YourPrefix ThemesConfig"]["yourModule.yourRepProperty"]}</portal-fmt:out>",<%--
--%>}}}});
```

   If the *yourcoCfg* global variable and **themesConfig** child property do not exist, the merge automatically creates them. You can also mix in your properties with any other properties that might already be present if the *yourcoCfg* object exists.
4. If you have JSP reloading turned on in your web applications, then restart the web application for your modules and the web application for your theme. Otherwise, restart the portal server.
5. Restart your portal server.

Configuration settings for capability filters:

Set the following properties in the **Wp ConfigService** Resource Environment Provider to enable or disable the various capability filters.

Enable or disable the runtime filter for the local rendering use case

```
Property : resourceaggregation.enableRuntimePortletCapabilitiesFilter
Possible Values:
true: Enables the runtime filter
false: Disables the runtime filter
Default: true
```

Enable or disable the buildtime filter for the local rendering use case

```
Property : resourceaggregation.enableBuildtimePortletCapabilitiesFilter
Possible Values:
true: Enables the buildtime filter
false: Disables the buildtime filter
Default: true
```

Set the themes to which the filters are applied in the local rendering case

```
Property : resourceaggregation.themeObjectIDs
Possible Values:
Comma separated list of unique names of themes for which the filters should apply.
Default: ibm.portal.80Theme, ibm.portal.85Theme
```

Note: This setting does not apply for the remote rendering use case (WSRP).

Note: CF03 This property is no longer supported in combined cumulative fix 03. The filters are applied for custom themes by default, and you must now disable it for custom themes, if you do not want them filtered. In previous versions, the opposite was true. To disable the filter for any theme, add the metadata `THEME_METADATA_DISABLE_THEME_FILTER` to your theme with the value of `true`. For more information about how to set metadata, see *Change the auto-loading of portlet capabilities*.

CF03

Disable theme filters in local rendering

Theme filters check whether a portlet can be rendered based on the current rendering context or not. This particular filter checks all `capability.*.id` preferences and validates them against the theme capabilities. If a capability is not available, the portlet is either not rendered or is not allowed to be added to the page. For more information, see *Module dependencies in portlets*.

This feature is enabled by default with combined cumulative fix 03 and can be disabled by adding the following theme metadata to your theme.

```
resourceaggregation.disableThemeFilter = true
```

The easiest way to set a theme metadata is through the themelist entry point. Modify the `metadata.properties`. You can also use XMLaccess to update your theme.

Enable or disable the runtime filter for the remote rendering use case (WSRP)

```
Property : resourceaggregation.enableRuntimePortletCapabilitiesFilterForWSRP
Possible Values:
true: Enables the runtime filter for WSRP
false: Disables the runtime filter for WSRP
Default: true
```

Enable or disable the buildtime filter

```
Property : resourceaggregation.enableBuildtimePortletCapabilitiesFilter
Possible Values:
true: Enables the buildtime filter
false: Disables the buildtime filter
Default: true
```

Disable JSON file filter

```
Property: resourceaggregation.load.json.only
Possible values:
true: Filters files other than json files when creating WebDav contribution and profile directories.
false: Does not filter any files in the WebDav contribution and profile directories.
```

Expression language beans for accessing programming models

Expression language (EL) beans are available for accessing WebSphere Programming models. These beans are accessed through the PortalBean represented in the global namespace by `wp`. The beans provide access to IBM WebSphere Portal Express models and associated classes.

PortalBean

The PortalBean provides access to EL Beans that represent some of the WebSphere Portal Express models. You can use these models to access resource information in your JSPs.

You can access the PortalBean (wp) with the following items. Append the following beans to `wp.` to create a bean in your JSP. For example, `wp.themeList.current` gets the current element and returns "Theme" on page 2762.

wp.ac Provides read access to the current access control permissions for a resource.

AccessControl
Provides read access to the current access control node for a resource.

wp.analyticsTagList
Attaches marketing information to Portal resources such as portal pages, portlets, or web content items. Reads the analytics tags that are associated with an identifiable portal resource.

AnalyticsTag
The AnalyticsTag expression bean represents a single analytics tag.

wp.clientProfile
Provides access to the client profile.

wp.identification
Provides access to the identification services serialize and deserialize.

wp.languageList
Provides access to the list of languages that are defined in portal.

Language
Provides access to the interface that represents a portal language.

wp.layoutModel
Provides access to the tree model representation of the layout of a page.

LayoutModel
Provides access to the tree model representation object of the layout of a page.

LayoutContainer
Provides access to the interface that represents a container in a LayoutModel.

LayoutControl
Provides access to the interface that represents a control in a LayoutModel.

wp.localizedDescription
Provides access to the description of the currently rendered page.

Example:

```
${wp.localizedDescription}
```

Returns: Description for the current page description; it is never null.

wp.localizedTitle
Provides access to the title of the currently rendered page.

Example:

```
${wp.localizedTitle}
```

Returns: Title for the current page title; it is never null.

wp.metadata
Provides access to the aggregated metadata of a node. The metadata that can be provided by individual nodes of the content model are combined according to the hierarchy that the content model exposes for these nodes. Values set on the node itself take precedence over values set for its parents.

Example:

```
${wp.metadata[wp.selectionModel.selected]['com.ibm.portal.layout.template.ref']}
```

Returns: Metadata, never null.

CF05 **wp.moduleList**

The module list bean accesses modules that are part of the modularized theme architecture. You can query individual modules and their attributes and identify of the currently used modules within the scope of the currently selected and rendered page and theme.

CF05 **Module**

Represents one individual module.

CF05 **CurrentModuleList**

The current module list always represents the list of modules within the scope of the current request, which is the currently selected page and theme. This module iterates through all modules, locate individual modules and query their capabilities. This is especially useful for portlet developers to check whether certain capabilities are available on the page or not.

CF05 **Module**

Represents one individual module.

CF05 **ModuleCapabilitiesList**

Represents the aggregated capabilities of a list of modules. This is usually the non-deferred or deferred capabilities of the currently selected page and depends on how this object was fetched. It is useful for portlet developers to check whether certain capabilities are available on the page or not.

CF05 **ModuleCapability**

Represents one capability as defined by a module.

wp.navigationModel

Provides access to the navigation model.

NavigationNode

Provides access to a navigation node in a navigation model.

ContentNode

Provides access to a content node. This interface offers a way to obtain the type of the content node.

wp.publicRenderParam

Public render parameters can be used by portlets to share context information. They are addressed with qualified names. The `wp.publicRenderParam` expression bean can be used within a theme or theme module to read the first String value of a public render parameter.

wp.publicRenderParamValues

The `wp.publicRenderParamValues` expression bean can be used within a theme or theme module to read the values of a public render parameter. The public render parameter is read in the context of the currently selected page that is determined internally.

wp.rep

Provides access to the set of configuration entries for the specified resource environment provider.

Properties

Object representing a set of properties mad available as part of the resource environment provider.

wp.selectionModel
Provides access to a selection model for a navigation model.

NavigationNode
Provides access to a navigation node in a navigation model.

ContentNode
Provides access to a content node. This interface offers a way to obtain the type of the content node.

wp.themeConfig
Encapsulates the theme configuration parameter lookup process.

wp.themeList
Provides access to all themes in the system and the currently selected theme.

"Theme" on page 2762
Provides access to the attributes of one theme.

ProfileList
Provides access to all profiles in a theme and the currently selected profile.

Profile
Provides access to the attributes of one profile.

wp.title
Provides access to the title of the currently rendered page or the title information set by a portlet.

Example:

```
${wp.title}
```

Returns: Title in the current locale as a string.

wp.user
Provides access to the active user.

Common beans

Common beans
The following beans are returned by many different beans and are used flexibly.

Description
Provides access to the description of certain objects such as Navigation, Content, Theme, Profile, and others.

Metadata
Provides access to the metadata of certain objects such as Navigation, Content, Theme, Profile, and others.

Title Provides access to the title of certain objects such as Navigation, Content, Theme, Profile, and others.

CF05 **UrlGeneration**
Creates a portal URL you can control with attributes.

CF05 **UrlGenerationPage**
Extends UrlGeneration on a page. All the UrlGeneration attributes are available in addition to these attributes.

CF05 **UrlGenerationPortlet**
Extends UrlGeneration in a portlet. All the UrlGeneration and UrlGenerationPage attributes are available in addition to these attributes.

Other Beans

These beans cannot be accessed through the PortalBean. To access the uiNavigationModel Bean, you must use the uiNavigationModel tag and define the variable name that you want the bean to be available under.

CF05 **uiNavigationModel**
By default, the uiNavigationModel lists the visible pages as part of its iterator. When the **Show hidden pages** option is selected in the toolbar, it also lists the hidden pages. There is a mobile hidden flag for pages. The model also helps you specify a mobile test device class expression, which is used to evaluate if the system is rendered as part of a mobile request.

CF05 **uiNavigationNode**
Provides access to a navigation node in a navigation model.

wp.ac - Access control:

Provides read access to the current access control permissions for a resource.

Example: `${wp.ac[node].hasPermission['editor']}`

Attributes:

get(id) Gets an individual access control node.

Example:

```
${wp.ac[wp.selectionModel.selected].selected}
```

Parameters:

id String or Identifiable object to look up the access control objects, must not be null.

Returns: AccessControl; it can be null if it is not found.

AccessControl:

Provides read access to the current access control permissions for a resource.

Attributes:

hasAddChildPermission
Determine whether the page is a non-private page and the current user has contributor, editor, manager, or admin permission for the specified page.

Example:

```
${wp.ac[wp.selectionModel.selected].hasAddChildPermission}
```

Parameters: none

Returns: Boolean; true if the check is successful, otherwise false.

hasEditSharedPermission
Determines whether the page is a non-private page and the current user has editor, manager, or admin permission for the specified page.

Example:

```
${wp.ac[wp.selectionModel.selected].hasEditSharedPermission}
```

Parameters: none

Returns: Boolean; true if the check is successful, otherwise false.

hasPersonalizePermission

Determines whether the specified page is a private page and the current user has PRIVILEGED_USER permission.

Example:

```
${wp.ac[wp.selectionModel.selected].hasPersonalizePermission}
```

Parameters: none

Returns: Boolean; true if the check is successful, otherwise false.

hasPermission

Determines whether the resource has a specific permission. Attribute is the case in-sensitive name of the `com.ibm.portal.ac.data.RoleType`.

Example:

```
${wp.ac[wp.selectionModel.selected].hasPermission['Administrator']}
${wp.ac[wp.selectionModel.selected].hasPermission['ManageR']}
${wp.ac[wp.selectionModel.selected].hasPermission['editor']}
```

Parameters: none

Returns: Boolean; true if the check is successful, otherwise false.

isPrivate

Determines whether the specified page is private.

Example:

```
 ${wp.ac[wp.selectionModel.selected].isPrivate}
```

Parameters: none

Returns: Boolean; true if the page is private, false if it is not.

wp.analyticsTagList:

Attaches marketing information to Portal resources such as portal pages, portlets, or web content items. Reads the analytics tags that are associated with an identifiable portal resource.

For more information, see “Analytics tags and site promotions” on page 1724

Attributes:

get(objectid)

Determines the list of analytics tags for the portal resource with the given objectID.

Example:

```
<c:forEach items="${wp.analyticsTagList[wp.identification[wp.selectionModel.selected]]}" v
     <span class="asa.tag.<c:out value='${current.name}'/>"><c:out value='${current.value}
</c:forEach>
```

Parameters:

objectid
An ObjectID, or Identifiable object to locate the resource; must not be null.

Returns: A list containing AnalyticsTag objects. You can use the forEach JSTL tag to iterate through the returned list.

AnalyticsTag:

The AnalyticsTag expression bean represents a single analytics tag.

Attributes:

name

Returns the name of the analytics tag.

Example:

```
<c:forEach items="${wp.analyticsTagList[wp.identification[wp.selectionModel.selected]]}" var
    <span class="asa.tag.<c:out value='${current.name}'/>"><c:out value='${current.value}' />
</c:forEach>
```

Parameters: none

Returns: A string representing the name of the analytics tag. It is never null.

value

Returns the value of the analytics tag.

Example:

```
<c:forEach items="${wp.analyticsTagList[wp.identification[wp.selectionModel.selected]]}" var
    <span class="asa.tag.<c:out value='${current.name}'/>"><c:out value='${current.value}' />
</c:forEach>
```

Parameters: none

Returns: A string representing the value of the analytics tag. It is never null.

wp.clientProfile:

Provides access to the client profile.

Attributes:

get(attribute)
Provides access to the defined attributes associated with the client/CCPP profile.

Example:

```
${wp.clientProfile['DeviceClass']}
```

The following example shows how to access the device class information for the client profile:

```
<c:set var="deviceClass" scope="request" value="${wp.clientProfile['DeviceClass']}" />
<c:choose>
<c:when test="${deviceClass == 'desktop'}">
<jsp:forward page="/jsp/html/desktop/View.jsp"/>
</c:when>
<c:when test="${deviceClass == 'tablet'}">
<jsp:forward page="/jsp/html/tablet/View.jsp"/>
</c:when>
```

```
<c:otherwise>
<jsp:forward page="/jsp/html/View.jsp"/>
</c:otherwise>
</choose>
```

Parameters:

attribute
String; the name of the client attribute you want to retrieve.

Returns: String; the value of the client profile's attribute name. Can be null.

wp.identification:

Provides access to the identification services to serialize and deserialize objectIDs.

Attributes:

get(object)
Serializes the objectID into a string.

Example:

```
${wp.identification[object]}
```

Parameters:

object
Identifiable object to be serialized.

Returns: String, a serialized representation of an object. It is null if it is not a valid object.

get(string)
Deserializes a string into an objectID.

Example:

```
${wp.identification[string]}
```

Parameters:

string
String to look up the identification objects, must not be null.

Returns: objectID; it can be null if the string is invalid or the object is not found.

wp.languageList:

The wp.languageList provides access to the list of languages that are defined in portal.

Attributes:

get(id) Get an individual language object.

Example:

```
${wp.languageList[id]}
```

Parameters:

id Identifiable object to look up the Language objects, must not be null.

Returns: Language object; It can be null if not found.

iterator

Iterates through languages.

Example:

```
<c:forEach var="node" items="${wp.languageList}">
</c:forEach>
```

Parameters: None

Returns: An iterator with Language objects; it is never null.

Language:

Provides access to the interface that represents a portal language.

Attributes:

created

Returns the creation date of the language.

Example:

```
<c:forEach var="node" items="${wp.languageList}">
     ${node.created}
</c:forEach>
```

Parameters: none

Returns: Date, the creation date object of the resource. It is never null.

description

The description of the language.

Example:

```
<c:forEach var="node" items="${wp.languageList}">
     ${node.description}
</c:forEach>
```

Parameters: none

Returns: Description object for the language node; it is never null. You can use the value of the title object to retrieve the description in current locale.

lastModified

Returns the last modification date of the language.

Example:

```
<c:forEach var="node" items="${wp.languageList}">
    ${node.lastModified}
</c:forEach>
```

Parameters: none

Returns: Date, the last modified date object of the resource. It is never null.

locale Returns the locale of the language.

Example:

```
<c:forEach var="node" items="${wp.languageList}">
     ${node.locale}
</c:forEach>
```

Parameters: none

Returns: Locale, the locale object of the resource. It is never null.

objectID

Returns the obect identifier for the current language.

Example:

```
<c:forEach var="node" items="${wp.languageList}">
     ${node.objectID}
</c:forEach>
```

Parameters: none

Returns: objectID associated with this language.

title The title of this language.

Example:

```
<c:forEach var="node" items="${wp.languageList}">
     ${node.title}
</c:forEach>s
```

Parameters: none

Returns: Title object for the language node; it is never null. You can use the value of the title object to retrieve the title in current locale.

wp.layoutModel:

The wp.layoutModel provides access to the tree model representation of the layout of a page.

Attributes:

children(node)
Returns an iterator of child nodes.

Example:

```
<c:forEach var="node" items="${wp.layoutModel.children[wp.identification[wp.selectionModel
 ${node}<br>
</c:forEach>
```

Parameters:

node
Identifiable, or NavigationNode object to look up the children; it must not be null.

Returns: An iterator with NavigationNode objects; it is never null.

get(id) Get the layout model for a navigation node or navigation node ID.

Example:
The following example displays getting the layout model for the currently selected node from the selection model. The second line retrieves the children of the root mode of the layout model.

```
<c:set var="layoutmodel" value="${wp.layoutModel[wp.selectionModel.selected]}"/>
<c:set var="containers" value="${layoutmodel.children[layoutmodel.root]}"/>
```

Parameters:

id String or identifiable object of the navigation object; must not be null.

Returns: LayoutModel for the navigation node. Can be null.

hasChildren
Determines whether the specified NavigationNode has associated nodes.

Example:

```
${wp.layoutModel.hasChildren[wp.selectionModel.selected]}
```

Parameters:

node
Identifiable, or NavigationNode object to look up the children; it must not be null.

Returns: Boolean; true if the node has children. Otherwise, it is false.

parent

Access to the parent of a NavigationNode.

Example:

```
${wp.layoutModel.parent[wp.selectionModel.selected]}
```

Parameters:

node
Identifiable or NavigationNode object to look up the children; it must not be null.

Returns: LayoutNode; the parent node for the node if there is a parent. Otherwise, it is null.

path(node)
Provides access to the path information for the node. The path represents the hierarchy from the root to the give node as a list. It is like a breadcrumb.

Example:

```
<c:forEach var="node" items="${wp.layoutModel.path[wp.selectionModel.selected]}">
 &lt;- ${node}
</c:forEach>
```

Parameters:

node
Identifiable or NavigationNode object to look up the children; it must not be null.

Returns: a list of LayoutNodes representing the path from the root to the node.

root Returns the root node of the layout model.

Example:

```
${wp.layoutModel.root}
```

Parameters: none

Returns: NavigationNode; it is never null.

LayoutModel:

Provides access to the tree and list model representation object of the layout of a page.

Many of the following attributes return LayoutNode. However, LayoutContainer and LayoutControl are types of LayoutNode, and when you iterate, you can encounter either type.

Attributes:

children
Returns the children of the specified node.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].children[node]}
```

Parameters:

node
This value represents an entry in a model.

Returns: Children of the specified node.

get(id) Gets an individual layout model.

Example:

```
${wp.layoutModel[id]}
```

Parameters:

id String or Identifiable object to look up the layout objects. It must not be null.

Returns: LayoutNode; it can be null if not found.

hasChildren
Determines whether the current specified LayoutNode has associated nodes.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].hasChildren[node]}
```

Parameters:

node
LayoutNode; node to check for child nodes.

Returns: Boolean; true if the layout node has children. Otherwise, it is false.

iterator
Iterates through layout nodes.

Example:

```
<c:forEach var="node" items="${wp.layoutModel[wp.selectionModel.selected]}">
</c:forEach>
```

Parameters: None

Returns: an iterator with LayoutNode objects; it is never null.

parent

Access to the parent of a node.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].parent[node]}
```

Parameters:

node
LayoutNode; the current node.

Returns: LayoutNode; the parent node for the node if there is a parent. Otherwise, it is null.

path Provides access to the path information for the node. The path represents the hierarchy from the root to the give node as a list. It is like a breadcrumb.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].path[node]}
```

Parameters:

node
LayoutNode; the current node.

Returns: a list of LayoutNodes representing the path from the root to a node.

root Returns the root node of the layout model.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].root}
```

Parameters: none

Returns: LayoutNode; it is never null.

LayoutContainer:

Provides access to the interface that represents a container in a LayoutModel.

Attributes:

description
The description of the layout container.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].root.description}
```

Parameters: none

Returns: Description object for the layout container; it is never null. You can use the value of the title object to retrieve the description in current locale.

metadata
Metadata that is associated with this layout container.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].root.metadata}
```

Parameters: none

Returns: Metadata, never null.

objectID
Returns the obect identifier for the current layour container.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].root.objectID}
```

Parameters: none

Returns: Object Identifier for the current control. The following displays an example of getting the layout model for the currently selected node from the selection model. The second line retrieves the children of the root node of the layout model. The children of the root node is represented as LayoutContainer.

```
<c:set var="layoutmodel" value="${wp.layoutModel[wp.selectionModel.selected]}"/>
<c:set var="containers" value="${layoutmodel.children[layoutmodel.root]}"/>
```

title The title of this container.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].root.title}
```

Parameters: none

Returns: Title associated with the current layout container object.

LayoutControl:

Provides access to the interface that represents a control in a LayoutModel.

Attributes:

description
The description of the current control.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].root.description}
```

Parameters: none

Returns: Description object for the current control; it is never null. You can use the value of the title object to retrieve the description in current locale.

metadata
The metadata map of the current control.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].root.metadata}
```

Parameters: none

Returns: Metadata, never null.

objectID
Description

Example:

```
${wp.layoutModel[wp.selectionModel.selected].root.objectID}
```

Parameters:

Returns: Object identifier for the current control.

title The title of the current control.

Example:

```
${wp.layoutModel[wp.selectionModel.selected].root.title}
```

Parameters: none

Returns: Title object for the current control; it is never null. You can use the value of the title object to retrieve the title in current locale.

wp.metadata:

Provides access to the aggregated metadata of a node. The metadata that can be provided by individual nodes of the content model are combined according to the hierarchy that the content model exposes for these nodes. Values set on the node itself take precedence over values set for its parents.

Attributes:

get(id) Gets the aggregated metadata map of the content node that is specified.

Example:

```
${wp.metadata[wp.selectionModel.selected]}
```

Parameters:

id String or Identifiable object to look up the content node; it must not be null.

Returns: Metadata; It can be null if not found.

wp.moduleList:

The module list bean accesses modules that are part of the modularized theme architecture. You can query individual modules and their attributes and identify of the currently used modules within the scope of the currently selected and rendered page and theme.

Attributes:

current

Returns the module list for the currently selected page and theme.

Example:

```
<c:forEach var="node" items="${wp.moduleList.current}">
    ${node.name}/${node.version},
</c:forEach>
```

Parameters: none

Returns: CurrentModuleList; Never null.

get(moduleKey)

Returns the module for the module key. The module key must be in the format *<module name>* or *<module name>/<module version>*. The version is optional. If no version is used, then the module with the highest version is selected.

Example:

```
${wp.moduleList["wp_portal"]}
${wp.moduleList["wp_portal/0.0"]}
```

Parameters:

moduleKey

String representing the module. Must be in the format *<module name>* or *<module name>/<module version>*.

Returns: Module. It can be null if it is not found.

Module:

Represents one individual module

Attributes:

name Returns the name of the module.

Example:

```
<c:forEach var="node" items="${wp.moduleList.current}">
    ${node.name}/${node.version},
</c:forEach>
```

Parameters: none

Returns: String; never null.

version

Returns the version of the module.

Example:

```
<c:forEach var="node" items="${wp.moduleList.current}">
    ${node.name}/${node.version},
</c:forEach>
```

Parameters: none

Returns: String; never null.

CurrentModuleList:

The current module list always represents the list of modules within the scope of the current request, which is the currently selected page and theme. This module iterates through all modules, locates individual modules and queries their capabilities. It is useful for portlet developers to check whether certain capabilities are available on the page or not.

Attributes:

iterator

Iterates through modules.

Example:

```
<c:forEach var="node" items="${wp.moduleList.current}">
    ${node.name}/${node.version},
</c:forEach>
```

Parameters: None

Returns: An iterator with Module objects; it is never null.

capabilities

Returns the aggregated non-deferred capabilities for all modules that are part of the currently selected page and theme.

Example:

```
<c:forEach var="node" items="${wp.moduleList.current.capabilities}">
    ${node.name}/${node.value},
</c:forEach>
```

Parameters: none

Returns: ModuleCapabilitiesList; Never null.

deferredCapabilities

Returns the aggregated deferred capabilities for all modules that are part of the currently selected page and theme.

Example:

```
<c:forEach var="node" items="${wp.moduleList.current.deferredCapabilities}">
    ${node.name}/${node.value},
</c:forEach>
```

Parameters: none

Returns: ModuleCapabilitiesList; Never null.

get(moduleKey)

Returns the module for the module key. The module key must be in the format *<module name>* or *<module name>/<module version>*. The version is optional. If no version is used, then the module with the highest version is selected.

Example:

```
${wp.moduleList.current["wp_portal"]}
${wp.selectionModel.selected.moduleList["wp_portal"]}
```

Parameters:

moduleKey

String representing the module. Must be in the format *<module name>* or *<module name>/<module version>*.

Returns: Module. Can be null if it is not found.

Module:

Represents one individual module

Attributes:

name Returns the name of the module.

Example:

```
<c:forEach var="node" items="${wp.moduleList.current}">
    ${node.name}/${node.version},
</c:forEach>
```

Parameters: none

Returns: String; never null.

version

Returns the version of the module.

Example:

```
<c:forEach var="node" items="${wp.moduleList.current}">
    ${node.name}/${node.version},
</c:forEach>
```

Parameters: none

Returns: String; never null.

ModuleCapabilitiesList:

Represents the aggregated capabilities of a list of modules. This is usually the non-deferred or deferred capabilities of the currently selected page and depends on how this object was fetched. This is especially useful for portlet developers to check if certain capabilities are available on the page or not.

Attributes:

get(key)

Returns the module for a key.

Example:

```
${wp.moduleList.current.capabilities['oneUI'].value
${!empty wp.moduleList.current.capabilities['oneUI']}
```

Parameters:

key

String, the name of the capability.

Returns: ModuleCapability. May be null if it is not found.

iterator

Iterates through capabilities.

Example:

```
<c:forEach var="node" items="${wp.moduleList.current.capabilities}">
    ${node.name}/${node.value},
</c:forEach>
```

Parameters: None

Returns: An iterator with ModuleCapability objects; it is never null.

ModuleCapability:

Represents one capability as defined by a module.

Attributes:

name Returns the name of the capability.

Example:

```
${wp.moduleList.current.capabilities['oneUI'].name}
```

Parameters: none

Returns: String; never null.

version

Returns the version of the capability.

Example:

```
${wp.moduleList.current.capabilities['oneUI'].value}
```

Parameters: none

Returns: String; never null.

wp.navigationModel:

The wp.navigationModel provides access to the navigation model. The navigation model is a tree representation of all pages.

Attributes:

children(node)

Returns an iterator of child nodes.

Example:

```
<c:forEach var="node" items="${wp.navigationModel.children[wp.identification[wp.selectionM
 ${node}<br>
</c:forEach>
```

Parameters:

node

Identifiable, or NavigationNode object to look up the children; it must not be null.

Returns: An iterator with NavigationNode objects; it is never null.

get(id) Get an individual navigation node.

Example:

```
${wp.navigationModel[id]}
```

Parameters:

id String or Identifiable object to look up the navigation object; it must not be null.

Returns: NavigationNode; it can be null if not found.

hasChildren

Determines whether the specified NavigationNode has associated nodes.

Example:

```
${wp.navigationModel.hasChildren[wp.selectionModel.selected]}
```

Parameters:

node

Identifiable, or NavigationNode object to look up the children; it must not be null.

Returns: Boolean; true if the node has children. Otherwise, it is false.

parent

Access to the parent of a NavigationNode.

Example:

```
${wp.navigationModel.parent[wp.selectionModel.selected]}
```

Parameters:

node

Identifiable or NavigationNode object to look up the children; it must not be null.

Returns: NavigationNode; the parent node for the node if there is a parent. Otherwise, it is null.

path(node)

Provides access to the path information for the node. The path represents the hierarchy from the root to the give node as a list. It is like a breadcrumb.

Example:

```
<c:forEach var="node" items="${wp.navigationModel.path[wp.selectionModel.selected]}">
 &lt;- ${node}
</c:forEach>
```

Parameters:

node

Identifiable or NavigationNode object to look up the children; it must not be null.

Returns: a list of NavigationNodes representing the path from the root to the node.

root Returns the root node of the navigation model.

Example:

```
${wp.navigationModel.root}
```

Parameters: none

Returns: NavigationNode; it is never null.

NavigationNode:

Represents a navigation node in a navigation model.

Attributes:

contentNode
Returns the content node that is associated with the navigation node.

Example:

```
${wp.selectionModel.selected.contentNode}
${wp.navigationModel.selected.contentNode}
```

Parameters: none

Returns: ContentNode. It is never null.

description
The description of the navigation node.

Example:

```
${wp.selectionModel.selected.description}
${wp.navigationModel.selected.description}
```

Parameters: none

Returns: Description object for the navigation node; it is never null. You can use the value of the title object to retrieve the description in current locale.

isPrivate
Determines whether the current node is private.

Example:

```
${wp.selectionModel.selected.isPrivate}
${wp.navigationModel.selected.isPrivate}
```

Parameters: none

Returns: Boolean, true if the page is private, otherwise false.

metadata
The metadata map of this navigation node.

Example:

```
${wp.selectionModel.selected.metadata['com.ibm.portal.Hidden']}
${wp.navigationModel.selected.metadata['com.ibm.portal.Hidden']}
```

Parameters: none

Returns: Metadata, never null.

CF05 **moduleList**
Returns the module list for the currently selected page and theme.

Example:

```
<c:forEach var="node"items="${wp.selectionModel.selected.moduleList}">
    ${node.name}/${node.version},
</c:forEach>
<c:forEach var="node"items="${wp.navigationModel.selected.moduleList}">
    ${node.name}/${node.version},
</c:forEach>
```

Parameters: none

Returns: CurrentModuleList, never null.

objectID

Returns the ObjectID associated with this navigation node.

Example:

```
${wp.selectionModel.selected.objectID}
${wp.navigationModel.selected.objectID}
```

Parameters: none

Returns: ObjectID. Never null.

profileRef

Returns the profile reference for the page. If it is empty or null, the default theme profile reference is used.

Example:

```
${wp.selectionModel.selected.profileRef}
${wp.navigationModel.selected.profileRef}
```

Parameters: none

Returns: String, the profile reference within the theme. It can be null if you are using a non-modularized theme.

projectID

Returns the project identifier that is associated with this navigation node, or null of no project is associated.

Example:

```
${wp.selectionModel.selected.projectID}
${wp.navigationModel.selected.projectID}
```

Parameters: none

Returns: String representing the associated project. It can be null if no project is associated.

themeID

Returns the set theme ID for the page. If it is not set for the page, this function returns the inherited theme or default system theme.

Example:

```
${wp.selectionModel.selected.themeID}
${wp.navigationModel.selected.themeID}
```

Parameters: none

Returns: ObjectID of the referenced theme. Never null.

title The title of this navigation node.

Example:

```
${wp.selectionModel.selected.title}
${wp.navigationModel.selected.title}
```

Parameters: none

Returns: Title associated with the current object.

CF05 **url**

Short hand for urlGeneration that returns a string and cannot be manipulated any further.

Example:

```
${wp.selectionModel.selected.url}
${wp.navigationModel.selected.url}
```

Parameters: none

Returns: String; the URL pointing to this page.

CF05 **urlGeneration**

Creates a portal URL you can control with attributes. The URL attributes can be set by using further methods on the UrlGeneration object as shown in the examples section.

Example:

```
${wp.selectionModel.selected.urlGeneration}
${wp.navigationModel.selected.urlGeneration}
```

More examples:

```
<c:set var="node" value="${wp.selectionModel.selected}"/>
<a href="${node.url}">Simple URL, no modifications possible</a>
<a href="${node.urlGeneration}">Simple URL</a>
<a href="${node.urlGeneration.keepNavigationalState}">With NavState</a>
<a href="${node.urlGeneration.noNavigationalState}">Without NavState</a>
<a href="${node.urlGeneration.setThemeTemplate('Plain')}">With ThemeTemplate</a>
<a href="${node.urlGeneration.forcePublic}">Public Link</a>
<a href="${node.urlGeneration.secure}">Secure Link</a>
<a href="${node.urlGeneration.setLocale('de')}">In Deutsch</a>
<a href="${node.urlGeneration.setParam('a','b')}">With Params</a>
<a href="${node.urlGeneration.setParam('a','b').setParam('c','d').forcePublic.setLocale('c
Complex URL</a>
<a href="${node.urlGeneration.logout}">Logout</a>
<a href="${node.urlGeneration.login}">Login</a>
<a href="${node.urlGeneration.normalize}">Normalized URL</a>
<a href="${node.urlGeneration.allowRelativeURL}">Relative URL</a>
<a href="${node.urlGeneration.disallowRelativeURL}">Disallow Relative URL</a>
<a href="${node.urlGeneration.forceAbsolute}">Absolute URL</a>
```

```
<c:set var="node" value="${wp.navigationModel.selected}"/>
<a href="${node.url}">Simple URL, no modifications possible</a>
<a href="${node.urlGeneration}">Simple URL</a>
<a href="${node.urlGeneration.keepNavigationalState}">With NavState</a>
<a href="${node.urlGeneration.noNavigationalState}">Without NavState</a>
<a href="${node.urlGeneration.setThemeTemplate('Plain')}">With ThemeTemplate</a>
<a href="${node.urlGeneration.forcePublic}">Public Link</a>
<a href="${node.urlGeneration.secure}">Secure Link</a>
<a href="${node.urlGeneration.setLocale('de')}">In Deutsch</a>
<a href="${node.urlGeneration.setParam('a','b')}">With Params</a>
<a href="${node.urlGeneration.setParam('a','b').setParam('c','d').forcePublic.setLocale('c
Complex URL</a>
<a href="${node.urlGeneration.logout}">Logout</a>
<a href="${node.urlGeneration.login}">Login</a>
<a href="${node.urlGeneration.normalize}">Normalized URL</a>
<a href="${node.urlGeneration.allowRelativeURL}">Relative URL</a>
<a href="${node.urlGeneration.disallowRelativeURL}">Disallow Relative URL</a>
<a href="${node.urlGeneration.forceAbsolute}">Absolute URL</a>
```

Parameters: none

Returns: UrlGenerationPage; the URL object pointing to this page

ContentNode:

Provides access to a content node. This interface offers a way to obtain the type of the content node.

Attributes:

contentNodeType

Returns the type of this content node as `com.ibm.portal.content.ContentNodeType`.

Example:

```
${wp.navigationModel.selected.contentNode.contentNodeType}
${wp.selectionModel.selected.contentNode.contentNodeType}
```

The following example displays how to check whether the currently selected node is a label:

```
<c:if test="${wp.navigationModel.selected.contentNode.contentNodeType == 'LABEL'}">
<c:if test="${wp.selectionModel.selected.contentNode.contentNodeType == 'LABEL'}">
```

Parameters: none

Returns: `com.ibm.portal.content.ContentNodeType – COMPOSITION, EXTERNALURL, LABEL, PAGE, STATICPAGE`

description

The description of the content node.

Example:

```
${wp.navigationModel.selected.contentNode.description}
${wp.selectionModel.selected.contentNode.description}
```

Parameters: none

Returns: ContentNode object for the navigation node; it is never null. You can use the value of the title object to retrieve the description in current locale.

metadata

The metadata map of this content node.

Example:

```
${wp.navigationModel.selected.contentNode.metadata['com.ibm.portal.Hidden']}
${wp.selectionModel.selected.contentNode.metadata['com.ibm.portal.Hidden']}
```

Parameters: none

Returns: Metadata, never null.

CF05 **moduleList**

Returns the module list for the currently selected page and theme.

Example:

```
<c:forEach var="node" items="${wp.navigationModel.selected.contentNode.moduleList}">
 ${node.name}/${node.version},
</c:forEach>
<c:forEach var="node" items="${wp.selectionModel.selected.contentNode.moduleList}">
 ${node.name}/${node.version},
</c:forEach>
```

Parameters: none

Returns: CurrentModuleList, never null.

objectID

Returns the ObjectID associated with this content node.

Example:

```
${wp.navigationModel.selected.contentNode.objectID}
${wp.selectionModel.selected.contentNode.objectID}
```

Parameters: none

Returns: ObjectID. Never null.

profileRef

Returns the profile reference for the page. If it is empty or null, the default theme profile reference is used.

Example:

```
${wp.navigationModel.selected.contentNode.profileRef}
${wp.selectionModel.selected.contentNode.profileRef}
```

Parameters: none

Returns: String, which represents the reference to a profile that exists within the theme. It can be null if you are using a non-modularized theme.

themeID

Returns the set theme ID for the page. If it is not set for the page, this function returns the inherited theme or default system theme.

Example:

```
${wp.navigationModel.selected.contentNode.themeID}
${wp.selectionModel.selected.contentNode.themeID}
```

Parameters: none

Returns: ObjectID of the referenced theme. Never null.

title The title of this content node.

Example:

```
${wp.navigationModel.selected.contentNode.title}
${wp.selectionModel.selected.contentNode.title}
```

Parameters: none

Returns: Title associated with the current object.

CF05 **url**

Short hand for urlGeneration that returns a string and cannot be manipulated any further.

Example:

```
${wp.navigationModel.selected.url}
${wp.selectionModel.selected.url}
```

Parameters: none

Returns: String; the URL pointing to this page.

CF05 **urlGeneration**

Creates a portal URL you can control with attributes. The URL attributes can be set by using further methods on the UrlGeneration object as shown in the examples section.

Example:

```
${wp.navigationModel.selected.urlGeneration}
```

```
${wp.selectionModel.selected.urlGeneration}
```

More examples:

```
<c:set var="node" value="${wp.navigationModel.selected}"/>
<a href="${node.url}">Simple URL, no modifications possible</a>
<a href="${node.urlGeneration}">Simple URL</a>
<a href="${node.urlGeneration.keepNavigationalState}">With NavState</a>
<a href="${node.urlGeneration.noNavigationalState}">Without NavState</a>
<a href="${node.urlGeneration.setThemeTemplate('Plain')}">With ThemeTemplate</a>
<a href="${node.urlGeneration.forcePublic}">Public Link</a>
<a href="${node.urlGeneration.secure}">Secure Link</a>
<a href="${node.urlGeneration.setLocale('de')}">In Deutsch</a>
<a href="${node.urlGeneration.setParam('a','b')}">With Params</a>
<a href="${node.urlGeneration.setParam('a','b').setParam('c','d').forcePublic.setLocale('de')
Complex URL</a>
<a href="${node.urlGeneration.logout}">Logout</a>
<a href="${node.urlGeneration.login}">Login</a>
<a href="${node.urlGeneration.normalize}">Normalized URL</a>
<a href="${node.urlGeneration.allowRelativeURL}">Relative URL</a>
<a href="${node.urlGeneration.disallowRelativeURL}">Disallow Relative URL</a>
<a href="${node.urlGeneration.forceAbsolute}">Absolute URL</a>
```

```
<c:set var="node" value="${wp.selectionModel.selected}"/>
<a href="${node.url}">Simple URL, no modifications possible</a>
<a href="${node.urlGeneration}">Simple URL</a>
<a href="${node.urlGeneration.keepNavigationalState}">With NavState</a>
<a href="${node.urlGeneration.noNavigationalState}">Without NavState</a>
<a href="${node.urlGeneration.setThemeTemplate('Plain')}">With ThemeTemplate</a>
<a href="${node.urlGeneration.forcePublic}">Public Link</a>
<a href="${node.urlGeneration.secure}">Secure Link</a>
<a href="${node.urlGeneration.setLocale('de')}">In Deutsch</a>
<a href="${node.urlGeneration.setParam('a','b')}">With Params</a>
<a href="${node.urlGeneration.setParam('a','b').setParam('c','d').forcePublic.setLocale('de')
Complex URL</a>
<a href="${node.urlGeneration.logout}">Logout</a>
<a href="${node.urlGeneration.login}">Login</a>
<a href="${node.urlGeneration.normalize}">Normalized URL</a>
<a href="${node.urlGeneration.allowRelativeURL}">Relative URL</a>
<a href="${node.urlGeneration.disallowRelativeURL}">Disallow Relative URL</a>
<a href="${node.urlGeneration.forceAbsolute}">Absolute URL</a>
```

Parameters: none

Returns: UrlGenerationPage; the URL object pointing to this page

wp.publicRenderParam:

Public render parameters can be used by portlets to share context information. They are addressed with qualified names. The `wp.publicRenderParam` expression bean can be used within a theme or theme module to read the first String value of a public render parameter.

The public render parameter is read in the context of the currently selected page that is determined internally. If your public render parameter has multiple values, you must use the wp.publicRenderParamValues expression bean instead.

Attributes:

get(qname)

Reads the first string value of the public render parameter that is identified by the qualified name.

Example:

```
<c:set var="editModeQName" value="{http://www.ibm.com/xmlns/prod/websphere/portal/publicpa
<c:set var="isEditModeActive" value="${wp.publicRenderParam[editModeQName]}" />
<c:if test="${isEditModeActive}">
    ...
</c:if>
```

Parameters:

qname
The serialized qualified name of the public render parameter. Its format is {<namespaceURI>}<localname>. This format corresponds with the serialization format defined by the javax.xml.namespace.QName class. To avoid issues with the JSP expression parser, store the qualified name in a separate JSP variable. The qname parameter is mandatory. It must not be null.

Returns: A String representing the first value of the addressed public render parameter or null.

wp.publicRenderParamValues:

The wp.publicRenderParamValues expression bean can be used within a theme or theme module to read the values of a public render parameter. The public render parameter is read in the context of the currently selected page that is determined internally.

Attributes:

get(qname)

Reads the first string value of the public render parameter that is identified by the qualified name.

Example:

```
<c:set var="pageModesQName" value="{http://www.ibm.com/xmlns/prod/websphere/portal/publicp
<c:set var="pageModes" value="${wp.publicRenderParamValues[pageModesQName]}" />
<c:forEach var="mode" items="${pageModes}">
    ...
</c:forEach>
```

Parameters:

qname
The serialized qualified name of the public render parameter. Its format is {<namespaceURI>}<localname>. This format corresponds with the serialization format defined by the javax.xml.namespace.QName class. To avoid issues with the JSP expression parser, store the qualified name in a separate JSP variable. The **qname** parameter is mandatory. It must not be null.

Returns: A String array that contains the values of the addressed public render parameter or null. You can use the forEach JSTL tag to loop over the returned array.

wp.rep - Resource Environment Provider:

The wp.rep provides access to the set of configuration entries for the specified resource environment provider.

Attributes:

get(provider key)

Retrieves the property that is defined in the Resource Environment Provider.

Example:

```
${wp.rep['resourceEnvironmentProvider']['property']}
```

To retrieve the Portal defined Dojo context root.

```
${wp.rep['WP GlobalThemeConfig']['resources.js.dojo.contextRoot']}
```

Parameters: String; specifies the provider key. .

Returns: Properties; it can be null if not found.

Properties:

Object representing a set of properties made available as part of the resource environment provider.

Attributes:

get(key)

Retrieves the property that is defined on the Resource Environment Provider.

Example:

```
${wp.rep['resourceEnvironmentProvider']['property']}
```

To retrieve the Portal defined Dojo context root.

```
${wp.rep['WP GlobalThemeConfig']['resources.js.dojo.contextRoot']}
```

Parameters: String; specifies the property key.

Returns: String; specifies the property value. It can be null if not found.

iterator

Retrieves all properties that are stored in the resource environment provider.

Example:

```
<c:forEach var="node" items="${wp.rep['WP GlobalThemeConfig']}">
${node.key}  =>  ${node.value}<br>
</c:forEach>
```

Parameters: None

wp.selectionModel:

The NavigationSelectionModel provides access to a selection model for a navigation model. The selection model is the navigation model from the perspective of the currently selected page, from which you can get to the selected page's ancestors and descendents.

Attributes:

children(node)

Returns an iterator of child nodes.

Example:

```
<c:forEach var="node" items="${wp.selectionModel.children[wp.identification[wp.selectionMode
 ${node}<br>
</c:forEach>
```

Parameters:

node
Identifiable, or NavigationNode object to look up the children; it must not be null.

Returns: An iterator with NavigationNode objects; it is never null.

hasChildren
Determines whether the specified NavigationNode has associated nodes.

Example:

```
${wp.selectionModel.hasChildren[wp.selectionModel.selected]}
```

Parameters:

node
Identifiable, or NavigationNode object to look up the children; it must not be null.

Returns: Boolean; true if the node has children. Otherwise, it is false.

parent

Access to the parent of a NavigationNode.

Example:

```
${wp.selectionModel.parent[wp.selectionModel.selected]}
```

Parameters:

node
Identifiable or NavigationNode object to look up the children; it must not be null.

Returns: LayoutNode; the parent node for the node if there is a parent. Otherwise, it is null.

path(node)
Provides access to the path information for the node. The path represents the hierarchy from the root to the give node as a list. It is like a breadcrumb.

Example:

```
<c:forEach var="node" items="${wp.selectionModel.path[wp.selectionModel.selected]}">
 &lt;- ${node}
</c:forEach>
```

Parameters:

node
Identifiable or NavigationNode object to look up the children; it must not be null.

Returns: a list of LayoutNodes representing the path from the root to the node.

root Returns the root node of the layout model.

Example:

```
${wp.selectionModel.root}
```

Parameters: none

Returns: NavigationNode; it is never null.

selected

Returns the currently rendered page.

Example:

```
${wp.selectionModel.selected}
```

Parameters: none

Returns: NavigationNode.

NavigationNode:

Represents a navigation node in a navigation model.

Attributes:

contentNode

Returns the content node that is associated with the navigation node.

Example:

```
${wp.selectionModel.selected.contentNode}
${wp.navigationModel.selected.contentNode}
```

Parameters: none

Returns: ContentNode. It is never null.

description

The description of the navigation node.

Example:

```
${wp.selectionModel.selected.description}
${wp.navigationModel.selected.description}
```

Parameters: none

Returns: Description object for the navigation node; it is never null. You can use the value of the title object to retrieve the description in current locale.

isPrivate

Determines whether the current node is private.

Example:

```
${wp.selectionModel.selected.isPrivate}
${wp.navigationModel.selected.isPrivate}
```

Parameters: none

Returns: Boolean, true if the page is private, otherwise false.

metadata

The metadata map of this navigation node.

Example:

```
${wp.selectionModel.selected.metadata['com.ibm.portal.Hidden']}
${wp.navigationModel.selected.metadata['com.ibm.portal.Hidden']}
```

Parameters: none

Returns: Metadata, never null.

CF05 **moduleList**

Returns the module list for the currently selected page and theme.

Example:

```
<c:forEach var="node"items="${wp.selectionModel.selected.moduleList}">
    ${node.name}/${node.version},
</c:forEach>
```

```
<c:forEach var="node"items="${wp.navigationModel.selected.moduleList}">
    ${node.name}/${node.version},
</c:forEach>
```

Parameters: none

Returns: CurrentModuleList, never null.

objectID

Returns the ObjectID associated with this navigation node.

Example:

```
${wp.selectionModel.selected.objectID}
```

```
${wp.navigationModel.selected.objectID}
```

Parameters: none

Returns: ObjectID. Never null.

profileRef

Returns the profile reference for the page. If it is empty or null, the default theme profile reference is used.

Example:

```
${wp.selectionModel.selected.profileRef}
```

```
${wp.navigationModel.selected.profileRef}
```

Parameters: none

Returns: String, the profile reference within the theme. It can be null if you are using a non-modularized theme.

projectID

Returns the project identifier that is associated with this navigation node, or null of no project is associated.

Example:

```
${wp.selectionModel.selected.projectID}
```

```
${wp.navigationModel.selected.projectID}
```

Parameters: none

Returns: String representing the associated project. It can be null if no project is associated.

themeID

Returns the set theme ID for the page. If it is not set for the page, this function returns the inherited theme or default system theme.

Example:

```
${wp.selectionModel.selected.themeID}
```

```
${wp.navigationModel.selected.themeID}
```

Parameters: none

Returns: ObjectID of the referenced theme. Never null.

title The title of this navigation node.

Example:

```
${wp.selectionModel.selected.title}
```

```
${wp.navigationModel.selected.title}
```

Parameters: none

Returns: Title associated with the current object.

CF05 **url**

Short hand for urlGeneration that returns a string and cannot be manipulated any further.

Example:

```
${wp.selectionModel.selected.url}
${wp.navigationModel.selected.url}
```

Parameters: none

Returns: String; the URL pointing to this page.

CF05 **urlGeneration**

Creates a portal URL you can control with attributes. The URL attributes can be set by using further methods on the UrlGeneration object as shown in the examples section.

Example:

```
${wp.selectionModel.selected.urlGeneration}
${wp.navigationModel.selected.urlGeneration}
```

More examples:

```
<c:set var="node" value="${wp.selectionModel.selected}"/>
<a href="${node.url}">Simple URL, no modifications possible</a>
<a href="${node.urlGeneration}">Simple URL</a>
<a href="${node.urlGeneration.keepNavigationalState}">With NavState</a>
<a href="${node.urlGeneration.noNavigationalState}">Without NavState</a>
<a href="${node.urlGeneration.setThemeTemplate('Plain')}">With ThemeTemplate</a>
<a href="${node.urlGeneration.forcePublic}">Public Link</a>
<a href="${node.urlGeneration.secure}">Secure Link</a>
<a href="${node.urlGeneration.setLocale('de')}">In Deutsch</a>
<a href="${node.urlGeneration.setParam('a','b')}">With Params</a>
<a href="${node.urlGeneration.setParam('a','b').setParam('c','d').forcePublic.setLocale('de')
Complex URL</a>
<a href="${node.urlGeneration.logout}">Logout</a>
<a href="${node.urlGeneration.login}">Login</a>
<a href="${node.urlGeneration.normalize}">Normalized URL</a>
<a href="${node.urlGeneration.allowRelativeURL}">Relative URL</a>
<a href="${node.urlGeneration.disallowRelativeURL}">Disallow Relative URL</a>
<a href="${node.urlGeneration.forceAbsolute}">Absolute URL</a>
```

```
<c:set var="node" value="${wp.navigationModel.selected}"/>
<a href="${node.url}">Simple URL, no modifications possible</a>
<a href="${node.urlGeneration}">Simple URL</a>
<a href="${node.urlGeneration.keepNavigationalState}">With NavState</a>
<a href="${node.urlGeneration.noNavigationalState}">Without NavState</a>
<a href="${node.urlGeneration.setThemeTemplate('Plain')}">With ThemeTemplate</a>
<a href="${node.urlGeneration.forcePublic}">Public Link</a>
<a href="${node.urlGeneration.secure}">Secure Link</a>
<a href="${node.urlGeneration.setLocale('de')}">In Deutsch</a>
<a href="${node.urlGeneration.setParam('a','b')}">With Params</a>
<a href="${node.urlGeneration.setParam('a','b').setParam('c','d').forcePublic.setLocale('de')
Complex URL</a>
<a href="${node.urlGeneration.logout}">Logout</a>
<a href="${node.urlGeneration.login}">Login</a>
<a href="${node.urlGeneration.normalize}">Normalized URL</a>
<a href="${node.urlGeneration.allowRelativeURL}">Relative URL</a>
<a href="${node.urlGeneration.disallowRelativeURL}">Disallow Relative URL</a>
<a href="${node.urlGeneration.forceAbsolute}">Absolute URL</a>
```

Parameters: none

Returns: UrlGenerationPage; the URL object pointing to this page

ContentNode:

Provides access to a content node. This interface offers a way to obtain the type of the content node.

Attributes:

contentNodeType

Returns the type of this content node as `com.ibm.portal.content.ContentNodeType`.

Example:

```
${wp.navigationModel.selected.contentNode.contentNodeType}
${wp.selectionModel.selected.contentNode.contentNodeType}
```

The following example displays how to check whether the currently selected node is a label:

```
<c:if test="${wp.navigationModel.selected.contentNode.contentNodeType == 'LABEL'}">
<c:if test="${wp.selectionModel.selected.contentNode.contentNodeType == 'LABEL'}">
```

Parameters: none

Returns: `com.ibm.portal.content.ContentNodeType – COMPOSITION, EXTERNALURL, LABEL, PAGE, STATICPAGE`

description

The description of the content node.

Example:

```
${wp.navigationModel.selected.contentNode.description}
${wp.selectionModel.selected.contentNode.description}
```

Parameters: none

Returns: ContentNode object for the navigation node; it is never null. You can use the value of the title object to retrieve the description in current locale.

metadata

The metadata map of this content node.

Example:

```
${wp.navigationModel.selected.contentNode.metadata['com.ibm.portal.Hidden']}
${wp.selectionModel.selected.contentNode.metadata['com.ibm.portal.Hidden']}
```

Parameters: none

Returns: Metadata, never null.

CF05 **moduleList**

Returns the module list for the currently selected page and theme.

Example:

```
<c:forEach var="node" items="${wp.navigationModel.selected.contentNode.moduleList}">
 ${node.name}/${node.version},
</c:forEach>
<c:forEach var="node" items="${wp.selectionModel.selected.contentNode.moduleList}">
 ${node.name}/${node.version},
</c:forEach>
```

Parameters: none

Returns: CurrentModuleList, never null.

objectID

Returns the ObjectID associated with this content node.

Example:

```
${wp.navigationModel.selected.contentNode.objectID}
${wp.selectionModel.selected.contentNode.objectID}
```

Parameters: none

Returns: ObjectID. Never null.

profileRef

Returns the profile reference for the page. If it is empty or null, the default theme profile reference is used.

Example:

```
${wp.navigationModel.selected.contentNode.profileRef}
${wp.selectionModel.selected.contentNode.profileRef}
```

Parameters: none

Returns: String, which represents the reference to a profile that exists within the theme. It can be null if you are using a non-modularized theme.

themeID

Returns the set theme ID for the page. If it is not set for the page, this function returns the inherited theme or default system theme.

Example:

```
${wp.navigationModel.selected.contentNode.themeID}
${wp.selectionModel.selected.contentNode.themeID}
```

Parameters: none

Returns: ObjectID of the referenced theme. Never null.

title The title of this content node.

Example:

```
${wp.navigationModel.selected.contentNode.title}
${wp.selectionModel.selected.contentNode.title}
```

Parameters: none

Returns: Title associated with the current object.

CF05 **url**

Short hand for urlGeneration that returns a string and cannot be manipulated any further.

Example:

```
${wp.navigationModel.selected.url}
${wp.selectionModel.selected.url}
```

Parameters: none

Returns: String; the URL pointing to this page.

CF05 **urlGeneration**

Creates a portal URL you can control with attributes. The URL attributes can be set by using further methods on the UrlGeneration object as shown in the examples section.

Example:

```
${wp.navigationModel.selected.urlGeneration}
${wp.selectionModel.selected.urlGeneration}
```

More examples:

```
<c:set var="node" value="${wp.navigationModel.selected}"/>
<a href="${node.url}">Simple URL, no modifications possible</a>
<a href="${node.urlGeneration}">Simple URL</a>
<a href="${node.urlGeneration.keepNavigationalState}">With NavState</a>
<a href="${node.urlGeneration.noNavigationalState}">Without NavState</a>
<a href="${node.urlGeneration.setThemeTemplate('Plain')}">With ThemeTemplate</a>
<a href="${node.urlGeneration.forcePublic}">Public Link</a>
<a href="${node.urlGeneration.secure}">Secure Link</a>
<a href="${node.urlGeneration.setLocale('de')}">In Deutsch</a>
<a href="${node.urlGeneration.setParam('a','b')}">With Params</a>
<a href="${node.urlGeneration.setParam('a','b').setParam('c','d').forcePublic.setLocale('c
Complex URL</a>
<a href="${node.urlGeneration.logout}">Logout</a>
<a href="${node.urlGeneration.login}">Login</a>
<a href="${node.urlGeneration.normalize}">Normalized URL</a>
<a href="${node.urlGeneration.allowRelativeURL}">Relative URL</a>
<a href="${node.urlGeneration.disallowRelativeURL}">Disallow Relative URL</a>
<a href="${node.urlGeneration.forceAbsolute}">Absolute URL</a>
```

```
<c:set var="node" value="${wp.selectionModel.selected}"/>
<a href="${node.url}">Simple URL, no modifications possible</a>
<a href="${node.urlGeneration}">Simple URL</a>
<a href="${node.urlGeneration.keepNavigationalState}">With NavState</a>
<a href="${node.urlGeneration.noNavigationalState}">Without NavState</a>
<a href="${node.urlGeneration.setThemeTemplate('Plain')}">With ThemeTemplate</a>
<a href="${node.urlGeneration.forcePublic}">Public Link</a>
<a href="${node.urlGeneration.secure}">Secure Link</a>
<a href="${node.urlGeneration.setLocale('de')}">In Deutsch</a>
<a href="${node.urlGeneration.setParam('a','b')}">With Params</a>
<a href="${node.urlGeneration.setParam('a','b').setParam('c','d').forcePublic.setLocale('c
Complex URL</a>
<a href="${node.urlGeneration.logout}">Logout</a>
<a href="${node.urlGeneration.login}">Login</a>
<a href="${node.urlGeneration.normalize}">Normalized URL</a>
<a href="${node.urlGeneration.allowRelativeURL}">Relative URL</a>
<a href="${node.urlGeneration.disallowRelativeURL}">Disallow Relative URL</a>
<a href="${node.urlGeneration.forceAbsolute}">Absolute URL</a>
```

Parameters: none

Returns: UrlGenerationPage; the URL object pointing to this page

wp.themeConfig:

The wp.themeConfig encapsulates the theme **configuration** parameter lookup process.

Attributes:

get(key)

The following list shows the lookup order:

1. Theme metadata
2. The provided Resource Environment Provider.

Example:

```
<c:set var="themeModuleContextRoot" value="${wp.themeConfig['resources.modules.ibm.contextRo
```

Parameters:

key
String, the property key to look up.

Returns: String, the property value. It can be null.

wp.themeList:

wp.themeList provides access to list of theme objects.

Provides access to the model for a list of installed portal themes. Elements of this model are implemented by Theme objects.

Attributes:

current
Gets the current theme.

Example:

```
${wp.themeList.current}
```

Parameters: none

Returns: Theme, never null.

Exception: `current` requires a valid main portal request. If the required context is not included, an exception is thrown.

get(id) Get an individual theme.

Example:

```
${wp.themeList[id]}
```

Parameters:

id String or Identifiable object to look up the theme objects; it must not be null.

Returns: Theme; it can be null if not found.

iterator
Iterates through themes.

Example:

```
<c:forEach var="node" items="${wp.themeList}">
</c:forEach>
```

Parameters: none

Returns: An iterator with Theme objects; it is never null.

Theme:

Provides access to the attributes of one theme.

Attributes:

description
The description of the theme.

Example:

```
${wp.themeList.current.description}
```

Parameters: none

Returns: Description object for the theme node; it is never null. You can use the value of the title object to retrieve the description in current locale.

metadata
The metadata map of this theme.

Example:

```
${wp.themeList.current.metadata['com.ibm.portal.Hidden']}
```

Parameters: none

Returns: Metadata, never null.

profiles
Represents the profile list of this theme.

Example:

```
${wp.themeList.current.profiles}
```

Parameters: none

Returns: ProfileList, it is never null.

themeTemplateURI
Represents the URI pointing to the theme template that is configured for the current page that is rendered.

Example:

```
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8.5/resolver" prefix="r" %
<r:dataSource uri='spa:${wp.identification[${wp.selectionModel.selected}]}' escape="none">
    <r:param name="themeURI" value="${wp.themeList.current.themeTemplateURI}"/>
    <r:param name="mime-type" value="text/html"/>
</r:dataSource>
```

Parameters: none

Returns: The URI pointing to the theme template that is configured for the current page that is rendered.

Exception: This attribute works for the current theme and current page that is rendered only.

title The title of this theme.

Example:

```
${wp.themeList.current.title}
```

Parameters: none

Returns: Title object for the theme node; it is never null. You can use the value of the title object to retrieve the title in current locale.

ProfileList:

Provides access to all profiles in a theme and the currently selected profile.

Attributes:

current
Gets the current profile.

Example:

```
${wp.themeList.current.profiles.current}
```

Parameters: none

Returns: Profile; it is never null.

Exception: `current` requires a valid main portal request. If the required context is not included, an exception is thrown.

iterator

Iterates through profiles.

Example:

```
<c:forEach var="profile" items="${wp.themeList.current.profiles}" varStatus="profileStatus">
     ${profile.title} / ${profile.relativePath}<br/>
</c:forEach>
```

Parameters: None

Returns: An iterator with Profile objects; it is never null.

Profile:

Provides access to the attributes of one profile.

Attributes:

description

The description of the profile.

Example:

```
${wp.themeList.current.profiles.current.description}
```

Parameters: none

Returns: Description object for the profile node; it is never null. You can use the value of the title object to retrieve the description in current locale.

metadata

The metadata map of this profile.

Example:

```
${wp.themeList.current.profiles.current.metadata['com.ibm.portal.Hidden']}
```

Parameters: none

Returns: Metadata, never null.

relativePath

The relative path of this profile.

Example:

```
${wp.themeList.current.profiles.current.relativePath}
```

Parameters: none

Returns: The URI of this profile as a string.

title The title of this profile.

Example:

```
${wp.themeList.current.profiles.current.title}
```

Parameters: none

Returns: Title object for the profile node; it is never null. You can use the value of the title object to retrieve the title in current locale.

uri The URI of this profile.

Example:

```
${wp.themeList.current.profiles.current.uri}
```

Parameters: none

Returns: The URI of this profile as a string.

wp.user - User:

The wp.user provides access to the active user.

Attributes:

get(profileAttribute)
Specifies the active profileAttribute

Example:

```
${wp.user['cn']}
```

Parameters:

profileAttribute
String; the attribute's name.

Returns: The value of the attribute from the user's profile.

objectID
Returns the object identifier for the current user.

Example:

```
${wp.identification[wp.user.objectID]}
```

Parameters: none

Returns: The object ID of the user.

Common beans:

The following beans are returned by many different beans and are used flexibly.

These beans are always returned.

"Title"
Provides access to the title of certain objects such as Navigation, Content, Theme, Profile, and others.

"Metadata" on page 2766
Provides access to the metadata of certain objects such as Navigation, Content, Theme, Profile, and others.

"Description" on page 2767
Provides access to the description of certain objects such as Navigation, Content, Theme, Profile, and others.

CF05 "UrlGeneration" on page 2768
Creates a portal URL you can control with attributes.

Title:

Provides access to the title of certain objects such as Navigation, Content, Theme, Profile, and others.

If no attribute is used, then the attribute `value` is used by default.

Attributes:

direction
Provides the direction that the title is read.

Example:
`${wp.title.direction}`

Parameters: none

Returns: String, either `ltr` or `rtl`; it is never null.

get(locale)
Gets the title in the specified locale.

Example:
`${wp.title['de']}`

Parameters:

`locale`
The locale code for the language you want.

Returns: String containing the title in the specified locale.

locale Provides the current locale.

Example:
`${wp.title.locale}`

Parameters: none

Returns: Locale object that represents the current locale.

value Provides the title in the current locale.

Example:
`${wp.title.value}`

Parameters: none

Returns: String containing the title in the current locale.

xmlLocale
Provides the current locale as defined by IETF BCP 47.

Example:
`${wp.title.xmlLocale}`

Parameters: none

Returns: String containing the current local in XML format. For example, `en-us`.

Metadata:

Provides access to the metadata of certain objects such as Navigation, Content, Theme, Profile, and others.

Attributes:

get(key)
Gets the metadata for the metadata *key*

Example:
`${wp.themeList.current.metadata['com.ibm.portal.Hidden']}`

Returns: String value of the metadata; it can be null if not found.

Description:

Provides access to the description of certain objects such as Navigation, Content, Theme, Profile, and others.

If no attribute is used, then the attribute `value` is used by default.

Attributes:

direction
Provides the direction that the description is read.

Example:
`${wp.description.direction}`

Parameters: none

Returns: String, either `ltr` or `rtl`; it is never null.

get(locale)
Gets the description in a specified locale.

Example:
`${wp.description['de']}`

Parameters:

`locale`
The locale code for the language you want.

Returns: String containing the description in the specified locale.

locale Provides the current locale.

Example:
`${wp.description.locale}`

Parameters: none

Returns: Locale object that represents the current locale.

value Provides the description in the current locale.

Example:
`${wp.description.value}`

Parameters: none

Returns: String containing the description in the current locale.

xmlLocale
Provides the current locale as defined by IETF BCP 47.

Example:
`${wp.description.xmlLocale}`

Parameters: none

Returns: String containing the current local in XML format. For example, `en-us`.

UrlGeneration:

Creates a portal URL you can control with attributes.

Attributes:

keepNavigationalState
The navigational state is included into the URL.

Example:

```
${wp.selectionModel.selected.urlGeneration.keepNavigationalState}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

noNavigationalState
The current navigational state that includes all portlet modes, states, and render parameters is not included in the URL, and the portal is reset to its default state.

Example:

```
${wp.selectionModel.selected.urlGeneration.noNavigationalState}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

setParam(name, value)
Use this attribute to add parameters to the URL. Parameters added to the URLGeneration object occur as unscoped query parameters. Parameter handling depends on the target of the URL. If the URL points to a page, the parameters are visible to all IBM portlets on that page. Parameters are not visible to standard portlets if the URL does not point specifically to that portlet.

Example:

```
${wp.selectionModel.selected.urlGeneration.setParam('a','b')}
```

Parameters:

`name`
String; the name of the parameter.

`value`
String; the value of the parameter.

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

setLocale(locale)
Use this attribute to change the active language in the navigational state in which the URL is generated.

Example:

```
${wp.selectionModel.selected.urlGeneration.setLocale('de')}
```

Parameters:

`locale`
String; the locale to be set.

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

clearThemeTemplate
Removes the theme template from the navigational state.

Example:

```
${wp.selectionModel.selected.urlGeneration.clearThemeTemplate}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

setThemeTemplate(template)
This specifies the theme template that is taken for rendering the requested page. Can be referenced as either a JSP or a class and is used as theme for this URL.

Example:

```
${wp.selectionModel.selected.urlGeneration.setThemeTemplate('Plain')}
```

Parameters:

template
String; the template name.

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

secure This attribute creates a secure URL (HTTPS).

Example:

```
${wp.selectionModel.selected.urlGeneration.secure}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

unsecure
This attribute creates an unsecure URL (HTTP).

Example:

```
${wp.selectionModel.selected.urlGeneration.unsecure}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

forceProtected
This attribute creates a URL pointing to the protected (logged in) page of the portal.

Example:

```
${wp.selectionModel.selected.urlGeneration.forceProtected}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

forcePublic
This attribute creates a URL pointing to the public (anonymous) page of the portal.

Example:

```
${wp.selectionModel.selected.urlGeneration.forcePublic}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

forceAbsolute
If you use this attribute, absolute URLs are enforced; in this case other settings that affect the generation of URLs might be overridden.

Example:

```
${wp.selectionModel.selected.urlGeneration.forceAbsolute}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

allowRelativeURL
This attribute indicates that a relative URL is generated. If not called for this `Urlgeneration`, then default is used, which is set by the property com.ibm.portal.state.accessors.url.URLContext.enableRelative in the StateManagerService.

Example:

```
${wp.selectionModel.selected.urlGeneration.allowRelativeURL}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

normalize
This attribute indicates that the URL to be generated should be normalized. If more parameters are set, the normalization is run first and afterward the other state modifications are accomplished. It normalizes the URL with the same XSL file used to normalize URLs for search engines. The normalized representation of the URL can also be used to bookmark a page.

Example:

```
${wp.selectionModel.selected.urlGeneration.normalize}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

logout Creates a URL that logs out the current user.

Example:

```
${wp.selectionModel.selected.urlGeneration.logout}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

login Creates a URL that logs in a user to portal. This attribute is typically used for the login panel. The **`user ID`** and **`password`** parameters must be carried with a login URL.

Example:

```
${wp.selectionModel.selected.urlGeneration.login}
```

Parameters: none

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

setPageEditMode(flag)
You can set the page edit mode as used by the toolbar.

Example:

```
${wp.selectionModel.selected.urlGeneration.setPageEditMode('true')}
```

Parameters:

flag
String that indicates a Boolean value as a string. The value `true` enables the page edit mode. The value `false` disables it.

Returns: UrlGeneration, which is the same object, so multiple method calls can be concatenated.

url Generates the url with all its attributes and returns it as a string. This is the default method that is called when no further attributes are specified.

Example:

```
${wp.selectionModel.selected.urlGeneration.url}
${wp.selectionModel.selected.urlGeneration}
```

Parameters: none

Returns: String; the generated URL as a string.

UrlGenerationPage:

Extends UrlGeneration on a page. All the UrlGeneration attributes are available in addition to these attributes.

Attributes:

setLayoutNode(node)
This attribute indicates the ID or unique name of the control that holds the portlet. The value wp.currentSelectedPortlet can be used inside a control when you generate a URL to the portlet within that control.

Example:

```
${wp.navigationModel['ibm.portal.Search Center'].urlGeneration.setLayoutNode('ibm.portal.S
```

Parameters:

node
String or Identifiable; defines the control to be used as a target for the URL.

Returns: UrlGenerationPortlet; a URL generation object for portlet URLs.

setPortlet(portlet)
This attribute indicates the ID or unique name of the control that holds the portlet. The value wp.currentSelectedPortlet can be used inside a control when you generate a URL to the portlet within that control.

Example:

```
${wp.navigationModel['ibm.portal.Search Center'].urlGeneration.setPortlet('ibm.portal.Sear
```

Parameters:

node
String or Identifiable; defines the control to be used as a target for the URL.

Returns: UrlGenerationPortlet; a URL generation object for portlet URLs.

autoSelectPortlet
This attribute automatically selects the first portlet on the page and addresses this as the target for the portlet URL.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.normal.setRenderParam('
```

Parameters: none

Returns: UrlGenerationPortlet; a URL generation object for portlet URLs.

UrlGenerationPortlet:

Extends UrlGeneration in a portlet. All the UrlGeneration and UrlGenerationPage attributes are available in addition to these attributes.

Attributes:

view This attribute sets the portlet mode VIEW.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.view}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

help This attribute sets the portlet mode HELP.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.help}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

edit This attribute sets the portlet mode EDIT.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.edit}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

editDefaults
This attribute sets the portlet mode EDIT_DEFAULTS.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.editDefaults}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

configure
This attribute sets the portlet mode CONFIGURE.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.configure}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

render This attribute generates URLs to a standard portlet's render processing method. If this attribute is omitted, the render method of the portlet is called.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.render}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

action This attribute generates URLs to a standard portlet's action processing method. If this attribute is omitted, the render method of the portlet is called.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.action}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

resource
This attribute generates URLs to a standard portlet's resource processing method. If this attribute is omitted, the render method of the portlet is called.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.resource}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

maximized
This attribute sets the window state MAXIMIZED.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.maximized}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

minimized
This attribute sets the window state MINIMIZED.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.minimized}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

normal

This attribute sets the window state NORMAL.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.normal}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

solo This attribute sets the window state SOLO.

Note: The portlet must be able to exist in solo state that uses the `createReturnURI()` method. If a portlet without this method is placed in solo state, then users must log out or close their browser windows to return to the portal.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.solo}
```

Parameters: none

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

setRenderParam

Use this attribute to add render parameters to the URL. Parameters are not visible to standard portlets if the URL does not point specifically to that portlet.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.setRenderParam('a','b')
```

Parameters:

`name`
String; the name of the parameter.

`value`
String; the value of the parameter.

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

setActionParam

Use this attribute to add action parameters to the URL. Parameters are not visible to standard portlets if the URL does not point specifically to that portlet.

Example:

```
${wp.navigationModel['wps.Selfcare'].urlGeneration.autoSelectPortlet.action.setActionParam('
```

Parameters:

`name`
String; the name of the parameter.

`value`
String; the value of the parameter.

Returns: UrlGenerationPortlet, which is the same object, so multiple method calls can be concatenated.

uiNavigationModel:

By default, the uiNavigationModel lists only visible pages as part of its iterator. When the **Show Hidden Pages** option is selected in the Toolbar, it also lists the hidden pages. There is a mobile hidden flag for pages. The model also helps you specify a mobile test device class expression, which is used to evaluate if the system is rendered as part of a mobile request.

Attributes:

children(node)
Returns an iterator of child nodes.

Example:

```
<c:forEach var="node" items="${uiNavigationModel.children[wp.selectionModel.selected]}" >
    <c:out value="${node}" /><br>
</c:forEach>
```

Parameters:

node
Identifiable, or uiNavigationNode object to look up the children; it must not be null.

Returns: An iterator with uiNavigationNode objects; it is never null.

get(id) Get an individual navigation node.

Example:

```
${uiNavigationModel[id]}
```

Parameters:

id String or Identifiable object to look up the navigation object; it must not be null.

Returns: uiNavigationNode; it can be null if not found.

hasChildren
Determines whether the specified uiNavigationNode has associated nodes.

Example:

```
${uiNavigationModel.hasChildren[wp.selectionModel.selected]}
```

Parameters:

node
Identifiable, or uiNavigationNode object to look up the children; it must not be null.

Returns: Boolean; true if the node has children. Otherwise, it is false.

parent Access to the parent of a uiNavigationNode.

Example:

```
${uiNavigationModel[wp.selectionModel.selected].parent}
```

Parameters:

node
Identifiable or uiNavigationNode object to look up the children; it must not be null.

Returns: uiNavigationNode; the parent node for the node if there is a parent. Otherwise, it is null.

path(node)
Provides access to the path information for the node. The path represents the hierarchy from the root to the give node as a list. It is like a breadcrumb.

Example:

```
<c:forEach var="node" items="${uiNavigationModel.path[wp.selectionModel.selected]}">
 &lt;- ${node}
</c:forEach>
```

Parameters:

node
Identifiable or uiNavigationNode object to look up the children; it must not be null.

Returns: a list of uiNavigationNodes representing the path from the root to the node.

root Returns the root node of the uiNavigation model.

Example:

```
${uiNavigationModel.root}
```

Parameters: none

Returns: uiNavigationNode; it is never null.

uiNavigationNode:

Provides access to a navigation node in a navigation model.

To access the uiNavigationModel Bean, you must use the uiNavigationModel tag and define the variable name that you want the bean to be available under. For example:

```
<portal-navigation:uiNavigationModel var="uiNavigationModel"
    mobileDeviceClassTest="smartphone/tablet">
uiNavigationNode_attribute</portal-navigation:uiNavigationModel>
```

Attributes:

contentNode
Returns the content node that is associated with the navigation node.

Example:

```
${uiNavigationModel.selected.contentNode}
```

Parameters: none

Returns: ContentNode. Never null.

description
The description of the navigation node.

Example:

```
${uiNavigationModel.selected.description}
```

Parameters: none

Returns: Description object for the navigation node; it is never null. You can use the value of the title object to retrieve the description in current locale.

isDraft

Returns whether the navigation node is part of a project or not.

Example:

```
${uiNavigationModel[wp.selectionModel.selected].isDraft}
```

Parameters: none

Returns: Boolean; true if the page is a draft page. False if it is not.

isHidden

Returns whether the navigation node is hidden or not.

Example:

```
${uiNavigationModel[wp.selectionModel.selected].isHidden}
```

Parameters: none

Returns: Boolean; true if the page is hidden. False if it is not.

isInSelectionPath

Returns whether the navigation node is part of the selection path. It returns whether a page is in the breadcrumb trail, but not necessarily the currently active page.

Example:

```
${uiNavigationModel[wp.selectionModel.selected].isInSelectionPath}
```

Parameters: none

Returns: Boolean; true if the page is part of the selection path. False if it is not.

isPrivate

Determines if the current node is private.

Example:

```
${uiNavigationModel.selected.isPrivate}
```

Parameters: none

Returns: Boolean, true if the page is private, otherwise false.

isSelected

Returns whether the navigation node is selected or the currently selected page.

Example:

```
${uiNavigationModel[wp.selectionModel.selected].isSelected}
```

Parameters: none

Returns: Boolean; true if the page is selected. False if it is not.

metadata

The metadata map of this navigation node.

Example:

```
${uiNavigationModel.selected.metadata['com.ibm.portal.Hidden']}
```

Parameters: none

Returns: Metadata, never null.

moduleList

Returns the module list for the currently selected page and theme.

Example:

```
<c:forEach var="node"items="${uiNavigationModel.selected.moduleList}">
    ${node.name}/${node.version},
</c:forEach>
```

Parameters: none

Returns: CurrentModuleList, never null.

objectID

Returns the ObjectID associated with this navigation node.

Example:

```
${uiNavigationModel.selected.objectID}
```

Parameters: none

Returns: ObjectID. Never null.

profileRef

Returns the profile reference for the page. If it is empty or null, the default theme profile reference is used.

Example:

```
${wp.selectionModel.selected.profileRef}
```

Parameters: none

Returns: String, the profile reference within the theme. It can be null if you are using a non-modularized theme.

projectID

Returns the project identifier that is associated with this navigation node, or null of no project is associated.

Example:

```
${uiNavigationModel.selected.projectID}
```

Parameters: none

Returns: String representing the associated project. It can be null if no project is associated.

title The title of this navigation node.

Example:

```
${uiNavigationModel.selected.title}
```

Parameters: none

Returns: Title associated with the current object.

themeID

Returns the set theme ID for the page. If it is not set for the page, this function returns the inherited theme or default system theme.

Example:

```
${wp.selectionModel.selected.themeID}
```

Parameters: none

Returns: ObjectID of the referenced theme. Never null.

url Short hand for urlGeneration that returns a string and cannot be manipulated any further.

Example:

```
${wp.selectionModel.selected.url}
```

Parameters: none

Returns: String; the URL pointing to this page.

urlGeneration

Creates a portal URL you can control with attributes. The URL attributes can be set by using further methods on the UrlGeneration object as shown in the examples section.

Example:

```
${wp.selectionModel.selected.urlGeneration}
```

More examples:

```
<c:set var="node" value="${wp.selectionModel.selected}"/>
<a href="${node.url}">Simple URL, no modifications possible</a>
<a href="${node.urlGeneration}">Simple URL</a>
<a href="${node.urlGeneration.keepNavigationalState}">With NavState</a>
<a href="${node.urlGeneration.noNavigationalState}">Without NavState</a>
<a href="${node.urlGeneration.setThemeTemplate('Plain')}">With ThemeTemplate</a>
<a href="${node.urlGeneration.forcePublic}">Public Link</a>
<a href="${node.urlGeneration.secure}">Secure Link</a>
<a href="${node.urlGeneration.setLocale('de')}">In Deutsch</a>
<a href="${node.urlGeneration.setParam('a','b')}">With Params</a>
<a href="${node.urlGeneration.setParam('a','b').setParam('c','d').forcePublic.setLocale('c
Complex URL</a>
<a href="${node.urlGeneration.logout}">Logout</a>
<a href="${node.urlGeneration.login}">Login</a>
<a href="${node.urlGeneration.normalize}">Normalized URL</a>
<a href="${node.urlGeneration.allowRelativeURL}">Relative URL</a>
<a href="${node.urlGeneration.disallowRelativeURL}">Disallow Relative URL</a>
<a href="${node.urlGeneration.forceAbsolute}">Absolute URL</a>
```

Parameters: none

Returns: UrlGenerationPage; the URL object pointing to this page

Drag-and-drop

Drag-and-drop uses HTML5 code to facilitate the layout of content.

Drag sources and drop targets do not need any JavaScript library. Some convenience functions are provided in the i$.dnd API. For example, with drag-and-drop, you can drag an item, such as a portlet or content item from the toolbar on the page. Or you can drag an item from one position on the page to another position.

"Customizing drop targets on the page" on page 2780
In edit mode, portal renders drop targets for all positions where a portlet can be added to the page. In the default theme, these drop targets are hidden unless an item is dragged over the surrounding container.

"Custom drag sources and drop targets" on page 2780
Drag sources and drop targets must be created according to the HTML 5 specification. In HTML 5, the **DataTransfer** object is used to exchange data from source to target.

Customizing drop targets on the page:

In edit mode, portal renders drop targets for all positions where a portlet can be added to the page. In the default theme, these drop targets are hidden unless an item is dragged over the surrounding container.

The markup for drop targets is defined in a file that is named `DropTarget.html`, which lies in the current skin folder in WebDAV. For example, `fs-type1/themes/Portal8.5/skins/Hidden/DropTarget.html`

The markup in `DropTarget.html` is always surrounded by a `<div>` tag, representing the drop target control component. Inside the `<div>` tag is an anchor tag that references the control-component at the position where a dropped item is inserted. For example:

```
<div class="portlet-window component-control portal-drop-target id-ID_of_control_component_at_insert_
<a class="portlet-window-ref" href="#ID_of_control_component_at_insert_position"></a>

        <DropTarget.html>

</div>
```

The styling for the CSS classes can be found in the `default_edit.css` in `fs-type1/themes/Portal8.5/css/default/default_edit.css`.

Portal also injects the following CSS classes during a drag operation:

- When an item is dragged over a column or row container, the container gets the CSS class `ibmDndDropZonesActive`.
- When an item is dragged over a drop target, the drop target gets the CSS class `ibmDndDropZoneOver`.

The following list shows CSS selector examples and the resulting action:

- `div.ibmDndDropZonesActive div.portal-drop-target` selects a drop target inside the currently active container, either a row or a column.
- `div.ibmDndDropZonesActive div.portal-drop-target.ibmDndDropZoneOver` selects a drop target where an item is currently dragged over.

A theme developer can customize the drop zones either by editing the `default_edit.css` or by modifying the `DropTarget.html`, or both.

Firefox currently does not support automatic scrolling during a drag-and-drop operation. There are plug-ins available to add this support to Firefox.

Custom drag sources and drop targets:

Drag sources and drop targets must be created according to the HTML 5 specification. In HTML 5, the **`DataTransfer`** object is used to exchange data from source to target.

The source sets the data with `dataTransfer.setData(format, data)` and the target reads the data with `dataTransfer.getData(format)`. WebSphere Portal Express always uses `format = "Text"`. The data is a stringified JSON object with the following structure:

```
{ "uri" : URI }
```

In the previous example, the *URI* is the URI of the object that is dragged. If more than one object is dragged, the structure looks like this example.

```
{ "uri" : [ URI_1, URI_2, ... ] }
```

Each URI can have a list of parameters. In this case, the JSON object has the following structure.

```
{ "uri" : [ { key_11 : value_11, key_12 : value_12, ... }, URI_1, { key_21 : value_21, key_22 : va
```

In the previous example, **key_1x:value_1x** are the parameters of *URI_1* and **key_2x:value_2x** are the parameters of *URI_2*.

The theme module `i$.dnd` provides two convenience functions that simplify the creation of HTML 5 drag sources and drop targets. To create a drag source, you can use the following code.

```
i$.dnd.addSource(parameter)
```

In the previous example, the parameter object needs to have the following elements:

{DOMNode} parameter.node
The DOM node that acts as the drag source.

{String} parameter.type
The type of data that is transferred, typically `"Text"`.

{Object} parameter.data
The data to transfer when dropped. When you exchang data with a standard WebSphere Portal Express drop target, it must be a stringified JSON object with the structure described before.

{DOMNode} parameter.avatar
The DOM node to use as the DnD avatar. (optional)

{Function} parameter.dragstart
A function to start when **dragstart** is called. (optional) The following parameters are passed to this function:

{Event} e
The event. For example, you can use the event to set `e.dataTransfer.effectAllowed = "copy";`.

{DOMNode} n
The **DomNode** of the source area.

{Function} parameter.dragend
A function to start when **dragend** is called. It has the same parameters as **parameter.dragstart**. (optional)

To create a drop target, you can use the following code.

```
i$.dnd.addTarget(parameter)
```

In the previous example, the parameter object must have the following elements:

{DOMNode} parameter.node
The **DOMnode** acting as the drop target.

{String} parameter.type
The type of data that is transferred, typically `"Text"`.

{Function} parameter.drop
Function to handle the drop event. The following parameters are passed to this function:

{Event} e
The drop event.

{DOMNode} n
The DOM node of the drop target.

{String} type
The type of data that is transferred.

{Object} data
The data that was transferred from the drag source. When receiving data from standard WebSphere Portal Express drag sources, it is a stringified JSON object with the structure described before.

{Function} parameter.dragenter
Function to start when **dragenter** is called. (optional) The following parameters are passed to this function:

{Event} e
The event.

{DOMNode} n
The DOM node of the drop target.

{Function} parameter.dragleave
Function to start when **dragend** is called with the same parameters as **dragenter**. (optional)

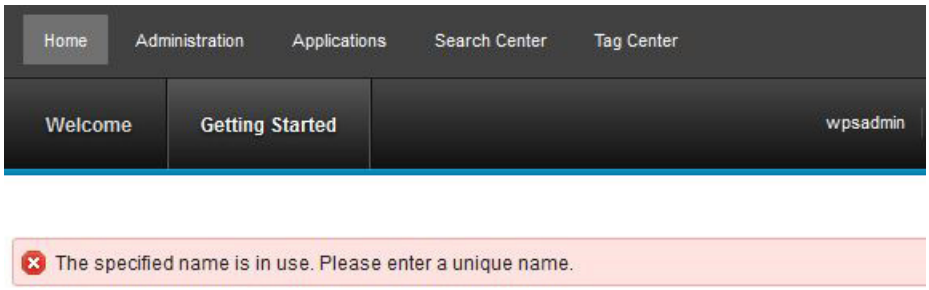
{Function} parameter.dragover
Function to start when **dragover** is called with the same parameters as **dragenter**. (optional)

Displaying messages in the status bar module

Displaying messages in the status bar module.

About this task

All ready-to-use theme profiles include the status_bar module, which provides an area beneath the header for displaying error, warning and information messages. The following image shows an example error message in red.



Procedure

1. Add a line of JavaScript to Use this status bar in your themes, modules, and portlets can use this status bar. The following example shows the StatusMessage JavaScript code:

```
i$.fireEvent("/portal/status",[{message: new com.ibm.widgets.StatusMessage
("error", "The specified name is in use. Please enter a unique name.", ""), uid: 'ibmStatusBox'}]);
```

`i$.fireEvent` is the recommended syntax. However, if you use the Dojo module, you can also use this alternative syntax:

```
dojo.publish("/portal/status",[{message: new com.ibm.widgets.StatusMessage
("error", "The specified name is in use. Please enter a unique name.", ""), uid: 'ibmStatusBox'}]);
```

a. The first argument in the StatusMessage can be either "error", "warning" or "info" to control the icon and color of the message box.
b. The second argument in the StatusMessage is a String representing the message itself to be displayed in the message box.
c. The third argument in the StatusMessage is an optional String representing any further details about the message. The details are not presented to the user by default, rather only if the user clicks the **Show Details** icon to expand the message box.

2. If you have an error that originates on the server, you can set a ibm.portal.operations.error cookie in the response, and the client shows the message when the response completes. Use parsable JSON code for the cookie string value, such as:

```
ibm.portal.operations.error={"errorType":"error","errorMessage":"The specified name is in use. Please enter a unique name.","errorDetails":""}
```

3. Messages are cleared automatically on page reload. If you must clear one or more messages from the client by using JavaScript, then you can use the following code:

   ```
   i$.fireEvent("/portal/status/clear", [{message: mymessage, uid: 'ibmStatusBox'}]);
   ```

   where *mymessage* is the StatusMessage instance you saved when displaying the message. Code like the following example is fine too:

   ```
   i$.fireEvent("/portal/status/clear", [{message: new com.ibm.widgets.StatusMessage ("error", "T
   ```

   The event clears any messages whose StatusMessage type, message, and details strings match, so you do not have to reuse the same actual StatusMessage instance.

   If no StatusMessage is passed, then it clears all messages. You can clear everything with the following code sample:

   ```
   i$.fireEvent("/portal/status/clear", [{uid: 'ibmStatusBox'}]);
   ```

Updating the content menu to open on click instead of on hover

The content menu opens when a user hovers over a portlet containing IBM Web Content Manager items. In combined Cumulative Fix 05, you can set the content menu to open when a user clicks an icon in the portlet skin instead.

About this task

Procedure

1. Add the content menu icon to your custom skin. Update the custom theme CSS sprite to include the new content menu icon image. Replace the master.png static resource with the Portal 8.5 default theme image in WebDAV at `/themes/Portal8.5/css/images/master.png`.
2. Add the HTML for the icon to the custom skins. Add the following code to the custom skin templates after the `<h2>` node.

   ```
   <a aria-haspopup="true" aria-label="Display component action menu" role="button" href="javascr
                   <span title="Display component action menu"><img aria-label="Display component
                   <span class="wpthemeAltText">Component Action Menu</span>
                   <!-- start CAM template -->
                   <span class="wpthemeMenu" data-positioning-handler="horizontallyCenteredBelow"
                       <div class="wpthemeMenuBorder">
                           <!-- define the menu item template inside the "ul" element.  only "css
                           <ul class="wpthemeMenuDropDown wpthemeTemplateMenu" role="menu">
   ```

```
                        <li class="${css-class}" role="menuitem" tabindex="-1"><span
                            class="wpthemeMenuText">${title}</span></li>
                    </ul>
                    <div class="verticalMenuPointer pointer"></div>
                </div> <!-- Template for loading -->
                <div class="wpthemeMenuLoading wpthemeTemplateLoading">${loading}</div>
                <!-- Template for submenu -->
                <div class="wpthemeAnchorSubmenu wpthemeTemplateSubmenu">
                    <div class="wpthemeMenuBorder wpthemeMenuSubmenu">
                        <ul id="${submenu-id}" class="wpthemeMenuDropDown"
                            role="menu">
                            <li role="menuitem" tabindex="-1"></li>
                        </ul>
                    </div>
                </div>
            </span>
            <!-- end CAM template -->
        </a>
```

3. Translate the values of the `aria-label` and `wpthemeAltText` to support any languages you support.
4. Add the CSS for the icon. Add the following code anywhere in the custom theme.

```
.wpthemeControlHeader a.wpthemeIcon.contextMenuInSkinIcon img {
        background-position:0 -1496px;
    }
```

5. Add the new content menu to the custom theme profile. Open the theme profile and add `wp_skin_cam` to the `deferredModuleIDs` section.

Displaying the draft page ribbon

The draft page ribbon is a strip of text that appears along both sides of a page that has a draft in the current project.

About this task

The draft page ribbon makes it easier for users to see if a page has pending changes waiting to be published.

Procedure

1. To get the draft page ribbon feature, add the `wp_draft_page_ribbon` module to your theme profile.
2. To add and remove ready-to-use modules to your theme, see Adding or removing a module from a profile.

Related concepts:

"Modules that add features to a theme" on page 2652
Theme modules contribute resources, such as JavaScript, CSS and HTML, to a theme or page. The following modules come with the modularized theme and specifically contribute a feature rather than working in the background. The modules can be added to a theme by listing them in the theme's default profile, or to a single page or set of pages.

Adding jQuery to a theme

The jQuery library is a JavaScript library. IBM WebSphere Portal Express includes a jQuery module for the jQuery core so you can use jQuery in a theme.

About this task

This jQuery module is not turned on by default. jQuery is an open framework and is not supported by IBM. The module makes it quick and easy to use jQuery and any of its plug-ins in a theme.

Procedure

1. To turn on jQuery, copy the `jquery1.10.2.json` module definition file into your theme's contributions folder in WebDAV `fs-type1`. This `jquery1.10.2.json` file can be found at *`PortalServer`*`\theme\wp.theme.jquery\installedApps\wp.theme.jquery.ear\wp.theme.jquery.war\v1.10.2`.
2. Optional: To enable plug-ins with the jQuery core, download the jQuery plug-in from the jQuery website For more information, see *jQuery plug-in download* in the related links. In this example, use the PowerTip plug-in. The `jquery.powertip-1.2.0.zip` file. To download the plug-in, see *jQuery PowerTip plug-in download* in the related links.
   a. Extract the contents of your plug-in file to any location.
   b. Create a subfolder in your theme's modules folder for the plug-in, such as `jquery_powertip` in this example.
   c. The PowerTip plug-in has two files that must be head contributions of your module, so create a head subfolder in your `jquery_powertip` folder.
   d. Copy the needed resource files from your extracted plug-in location into your head folder. The needed resource files in this case are:

      ```
      jquery.powertip.min.js
      jquery.powertip.js
      jquery.powertip.min.css
      jquery.powertip.css
      ```

   e. Copy both the min and non-min versions of the files. The min version is used automatically by default for performance and the non-min version is used automatically when debug mode is on.
   f. This example uses the default color scheme for the tips. But, PowerTip comes with multiple color schemes as defined in separate css files in its CSS folder. You can change to one of the other color schemes or create one of your own by placing the different css files into your head folder. For example, to get the light color scheme, you can instead copy the css files into your head folder.

```
jquery.powertip-light.min.css
jquery.powertip-light.css
```

g. Your `jquery_powertip` module `prereqs` the jQuery module, so create a file that is named `prereqs.properties` in your `modules\jquery_powertip` folder with the following content:

```
jquery
```

h. If you have more plug-ins, similar module definition folders can be defined for them in your theme's modules folder. For each module definition, give the module a folder name that starts with `jquery_`, such as `jquery_powertip` in this example. Prereq the `jquery` module.

3. Add the module `jquery` to the module listings in one of your theme's profiles. Rather than modify one of the existing profile files, it is best to copy one of them and modify the copy. Copy the base profile file that you want to be similar to, such as `profile_deferred.json`, rename it to something such as `profile_jquery_deferred.json` and add the module `jquery`. When you create a profile file, adjust the titles and descriptions so that your profile has a unique and recognizable title and description. For example, change the titles and descriptions to

```
"titles": [
      {
         "value": "jQuery Deferred",
         "lang": "en"
      }
   ],
   "descriptions": [
      {
         "value": "This profile has jQuery plus the full set of modules for the theme, but def
         "lang": "en"
      }
   ]
```

4. Optional: Add the plug-in modules to the module listings in your profile, such as add the module `jquery_powertip` in this example.
5. Invalidate the cache so that your profile and module changes are picked up by the Portal server. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Theme Analyzer**. Then, click **Utilities** > **Control Center** > **Invalidate Cache** > **Click to invalidate**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.
6. Apply your profile to a page. In **Edit Page Properties** > **Advanced**, select your Profile: `jQuery Deferred`.
7. To verify that jQuery is loaded on a page and what version it is, you can run `$().jquery` in the console of your browser's developer tools. It echoes the jQuery version number.

Results

Now the jQuery core and your plug-ins are ready and available for use. To learn the basics about jQuery core usage, see *jQuery basics* in the related links. You can learn the usage of your plug-ins at the same site where you downloaded the plug-in. For more information, see *PowerTip download*.

"Defining tooltips with PowerTip" on page 2788
Once your PowerTip module is active, you can add one or more tooltips to your pages through a dynamic content spot, or a config markup type subcontribution in a module.

Related information:

jQuery plug-in download

jQuery PowerTip plug-in download

jQuery basics

PowerTip download

Defining tooltips with PowerTip:

Once your PowerTip module is active, you can add one or more tooltips to your pages through a dynamic content spot, or a config markup type subcontribution in a module.

About this task

The PowerTip offers flexible tip positioning at the compass points. You can position the tip so it is never clipped off the edge of the view port. And, you can let the tip remain visible while the mouse is on it so the user can interact with the contents of the tip. Here is an example of PowerTip usage code for those options:

```
<script type="text/javascript">
 $(function() {
  $('#myelement').data('powertiptarget', 'mytip');
  $('#myelement).powerTip({ placement: 's', mouseOnToPopup: true, smartPlacement: true });
 });
</script>
<div id="mytip" style="display:none">
 <input type="text" />
 <input type="button" value="Search" />
</div>
```

In this example, *myelement* must be replaced with the ID of the element on the page that you want to add the tip to. And *mytip* is the ID of the `div` that is the tip itself, which is defined by the `div` in the example. Notice that the tip `div` is set to `display:none` initially. The PowerTip shows it when the user mouses over the `myelement` element.

You can define multiple tooltips by copying the data and PowerTip lines for each tooltip and copying the `div` block for each tooltip. Modify the IDs for each one.

You can put the example code anywhere on the page. You can add the tooltip to a dynamic content spot to add the code to the page. Or, you can add the code to a config markup type subcontribution of a module.

If your markup is visible and needs to be injected at a specific point on a page, use a dynamic content spot. If your markup is not visible initially and can be injected anywhere on a page, use the subcontribution method. The tooltip code can be anywhere on the page, so use the subcontribution method and follow these steps

Procedure

1. Create a `theme_powertips` subfolder in your theme's modules folder.
2. Your `theme_powertips` module will prereq the `jquery_powertip` module, so create a file that is named `prereqs.properties` in your `theme_powertips` folder with the following content:

   ```
   jquery_powertip
   ```
3. Create a config subfolder in your `theme_powertips` folder.

4. Create a `theme_powertips.html` markup file in your `config` folder. You can copy and paste the following code as an example:

```
<script type="text/javascript">
 $(function() {
  $('#wpthemeHelp img').data('powertiptarget', 'wpthemeHelpTip');
  $('#wpthemeHelp img').powerTip({ placement: 's', mouseOnToPopup: true, smartPlacement: true
 });
</script>
<div id="wpthemeHelpTip" style="display:none">
 <form method="get" action="http://www-10.lotus.com/ldd/portalwiki.nsf/xpSearch.xsp" target="w
  <input type="text" name="searchValue" />
  <input type="submit" value="Search" />
 </form>
</div>
```

   This example assumes that your theme has a help element with ID `wpthemeHelp` similar to the default theme. If your theme does not have an element with ID `wpthemeHelp`, then change the two instances of `'#wpthemeHelp img'` to a selector that identifies one of the elements in your theme, and rename the two instances of `'wpthemeHelpTip'`.

   This example uses a simple form on the tooltip that searches the IBM WebSphere Portal Express wiki documentation. You can change the markup in your tooltip `div` entirely to whatever you need to appear on your tooltip.
5. Add the module `theme_powertips` to the module listings in your jQuery profile file.
6. Invalidate the cache so the Portal server includes your profile and module changes. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Theme Analyzer**. Then, click **Utilities** > **Control Center** > **Invalidate Cache**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

Results

Go to your page that has your jQuery profile applied, move the mouse over the help icon, or whichever theme element you specified in step 4, and you see your tip appear.

If things do not work correctly, you can troubleshoot your modules. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Theme Analyzer**. Then, click **Examine Modules by Profiles**. Expand your theme in the tree and select your jQuery profile, such as **jQuery Deferred**, in the tree and examine the profile. Double-click your jQuery profile in the tree. Expand the Modules folder in the tree and select one-by-one your various jQuery modules, **jquery**, **jquery_powertip**, and **theme_powertips**. For each, examine the details to see if everything looks correct (in particular the prereqs and the contributions). If you spot and fix a problem, be sure to invalidate the cache after so the Portal server picks up the change.

Using Sametime with the WebSphere Portal Version 8.5 theme

You can add modules to your profile to use IBM Sametime with the IBM WebSphere Portal Express Version 8.5 theme.

About this task

To gain Sametime awareness with the WebSphere Portal Express Version 8.5 theme, you must add one of the following modules to your profile:

- **`wp_sametime_links`**: Provides existing STlinks support.
- **`wp_sametime_proxy`**: New Sametime proxy support.

When using the **wp_sametime_proxy** module you must update the following attribute in the **WP CommonComponentConfigService** resource environment provider on the WebSphere Portal server to activate the module:

Procedure

1. Set the **cc.sametime.proxy.enabled** attribute to `true`.
2. Set the **cc.sametime.proxy.scheme** attribute to `http` or `https`, depending on the way your Sametime Proxy Server is accessed.
3. Set the **cc.sametime.proxy.host** attribute to `hostname`. Include the domain name in the attribute, for example `hostname.domainname.com`.
4. Set the **cc.sametime.proxy.port**.
5. Set the **cc.sametime.connect.client** attribute to `true` if you want the Sametime Proxy to use the Sametime connect client, which is installed on the system with Sametime Proxy Server.
6. Set the **cc.sametime.proxy.version** attribute to 8.5.2 if you want the integrate with Sametime Proxy 8.5.2. Otherwise, set the attribute to 8.5.1 if you want to integrate with Sametime Proxy 8.5.1.

What to do next

For more information about using Sametime with WebSphere Portal Express, see Integrating with IBM Sametime.

Tags used by the portal JSPs

Learn about the most commonly used tags in the portal JSPs. Use these tags to modify the appearance and layout of the portal page.

The following links provide topics with summary descriptions of each tag - grouped by tag type. Each separate topic also provides tag descriptions and code examples:

Note: Do not use portal tags in portlet JSPs. The tags that are mentioned are only for use in theme and skin JSPs.

- "<portal-core/> tags" on page 2791 - Used to provide portal core functions such as entering the main render flow and URL-related aspects of the page.
- "<portal-dynamicui/> tags" on page 2794 - Used to enable dynamic user interface features such as closing dynamic portlets and pages.
- "<portal-fmt/> tags" on page 2794 - Used to provide enhanced portal formatting capabilities.
- "<portal-logic/> tags" on page 2799 - Used to provide conditional logic.
- "<portal-navigation/> tags" on page 2805 - Used to implement navigation tasks such as generating URLs and traversing the portal navigation model.

To use these tags, the following `taglib` declarations must be provided in the parent JSP of the theme:

```
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8.5/portal-navigation"
  prefix="portal-navigation" %>
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8.5/portal-dynamicui"
  prefix="portal-dynamicui" %>
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8.5/portal-logic"
  prefix="portal-logic" %>
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8.5/portal-core"
  prefix="portal-core" %>
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8.5/portal-fmt"
  prefix="portal-fmt" %>
```

The following `taglib` declarations must be provided to the parent JSP of the skin - in addition to the ones in the theme:

```
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8.5/portal-skin"
  prefix="portal-skin" %>
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8.5/portal-showtools"
  prefix="portal-showtools" %>
```

Notes:

- The tags in the `portal-internal.tld` tag library are not intended for customization, but for use only by internal portal code.
- The tags in the `engine.tld` and `portal-internal.tld` tag libraries are not intended for customization, but only to support compatibility with an earlier version and migration. The `engine.tld` tag library are not available in subsequent releases of WebSphere Portal Express.

  "<portal-core/> tags"
  The <portal-core/> tags are used to provide portal core functionality such as entering the main render flow as well as URL-related aspects of the page.

  "<portal-dynamicui/> tags" on page 2794
  The <portal-dynamicui/> tags are used to enable dynamic user interface features such as closing dynamic portlets and pages.

  "<portal-fmt/> tags" on page 2794
  The <portal-fmt/> tags are used to provide enhanced portal formatting capabilities.

  "<portal-logic/> tags" on page 2799
  The <portal-logic/> tags are used to provide tags for conditional logic.

  "<portal-navigation/> tags" on page 2805
  The `<portal-navigation/>` tags are used to implement navigation tasks such as generating URLs and traversing the portal navigation model.

<portal-core/> tags:

The <portal-core/> tags are used to provide portal core functionality such as entering the main render flow as well as URL-related aspects of the page.

The following table provides a brief description of each tag.

Note: Do not use portal tags in portlet JSPs. The following tags are only for use in theme and skin JSPs.

Table 447. Descriptions of <portal-core/> tags

Tag	Description
<portal-core:cacheProxyUrl/>	Creates a URL to the caching proxy servlet. **Note:** This tag is deprecated for IBM WebSphere Portal Express 8.0.
<portal-core:constants/>	Makes the <%= wpsBaseURL %> and <%= wpsDocURL %> constants available to the page.
<portal-core:defineObjects/>	Defines a set of objects which can be used later on (for example, `escapeXmlWriter`).
<portal-core:init-lazy-set/>	This tag initializes the lazy set functionality and is required to be called in the outer most JSP. For example in your theme it would be the `default.jsp`. It must not be placed in a dynamic content spot JSP.

Table 447. Descriptions of <portal-core/> tags (continued)

Tag	Description
<portal-core:lazy-set/>	This tag evaluate the given EL expression unless it has been cached already with the current request and stores a variable in the request scope with the given name (var). Attributes: **var** - variable name to be set into the request. **elExpression** EL expression to be evaluated. It must not contain the ${} because the JSP engine evaluates everything that is surrounded by ${} as an EL Bean. This invalidates all performance improvements. For example: `<portal-core:lazy-set var="deviceClass" elExpression="wp.c`
<portal-core:pageRender/>	Used in the Home screen to render the content of the selected page. Do not confuse this with the <portal-core:pageRender/> tag deprecated in V4.2.
<portal-core:screenRender/>	Starts the rendering of the screen. This tag should be used only in theme JSPs.
<portal-core:stateBase/>	Stores a base URL which can be used instead of full, newly-coded URLs on each occurrence of a URL in the markup. This tag should occur only in the header section of the markup, which is provided by theme JSPs.

Detailed descriptions of the <portal-core/> JSP tags

The following section provides detailed descriptions of the <portal-core/> JSP tags:

<portal-core:cacheProxyUrl forwardurl="*url_string*"/>

Creates a URL to the caching proxy servlet. The URL created is fully cacheable and includes information about the requesting client. The CC/PP client profile is used for gathering information about the client for the URL. The purpose of this tag is to link .CSS files into the JSP. The tag has one attribute.

Note: For security reasons, the cache proxy servlet will only serve URLs pointing to resources located in the themes, skins, and screens directories. This makes all resources underneath these directories public. Also, any URLs containing the ".." characters will not be served.

Attributes

forwardurl

Specifies the address to the file you want to be sent to the caching proxy servlet. This attribute can be set by passing in a String or a URL object.

The following code example uses this tag to link a CSS file in a JSP:

```
<link href="<portal-core:cacheProxyUrl
      forwardurl="<portal-logic:urlFindInTheme type="css"
               file="styles.jsp"/>"/>">
```

<portal-core:constants/>

Makes the following constants available to the page:

- <%= wpsBaseURL %>

  Provides the context path of the portal site as specified during installation, for example, `/wps`

- <%= wpsDocURL %>

  Provides the URL to the product documentation located in the WebSphere Portal Express Web application directory, including the Javadoc information, and portal help. The URL returned includes the locale of the client, for example, `/wps/doc/locale/`. For example, the following code would generate a URL to the portal help:

  ```
  <%= wpsDocURL %>/help/index.html
  ```

<portal-core:defineObjects/>

Defines a set of objects which can be used later (for example, `escapeXmlWriter`). Makes the following constants available to the page:

- <%= escapeXmlWriter %>

  This writer can be used to stream out URLs. The writer makes sure that the URL is written out in XML compliant representation:

  ```
  <portal-navigation:urlGeneration contentNode="wps.Links" portletMode="view">
    <c:set var="title"><portal-fmt:text bundle="nls.bundle" key="link" /></c:set>
    <a href="<% wpsURL.write(escapeXmlWriter); %>"><c-rt:out value='${title}' escapeXml='true' /></a>
   </portal-navigation:urlGeneration>
  ```

<portal-core:pageRender/>

Used in the Home screen to render the content of the selected page. Do not confuse this with the <portal-core:pageRender/> tag deprecated in V4.2. This tag renders the portal page without the navigation. When this tag is called, all pages that are available for the user are determined.

<portal-core:screenRender/>

Renders the current screen. Types of screens include Home (default), Login, and Error. This tag can only be used once in the portal. This tag should be used only in theme JSPs.

Example

This part of the `Default.jsp` portlets.

```
<div id="FLYParent">
 <%@ include file="./banner.jspf" %>
 <portal-logic:if portletSolo="no">
   <%@ include file="./topNav.jspf" %>
   <%@ include file="./sideNav.jspf" %>
 <portal-logic:if/>

 <a name="wpsMainContent">
 <%-- Call the portal engine command to render the portlets for this page --%>
 <div id="mainContent"><portal-core:screenRender/></div>

 <portal-logic:if portletSolo="no">
   <%@ include file="./footer.jspf" %>
   <%@ include file="./flyout.jspf" %>
 </portal-logic:if>
 <portal-logic:if loggedIn="yes">
</div>
```

<portal-core:stateBase/>

Stores a base URL which can be used instead of full, newly-coded URLs on each occurrence of a URL in the markup. This enables shorter URLs and can improve the page serving performance. This tag should occur only in the header section of the markup - it is not allowed to occur outside of the header section. Theme JSPs are responsible for the header section, using `Head.jsp` by default.

<portal-dynamicui/> tags:

The <portal-dynamicui/> tags are used to enable dynamic user interface features such as closing dynamic portlets and pages.

The following table provides a brief description of each tag.

Note: Do not use portal tags in portlet JSPs. The following tags are only for use in theme and skin JSPS.

Table 448. Tags for themes and skins JSP files

Tag	Description
<portal-dynamicui:closepage/>	Provides a URL that closes a dynamic page. This tag should be used only within a <portal-navigation:navigationLoop/>
<portal-dynamicui:closeportlet/>	Provides a URL that closes a dynamic portlet. This tag should be used only within a skin JSP.
<portal-dynamicui:pendingTasks/>	Through the use of scripting variables, notifies the user whenever a new, unclaimed task has been assigned. This tag should be used only within theme JSPs.

Detailed descriptions of the <portal-dynamicui/> tags

The following section provides detailed descriptions of the <portal-dynamicui/> JSP tags:

<portal-dynamicui:closePage/>
Provides a URL that closes a dynamically created task page. This tag should be used only within a <portal-navigation:navigationLoop/>.

<portal-dynamicui:closePortlet/>
Provides a URL that closes a dynamic portlet. This tag should be used only within a skin JSP. The content of this tag is rendered only if the portlet is dynamic.

<portal-dynamicui:pendingTasks/>
Through the use of scripting variables, notifies the user whenever a new, unclaimed task has been assigned. This tag should be used only within theme JSPs.

<portal-fmt/> tags:

The <portal-fmt/> tags are used to provide enhanced portal formatting capabilities.

The following table provides a brief description of each tag.

Note: Do not use portal tags in portlet JSPs. The following tags are only for use in theme and skin JSPS.

Table 449. Descriptions of <portal-fmt/> tags

Tag	Description
<portal-fmt:answer/>	Returns the answer text for a key in the specified language. This tag can be used only within a <portal-skin:portletRender/> or <portal-core:pageRender/> tag.
<portal-fmt:bidi/>	This tag is used to support the display of bidirectional languages.
<portal-fmt:description/>	Provides the description of an object that implements the `Localized` interface. This tag can be used in both theme and skin JSPs.
<portal-fmt:identification/>	Transforms a String representation of the ObjectID into an ObjectID. Also transforms an ObjectID into a String representation of the ObjectID.
<portal-fmt:problem/>	Returns the problem text for a key in the specified language. This tag can be used only within a `<portal-skin:portletRender/>` or `<portal-core:pageRender/>` tag.
<portal-fmt:text/>	Returns the text for a key in the specified language. For information about how to set the bundle refer to the `portletExt:setBundle` tag under "JSP tags for standard portlets" on page 3133.
<portal-fmt:textParam/>	If the text that is retrieved contains placeholders in the form of "{0}", "{1}", "{2}", it can be set with this tag. This tag can be used only in the body of the `<portal-fmt:text/>` tag.
<portal-fmt:title/>	Provides the title of an object that implements the interface. This tag can be used in both theme and skin JSPs.
<portal-fmt:user/>	If the user is logged in, this tag returns one of the specified values of **`attribute`**.

Detailed descriptions of the <portal-fmt/> tags

The following section provides detailed descriptions of the <portal-fmt/> JSP tags:

<portal-fmt:answer bundle="*bundle*">

Returns the answer text for a key in the specified language. The following keys can be looked up in the resource bundle.

- content.not.available.answer
- login.invalid.answer
- password.invalid.answer
- userid.invalid.answer
- portlet.not.active.answer
- portlet.not.authorized.answer
- portlet.not.available.answer
- portlet.title.not.available.answer

Each key corresponds to a problem key (without the `.answer` suffix). See the <portal-fmt:problem> tag for a complete description of each problem and an example.

<portal-fmt:bidi dir="rtl|ltr" attribute="portlet" locale="*locale*">

This tag is used to support bidirectional languages. Bidirectional languages contain text that reads in both directions. For example, URLs, code samples, or directory and file names can be read in the opposite direction of the rest of the text.

Attributes:

- `dir`

  Indicates the normal direction of text in the language. This attribute is required.

  - For `dir="rtl"`, the tag content is written only if the client's locale belongs to a bidirectional language. This is the default setting if `dir` is not specified.
  - For `dir="ltr"`, the tag content is written only if the client's locale does not belong to a bidirectional language.

- `attribute="portlet"`

  Indicates that the text is for the title of a portlet. This attribute is optional.

- locale

  The tag content is written only if the language belongs to the bidirectional languages that are defined by the portal. If attribute is specified, locale is ignored.

WebSphere Portal Express JSPs use this tag in a `BidiInclude.jsp` that creates the following scripting variables, which, in many cases, are easier to use than the `<portal-fmt:bidi/>` tag.

<%=bidiAlignRight%>

Resolves as the value `left` for bidirectional languages, `right` for all other languages. This is primarily intended for text alignment, such as in a table cell.

<%=bidiAlignLeft%>

Resolves as the value `right` for bidirectional languages, `left` for all other languages. This is primarily intended for text alignment, such as in a table cell.

<%=bidiImageRight%>

Resolves as the value `Left` for bidirectional languages, `Right` for all other languages. This is primarily intended to append the value to the file name for an image. For example, the theme directory provides two image files that can be used for the portlet window, `Album_Border_TopLeft.gif` and `Album_Border_TopRight.gif`.

<%=bidiImageLeft%>

Resolves as the value `Right` for bidirectional languages, `Left` for all other languages. This is primarily intended to append the value to the filename for an image. For example. The theme directory provide two image files that can be used for the portlet window, `Album_Border_TopLeft.gif` and `Album_Border_TopRight.gif`.

<%=bidiImageRTL%>

Resolves to the value _rtl for bidirectional languages, null for all other languages. This is primarily intended for graphic images. For

example, the skin previews provide two image files to preview the skin, `preview.gif` and `preview_rtl.gif`.

The following example shows how a directional image is invoked. The <%=bidiImageRTL%> scripting variable is used to invoke the appropriate icon, for example, `tab_next_rtl.gif`, when the locale belongs to a bidirectional language.

```
<img alt="<portal-fmt:text key="link.next" bundle="nls.engine"/>"
     src="<portal-logic:urlFindInTheme file='<%="tab_next"+bidiImageRTL+".gif"%>'/>
     border="0" align="absmiddle">
```

<portal-fmt:description locale="*locale*" varname="*scripting_variable*" />

Provides the description of the object that is specified by `varname` or of the navigation node that is set in the `<portal-navigation:navigationLoop/>` tag. This tag can be used in both theme and skin JSPs.

Attributes

locale Optional. Overrides the current language setting.

varname
Optional. Specifies the name of the scripting variable holding the object. The <portal:navigation/> tag sets this object to <%=wpsNavNode%>.

```
<portal-navigation:navigationLoop>
  <!-- write the description of the node in the current locale -->
    <portal-fmt:description varname="<%=wpsNavNode%>"/>
  <!-- write the description of the node in chinese -->
    <portal-fmt:description varname="<%=wpsNavNode%>" locale="zh"/>
</portal-navigation:navigationLoop>
```

<portal-fmt:identification action="*setting*" object="*object_name*" var="*variable_name*"/>

Transforms a String representation of the ObjectID into an ObjectID. Also transforms an ObjectID into a String representation of the ObjectID.

Attributes:

action Specifies the operation to be done on the object. Allowed values are `"serialize"` and `"deserialize"`

object Specifies the object that must be handled. Allowed values are an object of the type `com.ibm.portal.Identifiable` or `java.lang.String`.

var Specifies the name of the scripting variable where the generated value is stored.

The following example shows how this tag is used to set an identifiable object and translate it to a String representation:

```
<portal-fmt:identification object="<%=contentNode%>" action="serialize" var="oid_string">
 <p><portal-fmt:title varname="<%=contentNode%>"/> has the ObjectID <%=oid_string%></p>
</portal-fmt:identification>
```

The following example shows how this tag is used to set a unique name, which can also be an object ID string representation, and translate it to an object ID:

```
<portal-fmt:identification object="ibm.portal.Home" action="deserialize" var="oid">
 <% if (oid instanceof com.ibm.portal.ObjectID) { %>
  <p>This is how it works</p>
 <% } %>
</portal-fmt:identification>
```

<portal-fmt:problem bundle="*bundle*">

Returns the problem text for a given key in the specified language. The following keys can be looked up in the resource bundle.

- content.not.available - Occurs if there is no page content that can be displayed. Used in the <portal-core:pageRender/> tag.
- login.invalid - Occurs when the user ID, password, or both are not valid. This is used in the Login screen.
- password.invalid - Occurs when the password field is empty during login. This is used in the Login screen.
- portlet.not.active - Occurs when a portlet is not active. Used in the <portal-skin:portletRender/> tag.
- portlet.not.authorized - Occurs when a user does not have appropriate permissions on a portlet. Used in the <portal-skin:portletRender/> tag.
- portlet.not.available - Occurs when an error occurs that prevents a portlet from rendering. Used in the <portal-skin:portletRender/> tag.
- portlet.title.not.available - Occurs when a portlet title is not available. Used in the <portal-skin:portletTitle/> tag.
- userid.invalid - Occurs when the user ID field is empty during login. This is used in the Login screen.

There is a corresponding answer key for each problem (see the <portal-fmt:answer/> tag).

The resource bundle must be in a directory that is on the class path of the WebSphere Portal Express enterprise application. It is recommended that you create a new directory to separate your custom code from the base code. Add the new directory to the Portal application class path. For details, refer to the WebSphere Application Server documentation. The following sample retrieves the problem text from `/nls/problem_`*`locale`*`.properties`. The text is displayed only when an error is encountered rendering the page.

For example:

```
<portal-core:pageRender>
   <p align="center">
     <strong><portal-fmt:problem bundle="nls.problem"/></strong>
     <br>
     <portal-fmt:answer bundle="nls.problem"/>
   </p>
</portal-core:pageRender>
```

<portal-fmt:text key="*key*" bundle="*bundle*">

Returns the text for a key in the specified language. The *key* indicates a parameter in a resource bundle or properties file, indicated by *bundle*. Both attributes are required. See the description of <portal-fmt:textParam> for an example and further description of the attributes of <portal-fmt:text/>.

Where possible, the `<i18n:bundle/>` and `<i18n:message/>` tags of the I18N tag library can be used instead of <portal-fmt:text/>..

<portal-fmt:textParam>

If the text that is retrieved contains placeholders in the form of "{0}", "{1}", "{2}", these can be set with this tag. This tag can be used only in the body of the <portal-fmt:text/> tag. The text to be substituted for the placeholders must be entered as content for this tag. It can even be an expression.

Examples

The **welcome** parameter in a resource bundle is set as follows:

```
welcome = Welcome {0}!
```

In the following example, the value of the <portal-fmt:textParam> tag is written in place of the {0}.

```
<portal-fmt:text key="welcome" bundle="nls.engine">
    <portal-fmt:textParam>World</portal-fmt:textParam>
</portal-fmt:text>
```

<portal-fmt:title locale="*locale*" varname="*localized_object*"/>

Provides the title of the object that is specified in `varname`. The tag also implies the object if it is called inside of the <portal-navigation:navigationLoop/> tag.

Attributes

locale Optional. Overrides the current language setting.

varname

Optional. Specifies the name of the scripting variable holding the object. The <portal-navigation:navigation/> tag sets this object to <%=wpsNavNode%>.

<portal-fmt:user attribute="*value*"/>

If the user is logged in, this tag returns one of the specified user attributes. *value* can be any user attribute that is defined to Member Manager.

<portal-logic/> tags:

The <portal-logic/> tags are used to provide tags for conditional logic.

<portal-logic:find>

Used to access the portal-wide find URL that is specified in **Portal Settings**. The tag is conditional. If no URL is set, the body of the tag is not evaluated. A scripting variable that is called <% wpsPortalFindURL %> is available inside the body of the tag for accessing the URL. This tag can be used in both theme and skin JSPs.

<portal-logic:if *attribute*="*value*">

Through the attributes of this tag, several conditions can be checked. If the condition is true, the content of the tag's body is written to the page. Otherwise, the content is skipped. More than one condition can be evaluated. For example, the user must be logged in and the Home screen must be active for the content of the following tag to be rendered:

Note: All earlier attributes that started with "not" are deprecated. Use the <portal-logic:unless/> tag instead of these attributes.

```
<portal-logic:if loggedIn="yes" screen="Home">

   <!--  content area -->

</portal-logic:if>
```

Attributes of the <portal-logic:if/> tag:

capableOf="*capability*"

Indicates whether the client supports the specified capability. *capability* can be one of the following values:

- HTML_2_0

- HTML_3_0
- HTML_3_2
- HTML_4_0
- HTML_CSS
- HTML_FRAME
- HTML_JAVA
- HTML_JAVASCRIPT
- HTML_NESTED_TABLE
- HTML_TABLE
- WML_1_0
- WML_1_2
- WML_TABLE

deviceClass="*deviceClass*"
Compares whether the indicated device classes match the current device class. The value is a string that represents the expected device classes, and can be a single device class name or an equation of multiple device class names that use + for AND, / for OR, ! for NOT, and parentheses.

Example values:

- `smartphone`
- `smartphone/tablet`
- `smartphone+!android`
- `(smartphone+ios)/(tablet+ios)`

If you have a syntax error in your equation, such as mismatched parentheses, an exception with details of the syntax error are written to the `SystemOut.log` file, and the attribute condition is shown as false. So, if the content of the tag's body is being skipped unexpectedly, check the log.

locale="*locale*"
Indicates whether the locale of the client is that of the specified *locale* (or subtype of the specified locale). You can specify a comma-separated list, such as `en, en_US`.

loggedIn="yes|no"
Indicates whether the user is logged in. For example, the following code displays a login link if the user is not logged in:

```
<%-- login button --%>
<portal-logic:if loggedIn="no" notScreen="Login">
   <td class="wpsToolBar" valign="middle" nowrap>
      <a class="wpsToolBarLink"
         href='<portal-navigation:url home="public" screen="Login" ssl="false"/>'>
            <portal-fmt:text key="link.login" bundle="nls.engine"/>
      </a>
   </td>
</portal-logic:if>
```

navigationAvailable="yes|no"
Indicates whether a navigation is available.

newWindow="yes|no"
Indicates whether the portlet is rendered in a separate browser window or iFrame from the portal (HTML only).

nodeInSelectionPath="yes|no"
Checks whether a page is selected. This means that the page is in the selected path by the user of which the content is shown.

pageAvailableNext="yes|no"
Checks if a subsequent set of pages is available to be accessed from the navigation.

pageAvailablePrevious="yes|no"
Checks if a previous set of pages is available to be access from the navigation. For example, use this tag in combination with <portal-navigation:navigationShift> to render a scroll icon. The scroll icon displays when the number of user-defined pages exceeds the number of displayed page tabs. This condition behaves contrary to the **pageAvailableNext** attribute.

pageCompletelyActive="yes|no"
Indicates whether the page and its parents are active. The following example displays a message if the page is not active.

```
<portal-logic:if pageCompletelyActive="no">
   <p align="center" class="wpsFieldErrorText"><b><br>
      &gt;&gt;&gt;
            <portal-fmt:text key="info.pagenotcompletelyactive" bundle="nls.er
      &lt;&lt;&lt;
   <br></b></p>
</portal-logic:if>
```

pageBookmarkable="true|false"
Renders its contents if the page can be bookmarked. A page can be set to bookmark with **Manage pages**. The following example provides an "Add to favorites" option in a select list. Users can bookmark the current page, if it can be bookmarked.

```
<portal-logic:if pageBookmarkable="true">
   <option value='<portal:url command="AddBookmark" alias="Favorites"/>' >
   <portal-fmt:text key='link.favorites.add' bundle='nls.engine'/>
</portal-logic:if>
```

portletMaximized="yes|no"
Renders its contents if the portlet is maximized. Use this call inside a JSP skin.

portletMode="edit|view|configure|help"
Checks if the portlet is in one of the modes. This tag is most useful in a customized skin.

Finding theme resources: See the *Location of theme resources* link in the Related section.

portletState="*portlet_state*"
Checks if the portlet is in the indicated state. Portlet states are `normal`, `maximized`, and `minimized`. For example, in `Control.jsp`, the following code sets the `tableHeight` variable to 100%.

```
<portal-logic:if portletState="Normal,Maximized">
    <% tableHeight = "height=\"100%\""; %>
</portal-logic:if>
```

portletSolo="yes|no"
Checks whether the portal is displaying a portlet in solo state. In the following example from `Default.jsp`, the navigation are hidden when the current portlet is displayed in solo state.

```
<portal-logic:if portletSolo="no">
   <%@ include file="./topNav.jspf" %>
   <%@ include file="./sideNav.jspf" %>
</portal-logic:if>
```

problem="*problem*"
Renders its contents if one of the following problems occurred.

- content.not.available
- login.invalid
- password.invalid
- portlet.not.active
- portlet.not.authorized
- portlet.not.available
- portlet.title.not.available
- userID.invalid

resumeLevel="0|1|2"
Used in the Login.jsp screen to write the content of the tag if the value of this attribute is equal to the setting of the **persistent.session.level** key in the ConfigService.

resumeOption="0|1"
Used in the Login.jsp screen to write the content of the tag if the value of this attribute is equal to the setting of the persistent.session.option key in the ConfigService.

screen="*screen_name*"
Checks the value of the current screen name. Use a comma to separate multiple screen names. In the following example, the content of the tag is displayed only when the selected screen is Home, LoggedIn, or LoggedOut.

```
<portal-logic:if navigationAvailable="yes" screen="Home,LoggedIn,LoggedOut">

....

</portal-logic:if>
```

selection
Specifies the unique name or object ID of the currently selected page. For example:

```
<portal-logic:if selection="ibm.portal.Home">
  You are on Home
</portal-logic:if>
```

showTools="yes|no"
Indicates whether to display more controls for the portlet title bar and page tabs. In the following example, the show_tools_off.gif icon is displayed for the condition when showTools="no".

```
<portal-logic:if showTools="no">
 <% if (firstButton) { firstButton = false; } else { %> | <% } %>
   <a href='<portal-navigation:url command="ShowTools"/>'>
      <img border="0" align="absmiddle" width="16" height="19"
          src='<portal-logic:urlFindInTheme file="show_tools_off.gif"/>'
          alt='<portal-fmt:text key="link.show.tools" bundle="nls.engine"/>'
          title='<portal-fmt:text key="link.show.tools" bundle="nls.engine"/>'
      </a>
</portal-logic:if>
<portal-logic:if showTools="yes">
 <% if (firstButton) { firstButton = false; } else { %> | <% } %>
```

```
        <a href='<portal-navigation:url command="ShowTools"/>'>
           <img border="0" align="absmiddle" width="16" height="19"
                src='<portal-logic:urlFindInTheme file="show_tools_on.gif"/>'
                alt='<portal-fmt:text key="link.hide.tools" bundle="nls.engine"/>
                title='<portal-fmt:text key="link.hide.tools" bundle="nls.engine"
    </portal-logic:if>
```

For either condition, the <portal-navigation:url command="ShowTools"/> command is used to change the value of **showTools**. It allows the icon on the portal page to be used as a toggle. This condition is also checked in ShowTools.jsp to determine whether to render the move and delete portlet icons in the portlet title bar.

userImpersonated="true|false"

Used to access another user's system as though you are that user. Users such as support specialists can use the impersonation feature to find issues and errors. For example, if a portal administrator encounters a problem that they cannot resolve, a support specialist can use the impersonation feature and access that portal administrator's system to determine a solution to the problem.

For more information about the user impersonation feature, see Administering user impersonation.

<portal-logic:pageMetaData/>

Used to access metadata of the currently rendered page. The tag has two attributes:

varname

This attribute is mandatory and specifies the name of the variable that displays the metadata inside the body of the tag. The variable provides an object that implements com.ibm.portal.MetaData.

type This attribute is optional. Allowed values are direct and aggregated. The value aggregated is the default. If the type attribute is set to direct, only the metadata that is set specifically for the page are shown, otherwise the metadata of the page as provided by the content metadata model are used.

The Content metadata model is described in more detail in the Model SPI overview topic. The following example outputs a table with all names and values of the aggregated metadata of the current page.

```
<portal-logic:pageMetaData varname="pageMetaData">
  <table>
    <tr><th>Name</th><th>Value</th></tr>
    <c:forEach var="metaItem" items="${pageMetaData}">
      <tr><td>${metaItem.key}</td><td>${metaItem.value}</td></tr>
    </c:forEach>
  </table>
</portal-logic:pageMetaData>
```

<portal-logic:unless>

This tag operates in contrast to the <portal-logic:if> tag. Through the attributes of this tag, several conditions can be checked. If the condition is true, the content of the tag is not written to the page. Otherwise, the content is written. More than one condition can be evaluated. The following list of attributes can be evaluated. For more information, see the corresponding description for each attribute under the <portal-logic:if> tag.

- capableOf

- locale
- loggedIn
- newWindow
- navigationAvailable
- pageAvailableNext
- pageAvailablePrevious
- nodeInSelectionPath
- portletMaximized
- portletMode
- portletSolo
- portletState
- problem
- screen

<portal-logic:urlFind>

Generates a URL pointing to a file. The resource is searched under different paths that are based on the markup and locale that is supported by the client and the specified attributes of the tag.

Attributes

- `root="root"`
- `path="path"`
- `file="file"`

  This attribute is required
- `allowRelativeURL="true|false"`

The first place where the resource is found is used to construct the URL. The following search order that is used:

1. Root path
2. Markup name
3. Path
4. Markup version
5. Locale in diminishing sequence
6. File name

Read *Aggregation* for more information about how the portal server locates resources. The **allowRelativeURL** attribute indicates whether a fully qualified or relative URL is generated.

<portal-logic:urlFindInSkin file="*file_name*" id="*identifier*">

Similar to <portal-logic:urlFind>, this tag generates a URL that points to a file contained in the theme WAR file.

Finding theme resources: See the *Location of theme resources* link in the Related section.
The skin is taken from the user's or system's settings. The file attribute is required.

When id is specified, the tag initializes a scripting variable with the value normally written out and nothing is written to the output stream. The value of the id attribute is the name of the scripting variable.

Attribute:

forceAbsolute = "true|false"

This attribute is optional. It specifies whether the URL that is generated by this tag is to be absolute or not. If you set this attribute to `true`, absolute URLs are enforced; in these case other settings that affect the generation of URLs might be overridden.

<portal-logic:urlFindInTheme file="*file_name*" id="*identifier*">

Similar to <portal-logic:urlFind>, this tag generates a URL that points to a file contained in the theme WAR file.

Finding theme resources: See the *Location of theme resources* link in the Related section.
The theme is taken from the user or system settings. The file attribute is required.

When id is specified, the tag initializes a scripting variable with the value normally written out and nothing is written to the output stream. The value of the id attribute is the name of the scripting variable.

Attribute:

forceAbsolute = "true|false"

This attribute is optional. It specifies whether the URL that is generated by this tag is to be absolute or not. If you set this attribute to `true`, absolute URLs are enforced; in these case other settings that affect the generation of URLs might be overridden.

Related concepts:

"Administering user impersonation" on page 1230
Use the impersonation feature to access another user's system as though you are that user. Use caution with this configuration. The user who is doing the impersonation might get more permissions than initially granted to them.

"Understanding the Portal Version 8.5 modularized theme" on page 2521
Modern websites and browsers enable incredible new capabilities that can greatly enhance your user's web experiences. However, these capabilities are not without cost in terms of large page sizes and more processing in the browser when each page is rendered. These capabilities are worth it when you need them, but removing them for an entire site or including them only on pages that take advantage of these capabilities provides for more flexibility.

<portal-navigation/> tags:

The `<portal-navigation/>` tags are used to implement navigation tasks such as generating URLs and traversing the portal navigation model.

The following section provides detailed descriptions of the `<portal-navigation/>` JSP tags:

CF05 **<portal-navigation:uiNavigationModel var="*uiNavigationModel*" mobileDeviceClassTest="*device class equation*" showHidden="*true*|*false*" selectedNodeID="*page ID*" selectionPath="*page IDs*" selectionPathSeparator="*selectionPath delimiter*">**

The uiNavigationModel tag helps the JSP developer concentrate on building the navigation rather than worrying about the portal-specific implementation details.

By default, the uiNavigationModel lists the visible pages as part of its iterator. When the **Show hidden pages** option is selected in the toolbar, it lists the hidden pages also. There is a special mobile hidden flag for pages.

The model also allows you to specify a mobile test device class expression, which is used to evaluate if the system is rendered as part of a mobile request.

The uiNavigationModel tag makes the uiNavigationModel EL Bean available as a variable that can be specified as part of the var attribute.

Example:

```
<portal-navigation:uiNavigationModel var="uiNavigationModel" mobileDeviceClassTest="smartphon
    <%-- loop through all children of the page at the given curLevel --%>
    <c:forEach var="node" items="${uiNavigationModel.children[selectionPath[curLevel]]}">

        <%-- print out the page and highlight it if it is in the selection path
             (the current page or an ancestor of the current page) --%>
        <li class="wpthemeNavListItem wpthemeLeft<c:if test="${node.isInSelectionPath}"> wpth

            <%-- output a link to the page --%>
            <a href="${fn:escapeXml(node.urlGeneration)}" class="wpthemeLeft ${node.isHidden
                 'wpthemeHiddenPageText' : ''} ${node.isDraft? 'wpthemeDraftPageText' : ''}">

                <%-- start page title markup --%>
                <span lang="${node.title.xmlLocale}" dir="${node.title.direction}"><%--

                    <!-- print out the page title -->
                    --%><c:out value="${node.title}"/><%--

                    <!-- mark the page if it is currently selected for accessibility -->
                    --%><c:if test="${node.isSelected}"><span class="wpthemeAccess">
                    <portal-fmt:text key="currently_selected" bundle="nls.commonTheme"/></spa

                --%></span><%-- end page title markup --%>
            </a>
        </li>
    </c:forEach>
</portal-navigation:uiNavigationModel>
```

Required parameters:

var This mandatory attribute specifies the name of a scripting variable that is exposed in the body of the tag. This variable is a uiNavigationModel EL Bean.

mobileDeviceClassTest
This attribute is a device class equation, that describes whether the request is part of a mobile device or not.

The following parameters are all optional. If they are not provided, the information is automatically fetched from the request. In some cases, the selection information is not available and must be passed in explicitly. Use the following attributes in that case.

showHidden
Defines whether to show the hidden pages or not.

selectedNodeID
String; specifies the selected page ID.

selectionPath
String; list of page IDs defining the selection path, or breadcrumb, in one string. The delimiter can be configured through selectionPathSeparator.

selectionPathSeparator
String; is the delimiter that is used to parse the selectionPath.

Returns: Each individual navigation node that is returned by the uiNavigationModel is also a wrapper around the NavigaitonNode EL Bean and provides additional information, such as isHidden, isDraft, isInSelectionPath, and isSelected. For more information, see uiNavigationModel.

<portal-navigation:url command="ChangeLanguage">
This tag is used to change the active language in the navigational state in which the URL is generated.

The following code example uses this tag to change the language to German.

```
<a href='<portal-navigation:url
        command="ChangeLanguage"><portal-navigation:urlParam name="locale"
        value="de"/></portal-navigation:url>'>Diese Seite in deutsch
</a>
```

<portal-navigation:urlParam name="*parameter_name*" value="*parameter_value*">
This tag is used to add parameters to the parent URL. Parent tags include `<portal-navigation:url/>` and `<portal-navigation:urlGeneration/>`. Parameters added to the `<urlGeneration/>` tag occur as unscoped query parameters unless the attributes specified on `<urlGeneration/>` specify otherwise. Parameter handling depends on the target of the URL. If the URL points to a page, the parameters are visible to all IBM portlets on that page. Parameters are not visible to standard portlets if the URL does not point specifically to that portlet.

Attributes are as follows:

name This attribute is required. It indicates the name of the parameter.

value This attribute is required. It indicates the value of the parameter.

type This attribute is optional. It indicates one of the following types:

query The name-value pair is added to the URL as a query parameter. It is the default value if type is not specified.

render The parameter is available as a render parameter for the portlet.

action
The parameter is available as an action parameter for the portlet.

<portal-navigation:urlGeneration *attribute*="*value*">
This tag creates a URL to pages or portlets. The tag is conditional. If the URL cannot be found, the body of the tag is not evaluated. Inside the body of the tag, the <% wpsURL %> scripting variable can be used to write the URL directly to the output stream. For example:

```
<a class="wpsToolBarLink" href='<% wpsURL.write(out); %>'>My page</a>
```

Attributes are as follows:

accessControlCheck="permission_constant"
This attribute indicates the permissions to be checked. The following constants can be used:

- CreatePage
- EditLayout
- DeletePage
- AssignRoles
- NoCheck

- EditApplicationProperties
- EditApplicationLayout
- AssignApplicationMember
- ManageApplicationRoles
- SaveAsTemplate

If the user does not have the required permission, the body of the tag is not executed. If the user has the necessary permissions, the current page ID is appended to the URL. If the parameter is set to `'NoCheck'`, the current page ID is appended without checking the access control permissions. This is necessary for the target page or portlet to create a back button.

actionName="name"

This attribute indicates the name of an action that would be called by the URL to an IBM portlet. The following example generates a URL that calls the `myAction` action of the portlet, which is contained by `my.LayoutNode` on `my.ContentNode`.

```
<portal-navigation:urlGeneration actionName="myAction" contentNode="my.ContentNode"
                                 layoutNode="my.LayoutNode">
       <a href="<%wpsURL.write(out);%>">Link to portlet with myAction</a>
    </portal-navigation:urlGeneration>
```

The following code is from the `actionPerformed()` aspect of the portlet that handles the `myAction` action.

```
PortletURI actionURL = portletResponse.createURI();
actionURL.addAction("myAction");
```

allowRelativeURL="true | false"

This attribute indicates whether a fully qualified or relative URL is generated. The default is set by the property `com.ibm.portal.state.accessors.url.URLContext.enableRelative` in the `StateManagerService`.

contentNode="*id* | *name*"

This attribute indicates the ID or unique name of the page. The name or ID of the content node is also used to specify the page where the portlet can be found.

keepNavigationalState="true | false"

If you set this attribute to `false`, the current navigational state that includes all portlet modes, states, and render parameters is not included in the URL, and the portal is reset to its default state. If this value is set to `true`, the navigational state is included. True is the default setting.

layoutNode="*id* | *name* | *wp.currentSelectedPortlet*"

This attribute indicates the ID or unique name of the control that holds the portlet. It must be used in combination with `contentNode` to identify the page where the portlet is located. The value `wp.currentSelectedPortlet` can be used inside a control when you generate a URL to the portlet within that control.

newWindow="true | false"

This attribute creates a session partition. For portlet URLs, you can use it if you want to display the portlet either in a new window or in an iFrame. The default value is false. The portlet window state for the addressed portlet in the new window is set to maximized. The portlet mode is set to the value of the current parent window. In the `control.jsp` of skins that use iFrames, the `<portal:if/>` tag

can be used to distinguish between rendering in the main window or in an iFrame or detached window.

portletMode="view | help | edit | edit_defaults | configure"
For URLs to a portlet as specified by the parameter `layoutNode`, this attribute sets the portlet mode. This parameter is ignored if the parameter `layoutNode` is not set. Specifying `portletMode="edit_defaults"` opens the portlet in the Edit defaults mode directly.

portletParameterType="render | action"
This attribute generates URLs to a standard portlet's render or action processing methods. If this attribute is omitted, the render method of the portlet is called. Any parameters added to the body of the tag that uses `<portal-navigation:urlParam/>` are passed to the corresponding method.

portletWindowState="maximized | minimized | solo | normal"
For a portlet, this attribute indicates the state of the portlet window when it is displayed. If portlet state is not specified, the page is shown with the previous state of the portlet. This parameter is ignored if `layoutNode` is not set.

Note: Use caution when you use this tag to address portlets in solo state. The portlet must be able to exist in solo state that uses the `createReturnURI()` method. If a portlet without this method is placed in solo state, then users are forced to log out or close their browser windows to return to the portal.

themeTemplate="template_name"
This specifies the theme template that is taken for rendering the requested page. Can be referenced as either a JSP or a class and is used as theme for this URL.

normalize="true | false"
This attribute indicates that the URL to be generated must be normalized. If more parameters are set, the normalization is executed first and afterward the other state modifications are accomplished. Setting the "normalize" parameter to true normalizes the URL with the same XSL file used to normalize URLs for search engines. The normalized representation of the URL can also be used to bookmark a page. The following example shows how to use the tag with this attribute:

```
<portal-navigation:urlGeneration normalize="true" >
      <a href="<% wpsURL.write(out); %>">
        This is the normalized URL of the current
        selected page.
      </a>
</portal-navigation:urlGeneration>
```

If more parameters are set for the `<portal-navigation:urlGeneration>` tag the XSL transformation is executed first and all other state modifications is accomplished afterward.

forceAbsolute = "true | false"
This attribute is optional. It specifies whether the URL that is generated by this tag is to be absolute or not. If you set this attribute to `true`, absolute URLs are enforced; in this case other settings that affect the generation of URLs might be overridden.

<portal-navigation:url>

Creates a portal URL depending on the specified attribute. Attributes are as follows:

home="public | protected"

This attribute creates a URL pointing to the public or protected (logged in) page of the portal.

screen="screen_name"

This attribute creates a URL pointing to the screen name to be displayed.

command="LoginUser | LogoutUser | ShowTools"

This attribute creates a URL that issues the command to the portal. `command="LoginUser"` is used for the login panel, and `command="LogoutUser"` is used for the logout button. The `"userid"` and `"password"` parameters must be carried with a login URL. `command="ShowTools"` toggles the value of the showTools indicator. See the `<portal-logic:if/>` tag `"showtools"` attribute in for an example.

commandParam="parameter_name"

This attribute directs the portal engine to obtain the actual command to execute from an HTTP request parameter instead of on the URL directly. The name of the parameter is the value of the commandParam attribute. This is useful in situations where different commands need to be conditionally executed yet only one URL can be specified. Such is the case when using a `<form>` tag with a `<select>`. This enables use of the HTML form without requiring JavaScript. For example:

```
<form name="someFormName" method="GET" style="margin-bottom: 0"
            action='<portal-navigation:url commandParam="requestParamName"/>'>
        <select name="requestParamName" onchange="javascript: this.form.submit(); ">
                <portal-navigation:someLoop>
                        <option value="<%= theUrl %>" >Some title goes here
                </portal-navigation:someLoop>

        </select>
        <noscript>
                <input type="image" border=0 align=absmiddle src='go.gif'/>Go
        </noscript>
</form>
```

The previous code example works both with and without JavaScript enabled.

ssl="yes | no | true | false"

This attribute creates a secure URL (HTTPS).

forceAbsolute = "true | false"

This attribute is optional. It specifies whether the URL that is generated by this tag is to be absolute or not. If you set this attribute to true, absolute URLs are enforced; in this case other settings that affect the generation of URLs might be overridden.

Example: The following example shows part of a user login form that uses the `<portal:url>` tag to process input fields, user ID, and password.

```
<FORM method="POST"
     action='<portal-navigation:url command="LoginUser"/>'
     enctype="application/x-www-form-urlencoded"
     name="LoginPage">
```

<portal-navigation:navigationUrl type="link | expand | collapse | launch" varname="*node_name*" var="*variable_name*"/>

Creates URLs for navigation nodes. The tag is used inside the body of the <portal-navigation:navigationLoop> tag and outputs links for the current navigation node according to the *type* attribute.

Attributes are as follows:

type Use one of the following values:

type="link"
This attribute creates a URL to change the selected node.

type="expand"
This attribute creates a URL that expands the node to reveal its child nodes. This is intended for expanding the navigation tree.

type="collapse"
This attribute creates a URL that collapses the node to conceal its child nodes. This is intended for collapsing the navigation tree.

type="launch"
This attribute creates a URL that either launches a page if all conditions for the page launch are fulfilled for the navigation node or if just like in the selection URL in `type="link"`.

Note: The global state of the portal navigation trees is collapsed by default (with some exceptions, such as the Portal Administration navigation). You can configure the default state of the portal navigation trees to expand all nodes by setting the Portal Configuration Service property `navigation.expansion.defaultstate` to `true`.

varname
This attribute specifies an object of type `com.ibm.portal.navigation.NavigationNode` for which the URL is to be generated. The attribute is optional.

var This attribute specifies the name of a scripting variable that is exposed in the body of the tag. The attribute is optional. The variable exposes an object that implements `com.ibm.portal.DisposableURL` that can be used to stream the URL to the output. If the content node referenced by the navigation node is an internal URL, the body is evaluated only if the target of the internal URL is accessible.

forceAbsolute = "true | false"
This attribute is optional. It specifies whether the URL that is generated by this tag is to be absolute or not. If you set this attribute to `true`, absolute URLs are enforced; in this case other settings that affect the generation of URLs might be overridden.

keepNavigationalState="true | false | auto"
If this attribute is set to false, the current navigational state (including all portlet modes, states, and render parameters) is not included in the URL and the portal is reset to its default state. If set to true, which is the default, navigational state is included. If it is set to auto, the configuration determines if the navigational state is included. See the descriptions for `stateless.urls.enabled` and `generate.stateless.urls` in *Configuration Service*.

To generate the title or description of a navigation node, use the `<portal-fmt:title/>` or the `<portal-fmt:description/>` tags. This tag is used only in theme JSPs.

<portal-navigation:navigationShift by="*number*" maxPages="*number*">

This tag is used in the navigation to create a URL that scrolls to the next set of page links when the number of available pages exceeds maxPages. The *by* attribute indicates the number of page links to scroll. If this tag is not used, all page links for the current level are rendered.

This tag is nested in the <portal-navigation:navigation> tag and requires values for the startLevel and stopLevel attributes of the <portal-navigation:navigation> tag for its correct functioning.

<portal-navigation:navigationLoop>

This tag traverses through the navigation model. This tag is nested inside of the <portal-navigation:navigation/> tag when used. This tag indicates the part of the markup that is repeated once for each navigation node. There are no attributes for this tag. The body of this tag is executed for each navigation node. This tag makes several scripting variables available for obtaining information for the navigation. These scripting variables are accessible only within the body of the tag.

<portal-navigation:navigation>

This tag initializes a set of objects and makes them available through scripting variables. These objects are required for the rendering process of the navigation. The scripting variables are accessible only within the body of the tag. The settings of the `startLevel` and `stopLevel` attributes determine whether the content of the navigation tag is evaluated. The navigation tag uses an "in-order" traversal of the navigation tree to select the nodes.

Attributes are as follows:

startLevel

Optional. The level on which this navigation is to begin showing information. If no start level is given, this tag will start at the navigation node after the levels that where shown by other JSPs. Otherwise, the default is level 1.

stopLevel

Optional. The level on which this navigation is to stop showing information. Default is to render all levels.

computeNumLevelsToDisplay

Optional. Compute the number of levels that are shown by this navigation. When this attribute is set to `true`, a scripting variable is made available inside the body of the navigation tag named `wpsNumLevelsToDisplay` of Java type java.lang.Integer.

scopeUniqueName

Specifies where to start the rendering of the portal navigation. The expected value is a unique name or string representation of the navigation node's ObjectID. This also replaces the `<portal:favoritesLoop/>` tag for enabling Organize Favorites functionality. The following code example shows how to use the `<portal-navigation:navigation>` with the `scopeUniqueName` attribute to enable Organize Favorites:

```
<portal-navigation:navigation scopeUniqueName="wps.Favorites">
   <portal-navigation:navigationLoop>
     <a href='<portal-navigation:navigationUrl type="link"/>'
        title='<portal-fmt:description varname="<%=wpsNavNode%>"/>'>
           <portal-fmt:title varname="<%=wpsNavNode%>"/>
     </a>
   </portal-navigation:navigationLoop>
 </portal-navigation:navigation>
```

<portal:favoritesLoop/>

This tag is deprecated and must be replaced by using the `<portal-navigation:navigation/>` tag with its `scopeUniqueName` attribute.

The following code example uses this tag to create the Organize Favorites functionality. To use this code, you must place it within the themes that you want to have this functionality.

```
<%@ taglib uri="/WEB-INF/tld/portal.tld" prefix="portal" %>
<portal-logic:if loggedIn="yes" notScreen="SelfcareUserForm,SelfcareUserConf">
<table border="0" cellspacing="0" cellpadding="0" >
 <tr>
 <td align="<%=bidiAlignRight%>" valign="middle" dir="ltr" nowrap>

Developing themes for a production portal

Use the theme artifacts to package a theme for staging to production.

"Development and operations overview"
The steps for developing themes for a production portal, includes the development of the theme components, their packaging, and their deployment to systems.

"Packaging themes for deployment" on page 2816
You must repackage the static content as a WAR file, or an EAR file containing the WAR file when it is not possible to exchange the static content with the Operations Team as a separate compressed file.

"Exporting content from the filestore" on page 2820
You must export content from the filestore to create your custom theme. There are different options available to export files from the portal file store.

Development and operations overview

The steps for developing themes for a production portal, includes the development of the theme components, their packaging, and their deployment to systems.

The package is either created as the result of a build process that takes the code from a version control system and creates the correct artifacts or the artifacts are created by developers. Multiple artifacts create a release and the team that operates the integration and production servers receive and deploy them.

The components of a portal theme include:

Static content
Is similar to the content of a static website. The markup is defined by HTML files. Static content also includes the CSS and JavaScript files that are used by the themes.

The difference between a static website and a portal is that three kinds of HTML files exist:

`theme.html`
Defines the markup that is identical for all the pages that this theme is applied to.

`layout.html`
Defines the decoration of the content area that can be different between pages.

`skin.html`
Defines the decoration of the individual portlets on the page.

If the files used by the theme are not part of the theme folder, and therefore not part of the theme structure, then those files are named external. External files are shared by multiple themes.

Dynamic content
Generated based on the data model of WebSphere Portal Express with technologies such as JavaServer Pages or Java code.

Configuration
Scripts are used to register the theme and skins with WebSphere Portal.

Runtime Configuration components are server configurations, similar to Resource Environment Provider settings, that are required for the themes and skins to work correctly.

Developing Theme Components

There are several ways to develop a custom theme.

Developing within an IDE

With an integrated development environment, you can set up a project first, usually using the form that you selected for packaging afterward, and add the artifacts like HTML, CSS, and JavaScript files. Next, you export the project and deploy it to your server, either as a compressed file in the file store or an EAR file. Finally, you register the theme with a custom developed `theme.xml` file.

You might fill the project initially with the content of one of the ready-to-use themes or start from scratch.

Developing on the live server

This method of developing a theme was introduced recently and is driven through the WebDAV entry point to the file store. You can copy a theme to start with the existing content from one of the ready-to-use WebSphere Portal Express themes or create a folder to start. Add your custom HTML, CSS, and JavaScript files and export these files to create your theme component package. For more information about exporting files, see Exporting content from the file store.

Packaging theme Components

The packaging of a custom developed theme depends on how it was developed and what the preferred approach for static files is. For example, you can combine all static files for all themes and all external files that are shared between themes into one installable artifact or split the files into multiple artifacts. Because the method that you choose has different implications for the development team and the team operating the portal, include both groups when deciding how to package the components.

All packages must contain an XML Access script to deploy the theme and a list of runtime configurations that need to be applied to the server.

The following description shows the options available when all files are packaged together. If the files are separated, the number of files changes but the options are identical.

- If you only created static resources, but used dynamic spots that are included within WebSphere Portal Express or custom dynamic spots that are generally available, the following options exist:
  - Create a package that contains a compressed file that contains the static resources that can be deployed to the file store.
  - Create a package that contains an EAR file that contains a WAR file with the static resources that can be deployed to the application server.
- If you created custom dynamic spots, like components that are based on JSP technology, that are to be packaged with the theme, the following options exist:
  - Create a package that contains a compressed file containing the static resources that can be deployed to the file store and an EAR file containing a WAR file that contains the dynamic resources.
  - Create a package that contains an EAR file that contains one WAR file with the static resources and a second WAR file that contains the dynamic resources. This file can be deployed to the application server.

You can also package the artifacts that you created in a Portal Application Archive (PAA) file for the Solution Installer. The Solution Installer automatically performs the steps to deploy the artifacts.

Deploying theme components

How the theme components were packaged determines the method that is used to deploy themes. All options require an **XMLAccess** script and runtime configuration options or a PAA file.

Compressed file without EAR file
Use the **webdav-deploy-zip-file** command to deploy the compressed file and use the **XMLAccess** command to run the script. Use the WebSphere Integrated Solutions Console to add the runtime configuration.

Compressed file with EAR file
Use the **webdav-deploy-zip-file** command to deploy the compressed file. Use the WebSphere Integrated Solutions Console or scripts to deploy the EAR file. Use the **XMLAccess** command to run the script.

An EAR file with no compressed file
Use the WebSphere Integrated Solutions Console or scripts to deploy the EAR file, and use the **XMLAccess** command to run the script.

PAA file
The Solution Installer automatically detects the steps to perform deployment.

Packaging themes for deployment

You must repackage the static content as a WAR file, or an EAR file containing the WAR file when it is not possible to exchange the static content with the Operations Team as a separate compressed file.

Create a custom theme before starting this process. To create a theme based on the Version 8.5 theme see Create a copy of the theme.

You must create and collect the required code artifacts, the scripts to register the theme and skins, and the list of required runtime configuration changes. Create an EAR file that contains one WAR file containing the dynamic content of the theme and one WAR file containing the static content.

Theme is created based on the modularized portal theme.
Create a custom version of the dynamic content as a new EAR file and a custom version of the static content by creating a folder in the file store. For more information about copying a theme for customization, see Create a copy of the theme. No further customization was performed so far. Also an XML Access script is used to register the themes and skins that are part of the EAR file.

If you performed additional changes, like deleting files or changing file names, then you need to map the following steps accordingly.

Cache headers are not automatically set for static files served from a war file. External means, such as overwriting headers in the HTTP Server, must be used in this case. When you use this approach, complete the Base Portal Tuning - Web Server tuning chapter of the *Performance Tuning Guide* for optimal performance.

"Add static content to your custom theme" on page 2817
Add static content for you custom theme that you created based on one of the ready-to-use themes.

"Adapt the scripts that register the custom theme and skins" on page 2818
You must adapt the scripts that register the custom theme and skins that were moved from the file store.

"Adapting the list of required runtime configuration changes for your theme" on page 2819
You must adapt the list of required runtime configuration changes for your theme.

"Test the custom EAR file" on page 2819
Test the new custom EAR file on your test server to verify that it deploys successfully.

Add static content to your custom theme:

Add static content for you custom theme that you created based on one of the ready-to-use themes.

Procedure

1. Export the content from the file store. For more information, see *Exporting content from the file store*.
2. Export the files that are required by your custom theme to the following folders:
   - `themes`
   - `skins`
   - `layout-templates`
   - `common-resources`
3. Save the files to your disk.
4. Add a web module to your existing custom theme. For this example, an EAR file name `MyEar` was created for the existing custom theme. The EAR file contains a web module named `MyDynamicContent.war` that uses the context path `/MyDynamicContent`. If you created a WAR file instead, you must create an EAR file before you can proceed.
   a. Open your existing project, or import your existing EAR file as a project in the tool used to create the custom theme.
   b. Add a WAR file to the existing EAR file. In this sample, the name is `MyStaticContent.war` and the context root is `/MyStaticContent`.
   c. The `web.xml` file for the new web module can be as simple as the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/javaee"
         xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
         xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
         http://java.sun.com/xml/ns/javaee/web-app_2_4.xsd"
         version="2.4">
    <display-name>StaticHTMLContent</display-name>
    </web-app>
```

The structure of the resulting EAR file looks like the following sample:

```
MyEar
    META-INF
        application.xml
    MyStaticContent.war
    MyDynamicContent.war
```

The following code is a sample of the `application.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE
    application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application
    1.3//EN" "http://java.sun.com/dtd/application_1_3.dtd">
<application id="MyEar">
    <display-name>MyEar</display-name>
    <module id="MyStaticContent">
        <web>
            <web-uri>MyStaticContent.war</web-uri>
            <context-root>/MyStaticContent</context-root>
        </web>
    </module>
```

```
    <module id="MyDynamicContent">
        <web>
            <web-uri>MyDynamicContent.war</web-uri>
            <context-root>/MyDynamicContent</context-root>
        </web>
    </module>
</application>
```

5. Add the exported static content to the web module.
   a. Copy the static content that you exported in step 1 into the WAR file.
      The structure of the WAR file looks like the following sample:

```
MyStaticContent
  themes
  skins
  layout-templates
  common-resources
  WEB-INF
  web.xml
```

6. Make whitelist and black lists For security reasons, the WAR data source does not serve content until a special context parameter is set. This context parameter defines which files from your web module WebSphere Portal Express is able to serve.

   You must define a whitelist using a regular expression that matches the files that you want to make available. In addition, with a blacklist you remove certain entries from the set of files that are available in the whitelist. A blacklist is helpful if you want to serve a folder but not a certain file within that folder.

   The expressions are case-sensitive, for example `WEB-INF` is different from `Web-Inf`.

   The parameters are set in the `web.xml` file of the web module that contains the static theme content.

   Sample: Serve all files that are not part of the `WEB-INF` folder.

```
<web-app>
  ........
  <context-param>
  <description>A regular expression that defines which of the resources in the war file can
               be served by the portal war datasource.</description>
  <param-name>com.ibm.portal.whitelist</param-name>
  <param-value>.*</param-value>
  </context-param>
  <context-param>
  <description>A regular expression that defines which of the resources in the war file cannot
               be served by the portal war datasource.</description>
  <param-name>com.ibm.portal.blacklist</param-name>
  <param-value>WEB-INF/.*</param-value>
  </context-param>
  ....
</web-app>
```

Adapt the scripts that register the custom theme and skins:

You must adapt the scripts that register the custom theme and skins that were moved from the file store.

Procedure

1. Open the `theme` file and adapt the following properties of the theme by changing the code `dav:fs-type1` to `war`:

```
   <parameter name="com.ibm.portal.theme.template.ref" type="string" update="set">
<![CDATA[war:<context-root-static-war>/<customThemePath>/]]>
   </parameter>

   <parameter name="com.ibm.portal.layout.template.href" type="string" update="set">
<![CDATA[war:<context-root-static-war>/layout-templates/2ColumnEqual/]]>
   </parameter>
```

2. Adapt the following properties for all the skins moved from the file store to an EAR file by changing the code `dav:fs-type1` to `war` for the following parameters:

```
<parameter name="com.ibm.portal.skin.template.ref" type="string" update="set">
   <![CDATA[war:<context-root-static-war>/<customSkinPath>/skins/Hidden/]]>
</parameter>
```

Adapting the list of required runtime configuration changes for your theme:

You must adapt the list of required runtime configuration changes for your theme.

Procedure

1. Modify the dynamic resource references in static resources of your theme static resources. For more information about dynamic resource references, see Copying the theme.
2. Change the common-resources root node.
   a. Open the WebSphere Integrated Solutions Console.
   b. Open**Resources** > **Resource Environment** > **Resource Environment Providers** > **WP GlobalThemeConfig** > **Custom Properties**.
   c. Change **behaviors.layout.defaultLayout** from `dav:fs-type1/layout-templates/2ColumnEqual/` to `<context-root-static-war>/layout-templates/2ColumnEqual/`. For example, if your context root is `/MyStaticContent`, the value would be `war:MyStaticContent/layout-templates/2ColumnEqual/`.
3. Change **resources.commonResourcesRootURI** from `dav:fs-type1/common-resources` to `war:/common-resources.` For example, if your context root is `/MyStaticContent`, the value would be `war:MyStaticContent/common-resources`
   a. Open the WebSphere Integrated Solutions Console.
   b. Open**Resources** > **Resource Environment** > **Resource Environment Providers** > **WP ConfigService** > **Custom Properties**.
   c. Create or adapt a regular expression for the **refreshPageLayout.template.regexp** parameter. The portal default is `dav:fs-type1/layout-templates/.*|dav:fs-type1/themes/.*`. The following example shows a regular expression:

      ```
      dav:fs-type1/layout-templates/.*|dav:fs-type1/themes/.*|war:/themes/.*
      ```

      Note: If you do not perform the last step, users must have the **Markup Editor** role that is assigned to be able to change a layout.

What to do next

You can define the secure locations of layout templates by using this setting. If portal receives a request to create or update a page that contains a layout link, and that link is matching this regular expression, the markup editor role is not enforced on that layout. Include only locations in the regular expression that are under Access Control enforcement. For example, the layout templates and theme folders can be changed only by users that have the Theme Manager role. References to war files are also usable, as the war file deployment is secured by Java Platform, Enterprise Edition rights.

Test the custom EAR file:

Test the new custom EAR file on your test server to verify that it deploys successfully.

If you already deployed the dynamic WAR file, you must uninstall the WAR file before this step because it is redeployed in the ear file. Do not delete the theme in portal when you uninstall the WAR file.

Deploy the EAR file, run the XML Access scripts to register the theme and skins. Also, update the runtime configuration as described before.

Restart your portal server and test the new custom ear file on your test server to verify that it deploys successfully.

Exporting content from the filestore

You must export content from the filestore to create your custom theme. There are different options available to export files from the portal file store.

Exporting content from the filestore is required in different scenarios, however with different files to be exported. See the concrete scenario description for the detailed list of files to export.

You can access the filestore by using the following URL:

- http://<server>:<port>/wps/mycontenthandler/dav/fs-type1/

Use one of the following options to export the files stored there.

Get a compressed file using your browser

You can obtain a compressed file of the content in the filestore using your browser. Enter the following url in your browser:

```
http://<server>:<port>/wps/mycontenthandler/dav/fs-type1/<folder-name>/?mime-type=application/zip
```

Where:

- The <server> value is the host name of the portal.
- The <port> value is the port number for WebSphere Portal Express.
- The <folder-name> value is the folder to be compressed. This value is optional.

Note: A / must follow the folder name.

The URL triggers a download of a compressed file. If you are prompted for a user and password enter the admin user ID and password for WebSphere Portal Express. Store the file on the local file system.

This following url downloads the complete content of the filestore:

```
http://<server>:<port>/wps/mycontenthandler/dav/fs-type1/<folder-name>/?mime-type=application/zip
```

The following url downloads the content of the themes folder:

```
http://<server>:<port>/wps/mycontenthandler/dav/fs-type1/themes/?mime-type=application/zip
```

Automate the export using an Ant task

If you want to automate the export, you can write an Ant task as depicted in the following example:

```
<target name="export-mytheme">
    <get src="http://<server>:<port>/wps/mycontenthandler/dav/fs-type1/<folder-name>/?mime-type=application/zip"
        username="PortalAdminID"
        password="PortalAdminPwd"
        dest="/tmp/mytheme.zip" />
</target>
```

Where:

- The <server> value is the host name of the portal.
- The <port> value is the port number for WebSphere Portal Express.

- The <folder-name> value is the folder to be compressed. This value is optional.

Note: A / must follow the folder name.

Use WebDAV to connect to the filestore

Use a WebDav Client to connect to the filestore using the following url:

- http://<server>:<port>/wps/mycontenthandler/dav/fs-type1/

Browse to the folder you need and copy the files to your local drive.

Device classes

Device classes are used in IBM WebSphere Portal Express as an abstraction for common properties for the device of a client. For instance, tablet computers can be grouped into a device class `tablets`, since they share a form factor and possibly other traits such as touch interface, or additional hardware sensors.

Note: The abstraction provided by device classes does not make the defining properties explicit, but is rather indirectly done by the assignment of device classes to clients.

1. "Device classes overview"
   Device classes can be implemented to organize Clients in to groups. After you defined a device class, you can then assign it to clients. You can assign multiple device classes to a client to help scope your environment.
2. "Additional information about device classes for developers" on page 2822
   The `DeviceClass` profile attribute contains only the highest priority device class on the client. Highest priority is determined as the first device class listed for the client. `DeviceClassList` provides access to all device classes on a client, as a string of comma-separated values.
3. "mvc:URI scheme" on page 2823
   The `mvc:URI` scheme is a special URI format that accesses different resources, depending on the device class. This scheme is used by the Portal 8001 theme in the definition of several dynamic content spots.
4. "Creating and deleting device classes" on page 2824
   You can create and delete device classes using the XML configuration interface.
5. "Assigning device classes" on page 2824
   The process of assigning a device class to one of the supported clients in WebSphere Portal. Usually, when a certain device class needs to be supported, the first step is to create client definitions for each of the devices that belong to this class. Then, you create a device class and assign the device class to the clients. The assignment of device classes on clients is done in the Supported Clients administration section, using a specific capability on the client.
6. "Device class equations" on page 2825
   Device class equations are expressions that involve a mixture of device class operands and boolean logic operators.

Device classes overview

Device classes can be implemented to organize Clients in to groups. After you defined a device class, you can then assign it to clients. You can assign multiple device classes to a client to help scope your environment.

The following device classes are defined.

- `smartphone`

- tablet
- android
- blackberry
- iemobile
- ios
- worklight

Note: You can create extra device classes, or you can remove any of these device classes.

These are the device classes and Portal resources.

Clients
A client can be assigned a device class by assigning a capability. The name of the capability must start with `com.ibm.portal.devicesupport.deviceclass=` and continue with the administrative name of a device class, as provided with their definition.

Pages Device classes can be used to filter pages from the content model. For more information, see Filtering the content model.

Layout templates
A layout template for a static portal page can specify variants for device classes that use a naming convention. The layout template that matches the client's device class can then be used to render the page. For more information about how to define static pages and layout templates, see Creating a static page.

Theme modules
A contribution in a theme module can define subcontributions for a specific device class. For more information, see Defining theme modules.

Additional information about device classes for developers

The `DeviceClass` profile attribute contains only the highest priority device class on the client. Highest priority is determined as the first device class listed for the client. `DeviceClassList` provides access to all device classes on a client, as a string of comma-separated values.

EL Bean
The `clientProfile` bean can be used to obtain the list of device classes that are assigned to the client. For instance:`<c:set var="deviceClasses" scope="request" value="${wp.clientProfile['DeviceClass']}" />`

CC/PP Profile
The device class can also be directly obtained from the client profile information (CC/PP). For more information about the CC/PP API, see Client profile information (CC/PP) in portlets.

JavaScript
An array of device classes is available on the window object named `com_ibm_device_class`. This array object includes the same set of device classes that are defined for DeviceClassList within the CC/PP profile. You can query the array to check whether the environment is available. For example:

```
if(com_ibm_device_class.indexOf("smartphone") > -1){
 // action performed for smartphone devices
}else{
 // action performed for all non-smartphones
}
```

SPI Portal defines several services to obtain the list device classes that are assigned to the client. There is also a service to determine which device class matches best for a client. The package documentation for `com.ibm.portal.devicesupport` helps get you started.

URI schemes
The Portal theme provides and uses special URI formats that work with device classes.

mv: URI scheme
The `multiview` URI scheme provides a way to select the best matching resource for a client from an Atom listing of available resources that are based on naming conventions.

mvc:URI
The `multiview choice` URI scheme provides a way to select the best matching resource for a client from a listing of available resources that is directly contained in the scheme-specific part.

Related concepts:

Client profile information (CC/PP) in portlets
The Portal provides a standard API named "CC/PP" for accessing client profiles; learn how the client profile can be accessed through a request attribute. Learn about the attributes and components that are supported by the default profile implementation in the portal.

Related information:

Package com.ibm.portal.devicesupport

mvc:URI scheme

The `mvc:URI` scheme is a special URI format that accesses different resources, depending on the device class. This scheme is used by the Portal 8001 theme in the definition of several dynamic content spots.

The syntax of its scheme-specific part allows the following options:

- Specify the default URI to be used when no other listed URI matches.
- Map to an empty URI by using the syntax `...,name@,...`
- Create a comma-separated list of entries where:
  - The individual entries of the list are key and value pairs that are separated with '@'.
  - The keys represent one device class name or multiple device class names in equation form, where the equation can use '/' for OR, '+' for AND, '!' for NOT, and parentheses for grouping.
  - The value is a URI that must be properly encoded to not use any of the special characters that are described here. Therefore, certain values such as the comma must be double-encoded.

You can also use URIs with query parameters, for example `mvc:uri1?foo=bar &hugo=123,tablet@uri1_tablet%252ftoken1`. Note the use of double encoding to represent a comma as part of a resource URI `, = pct %2f, % = pct %25`.

The following examples demonstrate some of the possible combinations:

- `mvc:res:/hello.jsp`: Uses a single default URI.
- `mvc:res:/hello.jsp,smartphone@res:/hello_smartphone.jsp`: Uses `res:/hello.jsp` as the default URI and `res:/hello_smartphone.jsp` as the URI for smartphones.

- `mvc:res:/hello.jsp,smartphone/tablet@res:/hello_mobile.jsp`: Uses `res:/hello.jsp` as the default URI and `res:/hello_mobile.jsp` as the URI for smartphones and tablets.
- `mvc:res:/hello.jsp,smartphone@,tablet@res:/hello_tablet.jsp`: Uses `res:/hello.jsp` as the default URI and `res:/hello_tablet.jsp` as the URI for tablets. No URI is assigned for smartphones.
- `mvc:res:/hello.jsp,smartphone+ios@res:/hello_smartphone_ios.jsp,(smartphone/tablet)+android@res:/hello_mobile_android.jsp`: Uses `res:/hello.jsp` as the default URI, `res:/hello_smartphone_ios.jsp` as the URI for iOS smartphones, and `res:/hello_mobile_android.jsp` as the URI for Android smartphones and tablets.

Creating and deleting device classes

You can create and delete device classes using the XML configuration interface.

Create a device class

The following example creates a device class with the name `smartphone` and the unique name `wps.deviceclass.smartphone`.

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="update" create-oids="true"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
 <portal action="locate">
  <device-class action="update" name="smartphone" uniquename="wps.deviceclass.smartphone" />
 </portal>
</request>
```

Delete a device class

The following example deletes the device class with the unique name `wps.deviceclass.smartphone`.

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="update" create-oids="true"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
    <portal action="locate">
        <device-class action="delete" uniquename="wps.deviceclass.smartphone"/>
    </portal>
</request>
```

Assigning device classes

The process of assigning a device class to one of the supported clients in WebSphere Portal. Usually, when a certain device class needs to be supported, the first step is to create client definitions for each of the devices that belong to this class. Then, you create a device class and assign the device class to the clients. The assignment of device classes on clients is done in the Supported Clients administration section, using a specific capability on the client.

"Assigning a device class manually to a client" on page 2825
You can manually assign a device class to a client.

"XML sample for assigning a device class" on page 2825
This example creates a client that matches devices that send `iPhone` in the user agent. The device class `smartphone` and `ios` are assigned to the client.

Assigning a device class manually to a client:

You can manually assign a device class to a client.

About this task

In the Supported Clients administration section, add a specific capability on the client:

Procedure

To assign a client the device class `smartphone`, add the following capability: `com.ibm.portal.devicesupport.deviceclass=smartphone`.
You can add multiple device classes to a client, ensure that they are separated by a comma: `com.ibm.portal.devicesupport.deviceclass=smartphone,worklight,ios`.

Note: During the matching process between the client user agent and the client, only one client is chosen. If multiple clients match, the highest priority client is used. Only the device classes that are assigned to the highest priority client are available. The priority is set with the ordinal attribute on the client definition. The larger the value of the ordinal, the higher priority it has during the matching process. The lowest priority client has an ordinal set to zero.

XML sample for assigning a device class:

This example creates a client that matches devices that send `iPhone` in the user agent. The device class `smartphone` and `ios` are assigned to the client.

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="update" create-oids="true"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
  <portal action="locate">
      <!--  iPhone -->
      <client action="update" manufacturer="Apple" markup="html"
        markup-version="" name="iPhone" ordinal="10000" uniquename="wps.client.iphone"
        version="7.0">
        <useragent-pattern>.*iPhone.*</useragent-pattern>
        <client-capability update="set">HTML_4_0</client-capability>
        <client-capability update="set">com.ibm.portal.devicesupport.deviceclass=smartphone
        </client-capability>
      </client>
  </portal>
</request>
```

Note: The ordinal attribute on the client definition sets the priority of the client during the matching process. Only one client is chosen and the device classes on that client are made available.

Device class equations

Device class equations are expressions that involve a mixture of device class operands and boolean logic operators.

Valid syntax includes the following operators:

- Parentheses
- The `NOT` operator that is represented by "`!`"
- The `AND` operator that is represented by "`+`"
- The `OR` operator that is represented by "`/`"

The order of operations when you parse an equation follows the normal boolean logic order of operations: parentheses, `NOT`, `AND`, `OR`.

For example:

```
android+smartphone
worklight+(ios/android)
(android/ios)+smartphone+!blackberry
```

This dynamic content spot only displays for android smartphones.

```
{
  "modules": [{
    "id" : "topnavoverlay",
    "prereqs": [{
      "id":"wp_dynamicContentSpots_85"
    }],
     "contributions": [{
      "type":"dyn-cs",
      "sub-contributions": [{
        "type":"markup",
        "ref-id":"85theme_topNav",
        "uris": [{
          "value":"res:/your/sample.html"
         "deviceClass": "android+smartphone"
        }]
      }]
    }]
  }]
}
```

Where to use device equations

Clients can have multiple device classes that are assigned in a comma separated list. These device classes on a client are then used in the device equations to determine what resources to provide or logic to run.

Device class equations are currently used with the Resource Aggregator. Subcontributions that use the device class attribute can now use equations to target resources to the device classes of the client that is accessing the resources.

MVC architecture for use in jsp's for loading dynamic spots that are based on client device classes.

Portal-if tag has a device class attribute that allows checking the client for a device equation.

Responsive Web Design

Responsive Web Design provides content parity between mobile devices and desktop channels, which enhances user experience and brand consistency. Seamless changes in screen size, from small to large, are now possible while the order of the content is maintained. Content maintenance is simplified by having one site that is represented by one set of assets.

"Mobile navigation" on page 2827
The IBM WebSphere Portal Express 8.5 ready-to-use theme provides two new responsive page navigation designs for mobile devices. One is aimed at smartphones, while the other is designed for tablets. The user agent for a device is parsed to determine which navigation to render on the portal page.

"Standard portal pages and mobile devices" on page 2831
IBM WebSphere Portal Express has two types of pages, Standard Portal Pages and Static Pages. Static pages use HTML templates to organize layout

containers and controls, and are used as the default page type since version 7.0. Standard Portal pages use table-based layouts.

"Relative width CSS classes for theme layouts" on page 2831
To assist with making the elements of a page responsive to various widths, relative width CSS classes have been added to the theme layouts. These classes are marker classes only. There are no styles that are defined for these classes by default. They are there on the containers, rows and columns, of the layouts so that you can define your own styles that are associated with the classes as needed to make your page elements responsive to various widths.

Mobile navigation

The IBM WebSphere Portal Express 8.5 ready-to-use theme provides two new responsive page navigation designs for mobile devices. One is aimed at smartphones, while the other is designed for tablets. The user agent for a device is parsed to determine which navigation to render on the portal page.

Smartphone navigation design

Figure 32. Welcome page displayed on a smartphone

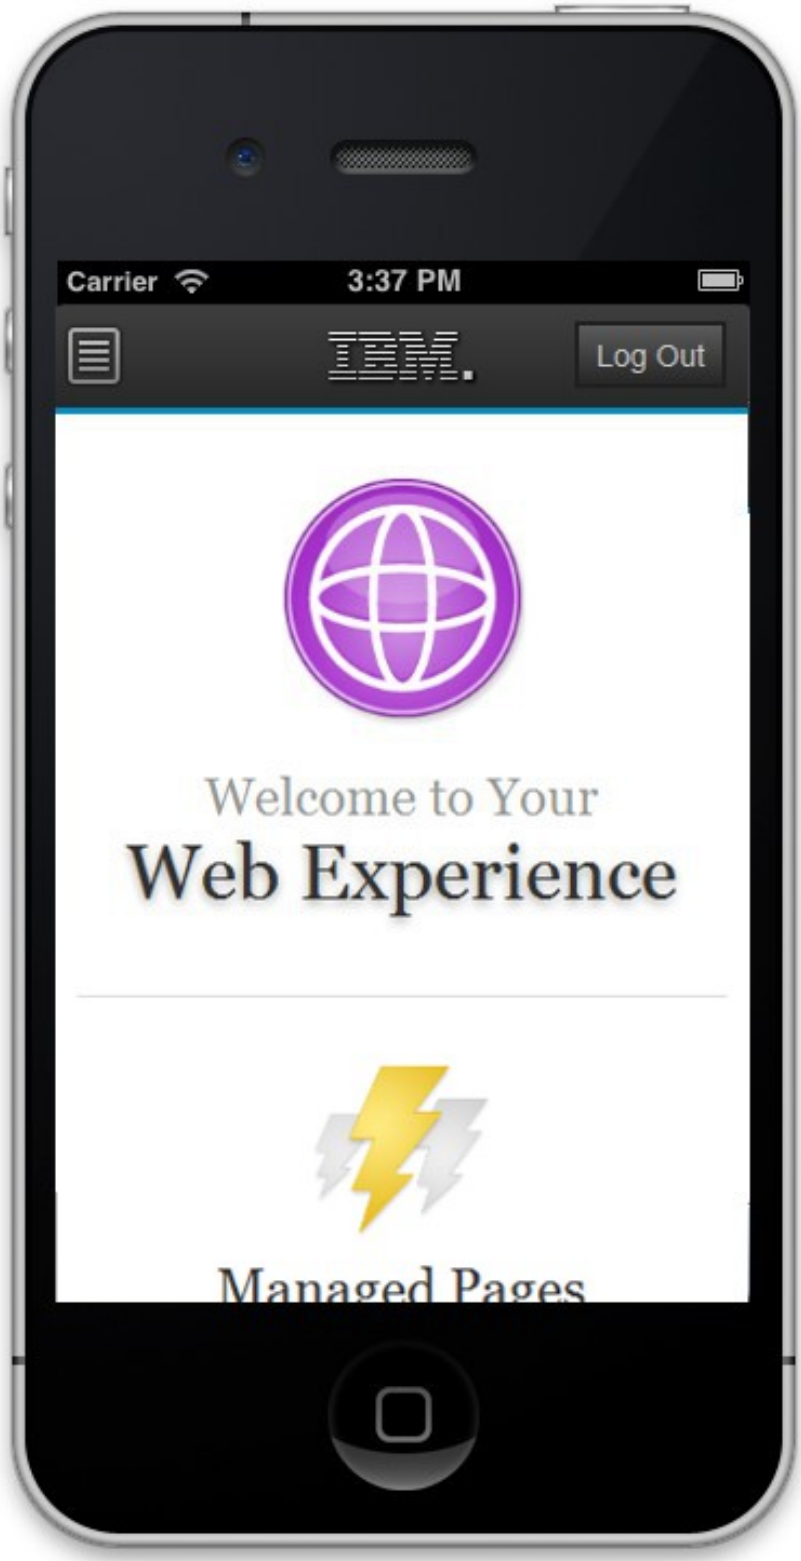

Figure 33. Mobile navigation displayed on a smartphone.

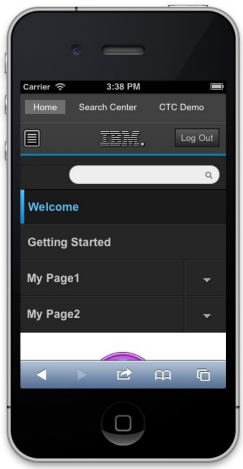

1. Scroll up to display the navigation toggle: When the portal loads, this level of navigation is hidden to maximize the limited real estate on a smartphone.
2. Tap the navigation button to show the navigation for your portal.
3. Tap this link to return to the portal home page.
4. Tap the name of the page to load a specific page.
5. Tap the arrow near the page name to display the child pages for that page.

Tablet navigation design

Figure 34. Welcome page displayed on a tablet.

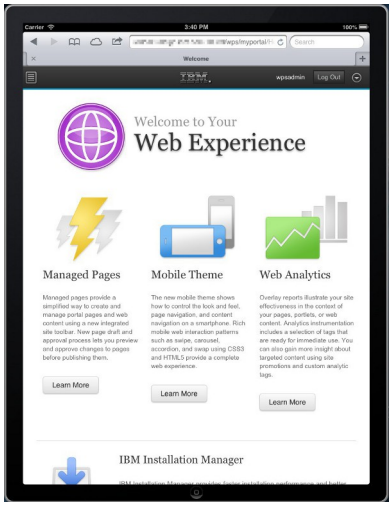

Figure 35. Mobile navigation displayed on a tablet.

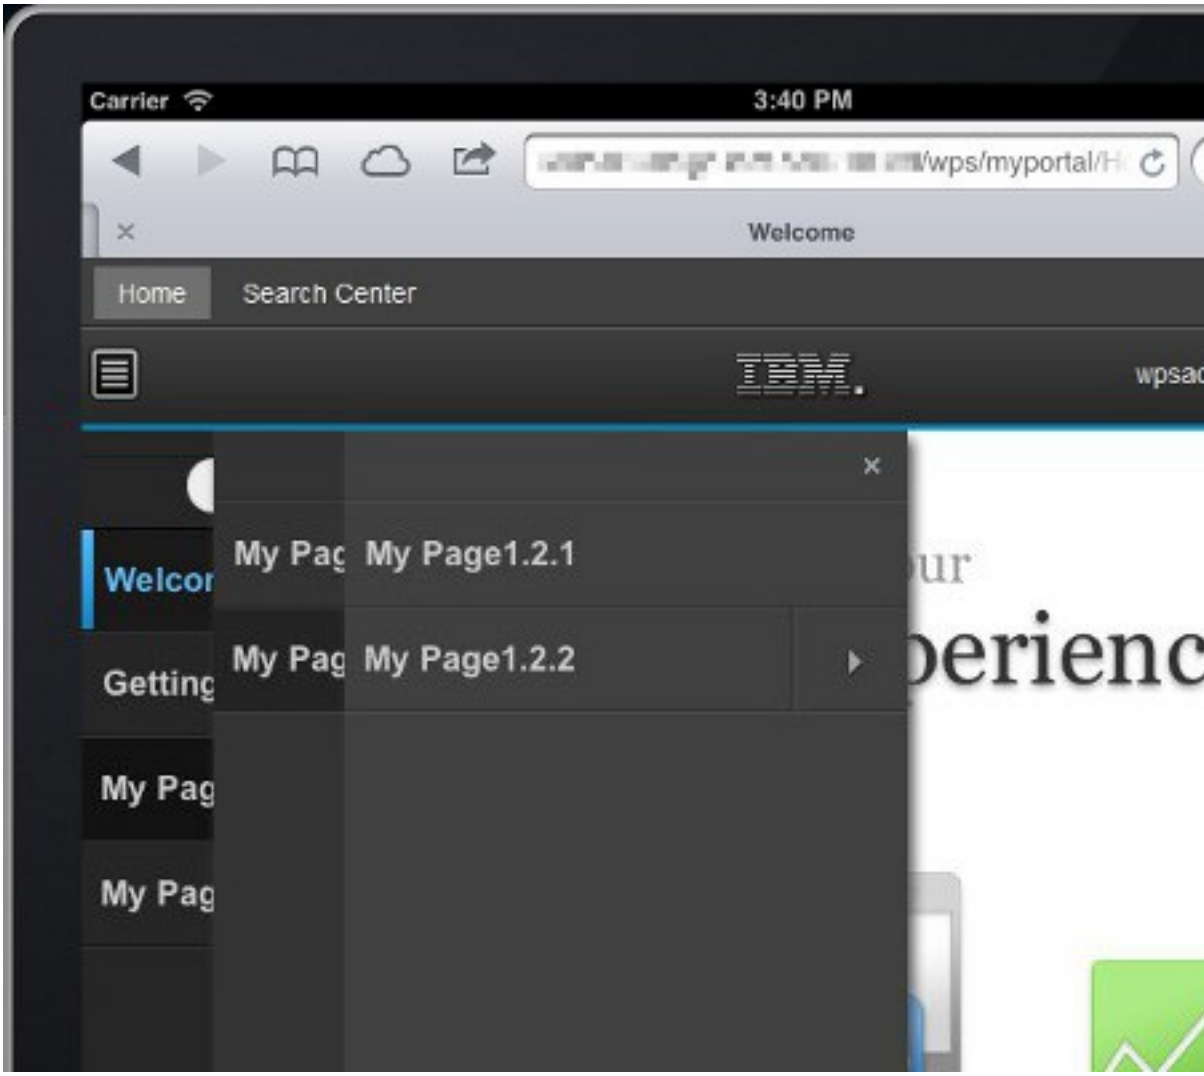

1. Tap the navigation button to show the navigation for your portal.
2. Tap this link to return to your portal home page.
3. Tap the arrow button to show the navigation.
4. Tap the name of the page to open a specific page.
5. Tap the arrow near the page name to display the child pages for that page.

You can have the navigation and portal navigation open individually or at the same time without affecting the functionality of the portal.

Mobile navigation markup

The mobile navigation markup for both smartphone and tablet is created by the `mobileNavigation.jsp` file of the theme, found at *PortalServer_root*`/theme/wp.theme.themes/default85/installedApps/DefaultTheme85.ear/DefaultTheme85.war/themes/html/dynamicSpots`. The `mobileNavigation.jsp` file is controlled by the mobile navigation dynamic spot in `theme.html`: `dyn-cs:id:85theme_mobileNavigation`

The navigation on mobile devices is rendered by the `mobileNavigation.jsp` file. Therefore, the primary, secondary, breadcrumb, and side navigation that is used on the desktop do not produce any output for a mobile device. The navigation is rendered for mobile, but is hidden when the page loads. On a tablet, the arrow

button in the banner can be tapped to reveal the navigation. On a smartphone, the user can scroll up to see the first-level navigation pages. Since smartphones have little real estate, site designers might want to hide certain first-level pages, such as Administration, for these devices. Add the `com.ibm.portal.mobile.Hidden` metadata to the page to hide certain first-level pages. By default, the Administration, Application, and Tag Center pages are hidden.

Note: If the expanded navigation for your Portal site ends up being long on a smartphone, it is possible part of the navigation can get cut off. This cut off happens because a maximum height is required to be set on the navigation in order for the CSS3 animations to work correctly. If your navigation does not fit into this maximum height, it can be adjusted by editing the `mobilenav.css` file of your custom theme in WebDAV at `dav:fs-type1/themes/myCustomTheme/css/`. Look for the following style declaration, increase the max-height, and save.

```
.wpthemeMobileNav ul.wpthemeExpandNav {
   /* navigation lists */
   max-height: 100em;
}
```

Standard portal pages and mobile devices

IBM WebSphere Portal Express has two types of pages, Standard Portal Pages and Static Pages. Static pages use HTML templates to organize layout containers and controls, and are used as the default page type since version 7.0. Standard Portal pages use table-based layouts.

Since standard pages are table-based, it is more difficult to implement responsive web design on standard pages. Limited support for responsive web design is implemented for standard pages on smartphone devices. When a standard page is viewed on a smartphone, all of its layout containers and portlets stack vertically. Stacking the containers and portlets ensures that the page contents fit better on the screen. The look of standard pages remains unchanged on desktop and tablet devices, which have more available real estate.

If you want to introduce more responsiveness to the standard page layouts of your portal site, use CSS selectors for pinpointing containers and controls to achieve the preferred designs. To add this support to your theme, add the `wp_legacy_layouts` module to your theme profile. For more information, see *Adding or removing a ready-to-use module to a theme*.

For example, if you want to hide the third column of a three column layout on a tablet sized device, you can target the screen size by using a media query and the third column with an appropriate CSS selector:

```
@media (max-width: 800px) {
    table.layoutRow tbody tr td:nth-child(3) {
        display: none;
    }
}
```

Relative width CSS classes for theme layouts

To assist with making the elements of a page responsive to various widths, relative width CSS classes have been added to the theme layouts. These classes are marker classes only. There are no styles that are defined for these classes by default. They are there on the containers, rows and columns, of the layouts so that you can

define your own styles that are associated with the classes as needed to make your page elements responsive to various widths.

There are two types of relative width classes, and one of each is used on each layout container.

Semantic type, one of:

wpthemeThin

wpthemeNarrow

wpthemeMedium

wpthemeWide

wpthemeFull

These types allow for up to five variations in width and are described by using common width words, such as narrow and wide.

Grid type, one of:

wpthemeCol1of12

wpthemeCol2of12

wpthemeCol1of5

wpthemeCol3of12

wpthemeCol4of12

wpthemeCol2of5

wpthemeCol5of12

wpthemeCol6of12

wpthemeCol7of12

wpthemeCol3of5

wpthemeCol8of12

wpthemeCol9of12

wpthemeCol4of5

wpthemeCol10of12

wpthemeCol11of12

wpthemeCol5of5

wpthemeCol12of12

These types allow for up to 16 variations in width and are described by using a numbering system of nofn width units. At first glance it looks like a simple numbering system where a layout with five columns would use `wpthemeCol1of5`, `wpthemeCol2of5`, `wpthemeCol3of5`, `wpthemeCol4of5`, and `wpthemeCol5of5` to number the columns. However, the best way to look at this system is not as the number of the column, but rather as the number of width units that the column takes up on the page. So, `wpthemeCol2of5` means that the column takes up two of five width units of the page, or `2/5ths` of the width of the page, and `wpthemeCol8of12` means that the column takes up 8 of 12 width units of the page, or `3/4ths` of the width of the page. So, a layout with five columns of equal width would use `wpthemeCol1of5` on all of the columns.

The two class types map to each other in the following way:

Table 450. Relationship of the 2 relative width class types

Width of the page	Semantic Type	Grid Type
1/12th	wpthemeThin	wpthemeCol1of12
2/12ths (1/6th)	wpthemeThin	wpthemeCol2of12
1/5th	wpthemeThin	wpthemeCol1of5
3/12ths (1/4th)	wpthemeNarrow	wpthemeCol3of12
4/12ths (1/3rd)	wpthemeNarrow	wpthemeCol4of12
2/5ths	wpthemeNarrow	wpthemeCol2of5
5/12ths	wpthemeMedium	wpthemeCol5of12
6/12ths (1/2)	wpthemeMedium	wpthemeCol6of12
7/12ths	wpthemeMedium	wpthemeCol7of12
3/5ths	wpthemeMedium	wpthemeCol3of5
8/12ths (2/3rds)	wpthemeMedium	wpthemeCol8of12
9/12ths (3/4ths)	wpthemeWide	wpthemeCol9of12
4/5ths	wpthemeWide	wpthemeCol4of5
10/12ths (5/6ths)	wpthemeWide	wpthemeCol10of12
11/12ths	wpthemeWide	wpthemeCol11of12
5/5ths (1)	wpthemeFull	wpthemeCol5of5
12/12ths (1)	wpthemeFull	wpthemeCol12of12

The Semantic types maps to the following page width amount:

Table 451. Semantic type mapping to page width amounts

Semantic type	Amount of the page width
wpthemeThin	1/12th to 1/5th
wpthemeNarrow	1/4th to 2/5ths
wpthemeMedium	5/12ths to 2/3rds
wpthemeWide	3/4ths to 11/12ths
wpthemeFull	all

"Creating your own layout"
When you create your own `layout.html` files, it is important to apply one semantic type and one grid type relative width class to each container. Such as `wpthemeMedium` and `wpthemeCol6of12`. Applying both ensures that those creating portlets and other page elements do not have to define styles for both types. Along with neither type and both types, they also have the choice to define styles for just one of the types, depending on their needs of granularity.

"Creating portlets and page elements" on page 2834
When you create portlets and the page elements within them, you can now define your own style overrides as needed. Use these relative width CSS classes to make your page elements responsive to various widths.

Creating your own layout:

When you create your own `layout.html` files, it is important to apply one semantic type and one grid type relative width class to each container. Such as

wpthemeMedium and wpthemeCol6of12. Applying both ensures that those creating portlets and other page elements do not have to define styles for both types. Along with neither type and both types, they also have the choice to define styles for just one of the types, depending on their needs of granularity.

When you apply one of each type, it is also important to apply the properly matching ones. For example, it is important to use either wpthemeCol3of12, wpthemeCol4of12 or wpthemeCol2of5 with wpthemeNarrow. Never add one of the other mismatching ones, such as wpthemeCol9of12 with wpthemeNarrow.

Creating portlets and page elements:

When you create portlets and the page elements within them, you can now define your own style overrides as needed. Use these relative width CSS classes to make your page elements responsive to various widths.

Your portlet can be placed in a column of any width and run on a device of any screen width. The primary styles for the elements use elastic percentage widths rather than fixed widths in general to be responsive. For certain width columns, you might need to make additional overrides. For example, if something is too large to display correctly in a narrow column, you can add display:none to hide it entirely. You can also add font-size:1.5em for wide columns or font-size:0.8em for narrow columns. To load a smaller version of an image use background-image:url("myImage_small.jpg") for narrow columns.

If you care only about five levels of variation in width or less, then you need only to override for the semantic types. The following example shows three levels of variation:

```
/* Narrow width columns */
.wpthemeThin .myComponent, .wpthemeNarrow .myComponent {
    ...
}
/* Medium width columns */
.wpthemeMedium .myComponent, {
    ...
}
/* Wide width columns */
.wpthemeWide .myComponent, .wpthemeFull .myComponent {
    ...
}

If you care about more than 5 levels up to 16 levels of variation in width, then you only have to ov

/* 1/12th, 1/6th and 1/5th width columns */
.wpthemeCol1of12 .myComponent, .wpthemeCol2of12 .myComponent, .wpthemeCol1of5 .myComponent {
    ...
}
/* 1/4th and 1/3rd width columns */
.wpthemeCol3of12 .myComponent, .wpthemeCol4of12 .myComponent {
    ...
}
/* 2/5ths and 5/12ths width columns */
.wpthemeCol2of5 .myComponent, .wpthemeCol5of12 .myComponent {
    ...
}
/* 1/2 and 7/12ths width columns */
.wpthemeCol6of12 .myComponent, .wpthemeCol7of12 .myComponent {
    ...
}
/* 3/5ths and 2/3rds width columns */
.wpthemeCol3of5 .myComponent, .wpthemeCol8of12 .myComponent {
```

```
    ...
}
/* 3/4ths and 4/5ths width columns */
.wpthemeCol9of12 .myComponent, .wpthemeCol4of5 .myComponent {
    ...
}
/* 5/6ths and 11/12ths width columns */
.wpthemeCol10of12 .myComponent, .wpthemeCol11of12 .myComponent {
    ...
}
/* 5/5ths and 12/12ths (full) width columns */
.wpthemeCol5of5 .myComponent, .wpthemeCol12of12 .myComponent {
    ...
}
```

You can override for both types if you choose, but it is only necessary if you created a layout that does not use both types on all containers.

URL generation in WebSphere Portal

Generating Portal URLs correctly is one of the most important tasks in programming a WebSphere Portal Express based application. There are several programming tools and techniques available for generating WebSphere Portal Express URLs in custom code. The following section introduces the programming tools available and discusses when it is most appropriate to use each of the tools.

Types of Portal Urls

There are several different types of Portal URLs depending on what task you are trying to accomplish.

Render URLs
: This type of URL is used for retrieving a general view of a Portal page. It specifically does not include any portlet actions or cause any server-side state changes. A Render URL corresponds to an HTTP GET operation and is idempotent, that is, it can be run more than once without any harm. Normal WebSphere Portal Express page navigation is made up of render URLs.

Action URLs
: Action URLs are used for activities within portlets. The URLs correspond to HTTP POST or PUT and are often non-idempotent, meaning they must be run at most once. An Action URL typically targets a specific portlet, and might cause server-side state changes. The portlet action and the portlet at which the action is targeted are carried as parameters within the Navigation State document.

Friendly URLs
: Friendly URLs have human-readable strings in the URL that describe the path to a Portal page. These human-readable strings correspond to the Friendly URL Names that are associated with the pages or labels. In addition, there might also be Friendly Content Path tokens in the URL. The Friendly Content Path tokens are human-readable strings that describe the site area path to Web Content Management library associated with the page.

  Note: A friendly URL might also include an encoded Navigational State document. If it does not, it is a Stateless Friendly URL. There is a programming API specifically for working with Friendly URLs.

Vanity URLs

Vanity URLs are similar to Stateless Friendly URLs, in that they are human-readable and do not have an encoded Navigational State document. However, Vanity URLs are not tied to the Friendly URL Names associated with the Portal pages. Instead, Vanity URLs are intended to be aliases that are simple, easily remembered, and easily entered by hand if necessary. Vanity URLs are similar to Mapped URLs that were introduced in prior releases of WebSphere Portal. They are intended only as an initial entry point, and are not persistent in the browser address bar after interaction with the Portal site begins. There is a programming API specifically for working with Vanity URLs.

Piece-of-Content URLs

Piece-of-content URLs or PoC URLs are late binding mechanism that targets content instead of Portal artifacts such as pages. They use a different URL entry point into WeSphere Portal (typically *mypoc* or *mycontenthandler* instead of *myportal*). A programming API is available for working with Piece-of-Content URLs.

Methods for generating portal URLs

The complexity of a WebSphere Portal Express URL makes them difficult to hand-code, therefore do not try to build Portal URLs by string concatenation. The design intention is that most self-referential URLs in Portal are generated in code at run time to avoid broken links and to avoid manually maintaining links within a Portal-based site.

WebSphere Portal Express makes several options available to a programmer for generating these complex Portal URLs. These different options are designed to address different use-cases, from the simplest to the most complex.

- Portal JSP tags method is used in Theme and Skin JSPs.
- JSR 286 Portlet API and corresponding JSP tags. This method of URL generation addresses almost all URL generation requirements within a standard portlet.
  - Or if necessary when you modify an existing portlet, and upgrading is not a possibility, the older JSR 168 Portlet API is used.
  - The IBM Portlet API is no longer supported. Older portlets that are written to this API must be migrated to the current standard.
- CF05 WebSphere Portal defined public render parameters. This method can support many use cases that previously required the use of the Navigational State API.
- Friendly URL API method is specifically for use cases that involve Friendly URLs, including URLs that must be stateless (have no encoded Navigational State document).
- PoC URL API method is specifically for creating Piece-of-Content URLs.
- Vanity URL API method is specifically for working with Vanity URLs.
- Navigational State API method is the most full-featured and general programming tool for URL generation, but requires the most in-depth understanding and programming skill.

When you create cooperating portlets that require inter-portlet communication, the inter-portlet messaging might be carried in the URLs that are generated. Render parameters as supported by JSR 286 are one way of accomplishing this, but additional programming tools are also provided. JSR 286 techniques for cooperative portlets, and the additional tools are described in more detail in the

Portlet communication section. One example of such a tool is the Cooperative Portlet API for interoperability between JSR 286 and JSR 168 portlets.

Mapping use cases to available programming tools

Creating page navigation links between Portal pages at the theme level. For example, standard tabbed pages navigation.

These URLs are typically simple render URLs. In JSPs, use the *<portal-navigation/>* JSP tags. For more information about programming a Portal theme, see *Developing Themes and Skins* section.

A JSR 286 portlet, self-contained (no inter-portlet communication required), generating action URLs to itself and setting its own render parameters.

- JSR 286 defines a tag library for use in JSPs. This tag library is greatly expanded over the V1.0/JSR168 version. It has its own namespace to avoid collisions with the V1.0 library.

  ```
  <%@ taglib uri="http://java.sun.com/portlet_2_0"
  Prefix="portlet"%>
  ```

  Examples:

  – To generate a normal rendering URL with a render parameter:

  ```
  <a href="<portlet:renderURL>
  <portlet:param name="myRenderParameter"
  value="someValue"/>
  This is the text for the link</a>
  ```

  – To generate a portlet Action URL, which targets the current portlet on the current page:

  ```
  form method="POST"
  action="<portlet:actionURL/>">
  ```

  Note: An action URL must have the Navigational State document encoded on it.

- To do the equivalent in java code instead of using the JSP tags, use the JSR 286 Portlet API, which is in package javax.portlet.* For more information, see the related link *Package javax.portlet.* In particular, see the RenderResponse interface. A RenderResponse is passed to the portlet's render method by the portlet container. RenderPesponse implements MimeResponse, which provides 3 methods for creating self-referential URLs:
  – createRenderURL()
  – createActionURL()
  – createResourceURL()

A JSR 286 portlet that requires inter-portlet communication with another JSR 286 portlet, but no page navigation (Portal view remains on the current page).

It might be sufficient to use the JSR 286 render parameter support. However, other techniques also exist. For more information, see the *Portlet communication* section.

A JSR 286 portlet that needs to interoperate with a JSR 168 portlet.

A JSR168 portlet that worked with other portlets through inter-portlet communication is written to use the Cooperative Portlet API, also known as the Property broker. The Property broker was an IBM extension to the JSR 168 specification. JSR286 introduced the portlet event model, which superseded the Property Broker. JSR286 portlets and JSR 168 portlets can

interoperate if certain conditions are met. For more information, see the *Interoperability between JSR 286 portlet events and JSR 168 cooperative portlets* section.

A JSR 286 portlet that needs to perform the following tasks:

- Generate a render link to another Portal page (causes page navigation).
- Optionally control the mode or window state of the targeted portlet.
- Optionally control the Portal state.
- Optionally control the render parameters of the targeted portlet.
- Optionally control the locale for the generated request.

CF05 Starting with Portal 8.5 CF05, use the WebSphere Portal-defined public render parameters for all of these use cases, and more. These render parameters make various aspects of the current request context available as normal public render parameters in a WebSphere Portal specified namespace.

To read Navigational State values as render parameters:

These special public render parameters can be accessed through the normal JSR286 API `renderResponse.getParameter(<parameter qualified name>)`.

Where `<parameter qualified name>` is the concatenation of the NAMESPACE_URI and one of the render parameter names, as defined in the following section. For example, `http://www.ibm.com/xmlns/prod/websphere/portal/publicparams` selection.

To set Navigational State values by using render parameters:

They can be set by the normal JSR286 portlet API `baseURL.setParameter(<parameter qualified name>, <value>)`

By setting these specific render parameters by using the normal JSR286 APIs, the system encodes the correct navigational state settings into the Navigational State document on the new URL. This setting makes the new values available on the next request that results from rendering and clicking that new URL.

Notes:

- This support requires the use of stateful URLs because the render parameters are only carried in the encoded Navigation State document.
- All these values are available as public constants in the `com.ibm.portal.PublicRenderParameters` class, which is a public API within the `wp.model.api` component. For complete details, see the WebSphere Portal javadoc *IBM WebSphere Portal Express, Version 8.5.0.0 SPI Specification.*

The namespace of the WebSphere Portal Express specified public render parameter is `http://www.ibm.com/xmlns/prod/websphere/portal/publicparams` (available as NAMESPACE_URI). The following items are the special public render parameters that WebSphere Portal Express supports:

- **`selection (NAME_SELECTION)`**
- **`uri (NAME_URI)`**
- **`parameters (NAME_PARAMETERS)`**
- **`locale (NAME_LOCALE)`**
- **`themeTemplate (NAME_THEME_TEMPLATE)`**

- **labelMappings (NAME_LABEL_MAPPINGS)**
- **screenTemplate (NAME_SCREEN_TEMPLATE)**
- **themePolicy (NAME_THEME_POLICY)**
- **solo (NAME_SOLO)**
- **showTools (NAME_SHOW_TOOLS)**
- **hiddenContent (NAME_HIDDEN_CONTENT)**
- **hiddenPages (NAME_HIDDEN_PAGES)**
- **statePartition (NAME_STATE_PARTITION)**
- **path-info (NAME_PATH_INFO)**
- **focus (NAME_FOCUS)**
- **deviceClass (NAME_DEVICE_CLASS)**
- **digest (NAME_DIGEST)**
- **pageMode (NAME_PAGE_MODE)**
- **editMode (NAME_PAGE_EDIT_MODE)**
- **infoMode (NAME_PAGE_INFO_MODE)**
- **helpMode (NAME_PAGE_HELP_MODE)**

There also exists a Portal URL Generation Convenience API. This convenience API supports render URLs only. No state changes (action URLs) can be generated by using this API. The following items are the key classes in this API:

- `com.ibm.portal.portlet.service.url.PortalURLGenerationService`
- `com.ibm.portal.portlet.service.url.PortalURLWriter`

Per the javadoc of the *com.ibm.portal.portlet.service.url* package, a programmer:

1. Obtains an instance of a `PortletServiceHome` by JNDI lookup.
2. On that home interface, calls `getPortletService(PortalURLGenerationService.class)`.
3. On that service, calls `getPortalURLWriter(request, response)`
4. Uses the methods on the `PortalURLWriter` object to create and manipulate the render URL.

An equivalent set of JSP tags for the URL Generation Convenience API exists.

```
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8/portlet/ibm-portlet-ext"
```

For more information, see *JSP tags for standard portlets*. An example of creating a render URL by using the Convenience API tag is`<portlet-ext:portalRenderURL>`.

Friendly URL

A Friendly URL also known as a Friendly URL Name is a human-readable name for a Portal page. It is set as an attribute of the page, and each page can have at most one Friendly URL.

Notes:

- If a page has a correctly configured Friendly URL, then WebSphere Portal Express guarantees that any request which renders the page has the Friendly URL. The request does not have the Friendly URL only if the Friendly URL enforcement is explicitly turned off by using the `friendly.redirect.enabled` configuration setting.

- Friendly URLs do not guarantee that they are free of Navigational State. If it is necessary to remove Navigational State, further techniques are available. You might also want to explore *Vanity URLs* or *URL Mappings* for these use cases.

To use the Friendly URL API, you need to get a `FriendlyURLFactory` instance. Depending on the type of code you are writing, you can get a `FriendlyURLFactory` instance in one of two ways:

If you are writing a portlet:

- Start with the `com.ibm.portal.resolver.friendly.service.PortletFriendlySelectionServiceHo` class. You need to obtain an instance of that class in 2 steps:
  1. Do a JNDI lookup by using the constant `PortletFriendlySelectionServiceHome.JNDI_NAME`. This JNDI lookup returns an instance of a `PortletServiceHome`.
  2. On the `PortletServiceHome` object, call `getPortletService(PortletFriendlySelectionServiceHome.class)`. The call returns a `PortletFriendlySelectionServiceHome` instance.
- For efficiency, do the JNDI lookup and `getPortletService` call within the `init(PortletConfig)` method of your portlet, and save the `PortletFriendlySelectionsServiceHome` instance to be reused. It is not necessary to do these calls on a per-request basis.
- On a per-request call, such as the `doView(RenderRequest,RenderResponse)` method of the portlet, use the saved `PortletFriendlySelectionServiceHome` to call `getPortletFriendlySelectionService(request,response)`. The call returns a `PortletFriendlySelectionService` instance.

  Note: This instance must be disposed by calling `dispose()` before it goes out of scope.
- On the returned `PortletFriendlySelectionService` instance, call `getURLFactory()`.

If you are writing theme code:

- Start with the `com.ibm.portal.resolver.friendly.service.PortalFriendlySelectionServiceHom` class. Do JNDI lookup by using the constant `PortalFriendlySelectionServiceHome.JNDI_NAME`. This lookup returns an instance of a `PortalFriendlySelectionServiceHome`.
- For efficiency, do the JNDI lookup within the constructor or other initialization method of your class, and save the `PortalFriendlySelectionServiceHome` instance to be reused. It is not necessary to do this call on a per-request basis.
- On a per-request call, use the saved `PortalFriendlySelectionServiceHome` to call `getPortalFriendlySelectionsService(HttpServletRequest,HttpServletResponse)` The call returns a `PortalFriendlySelectionService` instance.

  Note: This instance must be disposed by calling `dispose()` before it goes out of scope.
- On the returned `PortalFriendlySelectionService` instance, call `getURLFactory()`.

After you have a FriendlyURLFactory, you can call one of the newURL() methods to obtain a FriendlyURL instance. A FriendlyURL instance can be set up using the set* methods, which are written to the response by using the writer(Writer) method. The Writer is obtained from the response, and then is disposed by calling dispose().

Vanity URL

A Vanity URL is a simple, easy to remember URL that a user can enter by hand. Vanity URLs are managed by the webmaster with the WebSphere Portal Express administrative tools, such as the toolbar, administrative portlets, or XMLAccess scripting. However, sometimes when you render a response, it is necessary to produce a Vanity URL link.

The following section describes how to use the Vanity URL API to obtain a VanityURLNode, which can be used to render a Vanity URL link. Depending on the type of code package you are developing, use one of the 3 different ways to access and use the Vanity URL API.

Note: Be careful to select the correct SPI package for the code that is being developed.
The necessary interface documentation is in the WebSphere Portal Express SPI javadoc.

If you are writing a portlet:

- Locate the com.ibm.portal.portlet.service.model package.
- Start with the VanityURLModelProvider interface. You need to obtain an instance of a class, which implements that interface, in 2 steps:
  1. Obtain an instance of a PortletServiceHome by JNDI lookup by using the name constant VanityURLModelProvider.JNDI_NAME.
  2. On that PortletServiceHome object, call getPortletService(VanityURLModelProvider.class).
- Do the JNDI lookup and call getPortletService in the init() method of the portlet. Save the returned VanityURLModelProvider instance in a static field in your portlet class. This provider instance can be reused across requests.
- For each request, for example in the call to the doView() method of the portlet, call getVanityURLModel on the saved VanityURLModelProvider instance, passing the current portlet request and response. Models must not be reused across requests.
- On the VanityURLModel object, call getLocator().
- On the VanityURLModelLocator, you can call any of the findBy methods, which return either a single VanityURLNode or an IterableListModel<VanityURLNode> list.

If you are writing theme code:

- Locate the com.ibm.portal.model package.

  Note: Many of the class names in this set of instructions are identical to the class names for DataSource usage of the Vanity URL API, but the package name is different.
- Obtain an instance of a class, which implements VanityURLModelProvider, in 2 steps:

1. Obtain an instance of a VanityURLModelHome by JNDI lookup by using the name constant VanityURLModelHome.JNDI_NAME. See the com.ibm.portal.model.VanityURLModelHome javadoc for example code.
2. On that VanityURLModelHome object, call getVanityURLModelProvider().

- Do the JNDI lookup and call getVanityURLModelProvider() in the constructor or an init() method of your class. Save the returned VanityURLModelProvider instance in a static field in your class. This provider instance can be reused across requests.
- For each request, call getVanityURLModel on the saved VanityURLModelProvider instance, passing the current servlet request and response. Models must not be reused across requests.
- On the VanityURLModel object, call getLocator().
- On the VanityURLModelLocator, you can call any of the findBy methods, which return either a single VanityURLNode or an IterableListModel<VanityURLNode> list.

If you are writing a DataSource:

- Locate the com.ibm.portal.cor.service package.

  Note: Many of the class names in this set of instructions are identical to the class names for the theme code usage of the Vanity URL API, but the package name is different.
- Obtain an instance of a class, which implements VanityURLModelProvider, in 2 steps:
  1. Obtain an instance of a VanityURLModelHome by JNDI lookup by using the name constant VanityURLModelHome.JNDI_NAME. See the com.ibm.portal.cor.service.VanityURLModelHome javadoc for example code.
  2. On that VanityURLModelHome object, call getVanityURLModelProvider().
- Do the JNDI lookup and call getVanityURLModelProvider() in the constructor or an init method of your class, and save the returned VanityURLModelProvider instance in a static field in your class. This provider instance can be reused across requests.
- In a per-request method of the DataSource, call modelProvider.getVanityURLModel(com.ibm.content.operations.registry.api.Co

  Programming detail for a DataSource: In most cases, a DataSource is allocated by a dedicated factory. The factory is registered with the resolver framework to handle requests for a specific URI. When a request for that URI is received, the factory is started by the resolver framework and is passed a com.ibm.content.operations.registry.api.Context object. Make sure to understand the difference between this COR Context object and the javax.naming.Context class that is used by JNDI lookup. The factory allocates a new DataSource instance (or might retrieve an existing one from a pool) and calls reset() on the DataSource, passing the COR Context object. This object and the other parameters to reset(), must be saved in instance fields within the DataSource. They can be used on subsequent method calls until either dispose() is called or reset() is called again.

Use the COR Context object on the call to getVanityURLModel(com.ibm.content.operations.registry.api.Context).

- On the VanityURLModel object, call getLocator().
- On the VanityURLModelLocator, you can call any of the findBy methods, which return either a single VanityURLNode or an IterableListModel<VanityURLNode> list.

After you have a VanityURLNode instance through any of the appropriate ways, you can call the various methods of that interface to build a rendered representation of the VanityURL:

- VanityURLnode.isSecure() tells whether the target protocol is http or https.
- VanityURLnode.isProtected() tells whether the target URL mapping is to /portal or /myportal.
- VanityURLnode.getHost() returns the host name that is associated with this Vanity URL.
- VanityURLnode.getPort() returns the port number that is associated with this Vanity URL.
- VanityURLnode.getVpld() returns the Virtual Portal OID for this Vanity URL.
- VanityURLnode.getPath() returns the path string for this Vanity URL. This path string is what is thought of as the Vanity URL string.

Create, update, or delete Vanity URLs.

If you are writing code, which is intended to create, update, or delete Vanity URLs, rather than read and render them, use the following APIs:

- Locate the com.ibm.portal.model.controller package.
- You need to obtain an instance of a class, which implements VanityURLModelControllerHome through JNDI lookup by using the name constant VanityURLModelControllerHome.JNDI_Name. See the com.ibm.portal.model.controller.VanityURLModelControllerHome javadoc for example code.
- On that VanityURLModelControllerHome object, call getVanityURLModelControllerProvider().
- Do the JNDI lookup and call getVanityURLModelControllerProvider() in the constructor or an init method of your class, and save the returned VanityURLModelControllerProvider instance in a static field in your class. This provider instance can be reused across requests.
- You might also need to obtain a VanityURLModelProvider, by using the same code as described in the writing Theme code.
- In a per-request method,
  - On the VanityURLModelProvider, call getVanityURLModel(request,response).
  - On the VanityURLModelControllerProvider object, call createVanityURLModelController(model) passing the model that is returned from the call to getVanityURLModel.
- The subsequent calls to create the new Vanity URL and set its attributes are documented in the javadoc for VanityURLModelController and ModifiableVanityURLNode.

A JSR 286 portlet that needs to generate an action URL to a second specific portlet, or any other use case that is not listed here.
Navigational State API

Piece-of-Content URL

A Piece-of-Content or POC URL is a URL that targets a DataSource or a ResolutionService within the Resolver framework. Given such a DataSource or ResolutionService, the PoC URL API assists the programmer to create a URL that results in the Resolver framework to start the correct DataSource or ResolutionService.

To work with Piece-of-Content URLs, obtain an instance of a `com.ibm.portal.resolver.acessors.url.PocURLFactory`. Much like other URL APIs, the code for obtaining an instance of a URLFactory depends on whether you are writing a portlet, theme code, or if you are already running a code within the resolver framework.

If you are writing a portlet:

- In the Portal javadoc, locate the `com.ibm.portal.resolver.servicer.service` package.
- Obtain a `PortletPocServiceHome` instance in 2 steps:
  1. Do a JNDI lookup for the `PorletServiceHome` instance by using the name constant `PortletPocServiceHome.JNDI_NAME`. See the javadoc for `PortletPocServiceHome` for sample code.
  2. On the returned `PortletServiceHome` object, call `getPortletService(PortletPocServiceHome.class)`.
- Do the JNDI lookup and call `getPortletService` in the `init(PortletContig)` method of your portlet, and save the resulting `PortletPocServiceHome` instance in a class instance variable. It is not necessary to redo these calls on every request that is serviced by the portlet.
- In a per-request method, such as `render(RenderRequest,RenderResponse)`, call the appropriate `PortletPocServiceHome.getPortletPocService()` method based on the specific method that is implemented and the type of request and response that are passed. There are versions of this method for Action, Event, Render, Resource and plain PortletRequest and Response.

  Note: It is necessary to call `dispose()` on the returned service instance before it goes out of scope.
- On the `PortletPocService` or appropriate subclass, call `getURLFactory()`.

If you are writing theme code:

- In the Portal javadoc, locate the `com.ibm.portal.resolver.service` package.
- Do a JNDI lookup for the `PortalPocServiceHome`, by using the name constant `PortalPocServiceHome.JNDI_NAME`.
- Save the resulting `PortalPocServiceHome` instance in a class instance field. It is not necessary to do the JNDI lookup for every request.
- In per-request method of your class, on the saved `PortalPocServiceHome` instance call `getPortalPocService` passing the `HttpServletRequest` and `HttpServletResponse`.

Note: It is necessary to call `dispose()` on the returned service instance before it goes out of scope.

- On the resulting `PortalPocService` instance, call `getURLFactory()`.

If you are writing code that runs as a DataSource or ResolutionService:

- In the Portal javadoc, locate the `com.ibm.portal.resolver.service` package.
- Do a JNDI lookup for the `CorPocServiceHome`, by using the name constant `CorPocServiceHome.JNDI_NAME`.
- Save the resulting `CorPocServiceHome` instance in a class instance field. It is not necessary to do the JNDI lookup for every request.
- In per-request method of your class, on the saved `CorPocServiceHome` instance call `getCorPocService(com.ibm.content.operations.registry.api.Context)`.

  Note: It is necessary to call `dispose()` on the returned service instance before it goes out of scope.

  Programming detail for a DataSource: In most cases, a DataSource is allocated by a dedicated factory. The factory is registered with the resolver framework to handle requests for a specific URI. When a request for that URI is received, the factory is started by the resolver framework and is passed a `com.ibm.content.operations.registry.api.Context` object. Make sure to understand the difference between this `COR Context` object and the `javax.naming.Context` class that is used by JNDI lookup. The factory allocates a new DataSource instance (or might retrieve an existing one from a pool) and calls `reset()` on the DataSource, passing the `COR Context` object. This object and the other parameters to `reset()`, must be saved in instance fields within the DataSource. They can be used on subsequent method calls until either `dispose()` is called or `reset()` is called again. Use the `COR Context` object on the call to `getCorPocService (com.ibm.content.operations.registry.api.Context)`.
- On the resulting `CorPocService` instance, call `getURLFactory()`.

After you obtain a `PocURLFactory`:

- Call one of the `newURL` methods, to instantiate the desired type of `PocURL`.
- On the resulting `PocURL` instance, call the `setXXX` methods to define your URL attributes.
- Stream the URL to the response and dispose of the `PocURL` instance by calling `writeDispose()`. The Writer instance for use by `writeDispose` must be obtained from the response argument to the method.

"URL generation by using the Navigational State SPI" on page 2846
The Navigational State API is used to read and modify the Navigational State document within a Portal URL. The Navigational State document is the seemingly random string of characters that appears in WebSphere Portal URLs. This string is a compressed, encoded XML document that contains a large amount of information that supports various Portal functions, including bookmark-ability of Portal pages and back button support.

IBM WebSphere Portal, Version 8.5.0.0 SPI Specification

URL generation by using the Navigational State SPI

The Navigational State API is used to read and modify the Navigational State document within a Portal URL. The Navigational State document is the seemingly random string of characters that appears in WebSphere Portal URLs. This string is a compressed, encoded XML document that contains a large amount of information that supports various Portal functions, including bookmark-ability of Portal pages and back button support.

For details about the back button behavior and the support of bookmarks, see to the topic *Back button behavior*.

You can use the Navigational State SPI to read, create, and modify URLs that carry navigational state. The `com.ibm.portal.state` package is the main package of the Navigational State SPI. It holds the service interfaces and the interfaces that make up the navigational state object model.

The SPI offers two services (obtainable through JNDI) to create such URLs. Which service you choose depends on whether you are writing Portal-level code or portlet code, for example within a theme.

Portal-level code: Portal State Manager Service
A portal service that is used to realize use cases that go beyond what the portal tags provide. Use it to create URLs within portal artifacts such as themes, skins, and custom JSP tags. You can also use it in artifacts that are removed from the request processing, such as Enterprise JavaBeans. However, the Portal State Manager Service is not meant to be used for portlets. The Portal State Manager service classes are in package `com.ibm.portal.state.service`. A `PortalStateManagerService` instance is obtained with a JNDI look-up that uses a name constant from the `PortalStateManagerServiceHome` interface.

Portlet code: Portlet State Manager Service
The counterpart service that supports JSR168 and JSR286 compliant portlets. Use the Portlet State Manager Service to create URLs within

portlets that cannot be created by using the Standard Portlet APIs. A `PortalStateManagerService` instance is obtained with a `PortalStateManagerServiceHome` instance.

Tip: A `PortletStateManagerService` instance is obtained with a `com.ibm.portal.portlet.service.PortletServiceHome` instance.

Note: CF05 Consider the new Portal-defined public render parameters support for these use cases, instead of the Navigational State SPI. The render parameters provide most of the same functions in a much simpler way.

For more information about all SPI interfaces, see the Javadoc.

Object Model

Learn about the main object models used in the navigational state SPI.

Navigational state

The Navigational state object model is a hierarchy of state information, which is modeled as a DOM-like document containing untyped state information represented as strings because a typical page contains many URLs that require the navigational state to be serialized multiple times per request. The string-based memory allows for efficiently serializing navigational states into URLs, because it avoids processing time and CPU consuming object to string conversions during the serialization process.

The Navigational state is modeled via the following interfaces:

- `com.ibm.portal.state.StateHolder`
- `com.ibm.portal.state.StateHolderController`
- `com.ibm.portal.state.dom.DocumentModel`
- `com.ibm.portal.state.dom.DocumentController`

The `StateHolder` interface provides read access to the navigational state information by exposing a `getModel()` method that returns an interface to the untyped document model, namely the `DocumentModel` interface. The `DocumentModel` interface provides a set of methods to inspect both the hierarchical structure of the state document as well as single nodes being part of that document.

In addition, the `StateHolder` interface offers a `newState()` method which can be used to create a clone of that particular StateHolder instance. This is an important method because, typically, the current navigational state has to be cloned before

modifying it according to the specific semantics of the generated URL. For example if the programmer wants to create a URL that points to a particular portal page, the page selection information in the state document model has to be changed; however, this modification must not take effect on all URLs of a page.

Beyond that, the `StateHolderController` interface also allows you to modify state information by offering a `getController()` method that delivers a controller interface to the untyped state document called `DocumentController`. The `DocumentController` interface provides a means to modify the hierarchical structure of the state document, which includes creating document nodes, inserting them into the node hierarchy, and removing nodes.

Engine URLs

URLs are modeled via the `com.ibm.portal.state.EngineURL` interface. An `EngineURL` represents a URL that contains navigational state. The initial `StateHolder` an `EngineURL` refers to is specified when requesting a new `EngineURL` instance from the appropriate URL factory; see "URL generation services" on page 2851 for additional information. Typically it is a copy of the request-specific base state.

The `EngineURL` interface provides the following methods:

`StateHolderController getState()`
Returns a read-write interface to the navigational state carried by the URL.

`void setProtected(Boolean flag)`
Specifies whether the URL should point to the public or protected area.

`void setSecure(Boolean flag)`
Specifies whether a secure https connection is required.

`Writer writeCopy(Writer out)`
Streams the URL to the given writer. Maintains the state of the URL. For example this method can be used to write the URL multiple times.

`Writer writeDispose(Writer out)`
Streams the URL to the given writer and finally releases the state of the URL. The `EngineURL` object must not be accessed again after invoking this method.

`void dispose()`
The `dispose()` method is inherited from the `Disposable` interface. It must be invoked to indicate that the `EngineURL` object is no longer needed. The `EngineURL` object must not be accessed again after invoking this method. Alternatively, you can invoke the `writeDispose()` method, which calls `dispose()`.

The crucial method is the `getState()` method, which returns the state holder object this particular `EngineURL` instance refers to.

Note: The method returns a controller interface (`StateHolderController`) that allows the programmer to modify the state of this `EngineURL`. See "Accessor SPI" on page 2849 for additional information about modifying the state.

Resource URLs

URLs that address generic resources such as, but not limited to, files, icons, and voice grammars cannot contain navigational states and are therefore modeled

using a separate interface called com.ibm.portal.state.DisposableURL. The DisposableURL interface almost offers the same methods as EngineURL but does not provide a getState() method.

Resource URLs can also be created using the URL generation Services that are offered along with the Navigational State SPI. See "URL generation services" on page 2851 for additional information.

Accessor SPI

The Accessor SPI provides typed access to the state document model. It allows the programmer to query and modify navigational state information. The Accessor SPI is part of the package com.ibm.portal.state.accessors.*.

The Accessor SPI is an abstract layer that surrounds the access to particular nodes in the hierarchical document model. For more information about the hierarchical document model, see "Object Model" on page 2847. For each state aspect such as, but not limited to, page selection, expansion states, and portlet states, the SPI offers an accessor factory. The accessor factory provides read-only and read-write accessor controls that are designed for the particular state aspect they refer to. The accessors read from or write to the respective positions in the state document model and does the required type conversions.

The navigational state information is in the state document model and is available when the accessor factory is used. After the node is located, the accessor factory passes a node reference to the accessor or accessor controller during. The accessor and accessor controller are independent from the state document model structure; you can reuse accessors even if the information is moved to another node in the state document.

The SelectionAccessorFactory offers the following interfaces, as shown in the example:

SelectionAccessor getSelectionAccessor(StateHolder)
: This method returns a SelectionAccessor interface that allows for reading page selection information from the StateHolder.

SelectionAccessorController getSelectionAccessorController(StateHolderController)
: This method returns a SelectionAccessorController interface that allows programmers to modify page selection information. The controller uses the StateHolderController interface to modify the navigational state accordingly.

The flyweight pattern, where the StateHolder or StateHolderController is used as an argument, is commonly used in the accessor factory interfaces. The navigational state the accessor operates on cannot be the base state that is retrieved from the request URL; typically, it is the state clone created for a particular EngineURL. Call getState() on the EngineURL object to obtain the URL-specific state holder. The following example shows how to make a created EngineURL point to a certain portal page (for example, the "Stock Market" page) by using the SelectionAccessorController:

```
final EngineURL url = ...;
final SelectionAccessorFactory selectionFct = ...;

final SelectionAccessorController selectionCtrl =
    selectionFct.getSelectionAccessorController(url.getState());

try {
```

```
    selectionCtrl.setSelection("wps.StockMarket");
} catch (StateException e) {
    // include error handling here
} finally {
    selectionCtrl.dispose();
}
```

Using the SelectionAccessorController to create a page link

The base Accessor interface is derived from the com.ibm.portal.Disposable interface. Start the dispose() method to indicate when the accessor is no longer required. Using the dispose() method allows the accessor factory to store the accessors and accessor controllers in object pools to achieve better performance (due to less initialization and garbage collection overhead).

The Navigational State SPI offers the following accessor factories, each covering a certain state aspect:

SelectionAccessorFactory
: The SelectionAccessorFactory provides accessors to read and write portal page selection information. To create a URL that points to another page, the SelectionAccessorController needs to be requested from the factory to include the new selection into the state, the created EngineURL is associated with.

PortletAccessorFactory
: The PortletAccessorFactory provides accessors to read and write portlet-related navigational state information, which includes portlet mode, window state, and render parameters. In particular the PortletAccessorController can be used to change the navigational state of a portlet (for example, the portlet mode).

PortletTargetAccessorFactory
: The PortletTargetAccessorFactory provides accessors to read and write portlet action-related information. In particular the PortletAccessorController can be used to declare a portlet as the target of an action. This action allows the programmer to create URLs that trigger portlet actions.

SoloAccessorFactory
: The SoloAccessorFactory provides accessors to read and write the so-called Solo state. If the portal is in Solo state, it renders only one particular portlet of the current portal page; all navigation controls and toolbars are hidden. The SoloAccessorController can be used to create URLs that activate/deactivate the Solo state for a particular portlet.

ThemeTemplateAccessorFactory
: The ThemeTemplateAccessorFactory supports reading and writing theme template information. In particular the ThemeTemplateAccessorController can be used to create URLs that switch to a certain theme template.

LocaleAccessorFactory
: The LocaleAccessorFactory provides accessors to read and write locale information. The LocaleAccessorController can be used to set a special locale into the navigational state and thus into a URL.

  Note: A locale that is retrieved from such a URL takes precedence over user preferred locales or locales that are defined on your browser.

ExpansionStatesAccessorFactory
The ExpansionStatesAccessorFactory provides accessors to read and write expansion states information; for example, to determine whether a navigation node in a navigation tree control is expanded or collapsed. The ExpansionStatesAccessorController is typically used to generate URLs that toggle the expansion state of a navigation node.

ShowToolsAccessorFactory
The ShowToolsAccessorFactory provides accessors to read and write tool-related information. The ShowToolsAccessorController is typically used to create a URL that blends in the tool icons for portlet windows that offer functions such as moving/deleting the respective portlet.

StatePartitionAccessorFactory
The StatePartitionAccessorFactory provides accessors to read and write state partition identifiers. The StatePartitionAccessorController can be used to include a state partition identifier into the navigational state. A new state partition identifier is included into URLs that open new browser windows or iFrames.

EngineActionAccessorFactory
The EngineActionAccessorFactory provides controllers that are used to create engine action URLs. The EngineActionAccessorController, in particular, allows you to set action parameters.

Note: The EngineActionAccessorFactory does not offer a read-only accessor because the portal manages the engine actions.

URL generation services

Learn about the services that are used to create URLs in the navigational state SPI.

The Navigational State SPI offers the following two services that create URLs that are accessible through the Java Naming and Directory Interface (JNDI):

- The com.ibm.portal.state.service.PortalStateManagerService is a portal service that provides services beyond what the portal tags provide. Use the PortalStateManagerService to create URLs within portal artifacts. You can create URLs within portal artifacts such as themes and skins (for example custom JSP tags). And within the server-side artifacts that are removed from the request processing (for example Enterprise JavaBeans). This service is outside the portlet context.
- The com.ibm.portal.portlet.service.PortletStateManagerService supports JSR 168 and JSR 286 compliant portlets. Use the PortletStateManagerService to create URLs within portlets that cannot be created with the Standard Portlet API. This service is for portlets only.

Both services use a common interface that is called com.ibm.portal.state.service.StateManagerService, which provides the functions that are common to both services. You can reuse URL generation code in themes, skins, and portlets if they use the common interface. For example, you can use a custom JSP tag, which was originally designed for use in themes, in a portlet-specific JSP because only the service lookup is different.

Getting access to the PortalStateManagerService

Access the PortalStateManagerService through a JNDI lookup with the lookup name "portal:service/state/PortalStateManager". The lookup returns a com.ibm.portal.state.service.PortalStateManagerServiceHome interface that

provides the following two get commands that retrieve com.ibm.portal.state.service.PortalStateManagerService:

PortalStateManagerService getPortalStateManagerService(HttpServletRequest request, HttpServletResponse response)
The returned service is suitable for creating URLs in themes, skins, and custom JSP tags. All server-related information that is needed to generate the URLs (such as host name, protocol, server port, context path) is retrieved from the servlet request.

PortalStateManagerService getPortalStateManagerService(ServerContext ctx, Locale locale, Profile profile, boolean isProtected, boolean isSecure)
This method returns a PortalStateManagerService used for "offline" use cases such as creating URLs in environments where the servlet request is not available (for example, in an Enterprise JavaBeans). Using this method requires that the server-related information (such as host name, protocol, server port, context path) is provided in the ServerContext argument. The com.ibm.portal.state.accessors.url.ServerContext interface is the required abstraction for this kind of information. If you want to create URLs that point to a certain virtual portal, the provided ServerContext object needs to address that virtual portal. The ServerContext object addresses that virtual portal either through the context path or by host name. The two Boolean arguments specify whether the URLs must point to the protected area by default (isProtected) and whether the created URLs must be served with a secure connection by default (isSecure). To support creating resource URLs, the arguments locale and profile must be provided. The locale argument is needed to create URLs that address locale-specific resources such as language-dependent icons. The profile argument represents the client profile and in particular allows for checking the capabilities of the client.

The lifetime of a PortalStateManagerService object depends on whether you requested a "request-specific" service or "offline" service. The request-specific service has request scope; it is only used for the duration of one servlet request. For all subsequent servlet requests, request a new service instance from the home interface. The lifetime of the offline PortalStateManagerService corresponds with the lifetime of the ServerContext object.

The obtained PortalStateManagerServiceHome object is valid for the lifetime of the portal. You must do the JNDI lookup only once and store the retrieved home object accordingly, for example in an instance or static variable.

The following example shows how to get access to the service:

```
/** the JNDI name to retrieve the PortalStateManagerServiceHome object */
private static final String JNDI_NAME =
  "portal:service/state/PortalStateManager";

/** PortalStateManagerServiceHome object to retrieve the service from */
private static PortalStateManagerServiceHome serviceHome;

public void useRequestService(final HttpServletRequest request,
                              final HttpServletResponse response) {
  try {
    // get the request-specific service from our home interface
    final StateManagerService service
      = getServiceHome().getPortalStateManagerService(request, response);
    // use the service
    // ...
    // indicate that we do not need it any longer
```

```
    service.dispose();
  } catch (Exception e) {
    // error handling
  }
}

public void useOfflineService(final ServerContext ctx,
                              final Locale locale,
                              final Profile profile,
                              final boolean prot,
              final boolean secure) {
  try {
    // get the offline service from our home interface
    final StateManagerService service
      = getServiceHome().getPortalStateManagerService(ctx, locale, profile, prot, secure);
    // use the service
    // ...
    // indicate that we do not need it any longer
    service.dispose();
  } catch (Exception e) {
    // error handling
  }
}

/**
 * Looks up the PortalStateManagerServiceHome being valid
 * for the lifetime of the portal.
 */
private static PortalStateManagerServiceHome getServiceHome() {
  if (serviceHome == null) {
    try {
      final Context ctx = new InitialContext();
      serviceHome =
        (PortalStateManagerServiceHome) ctx.lookup(JNDI_NAME);
    } catch (Exception e) {
      // error handling
    }
  }
  return serviceHome;
}
```

Note: The `PortalStateManagerService` interface is derived from the generic `StateManagerService` interface. As the `StateManagerService` extends the `com.ibm.portal.Disposable` interface, you must indicate when you do not need to access the service any longer by starting the offered `dispose()` method on it. Dispose the request-specific `PortalStateManagerService` by the end of the processed servlet request.

Getting access to the `PortletStateManagerService`

Access the `PortletStateManagerService` through JNDI with the lookup name "`portletservice/com.ibm.portal.state.service.PortletStateManagerService`". The lookup returns a generic `com.ibm.portal.portlet.service.PortletServiceHome` interface, which offers a `getPortletService(Class)` method to get the `PortletStateManagerService`. The retrieved `PortletStateManagerService` instance is valid for the lifetime of the portal. You must do the service retrieval in the method of the portlet and store it in a portlet instance variable. The following example shows the required lookup code:

```
public class MyPortlet extends GenericPortlet {

  /** The JNDI name which is needed to lookup the service */
  private static final String JNDI_NAME =
    "portletservice/com.ibm.portal.state.service.PortletStateManagerService";
```

```
/** portlet state manager service */
protected PortletStateManagerService service;

/**
 * @see javax.portlet.GenericPortlet#init()
 */
public void init() throws PortletException {
  super.init();
  try {
    // lookup the portlet state manager service
    final Context ctx = new InitialContext();
    final PortletServiceHome serviceHome = (PortletServiceHome)
      ctx.lookup(JNDI_NAME);
    service = (PortletStateManagerService)
      serviceHome.getPortletService(PortletStateManagerService.class);
  } catch (NameNotFoundException e) {
    throw new PortletException(e);
  } catch (NamingException e) {
    throw new PortletException(e);
  }
}
```

You can use the actual service within the render method of the portlet to include URLs into the markup. Or use the service in the helper methods that serve the mandatory portlet modes such as `doView`, `doEdit`, and `doHelp`) to include URLs into the markup. Or use the service in the `processAction` method to send a redirect to a certain URL. The `PortletStateManagerService` interface shows the following two methods:

PortletStateManager getPortletStateManager(PortletRequest request, PortletResponse response)

This method returns a `PortletStateManager` object, which you can use during action processing and rendering (for example in the `processAction` method, `doView` method, `doEdit` method, etc.). The `PortletStateManager` interface adds more methods to extend the generic `StateManagerService` interface. For example, you can directly read the current request-specific navigational state of the portlet (portlet mode, window state, and render parameters).

PortletStateManagerController getPortletStateManagerController(ActionRequest request, Action response)

This method returns a `PortletStateManagerController` that extends the `PortletStateManager` interface. The `PortletStateManagerController` provides more methods that allow for modifying the navigational state of the portlet for the current request. And is therefore only accessible during action processing (for example, in the `processAction` method of the portlet).

Both the `PortletStateManager` and the `PortletStateManagerController` have request scope, which means that you must not store references to them across requests. Instead, you must retrieve the service from the `PortletServiceHome` object. To indicate that the retrieved `PortletStateManager` or `PortletStateManagerController` instance is no longer accessed in the scope of a request, you must start the dispose method. The dispose method is inherited from the Disposable interface on it. The following example shows you how to retrieve the service from the `PortletServiceHome` object:

```
/**
 * @see javax.portlet.GenericPortlet#doView(RenderRequest, RenderResponse)
 */
protected void doView(
```

```
  final RenderRequest request, final RenderResponse response)
  throws PortletException, IOException {
  response.setContentType(request.getResponseContentType());
  final PrintWriter writer = response.getWriter();
  try {
    // get the request-specific portlet state manager
    final PortletStateManager mgr = service.
      getPortletStateManager(request, response);
    // do something (create URLs etc.)
    // ...
    // indicate that we do not need the portlet state manager any longer
    mgr.dispose();
  } catch (StateException e) {
    throw new PortletException(e);
  }
}
```

The base interface `StateManagerService`

The `PortletStateManager` and the `PortalStateManagerService` are derived from the `com.ibm.portal.state.service.StateManagerService` interface, which offers functionality that is common to both URL generation services. The use cases that are common to both services refer to the creation of EngineURLs that carry navigational state and resource URLs. Therefore, the `StateManagerService` interface must be sufficient to implement most of the use cases. The interface provides the following two methods:

URLFactory getURLFactory()
: This method returns a `com.ibm.portal.state.URLFactory` object that offers several methods to create various URLs. For further details on the `URLFactory`.

AccessorFactory getAccessorFactory(Class accessorFactoryClass)
: This method provides access to the various accessor factories. For more information, see "Accessor SPI" on page 2849. You must pass the respective accessor factory interface in as a method argument to retrieve a certain accessor factory the `Class` object.

  Note: When you use the `PortletStateManagerService`, the set of accessor factories is restricted to the `SelectionAccessorFactory`, `PortletAccessorFactory`, `PortletTargetAccessorFactory`, `SoloAccessorFactory`, `ThemeTemplateAccessorFactory`, `LocaleAccessorFactory`, `StatePartitionAccessorFactory`, and `ExpansionStatesAccessorFactory`.

Typically, you request an `EngineURL` object from the `URLFactory` and then modify the navigational state according to the required URL semantics. To do this step, call the `getState()` method of the `EngineURL` to get the `StateHolderController` object that is required to modify the navigational state through the Accessor SPI. The following code snippet exemplarily illustrates this typical usage pattern. The following example shows how to call the `getState()` method of the `EngineURL`:

```
protected EngineURL createPageLink(final ObjectID pageID)
  throws StateException {
  // get the URL factory from the state manager service
  final URLFactory urlFactory = service.getURLFactory();
  try {
    // get a EngineURL from the factory; maintain navigational state
    final EngineURL url = urlFactory.newURL(null);
    final SelectionAccessorFactory selectionFct = (SelectionAccessorFactory)
      service.getAccessorFactory(SelectionAccessorFactory.class);
    // get a selection controller that operates on the URL-specific state
```

```
    final SelectionAccessorController selectionCtrl =
      selectionFct.getSelectionAccessorController(url.getState());
    try {
      // modify page selection and return URL
      selectionCtrl.setSelection(pageID);
      return url;
    } finally {
      selectionCtrl.dispose();
    }
  } finally {
    urlFactory.dispose();
  }
}
```

In the previous code sample, the `newURL(Constants.Clone)` method of the `URLFactory` is used. However, the `URLFactory` offers several more convenience methods to create `EngineURLs` and resource URLs. The following list provides a complete description of the `URLFactory` interface:

`EngineURL newURL(Constants.Clone type)`

Choose this method to create a `EngineURL` because it is suitable for all prevalent use cases. The method provides an `EngineURL`, which refers to the `StateHolder` representing the navigational state of the current request. The type argument specifies how the request-specific `StateHolder` must be cloned for the URL to be created. There are the following four pre-defined clone constants:

- The `SMART_COPY` indicates that a shallow `StateHolder` copy must be created. The copy records the state modifications that are applied for this particular `EngineURL` only, instead of copying all nodes in the document model to construct the clone. The `SMART_COPY` represents the default; therefore passing in null is equivalent to `SMART_COPY`. This clone method also allows the generation of relative "delta" URLs.
- The `DEEP_COPY` results in a complete copy of the request-specific `StateHolder`, for example each node and the node hierarchy is cloned. The deep copy prevents the generation of delta URLs.
- The `EMPTY_COPY` indicates that the contents of the request-specific `StateHolder` must be cleared, for example the created `EngineURL` is based on an empty state. Any interaction with such a URL results in the lost the navigational state of previous interactions.

If the `URLFactory` does not have access to the current request, a new empty `StateHolder` is created internally. In that case, the type argument does not take any effect.

`EngineURL newURL(StateHolder state, Constants.Clone type)`

This second `getURL` method requires that the `StateHolder` the `EngineURL` is based on, is passed explicitly. Accordingly, the type argument refers to this particular `StateHolder`. Use this method when the URL to be created must encode a `StateHolder` that was defined programmatically. Clicking this URL results in the lost the navigational state of previous interactions with the portal.

`EngineURL newURL(URLContext ctx, Constants.Clone type)`

With this variant, you can specify whether the created URL must be absolute, server-relative, or relative. This action can be achieved by passing an `URLContext` interface. The interface must be implemented accordingly; for example if the URL must be absolute, the `isAbsolute()` method must return true whereas `isRelative()` and `isServerRelative()` must return false. Because this method does not require an explicit `StateHolder`

argument, the `EngineURL` to be created encodes the `StateHolder` retrieved from the request. To reduce markup size, it is strongly recommended to pass in an `URLContext` that allows for relative URLs. If the `URLFactory` does not have access to the current request, a new empty `StateHolder` is created internally. In that case, the type argument does not take any effect.

`EngineURL newURL(URLContext ctx, Constants.Clone type)`
This method is the counterpart of the previous method and takes a `StateHolder` defined as an explicit argument.

`DisposableURL newResourceURL( String name, PortalResources.Type type)`
This method creates a URL that points to a generic resource. The file name and resource type identify the resource. The resource lookup takes request-specific information such as the current locale, the client device, and the markup name into account (if the request is available). The `com.ibm.portal.state.accessors.url.PortalResources` interface provides several useful constants for the resource type that represents resource types such as files, sounds, icons, voice grammars.

`DisposableURL newResourceURL( String name, PortalResources.Type type, PortalResources.State state)`
This method creates a URL that points to a generic resource. The file name and resource type identify the resource. It can also contain a resource state that is used to further distinguish the lookup of the resource. The resource lookup takes additional information from the request into account (if available). This is the current locale, the client device, markup that is chosen for the client, and the theme name.

Note: An absolute URL is a complete URL containing protocol, host name, and port. If there is a server-relative URL, the browser implies the current protocol, host name, and port. If there is a relative URL, the browser appends the URL to either the current request URL or to the value of the HTML base tag (if any). Server-relative and relative URLs cannot be enforced. In a protocol switch from "http" to "https", for example, the generated URL is absolute in any case.

Changing the host name of absolute URLs

You can change the host name of absolute URLs for security reasons. For example, you can do this change if the DOM of an application, such as a portlet, runs within an iframe and you do not want the JavaScript code within that iframe to be able to access the DOM of the HTML document. If all URLs within that iframe are absolute URLs and the host name of these URLs is different from which the document originates, then the iframe has access to itself only. In other words, it cannot manipulate or access the rest of the document DOM. To ensure this action, create all URLs within the portlet by using the Navigational State SPI with absolute URLs. The portlet must then define a virtual host name, which must be rerouted by a proxy to the portal server again. In addition, the portlet must ensure that all requests in which the required absolute URLs are to be generated contain a special request header. The request header tells the portal, the name of the virtual host name. The headers are as follows:

com.ibm.lotus.openajax.virtualhost
Use this header for setting the host name of every generated absolute URL to the value of this request header.

com.ibm.lotus.openajax.virtualport
Use this header for setting the port of every generated absolute URL to the value of this request header.

Model SPI overview

Models provide information that is needed by WebSphere Portal Express to perform tasks such as content aggregation or building navigation to browse the aggregated content. The information that is aggregated is represented through models that can be accessed programmatically by using the Model SPI (read-only). The information of a model is usually persistent (stored in a database) but can also be transient (computed and stored only in memory). Models can be represented by using a tree structure (nodes have a parent-child relationship), a list structure, or a selection structure (a selected element in a tree structure).

The following models can be obtained by using the Model SPI:

Content Model
Describes the topology in which the content is structured. The content model is a tree structure that is composed of content nodes. Types of content nodes include pages, labels, internal URLs, and external URLs.

Navigation Model
Describes the topology of the navigation visible to a specific user, which is composed of navigation nodes. Navigation nodes are implied by the structure of the content model. A navigation node references content that is represented by content nodes.

Navigation Selection Model
Describes the selected node in the navigation.

Content Metadata Model
Provides access to metadata of nodes of the Content Model. The metadata are aggregated by using the hierarchy that the content model exposes.

Language List
A list of supported languages.

Layout Model
Describes the layout of a page, which is composed of layout nodes. Layout nodes can be containers, which affect the layout of the page (rows and columns), or controls, which affect the content (portlets) of a page.

Markup List
A list of supported markup languages.

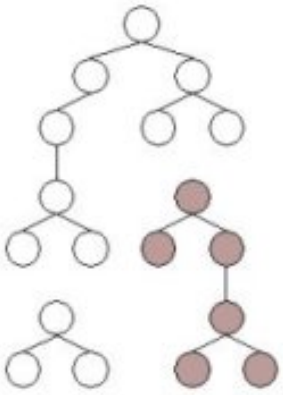
Skin List
A list of skins.

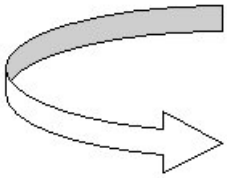
Theme List
A list of themes.

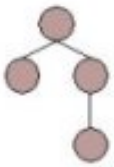
PortletModel, AdminPortletModel
Describes portlets and their associated configuration data.

The following table shows how a model is requested for specific use from the model source, and the target model that is returned.

Table 452. Representations of a model source, request and return from a model, and the model target, with the resulting filtered model

Model source	The specific model is requested from the source, and the source returns the specific model	Model target that is returned and filtered for a specific use
		






Create a specific model from source information

The interfaces of the public object model provide read only access to resources. Manipulation is possible only through the Controller SPI .

The models and their elements are all described through interfaces that are contained in the package `com.ibm.portal` and its sub packages. The more common interfaces are located higher in the package hierarchy. For example, `Identifiable`, an interface present on almost all resources, is located directly under `com.ibm.portal`.

Model scope

The models present information based on access control. Therefore, models are scoped to a specific user, and requests to retrieve model information return only the resources to which the user has access.

The concept of virtual portals scopes some models to the virtual portal in which a user operates. At the moment, this scoping concept applies to the content model, the navigation model, and the navigation selection model. These models scope their resources to the virtual portal in which a user operates.

The main package, com.ibm.portal

The `com.ibm.portal` package holds interfaces that are commonly used throughout the object model. This document describes important interfaces and classes that are found in the object model. It does not describe every class. For the complete information about all interfaces, read the Javadoc documentation.

Most resources carry an identifier. You can use it to address or locate them. This identifier is defined with the interface Identifiable, by which you can retrieve the ID of an element. An object ID uniquely identifies an element in an installation - and beyond (the ID is also called GUID - globally unique ID). An object ID can

optionally have a unique name assigned (a name that can exist only once per installation) to make it easier to address specific elements.

Do not use `toString` on object IDs - a human readable representation is returned that cannot be parsed back into an ObjectID object. For conversion between an ObjectID object and its string representation, the Identification interface is used (see package `com.ibm.portal.identification`).

A common operation is to search for resources that have a specific object ID. To perform this search in a general way, the concept of a Locator is introduced: A locator is provided by a model and allows searching for elements of the model in specific ways. To obtain such a locator object, you must use the getLocator method of an object that implements the LocatorProvider interface.

You can use the generic locator interface to locate a resource by its object ID (findByObjectID) or by its unique name (findByUniqueName). Some models provide specialized locators that extend the generic locator to provide more search functions such as search by title or some other criterion.

On a generic level, models are either lists or trees. Therefore, a TreeModel and a ListModel interface exist in the main package. In a tree model, you can perform the following tasks.

- Obtain the root node of a tree model (getRoot)
- Query the children of a node of the model (hasChildren)
- Obtain the children of a node of the model (getChildren)
- Obtain the parent of a node of the model (getParent)

With these methods, it is possible to explore a tree model. You must obtain the input arguments that represent nodes of the model from the model itself.

Combined with the locator concept discussed previously, a tree model becomes a searchable tree model: SearchableTreeModel is a tree model that also extends from LocatorProvider.

Some models also take on the form of a list, for example the list of markups or the list of languages that WebSphere Portal Express supports. The generic way to directly access the elements of the list is through the iterator provided by it (iterator method). When a method returns a list model, it uses the interface ListModel. However, in some situations it might also return a PagedListModel, which extends from ListModel and additionally provides a paged iterator. It makes it possible to obtain the elements of the list model in chunks, which can give better performance than obtaining each element individually.

List models become searchable the same way by which tree models do: SearchableListModel is a list model that also extends from LocatorProvider.

A widespread interface on elements of models is Localized. This interface provides a title and description of an element. Title and description are properties that are locale-dependant. To obtain a title or description call getTitle(Locale) or getDescription(Locale), depending on the case.

Note: An element returns a title or description only if such information exists in the exact locale that is passed in to the methods mentioned. No fallback mechanism is implemented inside of these methods. A suitable fallback mechanism

must be employed by invokers of the methods of Localized, or the default that is provided by LocalizedStringResolver (see package `com.ibm.portal.model`) can be used.

"Sub packages of the Model SPI"
Sub packages provide information on installed resources, hold Identification interface, and define the navigational model and the content that is represented in the Portal. The sub packages also represent portlets and their configuration data in the portal and the interconnections between the portlets.

"Obtain a model from the portal" on page 2867
Portal models can be obtained by using three different ways, depending on where the code that uses them is located.

"Obtaining the object ID for a page or portlet" on page 2868
There are several use cases when a portlet needs to obtain the object ID used to uniquely identify a portlet or a page. For example, the object ID of a page definition is required for a portlet to start a dynamic instance of that page.

"Filtering the content model" on page 2869
By applying filters to the content model, you can exclude parts of the page hierarchy from the content model. Filtering is performed based on request data and metadata assigned to the pages.

"Model SPI samples" on page 2869
The Model SPI can be used in portlets, themes, and skins. The models can be used with authenticated users and also with the anonymous user.

"Remote Model SPI REST service" on page 2871
The Remote Model SPI gives you access to portal models through REST services. It allows you to obtain and modify portal resources that are exposed by some of the models of the model SPI remotely, that is from clients that are outside the JVM of the server. This is achieved by means of REST services.

Related concepts:

"Controller SPI " on page 2883
You can use the Controller SPI for portal administration. It allows you to modify portal resources. It enhances the read-only portal Model SPI by adding writable aspects.

Sub packages of the Model SPI

Sub packages provide information on installed resources, hold Identification interface, and define the navigational model and the content that is represented in the Portal. The sub packages also represent portlets and their configuration data in the portal and the interconnections between the portlets.

The Model SPI includes the following sub packages.

- "The sub package com.ibm.portal.admin" on page 2862
- "The sub package com.ibm.portal.content" on page 2862
- "The sub package com.ibm.portal.identification" on page 2864
- "The sub package com.ibm.portal.navigation" on page 2864
- "The sub package com.ibm.portal.portletmodel" on page 2865
- "The sub package com.ibm.portal.wire" on page 2866

See "Model SPI overview" on page 2858 for a description of the main package in the Model SPI: `com.ibm.portal`.

The sub package com.ibm.portal.admin

WebSphere Portal provides several list models that contain information on installed resources, such as supported languages, supported markups, skins, and themes. For each of these resources, a specific ListModel exists that provides information on these resources. This package defines several list models:

- Language list model
- Markup list model
- Skin list model
- Theme list model
- Device class model

Each list model contains elements that implement interfaces that coincide with their names: The language list model has Language elements. The markup list model has Markup elements. The skin list model has Skin elements. The theme list model has Theme elements, and the device class model has device class elements.

The LanguageList contains all languages that are supported by the portal. The MarkupList contains all markups that the portal generally supports. From these list models, a resource might support only a selection. The SkinList and the ThemeList hold the themes and skins that are installed for the portal. The DeviceClassModel contains the device classes that the portal generally supports.

The sub package com.ibm.portal.content

Elements of this package define how content is represented in the portal. The two main models of this package are the ContentModel and the LayoutModel. The content model defines a tree structure for content elements (such as pages and labels); it is used to group these content elements logically.

Note:
The topology of the content model currently dictates the topology of the navigation model. For more information, see section *The sub package com.ibm.portal.navigation*. Theoretically, the topologies of content model and navigation model are allowed to diverge.

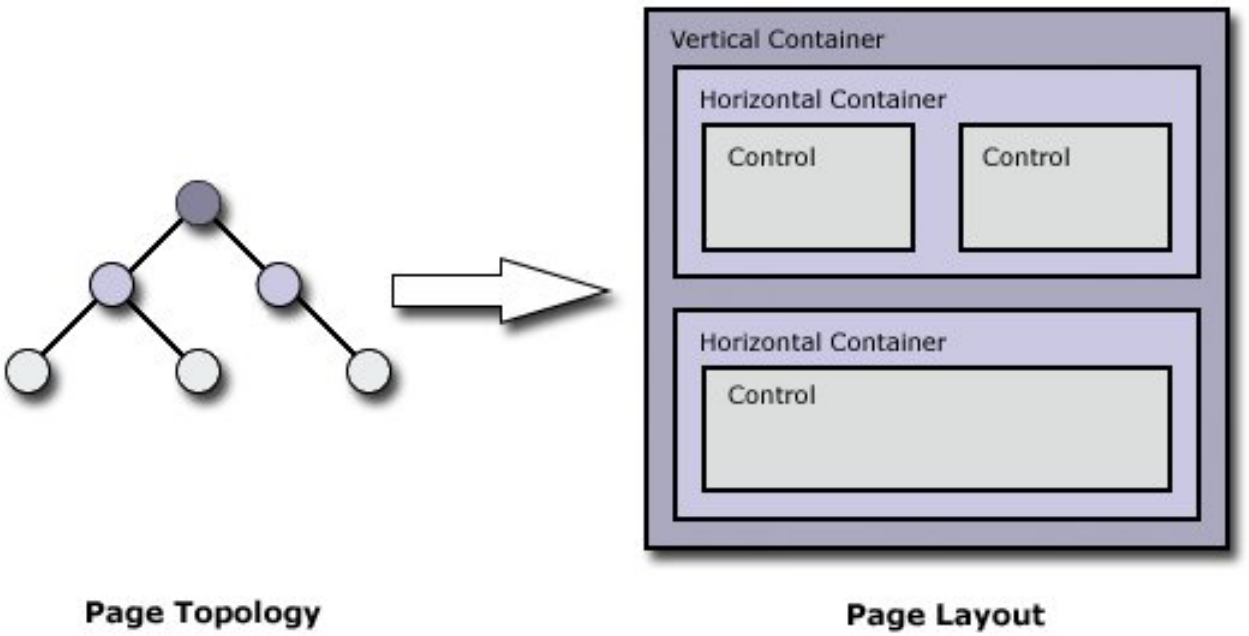
Currently, the elements of the content model can be pages, labels, or URLs. For each type, a specific ContentNode interface exists: ContentPage, ContentLabel, and ContentURL. Each content node has different information that is associated with it.

Each content node can provide the type of content node it represents; if this type is ContentNodeType.PAGE, a model exists that represents the layout of that page. It can be obtained with the getLayoutModel method of the content model. The layout model holds LayoutNode elements that describe the layout and contents of the page. Each layout node can return metrics in form of the LayoutMetrics interface. It can describe attributes of the node such as width or orientation (horizontal/vertical).

The elements of the layout model are either LayoutContainers that define rows and columns or LayoutControls, which represent portlets. This information is used when a page is rendered.

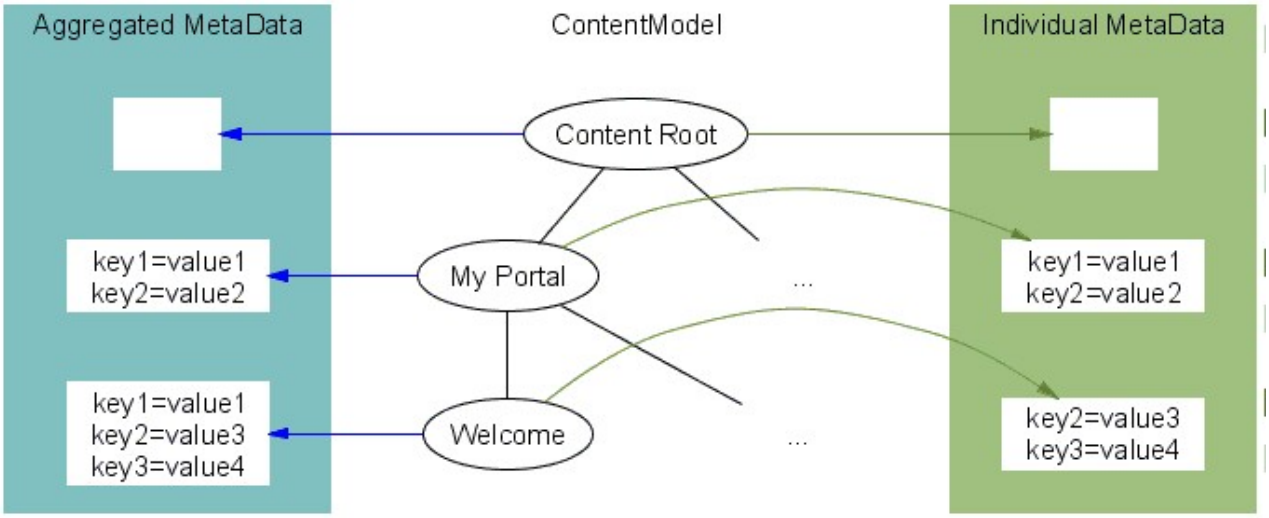
The following figure shows how page layout information and page content is represented. The figure depicts a page with three portlets. The surrounding vertical and horizontal containers define the layout while the controls hold the portlets that

provide the actual content presented to the user.



Content nodes can provide metadata through the com.ibm.portal.MetaDataProvider interface. Metadata can be used to associate arbitrary information with a content node. The content metadata model provides a view on metadata of the nodes in the content model. It aggregates the metadata of the individual nodes into one metadata object by using the hierarchy of the nodes as described in the content model.

The following figure shows the relationship between the individual metadata that are shown by content nodes and the aggregated view that the content metadata model provides:



The metadata of individual content nodes are shown in XML Access scripts by using the <parameter> tag.

The sub package com.ibm.portal.identification

This package holds the Identification interface, which allows the conversion between ObjectID objects and their string representation. This Identification interface is required where an object ID is to be passed as a parameter that can be only a String (for inclusion into URLs, for example). An implementation of this interface can be retrieved by using a JNDI lookup, as in the following example.

```
try
{
   Context ctx = new InitialContext();
   Name ctxName = new CompositeName("portal:services/Identification");
   Identification identification = (Identification) ctx.lookup(ctxName);
   String serializedOID = identification.serialize(aOID);

      ...

   ObjectID anotherOID = identification.deserialize(serializedOID);
}
catch (SerializationException sx)
{
   // some error handling code here
}
catch (NamingException nx)
{
   // some error handling code here
}
```

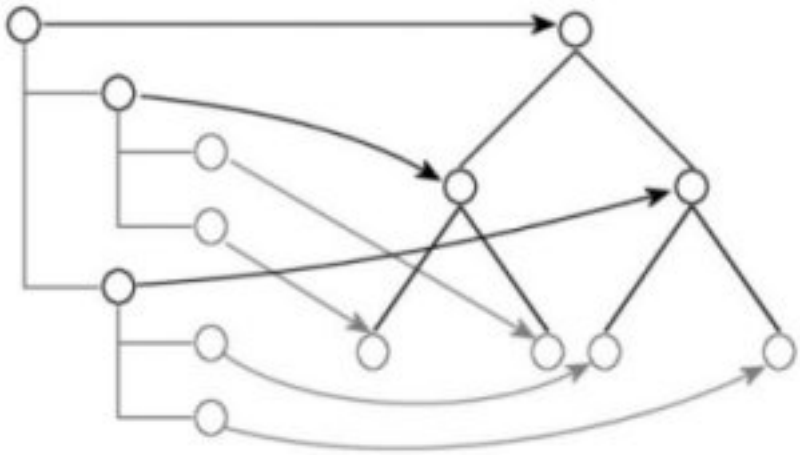
The sub package com.ibm.portal.navigation

This package defines the navigation model (NavigationModel) which represents a view on content model that is used for navigation. As described in section *The sub*

package com.ibm.portal.content, the topology of the navigation model currently corresponds with the content model. Each node in the content model has an equivalent navigation node at the same hierarchical level.

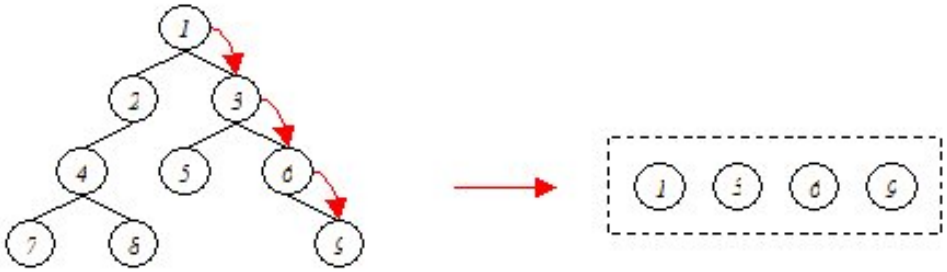
The elements of the navigation model are NavigationNodes. Each such node can reference a ContentNode. The navigation nodes have a title that is provided through the Localized interface. The following figure shows the connection between the navigation model and the content model.

The figure shows how nodes in the navigation model can reference a node in the content model.



When a user is going through the portal, the currently selected navigation node is important to render the current page. The NavigationSelectionModel reflects the current selection and represents a list that defines a path through the navigation model.

The figure shows how the navigation selection model defines a path through the navigation model.



The last node of this path is always the currently selected navigation node. Its referenced content node represents what is aggregated for the user to see (normally a page that is represented through a ContentPage object).

The sub package com.ibm.portal.portletmodel

The PortletModel represents portlets and their configuration data in the portal. It contains the following elements:

WebApplication
Represents a deployed WAR file in the portal.

Portlet
The programmer in the deployment descriptor of a portlet web application. Each portlet web application contains one or more portlets.

PortletDefinition
Represents administrator configuration for a portlet. Multiple portlet definitions can be associated with the same portlet so that the same portlet code can be started with different administrative settings. With the administrative UI of the portal, you can create new portlet definitions as copies of existing ones.

PortletEntity
Represents user configuration for a portlet. It is normally created by placing a portlet definition on a page; the same portlet definition can be added to multiple pages, resulting in multiple portlet entities. There can be two levels of user configuration (shared and personalized configuration) that are stored in the form of separate portlet entities.

PortletWindow
Represents a particular view on a portlet. It normally corresponds to a LayoutControl in the layout model. The same PortletWindow can be associated with different PorltetEntities for different users, if they personalize the portlet independently.

CommunicationEndpoint
Represents an endpoint that is available for communication that is defined for the portlet. Such endpoints can be of type CommunicationSource or CommunicationTarget and are available through the CommunicationEndpointProvider. This provider can be retrieved by the getEndpointProvider method on the PortletDefinition. For JSR 286 portlets that were developed for eventing, PublishingEventDefinition[s] and ProcessingEventDefinition[s] represent the events that a single portlet can process or publish as defined in the `portlet.xml`. The PublishingEventDefinition is a CommunicationSource and the ProcessingEventDefinition is a CommunicationTarget for JSR286 portlets.

The sub package com.ibm.portal.wire

The WireModel represents the interconnections between JSR 168 cooperative portlets or JSR 286 eventing portlets. A WireModel can be obtained from a LayoutModel by using the getWireModel method of the layout model. It contains only interconnections that originate from the page that the parent layout model represents. It contains the following element:

Wire Represents the interconnection between a CommunicationSource of the PortletDefinition of a PortletWindow on a source page and the CommunicationTarget of the PortletDefinition of a PortletWindow on a target page. Examples of interconnections are:

- Between a JSR 168 cooperative portlet with an output property and a JSR 168 cooperative portlet with a target action defined.
- Between a JSR 286 portlet that defines a publishing event and a JSR 286 portlet that defines a processing event.

Obtain a model from the portal

Portal models can be obtained by using three different ways, depending on where the code that uses them is located.

The different ways to obtain Portal models are as follows:

JNDI lookup

A JNDI lookup can be done for code that is in a request/response cycle of the portal, for example in a JSP. The lookup results in a home interface from which a model provider can be obtained. Interfaces for the models that are mentioned previously can be found in `com.ibm.portal.model`. To avoid calling the JNDI lookup too often, store the provider object. The following example, which is only applicable to non-portlet code that runs inside of a portal, shows how the content model is obtained by using a JNDI lookup.

```
try
{
   Context ctx = new InitialContext();
b   ContentModelHome home = (ContentModelHome)
                  ctx.lookup("portal:service/model/ContentModel");
   if (home != null) {
      ContentModelProvider provider = home.getContentModelProvider();
      ContentModel model =
                    provider.getContentModel(aRequest, aResponse);
    ...
   }
}
catch (NamingException nx)
{
    // some error handling code here
}
```

Figure 36. Obtaining a content model by using JNDI lookup.

Portlet service (standard portlet API)

Standard portlets can access models through specific portlet services. These portlet services are in `com.ibm.portal.portlet.service.model`. The following example shows how the navigation model is obtained by a standard portlet.

```
PortletServiceHome psh;
javax.naming.Context ctx = new javax.naming.InitialContext();
boolean serviceAvailable = false;
try {
   psh = (PortletServiceHome)
      ctx.lookup("portletservice/com.ibm.portal.portlet.service.model.NavigationModelProvider");
      serviceAvailable = true;
}
catch(javax.naming.NameNotFoundException ex)
{
    ... error handling...
}
...
if (serviceAvailable) {
   NavigationModelProvider provider = (NavigationModelProvider)
                           psh.getPortletService(NavigationModelProvider.class);
   NavigationModel model = provider.getNavigationModel(aRequest, aResponse);
   ...
}
```

Figure 37. Obtaining the navigation model.

Note the following limitations for obtaining a portal model:

1. WSRP portlets must not use the Model SPI.
2. Model access is only possible after the portal has initialized the request appropriately. Access is possible inside of code that is started through the portal servlet. Models cannot be accessed in servlet filters.

Obtaining the object ID for a page or portlet

There are several use cases when a portlet needs to obtain the object ID used to uniquely identify a portlet or a page. For example, the object ID of a page definition is required for a portlet to start a dynamic instance of that page.

You can use the lookup() method of the JNDI Context class to obtain the object ID for a portlet or a page, passing the unique name of the page or portlet. As an alternative for portlets, you can obtain the object ID by using JNDI lookup() and passing a combination of the portlet application ID and the portlet name.

- For standard portlets, the portlet application ID is the value of the ID attribute of the <portlet-app/> element in the `portlet.xml`. However, this attribute is not required by the Java Portlet Specification. If the ID attribute is not set, the portlet WAR file name is used as the portlet application ID.
- For IBM portlets, the portlet application ID is the UID attribute of the <portlet-app/> element. This attribute is required.

The following example shows both ways to find an object ID.

```
// initialization
Context ctx = new InitialContext();

// portal:uniquename prefix is required for unique name lookup
Name uniqueName = new CompositeName("portal:uniquename");

// portal:config/ prefix required for portlet definition lookup
Name portletName = new CompositeName("portal:config/portletdefinition");

// the unique name assigned to the page is example.org.page
uniqueName.add(org.example.page);

ObjectID oidForName = (ObjectID) ctx.lookup(uniqueName);

// appID and portletName have already been set programmatically
portletName.add(appID);
portletName.add(portletName);

ObjectID portletDefOID = (ObjectID) ctx.lookup(portletName);
```

The `Name` used for the lookup() method is created from a `CompositeName`, which is prepopulated with the required portal prefixes enclosed in quotation marks. This technique is used to avoid having to escape special characters in the prefix.

For this example, the following packages are required at a minimum for the import statements:

- `javax.naming.CompositeName`
- `javax.naming.Context`
- `javax.naming.Name`
- `com.ibm.portal.ObjectID`

Filtering the content model

By applying filters to the content model, you can exclude parts of the page hierarchy from the content model. Filtering is performed based on request data and metadata assigned to the pages.

About this task

There are two ways you can filter the content model:

- You can filter on the device class that is specified in the HTTP request. This filtering can be used to provide a unified content model for both desktop and mobile users. For pages that are specific to mobile users, you assign only the device class for the mobile client, such as a smartphone or tablet. These pages are then visible only to users who access the portal with one of the specified devices.
- You can filter on the markup language that pages support. This approach is useful when building mobile websites for older devices that use markup languages like WML or Compact HTML

Tip: When filtering for mobile devices that support HTML, filter only by device class.

Procedure

1. Enable content model filtering in the portal. By default, filtering is not enabled. This step must be done only once.
   a. Log in to the WebSphere Integrated Solutions Console.
   b. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
   c. Click **WP ConfigService**.
   d. Under **Additional Properties**, click **Custom Properties**.
   e. Click **New**, and enter the appropriate property name, depending on the type of filtering that you want to perform.

      Filter by device class
      Add **`content.topology.filter.deviceclass`**, and set the string value to the `true`.

      Filter by markup language
      Add **`content.topology.filter.markup`**, and set the string value to the `true`.
2. Save your changes, and restart the server.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Model SPI samples

The Model SPI can be used in portlets, themes, and skins. The models can be used with authenticated users and also with the anonymous user.

The following samples focus on JSPs, but the code can also be used in Java source files.

Displaying the portal selection path (breadcrumb trail)

The following example shows how to render a breadcrumb trail that shows the current selection path.

```
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/portal-fmt"
    prefix="portal-fmt" %>
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/portal-navigation"
    prefix="portal-navigation" %>
<%@ page import="com.ibm.portal.model.NavigationSelectionModelHome" %>
<%@ page import="com.ibm.portal.model.NavigationSelectionModelProvider" %>
<%@ page import="com.ibm.portal.navigation.NavigationSelectionModel" %>
<%@ page import="com.ibm.portal.navigation.NavigationNode" %>
<%@ page import="com.ibm.portal.ModelException" %>
<%@ page import="java.util.Iterator" %>
<%@ page import="javax.naming.InitialContext" %>
<%@ page import="javax.naming.Context" %>
<%@ page import="javax.naming.NamingException" %>

<%
try{
    Context ctx = new InitialContext();
    NavigationSelectionModelHome home = (NavigationSelectionModelHome)
        ctx.lookup("portal:service/model/NavigationSelectionModel");
    if (home != null) {
        NavigationSelectionModelProvider provider =
            home.getNavigationSelectionModelProvider();
        NavigationSelectionModel model =
            provider.getNavigationSelectionModel(request, response);
        for (java.util.Iterator i = model.iterator(); i.hasNext(); )
        {
            NavigationNode node = (NavigationNode) i.next();
            if (i.hasNext()) {
%>

        <a href="<portal-navigation:navigationUrl type='link' varname='<%=node%>'/>">
            <portal-fmt:title varname='<%=node%>'/>
        </a>
        &gt;
<%
            }
            else
            {
%>
        <portal-fmt:title varname='<%=node%>'/>
<%
            }
        }
    }
}
catch (ModelException mx) {
%>

<p><span style="color:#ff0000">A model exception occured</span></p>

<%
}
catch (NamingException nx) {
%>

<p><span style="color:#ff0000">A naming exception occured</span></p>

<%
}
%>
```

This example uses a JNDI lookup to obtain the navigation selection model. The model is then iterated and for each node a title is produced by using the <portal:title/> tag. Until the last node is reached, the <portal:navigationUrl/> tag is used to generate links to the referenced pages.

Getting page layout information

This example shows portlet code that displays layout information of a page as retrieved from the layout model of that page. The portlet outputs the layout structure of the page it is located. Two methods of the portlet are shown in the following example. The first, showTableModel, is the entry point for rendering a table that shows the layout of a page. The page is identified through the selected

navigation node of the navigation selection model. The other method, printLayoutElement, recursively traverses the layout model and outputs markup according to the element it meets.

```
/**
 * Displays a table model of the layout of a page.
 *
 * @param aWriter the writer where the output goes to
 * @param aLayoutModel the layout model to show
 * @param aPage the page for which to show the layout model\
 * @param aRequest the portlet request
 * @throws ModelException if an exception occurs
 */
private void showLayoutModel(final PrintWriter aWriter,
        final LayoutModel aLayoutModel, final ContentPage aPage,
        final RenderRequest aRequest)
      throws ModelException {
   aWriter.print("<h3>Layout for page ");
   aWriter.print(getTitle(aPage));
   aWriter.println("</h3>");
   // invoke the recursive traversal of the layout model;
   // start with the root node
   printLayoutNode(aWriter, aLayoutModel,
                 (LayoutNode) aLayoutModel.getRoot(), aRequest);
   }

/**
 * Outputs a single element of the layout model to the output writer.
 *
 * @param writer the writer where the output goes to
 * @param model the layout model to use
 * @param node the current node of the layout model
 * @param request the portlet request
 * @throws ModelException if an exception occurs
 */
private void printLayoutNode(final PrintWriter writer, final LayoutModel model,
        final LayoutNode node, final RenderRequest request) throws ModelException {
   if (node != null) {
      if (node instanceof LayoutControl) {
         // output control information
         writer.print("<b>Control</b> (");
         writer.print(getTitle((LayoutControl) node));
         writer.println(")");
      }
      else {
         writer.println("<table border=\"1\">");
         // get the layout metrics
         // (needed to find out the orientation of containers)
         final LayoutMetrics metrics = node.getLayoutMetrics();
         final Object info = metrics.getValue(LayoutMetrics.ORIENTATION);
         writer.print("<tr><td><b>Container</b> (");
         writer.print(info);
         writer.println(")");
         if (info == Orientation.HORIZONTAL) {
            writer.println("<table>");
            writer.println("<tr>");
            // recurse for the horizontal container
            if (model.hasChildren(node)) {
               for (Iterator i = model.getChildren(node); i.hasNext();) {
                  writer.println("<td valign=\"top\">");
                  printLayoutNode(writer, model, (LayoutNode) i.next(), request);
                  writer.println("</td>");
               }
            }
            writer.println("</tr>");
            writer.println("</table>");
         }
         else {
            // recurse for the vertical container
            if (model.hasChildren(node)) {
               writer.println("<table>");
               for (Iterator i = model.getChildren(node); i.hasNext();) {
                  writer.println("<tr><td>");
                  printLayoutNode(writer, model, (LayoutNode) i.next(), request);
                  writer.println("</td></tr>");
               }
               writer.println("</table>");
            }
         }
         writer.println("</td></tr></table>");
      }
   }
}
```

Remote Model SPI REST service

The Remote Model SPI gives you access to portal models through REST services. It allows you to obtain and modify portal resources that are exposed by some of the

models of the model SPI remotely, that is from clients that are outside the JVM of the server. This is achieved by means of REST services.

The Remote Model SPI supports the following models:

ContentModel
This allows you to obtain and modify the content topology and the properties of content nodes such as pages, labels, and content URLs.

NavigationModel
This allows you to obtain the navigation topology only, as the navigation model is implied by the structure of the content model.

LayoutModel
This allows you to obtain and modify the layout of a page, that is the topology of layout elements of a page, and the properties of layout elements, such as layout containers and layout controls.

PortletModel
This allows you to obtain, create, update, and delete portlets.

Note that the Remote Model SPI currently does not support the following models:

- LanguageList
- MarkupList
- SkinList
- ThemeList

The Remote Model SPI uses feeds in the Atom Syndication Format in conjunction with the Atom Threading Extension to expose model resources, and the HTTP-based Atom Publishing Protocol (APP) to modify portal resources. With the Remote Model SPI as a REST service, you must use the following HTTP verbs:

- To obtain model information: `HTTP GET`
- To modify existing model information: `HTTP PUT`
- To create model resources: `HTTP POST`
- To delete model resources: `HTTP DELETE`

"Feeds for REST services"
When you access a REST service to get information or to modify a portal resource, the response and in some cases also the request works by means of a feed. A feed contains information about one or more portal resources in a specific format as exposed by portal models. Learn how you obtain feeds for portal resources and what the format of such feeds is.

Feeds for REST services

When you access a REST service to get information or to modify a portal resource, the response and in some cases also the request works by means of a feed. A feed contains information about one or more portal resources in a specific format as exposed by portal models. Learn how you obtain feeds for portal resources and what the format of such feeds is.

You can request a feed by sending an HTTP request to a specific URL. A requested feed can contain links to dependent resources that can be used to request those resources iteratively. In order to modify resources, you can modify such a feed or create a new feed and send it to a specific URL by using an HTTP request.

Example: A feed that exposes full information on a layout container of a content page:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:atom="http://www.w3.org/2005/Atom"
           xml:base="/wps/mycontenthandler/"
           xmlns:thr="http://purl.org/syndication/thread/1.0"
           xmlns:xhtml="http://www.w3.org/1999/xhtml"
           xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base"
           xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model">

"Syntax for addressing portal resources"
To obtain information about a portal resource or to modify a portal resource, you need to obtain a feed for this resource, or you send a request to a certain URL that can contain a feed. Find out how you can construct URLs to which you can send HTTP requests related to the REST service.

"Elements of a model feed" on page 2877
These sections show sample feeds for the different models.

"Use cases for modifying resources" on page 2880
Portal Model REST services allow you to create new resources, modify, move and delete existing resources. View some common use cases of resource modifications.

Syntax for addressing portal resources:

To obtain information about a portal resource or to modify a portal resource, you need to obtain a feed for this resource, or you send a request to a certain URL that can contain a feed. Find out how you can construct URLs to which you can send HTTP requests related to the REST service.

For example, a URL can address a specific resource or can contain certain query parameters that allow you to control the extent and the way by which information on resources is exposed, or they allow you to control the way by which resources are modified.

In order to obtain a feed that contains certain portal resources, you send an HTTP GET request to the following URL:

`/wps/[my]contenthandler[/vpmapping]?(uri=model-uri)+(&mode=verb)?(&name=value)*`

The meanings of the syntax elements are as follows:

contenthandler
The name of the servlet for unauthenticated access. No J2EE security context is available.

mycontenthandler
The name of the servlet for authenticated access. There is a J2EE security context. Refer to the security topics for more details.

vpmapping
The optional name of the URL mapping to a virtual portal. If no mapping is given, the default virtual portal is assumed, otherwise the ID of the addressed virtual portal is associated with the current thread.

uri=*model-uri*
The identification of the addressed resource, as described in Model schemas for addressing resources. The `uri` parameter can appear only once.

mode=*verb*
An optional specification for the mode of access. By default `mode=download` is assumed.

name=value
An arbitrary set of parameters. These include additional query parameters. For details refer to the following topics.

"Model schemas for addressing resources"
Addressing a resource includes specifying the model to which the resource is associated. To do this, you specify a schema.

"Additional query parameters" on page 2875
In order to specify the extent and the contents of the requested feed, you may use additional query parameters. All additional query parameters are optional.

Model schemas for addressing resources:

Addressing a resource includes specifying the model to which the resource is associated. To do this, you specify a schema.

There is a schema defined for each model that the remote model SPI supports:

- For addressing a resource in the content model: `cm`
- For addressing a resource in the navigation model: `nm`
- For addressing a resource in the layout model: `lm`
- For addressing a resource in the portlet model: `pm`

Furthermore, you need to specify the resource of the model itself, as described in the following resource addressing specification:

```
model-uri = "cm:" page-oid |
            "nm:" navigationnode-oid |
            "lm:" [layoutnode-oid "@"] page-oid |
            "pm:" portlet-oid ["@" page-oid
```

The meanings of the syntax elements are as follows:

page-oid
This is the portal object ID of a content page. When you address portlet model resources, this is required for portlet windows, but it must not occur for any other portlet model resource identification.

navigationnode-oid
This is the object ID of a navigation model node.

layoutnode-oid
This is the object ID of a layout model node.

portlet-oid
This is the object ID of a layout control, portlet window, portlet entity, or portlet definition.

oid This is the serialized string that represents a portal object ID. This is URI-escaped with UTF-8 encoding. The character `@` is also escaped by using `%40`. You can also use unique names instead of object IDs. Unique names also have to be URI-escaped, and the `@` character must be escaped. Note that every object ID has the defined scheme `'oid:'`.

Note that the model schemes are mandatory for ambiguity reasons. For example content and navigation nodes currently have got the same object IDs.

Example 1: To obtain a feed of the root node of content model, that is the content node with the unique name `wps.content.root`, send an `HTTP GET` request to the following URL:

```
/wps/mycontenthandler?uri=cm:oid:wps.content.root
```

Example 2: To obtain a feed of the layout node with the object id `'_7_0830M4HTFF0SHFCQ_2BV' on the content page with the object id '_6_0830M4HTFF0SHFCQ_4D'`, send an `HTTP GET` request to the following URL:

```
/wps/mycontenthandler?uri=lm:oid:_7_0830M4HTFF0SHFCQ_2BV@oid:_6_0830M4HTFF0SHFCQ_4D
```

Additional query parameters:

In order to specify the extent and the contents of the requested feed, you may use additional query parameters. All additional query parameters are optional.

Levels

You can request a feed of a resource that is maintained in a tree model. If you do this, you can parameterize the URL,by the number of levels that the response should contain as follows:

```
[ &levels = levelcount ]
```

levelcount is an integer value that is greater than zero. Values have the following meaning:

0 This is not a valid value and therefore returns `400: Bad Request`.

1 This represents the model node itself. As a client, you can obtain a subtree of a model by requesting the root of the required subtree and any levels beneath it.

2 This represents the requested node including its direct children.

>2 These are entries for the requested node and its children up to the specified depth. The maximum path length is limited by the maximum depth of the requested (sub-) model and level count.

all If you specify this value, the obtained feed includes all descendants of the requested root node. As this can be an expensive call, a client should use this only for the layout model or for testing purposes.

(absent)
This is equivalent to an `all` levels parameter.

The `level` parameter for the portlet model:
The PortletModel is not a tree model, therefore the `level` parameter has a different meaning in the context of the PortletModel. You can set it to the following values:

0 This is not a valid value and therefore returns `400: Bad Request`.

<0 This returns all parents on the hierarchy higher than the given object ID with the depths of the value specified.

(absent)
This returns an ATOM feed that contains the addressed node of the PortletModel. This is equivalent for a levels parameter with the value `-1`.

1 This is equivalent to a value of `-1`.

-all This returns all levels up to the root web application.

The parameters `level` and `mode` are mutually exclusive if the value for `mode` is `view`.

Example: A URL that explicitly specifies that the node itself and all its direct children should be contained in the returned response:

```
/wps/mycontenthandler?uri=nm:oid:wps.content.root&levels=2
```

Representation mode

If the feed always transports all available information, it will be large. Therefore there is a way to limit the size of the feed. You can use the query parameter `rep` to specify the volume of information that is transported. You use the parameter as follows:

```
[ &rep = compact | full | empty ]
```

You can set the parameter to the following values:

Compact
This is the default value for the generated links. For performance reasons, this reduces the volume of returned information to a subset of the most important items. The meaning of the `compact` representation mode is defined separately and different for each model.

full The full representation mode exposes all available information.

empty
The empty representation mode returns no response body. However, the response headers, especially the HTTP status code, are the same as if you

use the compact or full representation modes. For example, you can use this mode if a client wants to modify the resource, but does not evaluate the response for performance reasons.

(absent)
If you omit the parameter, the full representation mode is used.

Extension parameter

For special use cases, for example in the context of federation, there is a parameter that allows you to manipulate the ATOM alternate link, also known as the view link. The value specified for this parameter must be a URI. If you specify this parameter, the Remote Model SPI performs a Piece Of Content (POC) lookup through the interface `com.ibm.portal.resolver.LookupService` with the view mode and the given URI. At this time the Remote Model SPI uses the default lookup service. Use the parameter as follows:

`[ &extension=`*`uri`* `]`

Explicit MetaData

Some metadata names are hidden, as they are not exposed in the MetaData iterator; for example, this is the case for all names that start with `com.ibm.portal`. These names also do not show up in a feed.

In the `compact` representation mode no metadata may be exposed, although some certain MetaData are required. Therefore, in order to expose them in a feed, you need to explicitly request them. To do this, use the `&mdname` parameter as follows:

`[ &mdname=`*`string`* `]`

You can use the parameter `mdname` multiple times in the same URL.

Example: This URL specifies explicitly that the otherwise hidden metadata `com.ibm.portal.Hidden` is exposed in the returned response:

`/wps/mycontenthandler?uri=nm:oid:wps.content.root&mdname=com.ibm.portal.Hidden`

Elements of a model feed:

These sections show sample feeds for the different models.

For more information on what information are exposed by the feeds refer to the section about mapping of feed elements to elements of the Model SPI.

Content Model feeds

In order to obtain information on the content model, you need to send an HTTP GET request to the content handler with the model schema `cm`.

Example: Content Model feed for the Content Model root node:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:atom="http://www.w3.org/2005/Atom"
           xml:base="http://wps128.boeblingen.de.ibm.com:10040/wps/mycontenthandler"
           xmlns:thr="http://purl.org/syndication/thread/1.0"
           xmlns:xhtml="http://www.w3.org/1999/xhtml"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
           xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
           xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base">
```

```
    <atom:author>

                    <base:nls-string xml:lang="en">Content Root</base:nls-string>
                </model:title>
                <model:active>true</model:active>
                <model:supportedMarkup>wml</model:supportedMarkup>
                <model:supportedMarkup>html</model:supportedMarkup>
            </model:content-label>
        </atom:content>
        <atom:link href="?uri=cm:oid:6_00000000000000000000000000A0&mode=download&levels=2&rep=compact"
                   rel="replies" type="application/atom+xml"/>
        <atom:link portal:rel="contextMenu"
                   portal:uri="wp.operations:page:oid:6_00000000000000000000000000A0"
                   portal:uniquename="wps.content.root"
                   href="?uri=wp.operations:page:oid:6_00000000000000000000000000A0&mode=download"
                   rel="related" type="application/vnd.mozilla.xul+xml"/>
    </atom:entry>
</atom:feed>
```

Layout Model feeds

In order to obtain information on the layout model, send an HTTP GET request to the content handler with the model schema `lm`.

Example: Layout Model feed for a Layout Model root node of a specific content node:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:atom="http://www.w3.org/2005/Atom"
           xml:base="http://wps128.boeblingen.de.ibm.com:10040/wps/mycontenthandler"
           xmlns:thr="http://purl.org/syndication/thread/1.0"
           xmlns:xhtml="http://www.w3.org/1999/xhtml"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
           xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
           xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base">
   <atom:author>
           <atom:name>IBM WebSphere Portal/6.1</atom:name>
   </atom:author>

               rel="related" type="application/atom+xml"/>
</atom:feed>
```

Navigation Model feeds

In order to obtain information on the Navigation Model, send an HTTP GET request to the content handler with the model schema `nm`.

Example: Navigation Model feed for the Navigation Model root node;

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:atom="http://www.w3.org/2005/Atom"
           xml:base="http://wps128.boeblingen.de.ibm.com:10040/wps/mycontenthandler"
           xmlns:thr="http://purl.org/syndication/thread/1.0"
           xmlns:xhtml="http://www.w3.org/1999/xhtml"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
           xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
           xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base">
    <atom:author>
           <atom:name>IBM WebSphere Portal/6.1</atom:name>
    </atom:author>
    <atom:title>IBM WebSphere Portal Model Feed</atom:title>
    <atom:id>nm:oid:6_000000000000000000000000A0</atom:id>
    <atom:link href="?uri=nm:oid:6_000000000000000000000000A0&mode=download&levels=1&rep=compact"
               rel="self" type="application/atom+xml"/>

    </atom:entry>
</atom:feed>
```

Use cases for modifying resources:

Portal Model REST services allow you to create new resources, modify, move and delete existing resources. View some common use cases of resource modifications.

The information exposed in Portal Model feeds is equivalent to the information exposed by the respective portal Model SPI. For information about how the elements of the feeds are mapped to the elements of the Model SPI refer to the information that follows here about use cases for modifying resources. Before you work with feed elements, make sure to familiarize yourself with the Model SPI.

Depending on the type of the modification, use the following HTTP verbs:

HTTP PUT
: Use this to update existing resources. This includes moving resources within model topologies,

HTTP POST
: Use this to create new resources.

HTTP DELETE
: Use this to delete existing resources

"Setting titles and descriptions of resources"
Portal Model REST services allow you to set titles and descriptions of resources.

"Creating Resources" on page 2881
Portal Model REST services allow you to create new resources.

"Putting a portlet on a page" on page 2882
Portal Model REST services allow you to put portlets on pages.

"Deleting resources" on page 2882
Portal Model REST services allow you to delete resources.

Setting titles and descriptions of resources:

Portal Model REST services allow you to set titles and descriptions of resources.

To set titles and descriptions of a resource, take the following steps:

1. Obtain the URI of resource for which you want to modify titles and descriptions.
2. Perform an HTTP PUT request to the URI that you obtained by the previous step, with a feed in the message body that contains titles and descriptions that you want to set.
3. Check for response `200 OK` from the server.

You can use the `update` parameter with either of the `merge` or `replace` modes:

`update=merge`
: Use the `merge` mode if you want to modify only the titles or descriptions of the resource. In this case, you need to send only the titles or descriptions that you want to modify.

`update=replace`
: Use the `replace` mode if you want to replace the complete entry of the resource. In this case, you need to send the complete resource.

Example: Feed to modify titles and description for a content node:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:atom="http://www.w3.org/2005/Atom"
           xml:base="http://wps128.boeblingen.de.ibm.com:10040/wps/mycontenthandler"
           xmlns:thr="http://purl.org/syndication/thread/1.0"
           xmlns:xhtml="http://www.w3.org/1999/xhtml"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
           xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
           xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base">
    <atom:author>
        <atom:name>IBM WebSphere Portal/6.1</atom:name>
    </atom:author>
    <atom:title>IBM WebSphere Portal Model Feed</atom:title>

    <atom:link href="?uri=cm:oid:6_000000000000000000000000A0&mode=download&levels=1&rep=compact"
               rel="self" type="application/atom+xml"/>
    <atom:updated>2008-02-26T06:36:02.239Z</atom:updated>
    <atom:entry>
        <atom:title>Content Root</atom:title>
        <atom:id portal:uniquename="wps.content.root">cm:oid:6_000000000000000000000000A0</atom:id>
        <atom:published>2002-05-31T22:00:00.000Z</atom:published>
        <atom:updated>2008-02-26T06:36:02.239Z</atom:updated>
        <atom:content type="application/xml">
            <model:content-label>
                <model:title>
                    <base:nls-string xml:lang="de">Mein neuer Titel</base:nls-string>
                    <base:nls-string xml:lang="en">My new title</base:nls-string>
                </model:title>
                <model:description>
                    <base:nls-string xml:lang="de">Meine neue Beschreibung</base:nls-string>
                    <base:nls-string xml:lang="en">My new description</base:nls-string>
                </model:description>
            </model:content-label>
        </atom:content>
    </atom:entry>
</atom:feed>
```

Creating Resources:

Portal Model REST services allow you to create new resources.

Example 1: Creating a page; note that this page has no layout or content defined:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base"
           xmlns:creation-context="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.2/portal-creation-context"
           xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
           xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
           xmlns:thr="http://purl.org/syndication/thread/1.0"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xmlns:atom="http://www.w3.org/2005/Atom">
    <atom:author>
        <atom:name>IBM WebSphere Portal/8.0</atom:name>
    </atom:author>
    <atom:title>IBM WebSphere Portal Model Feed</atom:title>
    <atom:id/>
    <atom:link href="." rel="self" type="application/atom+xml"/>
    <atom:updated>2007-07-04T13:28:37.721+0200</atom:updated>
    <atom:entry>
        <atom:title>test page - testpage_1183548505593</atom:title>
        <atom:id portal:uniquename="testpage_1183548505593">cid:testpage_1183548505593</atom:id>
        <atom:updated>2007-07-04T13:28:37.731+0200</atom:updated>
        <atom:content type="application/xml">
            <portal:content-page>
                <model:supported-markup>html</model:supported-markup>
                <model:supported-markup>wml</model:supported-markup>
                <model:title>
                    <base:nls-string xml:lang="en">test page - testpage_1183548505593</base:nls-string>
                </model:title>
```

```
            </portal:content-page>
        </atom:content>
        <thr:in-reply-to href="cm:oid:6_00000000000000000000000A0" ref="cm:oid:6_00000000000000000000000A0"
                         type="application/atom+xml"/>
    </atom:entry>
</atom:feed>
```

Example 2: Putting a layout container on a page:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base"
           xmlns:creation-context="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.2/portal-creation-context"
           xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
           xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
           xmlns:thr="http://purl.org/syndication/thread/1.0"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xmlns:atom="http://www.w3.org/2005/Atom">
  <atom:author>
    <atom:name>IBM WebSphere Portal/8.0</atom:name>
  </atom:author>
  <atom:title>IBM WebSphere Portal Model Feed</atom:title>
  <atom:id/>
  <atom:link href="." rel="self" type="application/atom+xml"/>
  <atom:updated>2007-07-04T13:28:56.358+0200</atom:updated>
  <atom:entry>
    <atom:title>lm:oid:newid_layout_0_1183548510931@oid:testpage_1183548505593</atom:title>
    <atom:id portal:uniquename="testpage_1183548505593_lmroot">lm:oid:testpage_1183548505593</atom:id>
    <atom:updated>2007-07-04T13:28:56.358+0200</atom:updated>
    <atom:content type="application/xml">
      <portal:layout-container/>
    </atom:content>
  </atom:entry>
</atom:feed>
```

Putting a portlet on a page:

Portal Model REST services allow you to put portlets on pages.

Example: Putting a portlet on a page:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base"
           xmlns:creation-context="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.2/portal-creation-context"
           xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
           xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
           xmlns:thr="http://purl.org/syndication/thread/1.0"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xmlns:atom="http://www.w3.org/2005/Atom">
    <atom:author>
        <atom:name>IBM WebSphere Portal/6.0.1</atom:name>
    </atom:author>
    <atom:title>IBM WebSphere Portal Model Feed</atom:title>
    <atom:id/>
    <atom:link href="." rel="self" type="application/atom+xml"/>
    <atom:updated>2007-07-04T13:29:14.444+0200</atom:updated>
    <atom:entry>
        <atom:title>lm:oid:newid_layout_5_1183548514616@oid:testpage_1183548505593</atom:title>
        <atom:id portal:uniquename="testpage_1183548505593_control">lm:oid:testpage_1183548505593</atom:id>
        <atom:updated>2007-07-04T13:29:14.444+0200</atom:updated>
        <atom:content type="application/xml">
            <portal:layout-control creation-context:portlet-definition="pm:oid:wps.p.Welcome"/>
        </atom:content>
        <thr:in-reply-to href="lm:oid:testpage_1183548505593_lmcontainer4@oid:testpage_1183548505593"
                         ref="lm:oid:testpage_1183548505593_lmcontainer4@oid:testpage_1183548505593"
                         type="application/atom+xml"/>
    </atom:entry>
</atom:feed>
```

Deleting resources:

Portal Model REST services allow you to delete resources.

To delete a resource, send an HTTP DELETE request to the resource that you want to delete.

Controller SPI

You can use the Controller SPI for portal administration. It allows you to modify portal resources. It enhances the read-only portal Model SPI by adding writable aspects.

The interfaces of the programming model for portal resources that are published under the topic *Model SPI overview* offered only read-only methods. The Controller SPI extends them by adding a set of new interfaces. These interfaces are derived from the read-only portal models and interfaces and map to them, but they also extend them with methods for modifying the resources that they represent. This way the Controller SPI allows you to modify portal resources to a certain extent.

Controller SPI overview

The Controller SPI provides controllers for portal resources. You can use these controllers to modify portal resources that are exposed by particular models of the Model SPI. Controllers offer methods to modify the topology and properties of the model and of its nodes. They expose the same interfaces as the corresponding read-only model, and they instantly reflect modifications that you apply to the controller.

Note: While the modifications come into effect immediately for the controller, they not reflected in the persistence layer until you commit the controller and the changes that you made by it.

The resources that are exposed by the controller can be modified through specific interfaces which match their read-only counterparts. For an example, refer to the following class list:

Classes from the read-only model . . .	**. . . are reflected in the Controller SPI by the following classes**
`ContentNode`	*`Modifiable`*`ContentNode`
• `MarkupCapable`	• *`Modifiable`*`MarkupCapable`
• `Localized`	• *`Modifiable`*`Localized`
• `Identifiable`	• *`Modifiable`*`Identifiable`
• `ActiveFlag`	• *`Modifiable`*`ActiveFlag`

Further benefits of the Controller SPI are as follows:

- Controller instances work as workspaces where you make your modifications. You can try your modifications and assess them in a preview mode. When your changes meet your requirements, you apply them to the portal by a commit step.
- You can make and apply your changes to a running portal environment. You do not need to restart the portal for the changes to take effect.

The Controller SPI provides the following controllers:

Content Model Controller

This allows you to modify the content topology and the properties of content nodes such as pages, labels, and content URLs.

Note: If you modify the content topology, this might also change the navigation of your portal for your users.

Layout Model Controller
This allows you to modify the layout of a page, such as the topology of layout elements of a page, and the properties of layout elements such as layout containers and layout controls.

Portlet Model Controller
This allows you to create, update and delete portlets.

Note: At this time there is no controller for the following models:

- `NavigationModel`. This is by implication of the structure of the content model.
- `NavigationSelectionModel`. This is computed from the navigational state per request.
- `LanguageList`, `MarkupList`, `SkinList`, and `ThemeList`.

A controller is based on the corresponding read-only model. This means when you first create the controller on the basis of a read-only model, both the controller and the model expose the same information. You can then use the controller to create, update, or delete information exposed through it. These changes will be reflected in the controller immediately. To persist changes that you made to the underlying read-only model, you need to commit the controller.

In particular, a controller offers methods to do all of the following:

- Provide modifiable instances of existing resources. These modifiable instances exist for each modifiable resource property, and they allow for these properties to be modified.
- Create and delete model resources.
- Obtain dependent controllers. This is optional. For example, a `ContentModelController` offers a method to obtain a `LayoutModelController`.
- Persist the modifications.

Note: Before you use the Controller SPI, be sure to familiarize yourself with the read-only models. Refer to *Model SPI overview*.

Scope of the Controller SPI

A controller instance is based on a read-only model instance. Therefore it has the same scope and lifetime as the corresponding read-only model. Consequently, the following equivalences apply:

- If the underlying model is scoped to a particular user, then so is the controller.
- If the underlying model is scoped to a request, then so is the controller.
- If the underlying model is scoped to a virtual portal, then so is the controller.

"Packages of the Controller SPI" on page 2885
The portal provides the SPI Controller in several separate packages.

"Working with controllers" on page 2886
When you modify a portal resource with the Controller SPI, you go through a set of steps.

"Making modifications by using the Controller SPI" on page 2888
The Controller SPI allows you to modify portal resources, the topology of your portal, and properties.

"Confirming modifications" on page 2901
Modifiable interfaces and Controller interfaces provide methods for confirming modifications. You can use these confirm methods to check whether modifications might be prevented by portal internal constraints.

"Hints and tips for using the Controller SPI" on page 2902
These are some hints and tips for using the Controller SPI.

Related concepts:

"Model SPI overview" on page 2858
Models provide information that is needed by WebSphere Portal Express to perform tasks such as content aggregation or building navigation to browse the aggregated content. The information that is aggregated is represented through models that can be accessed programmatically by using the Model SPI (read-only). The information of a model is usually persistent (stored in a database) but can also be transient (computed and stored only in memory). Models can be represented by using a tree structure (nodes have a parent-child relationship), a list structure, or a selection structure (a selected element in a tree structure).

IBM WebSphere Portal 8 API and SPI Reference

Packages of the Controller SPI

The portal provides the SPI Controller in several separate packages.

These packages are as follows:

- `com.ibm.portal`. This package holds the following interfaces:
  - Base interfaces for the Controller SPI, for example `Modifiable` and `Controller`.
  - Modifiable interfaces, such as `ModifiableActiveFlag`, `ModifiableLocalized`, `ModifiableMetaData`.
- `com.ibm.portal.admin`. This package holds modifiable interfaces, for example the `ModifiableMarkupCapable` and the `LanguageListController`.
- `com.ibm.portal.content`. This package holds the following interfaces:
  - Interfaces for content and layout model controller modifiable interfaces for content and layout nodes. For example, these can be `ModifiableContentPage` or `ModifiableLayoutContainer`.
  - Modifiable interfaces for modifiable aspects of content and layout nodes, for example `ModifiableBookmarkableFlag`
  - Creation contexts for creating content pages and layout nodes, for example `LayoutContainerCreationContext`.
- `com.ibm.portal.model.controller`. This package holds home and provider interfaces to obtain controllers, including a builder factory for `CreationContext` instances.
- `com.ibm.portal.model.controller.exceptions`. This package holds controller specific exceptions.
- `com.ibm.portal.portlet`. This package holds the following interfaces:
  - Interfaces for the portlet model controller.
  - Modifiable interfaces for portlet definitions, entities and preferences, for example `ModifiablePortletPreferences` and `ModifiablePortletEntity`.
  - Portlet creation and cloning context interfaces.

Note: A controller interface usually resides in the same package as its corresponding read-only Model SPI interface.

Working with controllers

When you modify a portal resource with the Controller SPI, you go through a set of steps.

About this task

For example, these steps can be as follows:

Procedure

1. Obtain the appropriate controller.
2. Obtain a modifiable instance of the resource that you want to modify from the controller.
3. Apply your modifications as required to the modifiable instance Commit the controller to persist the modifications.
4. Optionally repeat steps 2 and 3 as required.
5. Commit the controller to persist the modifications. This step saves and applies the modifications to your portal.

What to do next

Note: You can modify multiple resources with one controller before you commit the modifications.

For more detailed information about each of these steps refer to the following topics.

"Obtaining a controller for working with resources"
To modify, create, or delete portal resources by using the Controller SPI, you first need to create a controller.

"Committing and persisting your modifications" on page 2887
To persist the modifications that you applied to the controller, you commit the controller.

Obtaining a controller for working with resources

To modify, create, or delete portal resources by using the Controller SPI, you first need to create a controller.

About this task

You do this by using a JNDI based lookup for the correct "home" interface, that is, the corresponding read-only interface.

Note: The provider lookup for a controller home is possible from servlet level code and portlets.

The following controllers are available via JNDI:

ContentModelController
To obtain a ContentModelController, perform a lookup for the string `ContentModelControllerHome.CONTENT_MODEL_CONTROLLER_JNDI_NAME`.

PortletModelController
To obtain a ContentModelController, perform a lookup for the string `PortletModelControllerHome.PORTLET_MODEL_CONTROLLER_JNDI_NAME`.

The **LayoutModelController** cannot be obtained via a JNDI lookup. You obtain it through its associated **ContentModelController**.

Example - Obtaining a content model controller:

```
ContentModelController result = null;
final Context ctx = new InitialContext();
final ContentModelControllerHome home = (ContentModelControllerHome)
     ctx.lookup(ContentModelControllerHome.CONTENT_MODEL_CONTROLLER_JNDI_NAME);
if (home != null) {
     result = home.getContentModelControllerProvider().createContentModelController(aContentModel)
}
```

Note: To obtain a `ContentModelController`, you must pass an existing content model to the `createContentModelController` method of the `ContentModelControllerProvider`.

Example 2 - Obtaining a layout model controller for a specific page:

```
// locate the page for which you want to create a LayoutModelController
final Locator locator = cmController.getLocator();
final ContentPage page = (ContentPage) locator.findByUniqueName("MyPage");

// create a LayoutModelController
final LayoutModelController lmController = cmController.getLayoutModelController(page);
```

Related concepts:

"Obtain a model from the portal" on page 2867
Portal models can be obtained by using three different ways, depending on where the code that uses them is located.

Committing and persisting your modifications

To persist the modifications that you applied to the controller, you commit the controller.

About this task

You can commit only the `ContentModelController` and the `PortletModelController` as only these two implement the `Committable` interface. You cannot commit a `LayoutModelController`. Committing the `LayoutModelController` is included when you commit the `ContentModelController` from which you obtained the `LayoutModelController`. Committing the `ContentModelController` can include committing more than one `LayoutModelController`.

Notes:

1. After you have successfully committed a controller, you must not use it any more. In particular, do not invoke the `commit()` method again at a later stage.
2. After you have used a controller, you always need to dispose it.
3. If you do not want to persist the changes made by using the controller, dispose it without invoking `commit()` on it.

The following example shows how you commit a controller and then dispose it:

```
// commit the controller
try {
    controller.commit();
} finally {
    controller.dispose();
}
```

Making modifications by using the Controller SPI

The Controller SPI allows you to modify portal resources, the topology of your portal, and properties.

About this task

The following topics describe how you use the Controller SPI for different types of modifications. Some topics provide example code snippets. For these snippets to work, they need to be completed with preceding and subsequent code. Examples are shown in the following.

Preceding code: Each snippet must be preceded at least by the following code:

```
ContentModelController cmController= null;
final Context ctx = new InitialContext();
final ContentModelControllerHome home = (ContentModelControllerHome)
      ctx.lookup(ContentModelControllerHome.CONTENT_MODEL_CONTROLLER_JNDI_NAME);
if (home != null) {
      cmController = home.getContentModelControllerProvider().
           createContentModelController(aContentModel);
}
```

Depending on the modification that you want to make, you might require additional preceding code statements. For more details refer to “Obtaining a controller for working with resources” on page 2886.

Subsequent code: After you have completed your modifications, you commit the controller so that the modification take effect. After that you cannot use or commit the controller any more, but you dispose it. To commit your modifications and dispose the controller, add the following statements to your code:

```
// commit the controller
try {
    controller.commit();
} finally {
    controller.dispose();
}
```

For more details about this refer to “Committing and persisting your modifications” on page 2887.

“Modifying portal resources and topologies”
The Controller SPI allows you to modify portal resources and the topology of your portal in different ways.

“Modifying properties” on page 2893
The Controller SPI enables the modification of properties resources.

Related tasks:

“Obtaining a controller for working with resources” on page 2886
To modify, create, or delete portal resources by using the Controller SPI, you first need to create a controller.

“Committing and persisting your modifications” on page 2887
To persist the modifications that you applied to the controller, you commit the controller.

Modifying portal resources and topologies

The Controller SPI allows you to modify portal resources and the topology of your portal in different ways.

About this task

You can make the following modifications:

- Create new resources
- Insert new resources into the portal topology
- Move existing resources
- Delete existing resources.

Depending on the resource that you create or modify, you can perform different types of modifications. For more detailed information about each of these refer to the following topics.

"Creating resources"
You create resources by using methods of controllers. Each controller type enables the specific resources for its type of model.

"Moving or Inserting Nodes" on page 2891
To move existing nodes or insert new nodes, use the `insert()` method of the controller.

"Deleting Nodes" on page 2893
To delete nodes, use the `delete()` method of the controller.

Creating resources:

You create resources by using methods of controllers. Each controller type enables the specific resources for its type of model.

About this task

The following list shows the existing controllers and the resources that you can create by using them:

- `ContentModelController`. This enables the creation of resources of the following types:
  - `ContentPage`
  - `ContentLabel`
  - The following two types of content URL:
    - `ExternalContentURL`
    - `InternalContentURL`
- `LayoutModelController`. This enables the creation of resources of the following types:
  - `LayoutContainer`
  - `LayoutControl`
- `PortletModelController`. This enables the creation of resources of the following types:
  - `PortletDefinition`
  - `PortletEntity`

To create a resource, proceed by the following steps:

Procedure

1. Optional: Obtain a creation context. Take the following two steps:
   a. Obtain the creation context builder factory. For details about how to do this step, refer to "Obtaining creation contexts" on page 2890.

b. Obtain a creation context from the creation context builder. For details about how to do this step, refer to "Obtaining creation contexts."

2. Obtain a controller.
3. Create a resource. To do this step, use the `create(Class, CreationContext)` method of the controller and provide both arguments.

Results

1. The created resource is not part of the topology, unless you insert it into the topology by using the `insert()` method of the controller.
2. For content nodes, that is content pages, content labels, and content URLs, you must set a supported markup. Otherwise, they do not show in the read-only model.

Example

Example 1 - Creating a resource by using the creation context builder: This example creates a `ContentPage` that you can later insert into the content model.

```
// obtain creation context builder
final CreationContextBuilderFactory builder = CreationContextBuilderFactory.getInstance();

// obtain creation context
final CreationContext creationContext = builder.newIdentifiableCreationContext(objectID);

// create resource (which is not yet part of the topology of the controller!)
final Modifiable modifiable = controller.create(ContentPage.class, creationContext);
```

Example 2 - Cloning an existing portlet definition: To clone an existing portlet definition, create a portlet definition by using a portlet model controller and specify a `PortletDefinitionCloningContext`.

```
// obtain portlet definition cloning context; includes obtaining a portlet definition
final PortletDefinitionCloningContext context = ... (portletDefinition)

// create portlet definition
pmController.create(PortletDefinition.class, context);
```

The result of the `create()` method is a `Modifiable` instance of the created resource that you can cast to the type of the created resource as shown in the following example.

Example 3 - Casting a created resource to its type:

```
final ModifiableContentPage modifiableContentPage = (ModifiableContentPage)
      controller.create(ContentPage.class, creationContext);
```

"Obtaining creation contexts"
You need a creation context to define immutable properties of a resource that you create. You can use the creation context builder factory to generate multiple such creation contexts without having to implement those interfaces directly.

Obtaining creation contexts:

You need a creation context to define immutable properties of a resource that you create. You can use the creation context builder factory to generate multiple such creation contexts without having to implement those interfaces directly.

About this task

The creation context builder factory can do both of the following:

- Generate single creation contexts, that is contexts that contain only one or more immutable properties. Examples:

  - A creation context for an object ID contains only the object ID property.
  - A layout control creation context contains two properties, portlet definition and portlet entity.
- Combine several creation contexts into one in order to define multiple immutable properties.

Note: You can only combine creation contexts that have not already been combined by using the creation context builder.

Example

Example 1 - Obtaining a simple creation context:

```
// obtain creation context builder
final CreationContextBuilderFactory builder = CreationContextBuilderFactory.getInstance();

// obtain creation context
final CreationContext creationContext = builder.newIdentifiableCreationContext(objectID);
```

Example 2 - Obtaining a combined creation context:

```
// obtain creation context builder
final CreationContextBuilderFactory builder = CreationContextBuilderFactory.getInstance();

// obtain combined creation context
final CreationContext creationContext = builder.combine(new CreationContext[]
     {builder.newContentPageCreationContext(true), builder.newIdentifiableCreationContext(objectID)});
```

What to do next

The following list describes creation contexts that you can create by using the creation context builder factory:

ContentPageCreationContext
Use this creation context to define whether a page that you create is private. This applies to the resource type `ContentPage` on the `ContentModelController`.

DerivedContentPageCreationContext
Use this creation context to define the derivation parent of a page that you want to create. This applies to the resource type `ContentPage` on the `ContentModelController`.

Note: This creation context derives from the `ContentPageCreationContext`.

IdentifiableCreationContext
Use this creation context to define an object ID for a resource that you want to create. This applies all resource types: `ContentModelController`, `LayoutModelController`, `PortletModelController`.

PortletDefinitionCloningContext
Use this creation context to define the portlet definition ID, and optionally, the domain for the portlet definition that you want to clone. This applies to the resource type `PortletDefinition` on the `PortletModelController`.

PortletEntityCreationContext
Use this creation context to define the parent ID, and optionally, the domain for the portlet entity that you want to create. This applies to the resource type `PortletEntity` on the `PortletModelController`.

Moving or Inserting Nodes:

To move existing nodes or insert new nodes, use the `insert()` method of the controller.

About this task

1. When you create a node, you must insert it into the topology of the model, for example, to make it visible and accessible for users.
2. Operations that you defined on the controller itself, such as `hasChildren()` or `getLayoutModelController()`, work only after you insert the node.

Procedure

1. Obtain an appropriate controller.
2. Identify the target location in the topology. You must have that information in a later step.
3. Identify the resource that you want to move or insert as follows:
   - For moving a resource, locate an existing node with the appropriate locators of the controller.
   - For inserting a resource, create a modifiable instance that represents a new resource.
4. Insert the resource into the topology of the controller by using its `insert()` method and by specifying its target location. This resource can be one of the following list:
   - A parent node. In this case, the resource is inserted as the last child of the parent node.
   - A parent node and a sibling node. In this case, the resource is inserted as the child of the parent node in a position immediately before the sibling node.
   - No location information at all. In this case, the resource is inserted as a new root.

     Note: This insertion is not possible for all controllers. For example, you cannot insert a new root node into a `ContentModelController` that has a root node already.
5. Persist your modifications by using the `commit()` method of the controller.

Example

Example 1 - Moving an existing portlet to a different container (error handling omitted):

```
// obtain locator of LayoutModelController
final Locator locator = lmController.getLocator();

// locate portlet and target containers
final LayoutControl control = (LayoutControl) locator.findByUniqueName("MyControl");
final LayoutContainer parentContainer = (LayoutContainer) locator.findByUniqueName("MyParentContainer");
final LayoutContainer nextContainer = (LayoutContainer) locator.findByUniqueName("MyNextContainer");

// move portlet under parentContainer just before nextContainer
lmController.insert(control, parentContainer, nextContainer);
```

"Placing a portlet on a page"
To put a portlet on a page, use the `insert()` method of the controller.

Placing a portlet on a page:

To put a portlet on a page, use the `insert()` method of the controller.

Procedure

1. Obtain a layout model controller for the page the portlet is to be put on.
2. Obtain a `LayoutControlCreationContext`; this includes obtaining the portlet definition ID, and optionally the portlet entity ID.

3. Create a layout control by using the context from the previous step and by using the `create()` method of the layout model controller.
4. Insert the created layout control into the layout model controller.
5. Persist your modifications by using the `commit()` method of the controller.

Example

Example 1 - Placing a portlet on a page:

```
// obtain layout model controller
final LayoutModelController lmController = cmController.getLayoutModelController(page);

// obtain layout control creation context
final LayoutControlCreationContext context   = ... (portletDefinition, null);
//final LayoutControlCreationContext context = ... (portletDefinition, portletEntity);

// create layout control
final Modifiable control = lmController.create(LayoutControl.class, context);

// insert control into the topology of the layout model controller (given a container and a sibling)
lmController.insert(control, container, sibling);

// commit the content model controller
cmController.commit();
```

Deleting Nodes:

To delete nodes, use the `delete()` method of the controller.

Procedure

1. Obtain an appropriate controller.
2. Locate the resource that you want to delete. Use an appropriate locator of the controller, or search the model by iterating until the required node is found.
3. Delete the resource by using the `delete()` method of the controller.
4. Persist your modifications by using the `commit()` method of the controller.

Example

Example 1 - Deleting a node (error handling omitted):

```
// obtain locator of ContentModelController
final Locator locator = cmController.getLocator();

// locate page to delete
final ContentPage page = (ContentPage) locator.findByUniqueName("MyPage");

// delete the page
cmController.delete(page);

// commit the controller
cmController.commit();
```

Modifying properties

The Controller SPI enables the modification of properties resources.

Procedure

1. Obtain the appropriate controller for the model of which you want to modify a resource.
2. Obtain a modifiable instance of the resource from that controller.
3. Start the appropriate methods of the modifiable instance to run the modifications.
4. Persist the modifications by using the `commit()` method of the controller.

Setting titles and descriptions:

You can set the titles and descriptions of a resource.

Procedure

1. Obtain a modifiable instance of the resource for which you want to set titles or descriptions.
2. Check whether the resource implements the `ModifiableLocalized` interface. To check, use the operator `instanceof`. If the resource does not implement the `ModifiableLocalized` interface, you cannot modify it.
3. Use the appropriate methods to set titles and descriptions. For example, if you want to set a title, use the `setTitle` method.

   Note: You cannot set a description in a particular locale without having a title that is set in that same locale.

Example

Modifying titles and descriptions:

```
// obtain modifiable instance of a model node
final Modifiable modifiable = controller.getModifiableNode(node);

// check if the resource implements ModifiableLocalized interface
if (modifiable instanceof ModifiableLocalized) {

    // set title and description
    ((ModifiableLocalized) modifiable).setTitle(Locale.GERMAN, "Titel");
    ((ModifiableLocalized) modifiable).setDescription(Locale.GERMAN, "Beschreibung");
}
```

Setting unique names:

You can set unique names for resources.

About this task

To set the unique name for a resource, proceed by the following steps:

Procedure

1. Obtain a modifiable instance of the resource for which you want to set the unique name.
2. Check whether the resource implements the `ModifiableIdentifiable` interface. To do this, use the operator `instanceof`. If the resource does not implement the `ModifiableIdentifiable` interface, you cannot modify it.
3. Obtain a modifiable instance of the resource object ID, that is `ModifiableObjectID`. To do this, use the `getModifiableObjectID`.
4. Set the unique name by using the `setUniqueName()` method of the `ModifiableObjectID`.

Example

Example - Setting unique names:

```
// obtain modifiable instance of a model node
final Modifiable modifiable = controller.getModifiableNode(node);

// obtain modifiable instance of the resource's object id; note that modifiable
// instances of all model nodes implement the ModifiableIdentifiable interface
final ModifiableObjectID modifiableObjectID = ((ModifiableIdentifiable)
modifiable).getModifiableObjectID();

// set unique name
modifiableObjectID.setUniqueName("MyUniqueName");
```

Setting metadata:

You can set metadata on all modifiable instances that implement the `ModifiableMetaDataProvider` interface.

About this task

To set metadata for a resource, proceed by the following steps:

Procedure

1. Obtain a modifiable instance of the resource for which you want to set metadata.
2. Check whether the resource implements the `ModifiableMetaDataProvider` interface. To do this, use the operator `instanceof`. If the resource does not implement the `ModifiableMetaDataProvider` interface, you cannot modify it.
3. Obtain a modifiable instance of the metadata of the resource.
4. Set the metadata by using the appropriate methods. For example, if you want to set metadata, use the `setValue` method.

Example

Example - Setting metadata for a resource:

```
// obtain modifiable instance of a model node
final Modifiable modifiable = controller.getModifiableNode(node);

// check if the resource implements ModifiableMetaDataProvider interface
```

```
if (modifiable instanceof ModifiableMetaDataProvider) {

    // obtain modifiable intance of the resource's meta data
    final ModifiableMetaData modifiableMetaData = ((ModifiableMetaDataProvider)
        modifiable).getModifiableMetaData();

    // set meta data
    modifiableMetaData.setValue("MyKey", "MyValue");
}
```

Setting supported markups:

You can set supported markups on modifiable instances that implement the `ModifiableMarkupCapable` interface.

About this task

For example, these can be the following:

- `ModifiableContentPage`
- `ModifiableContentLabel`
- `ModifiableContentURL`

Note: For content nodes, that is content pages, content labels, and content URLs, you need to set a supported markup. Otherwise they will not show in the read-only model.
To set the supported markups for a resource, proceed as follows:

Procedure

1. Obtain a modifiable instance of the resource for which you want to set supported markups.
2. Use the appropriate methods of the `ModifiableMarkupCapable` interface to set supported markups. For example, if you want to set a markup, use the `addMarkup` method.

Example

Example - Setting a supported markup on a layout control (error handling omitted):

```
// obtain markup list
final MarkupList markupList = ...;

// obtain modifiable instance of a layout control
final Modifiable modifiable = lmController.getModifiableNode(control);

// obtain markup object
Markup markup = markupList.getByName("html");

// set markup
((ModifiableMarkupCapable) modifiable).addMarkup(markup);
```

What to do next

For more detail about the markup list in the first line of the example and how to obtain it refer to “Obtain a model from the portal” on page 2867.

Setting the orientation for layout containers:

You can set the orientation for modifiable instances of `LayoutContainer` nodes.

About this task

To set the orientation for a layout container, proceed by the following steps

Procedure

1. Obtain a modifiable instance of a layout container.
2. Obtain the modifiable layout metrics instance.
3. Set the orientation by using the `setValue()` method.

Example

Example - Setting orientation of an existing layout container:

```
//  get modifiable instance of layout container
final ModifiableLayoutNode modifiable = (ModifiableLayoutNode) lmController.getModifiableNode(cont

//  get modifiable layout metrics and set the orientation
ModifiableLayoutMetrics modifiableLayoutMetrics = modifiable.getModifiableLayoutMetrics();
modifiableLayoutMetrics.setValue(LayoutMetrics.ORIENTATION, Orientation.HORIZONTAL);
```

What to do next

Note: If you do not set the orientation of a container, it is automatically set when you insert the container into the topology of the controller by the following rules:

- If a new root container is inserted into an empty topology, horizontal orientation is used for the new root container.
- If a new root container is inserted into a topology that is not empty, the new root container is set to the opposite orientation of the existing root container. For example, if the existing root container had horizontal orientation, the new root container will have vertical orientation.
- If a container is inserted as the child of an existing parent container, the child container is set to the opposite orientation of the parent container.

Setting portlet preferences:

You can set the portlet preferences for portlet definitions and portlet entities.

"Setting portlet preferences for portlet definitions"
You can set the portlet preferences for portlet definitions.

"Setting portlet preferences for portlet entities" on page 2898
You can set the portlet preferences for portlet entities.

Related concepts:

Preference layers and portlet modes
Get an overview of portlet configuration preference layers and portlet modes to best implement the different layers on which preferences for portlet views can be configured.

Setting portlet preferences for portlet definitions:

You can set the portlet preferences for portlet definitions.

About this task

To set the portlet preferences for a portlet definition, proceed by the following steps:

Procedure

1. Obtain a modifiable instance of a portlet definition.
2. Obtain the modifiable portlet preferences layer.
3. Set the preferences by using the appropriate methods of the `ModifiablePortletPreferences` interface.

Example

Example - Setting portlet preferences on a portlet definition:

```
// obtain portlet model controller
final PortletModelController pmController = getPortletModelController(portletModel);

// obtain modifiable instance of a portlet definition
final Modifiable modifiable = pmController.getModifiableNode(portletDefinition);

// obtain modifiable preferences layer
final ModifiablePortletPreferences preferences = ((ModifiablePortletDefinition)
      modifiable).getModifiablePortletPreferencesLayer();

// set a single value
preferences.setStringValue("name", "value");
```

Setting portlet preferences for portlet entities:

You can set the portlet preferences for portlet entities.

About this task

To set the portlet preferences for a portlet entity, proceed by the following steps:

Procedure

1. Obtain a modifiable instance of a portlet entity.
2. Obtain the modifiable portlet preferences layer.
3. Set the preferences by using the appropriate methods of the `ModifiablePortletPreferences` interface.

Example

Example - Setting portlet preferences on a portlet entity:

```
// obtain portlet model controller
final PortletModelController pmController = getPortletModelController(portletModel);

// obtain modifiable instance of a portlet entity
final Modifiable modifiable = pmController.getModifiableNode(portletEntity);

// obtain modifiable preferences layer
final ModifiablePortletPreferences preferences = ((ModifiablePortletEntity)
    modifiable).getModifiablePortletPreferencesLayer();

// set a single value
preferences.setStringValue("name", "value");
```

Setting flags:

The Controller SPI allows you to set flags for resources. For example, you can set a flag for a page so that portal users can bookmark the page.

About this task

You set flags for resources either on modifiable instances of those resources or on controllers managing the resources. The following flags are available:

Table 453. Flags that you can modify

Flag	Flag is associated to resource	Flag is set on
ActiveFlag	ContentNode (resources that implement the ActiveFlag interface)	ModifiableContentNode
BookmarkableFlag	ContentNode (resources that implement the BookmarkableFlag interface)	ModifiableContentNode
ShareableFlag	ContentNode (resources that implement the ShareableFlag interface)	ModifiableContentNode
AllPortletsAllowedFlag	ContentPage	LayoutModelController
DeletableFlag	LayoutNode	LayoutModelController
ModifiableFlag	LayoutNode	LayoutModelController

Notes:

1. ContentNode is the super class of ContentPage, ContentLabel, ContentURL, and InternalContentURL.
2. LayoutNode is the super class of LayoutContainer and LayoutControl.

In case of layered resources, for example derived content pages, you set flags only on the layer on which you work. To set flags, use the appropriate method. For example, to set the ActiveFlag, use the setActiveFlag method on the ModifiableContentNode instance. For more details about how the flags are aggregated in derivation scenarios refer to the Model SPI documentation.

Example

Example 1 - Setting the DeletableFlag for a layout container:

```
// set modifiable flag on the layout model controller
lmController.setDeletableFlag(container, true);
```

Example 2 - Setting the BookmarkableFlag for a content page:

```
 // obtain modifiable instance of an existing content page
    final Modifiable modifiable = cmController.getModifiableNode(page);
// set modifiable flag on the modifiable instance
    ((ModifiableBookmarkableFlag) modifiable).setBookmarkableFlag(true);
```

Related concepts:

"Model SPI overview" on page 2858
Models provide information that is needed by WebSphere Portal Express to perform tasks such as content aggregation or building navigation to browse the aggregated content. The information that is aggregated is represented through models that can be accessed programmatically by using the Model SPI (read-only). The information of a model is usually persistent (stored in a database) but can also be transient (computed and stored only in memory). Models can be represented by using a tree structure (nodes have a parent-child relationship), a list structure, or a selection structure (a selected element in a tree structure).

Setting themes:

The Controller SPI enables the setting of themes on modifiable instances that implement the ThemeSetter interface, for example ContentPage and ContentLabel.

Procedure

1. Obtain a modifiable instance of the resource for which you want to set a theme.
2. Obtain a `Theme` object from the `ThemeList` model.
3. Check whether the resource implements the `ThemeSetter` interface. Use the operator `instanceof`. If the resource does not implement the `ThemeSetter` interface, you cannot set the theme.
4. Use the `setTheme()` method to set the theme.

Example

Setting a theme for a content page (error handling omitted):

```
final Modifiable modifiable = cmController.getModifiableNode(page);

// obtain theme to set from com.ibm.portal.admin.ThemeList
final Theme theme = ...

// set theme
if (modifiable instanceof ThemeSetter) {
    ((ThemeSetter) modifiable).setTheme(theme);
}
```

Setting URLs:

You can set URLs to point to external content (`ExternalContentURL`) or to internal content, that is to nodes in the portal (`InternalContentURL`).

About this task

"Setting external content URLs"
Learn how to set URLs that point to external content (`ExternalContentURL`).

"Setting internal content URLs" on page 2901
Learn how to set URLs that point to portal internal content (`InternalContentURL`).

Setting external content URLs:

Learn how to set URLs that point to external content (`ExternalContentURL`).

Procedure

1. Obtain a modifiable instance of an external content URL.
2. Obtain the markup for which you want to set the URL.
3. Set the required URL for the modifiable instance of the external content URL.

Example

```
// obtain modifiable instance of an existing ContentURL
final Modifiable modifiable = cmController.getModifiableNode(contentUrl);

// identify target of url
final String target = ...

// identify markup
final Markup markup = ...

// set URL
((ModifiableContentURL) modifiable).setURL(target, markup);
```

Setting internal content URLs:

Learn how to set URLs that point to portal internal content (`InternalContentURL`).

Procedure

1. Obtain a modifiable instance of an internal content URL.
2. Identify the content node to which you want to assign the URL.
3. Obtain the markup for which you want to set the URL.
4. Set the required URL for the modifiable instance of the internal content URL.

Example

```
// obtain modifiable instance of an existing InternalContentURL
final Modifiable modifiable = cmController.getModifiableNode(internalContentUrl);

// identify target of url
final Identifiable identifiable = ...

// identify markup
final Markup markup = ...

// set URL
((ModifiableInternalContentURL) modifiable).setTarget(identifiable, markup);
```

Confirming modifications

Modifiable interfaces and Controller interfaces provide methods for confirming modifications. You can use these confirm methods to check whether modifications might be prevented by portal internal constraints.

About this task

The confirm methods do not perform a modification, but they only indicate whether a modification can be performed or not. For example, if an administrator has locked the layout of a page, you cannot move portlets on that page by using the Controller SPI or by any other method.

For every method of the Controller SPI that modifies portal resources, the Controller SPI also provides a corresponding method to confirm the respective modification. All confirm methods start with the prefix `confirm` followed by the name of the method which is to be confirmed.

Example

Example - Confirming placement of a portlet by confirming the movement of the control of that portlet:

```
// check if the control may be moved to the specified layout container
final boolean result = lmController.confirmInsert(control, container, null);

// check result
if (result == true) {
    // control may be moved to specified layout container
} else {
    // control may not be moved to specified layout container
}
```

Note: There is no guarantee that a modification will indeed be successful after the related `confirm`*xxx* method returns `true`. This is due to the fact that the underlying data structure might have changed between the confirmation and the actual modification.

Hints and tips for using the Controller SPI

These are some hints and tips for using the Controller SPI.

- Reusing unique names: If you use a controller to directly or indirectly remove a portal resource that has a unique name assigned to it and if you want to reuse that unique name for another resource later, you need to use a new controller to do so, unless you used the same controller for creating the resource and removing it again.
- Reusing an existing object ID is limited: A resource that reuses an object ID must be of the same type as the resource that used this object ID previously.

User and group management

The Portal User Management Architecture (PUMA) System programming interface (SPI) provides interfaces for accessing the profiles of a portal User or Group.

PUMA SPI is used to find, create, modify, and delete users and groups. Also, profile information about the currently logged in user can be retrieved. The User and Group interfaces that are returned by the SPI inherit the getObjectID() method from the com.ibm.portal.Identifiable interface of the Model SPI. This method is used to obtain the ObjectID that uniquely identifies a resource, in this case a user or group in the portal user registry. The following provider objects are used to access the User and Group objects.

PumaProfile
Contains methods that provide read-only access to the User and Group attributes and identifiers. You can use this interface to get the User object for the current user.

PumaLocator
Contains methods for looking up User and Group objects. You can use this interface to obtain a List of Group objects for all of the groups in which the current user is a member. Beginning with Version 7.0 of WebSphere Portal Express, paging is supported. Which means that the result set is split up into subsets (pages) and a special iterator can be used to access the pages.

PumaController
Contains methods for creating and deleting Users and Groups and for modifying the User and Group profiles and membership.

PumaEnvironment
Contains methods to retrieve virtual principals, access general properties for user management, and a method to bypass access control for the user and group management layer.

Before the portlet can use these provider objects, it must first retrieve the appropriate home interface, depending on the type of application.

Standard portlet
com.ibm.portal.um.portletservice.PumaHome

IBM portlet
com.ibm.portal.um.portletservice.legacy.PumaHome

Portal application (for example, theme or skin)
com.ibm.portal.um.PumaHome

Examples of how these interfaces are retrieved are provided in the accompanying Javadoc documentation. The following example shows how a standard portlet would obtain the identifier of a User as a String.

```
PortletServiceHome psh;
try{
   javax.naming.Context ctx = new javax.naming.InitialContext();
   psh = (PortletServiceHome)
         ctx.lookup("portletservice/com.ibm.portal.um.portletservice.PumaHome");
   if (psh != null){
      PumaHome service = (PumaHome) psh.getPortletService(PumaHome.class);
      PumaProfile pp = service.getProfile(request);
      User user = pp.getCurrentUser();
      String user_objid = pp.getIdentifier(user);
   }
}
catch (PumaException pe){
   // ... error handling ...
} catch(javax.naming.NameNotFoundException ex) {
   // ... error handling ...
} catch(javax.naming.NamingException ex) {
   // ... error handling ...
}
```

Note: Because PumaProfile, PumaLocator and PumaController store the current user, you must not store these objects in a session or anywhere else. But you can retrieve them from PumaHome each time you use them. PumaHome, however, can be stored.

The following sample shows how a standard portlet would do a standard search for reading and writing attributes:

```
List<User> usersStartingWithA = pumaLocator.findUsersByAttribute("uid", "a*");
// if no value for ibm-primaryEmail attribute is set, then set it
List<String> requestedAttributes = new ArrayList<String>(2);
requestedAttributes.add("uid");
requestedAttributes.add("primaryEmail");
for(User user: usersStartingWithA) {
Map<String, Object> attributes =
pumaProfile.getAttributes(user, requestedAttributes);
if (attributes.get("primaryEmail")==null
|| "".equals(attributes.get("ibm-primaryEmail"))){
pumaController.setAttributes(user, Collections.singletonMap(
"ibm-primaryEmail", attributes.get("uid")+"@ibm.com"));
}
}
```

The following sample shows how to do a paged search:

```
// create a properties map that requests 10 results per Page
Map<String, Object> pageProperties = new HashMap<String, Object>(2);
pageProperties.put(PumaLocator.RESULTS_PER_PAGE, 10);
PagingIterator<User> pageIter = pumaLocator.findUsersByAttribute(
"uid", "a*", pageProperties);
List<User> buffer = new ArrayList<User>(10);
do {
pageIter.getNextPage(buffer); //=> always has a first page
if (pageIter.getCurrentPageNumber()==0)
{
System.out.println("Total results: "+pageIter.getNumberOfTotalResults());
System.out.println("Total pages: "+pageIter.getNumberOfPages());
}
for (User aUser: buffer)
{ display(aUser);
}
```

```
} while (pageIter.hasNextPage());
// now jump to page 5
// => will throw NoSuchPageException if NumberOfPages < 6
List<User> result = pageIter.getPage(null, 5);
```

"Remote REST service for PUMA"
The remote PUMA SPI gives you access to user profiles through REST services. It provides a remote interface for user and group management for the configured Portal user repository. It is based on the REST (REpresentational State Transfer) architecture model.

Remote REST service for PUMA

The remote PUMA SPI gives you access to user profiles through REST services. It provides a remote interface for user and group management for the configured Portal user repository. It is based on the REST (REpresentational State Transfer) architecture model.

The remote REST service for PUMA allows you to remotely perform the following tasks related to user and group data based on the HTTP protocol:

- Access, retrieve, and modify information about available user or group attributes and their metadata
- Search for users or groups based on attributes or group membership
- Create, update, or delete user or group profiles and group membership relations.

The first part of this documentation describes the basic interface that lists all possible operations, including their parameters and a minimum schema to describe the resources that are involved. The second part explains specific details for the current implementation of this interface for this version of WebSphere Portal Express.

"Structure of the remote REST service for PUMA"
The interface provided by the remote REST service for PUMA defines single operations that are characterized by a particular URI path, the HTTP method, the expected input or output, and a list of query parameters. With regards to the input or output format, the interface only describes a common baseline for the payload, which can be wrapped or represented individually by different implementations of the service.

"How the portal implements the remote PUMA REST service" on page 2915
The previous topics describe the general part of the remote REST service for PUMA Interface. This interface can be implemented by different providers that can be based on different backend systems or user repositories and provide their own input and output formats. The implementation of the interface described here is the one based on WebSphere Portal Express Version 8.5.

Structure of the remote REST service for PUMA

The interface provided by the remote REST service for PUMA defines single operations that are characterized by a particular URI path, the HTTP method, the expected input or output, and a list of query parameters. With regards to the input or output format, the interface only describes a common baseline for the payload, which can be wrapped or represented individually by different implementations of the service.

All URI paths that the interface defines start with the prefix `/um`. This can be considered as the identifying part of the service. Implementations of the service can add additional path elements before the `/um` element, for example to represent the context root of a servlet. Therefore clients should not assume that the complete servlet path always starts with `/um`.

URI paths that start with `/um/secure` will be served only within a valid user context, that is only in an authenticated request. If the `/secure` path element is omitted, this means that the operation is performed in the context of the anonymous user. For simplicity, the interface description denotes all URI paths without the `/secure` element. However, all corresponding operations can be performed for both authenticated and anonymous users. For operations related to authenticated users you have to prefix the `/secure` element. This also implies that the particular implementation of the interface has to make sure to apply the appropriate access control checks before executing an operation.

Variable parts within URI paths or query parameters can contain special characters. These must be encoded in order to represent valid path elements or parameters. The interface defines that UTF-8 must be used by the client and that URLs returned by the server are UTF-8 encoded.

Some operations of the interface make use of HTTP PUT and DELETE operations, but many environments only allow GET or POST operations for HTTP requests for security reasons. To be compatible to such scenarios, the interface defines a general replacement mechanism for PUT and DELETE operations by POST requests:

- Request parameter `postAction` with a value of `put` or `delete`. The case is ignored.
- Request header `X-Method-Override` with a value of `put` or `delete`. The case is ignored.

The implementation must make sure that it is possible to enable or disable this tunneling of request methods as needed. For each operation, you can specify the input and output format. You can do this by using either the request parameter `mime-type` or by using the `accept` request header as defined in the HTTP specification RFC 2616. If you set the request parameter, the information from the accept header is ignored.

"Interface operations" on page 2906
View all operations of the remote REST service for PUMA including the necessary attributes and a description.

"Payload description" on page 2909
The actual data that is processed by the remote REST service for PUMA that is the attributes and their values, user or group profiles, and membership lists, is described by an XML schema document. This schema is normative for all kinds of input and output formats. Therefore, for representations that are not based on XML, such as JSON, you need to apply an appropriate transformation.

"PUMA REST service XML schema document" on page 2911
The data processed by the remote REST service for PUMA is described by an XML schema document. View the XML schema for the PUMA REST service XML schema document.

"Error codes" on page 2913
If the operations described previously fail for some reason, the remote REST service for PUMA returns a subset of the HTTP error codes. They include a message with a detailed description of the error.

"Data types for attributes" on page 2914
Data types for attributes belong to a subset of the XML Schema data type specification.

Interface operations:

View all operations of the remote REST service for PUMA including the necessary attributes and a description.

The following list shows and describes all the possible URI path operations, together with the related query parameters. Note that some URI path operations apply to different HTTP methods - GET, or PUT and POST, or DELETE.

Notational convention: Parameter values are separated by vertical slashes (|). Default values are indicated with an asterisk (*).

/um/attributes/users

For the HTTP method GET:
This URI path operation returns the list of references to the attribute definitions that are available for users with references to the URI path operation `/um/attributes/users/`*`attribute name`*. This URI path operation has the following query parameter:

expandRefs=true | *false
If you set this parameter to `true`, the representations of the attribute definitions are embedded in the list of references. The default value is `false`.

/um/attributes/users/*attribute name*

For the HTTP method GET:
This URI path operation returns a representation of the attribute definition. For details refer to the topic about payload description. This URI path operation has no query parameter.

/um/attributes/groups

For the HTTP method GET:
This URI path operation returns the list of references to the attribute definitions that are available for groups with references to the URI path operation `/um/attributes/groups/`*`attribute name`*. This URI path operation has the following query parameter:

expandRefs=true|*false
If you set this parameter to `true`, the representations of the attribute definitions are embedded in the list of references. The default value is `false`.

/um/attributes/groups/*attribute name*

For the HTTP method GET:
This URI path operation returns a representation of the attribute definition. For details refer to the topic about payload description. This URI path operation has no query parameter.

/um/currentuser/profile

For the HTTP method GET:
This URI path operation returns the profile of the current user. If this operation is performed without authentication, the profile of the anonymous user is returned. This URI path operation has no query parameter.

For the HTTP methods PUT or POST:
This URI path operation updates the user profile with the profile

representation contained in the request body. Only the attributes provided in this representation are considered, therefore post only the attributes that you want to change. This URI path operation has the following query parameters:

update=*replace | merge | delete
This defines how the update is performed. Valid values are as follows:

replace
All attribute values provided in the update replace the existing ones. This is the default.

merge The new attribute values are merged with existing ones. This is only relevant for multi-value attributes.

delete The values of all attributes provided in the update are removed from the profile. Consequently, the actual attribute values given in the update are ignored.

/um/users/profiles
/um/groups/profiles

`For the HTTP method GET:`
This URI path operation returns the list of references to all user or group profiles that correspond to the search criteria and other parameters. If there are no limiting parameters, all available users or groups are returned. The list that is returned is access control filtered for the current user. This URI path operation has the following query parameters:

expandRefs=true | *false
If you set this to `true`, the complete profiles are embedded in the references. The default is `false`.

includeAttributes
The attributes contained in the profiles are limited to those specified in the comma-separated list provided by this attribute. By default, if you omit this parameter, the basic set of attributes is returned for users, or the minimum set of attributes is returned for groups.

memberOf=*unique ID of group*
The response contains only profiles of users or groups that a are member of the specified group.

showNested=true | *false
If you set the `memberOf` parameter, this parameter specifies whether nested groups are considered or not. If you set the parameter to `false`, only direct membership is evaluated. The default value is `false`.

searchAttributes
Use this query parameter to define a search string that specifies various combinations of attribute values as search criteria. All implementations have to support at least values such as *`attribute name`*`%3D`*`attribute value`*, where the attribute value can contain an asterisk (*) as a wildcard character.

identifier
The returned list will contain only the one user or group with

the specified unique identifier. The implementation decides what is to be used as the unique identifier. For example, this can be the distinguished name.

resultsPerPage
The returned list will contain only the given number of results. Additionally, links to additional result pages (first, last, next, previous) will be included in the response, if available.

sortByAttributes
Comma-separated list that specifies the sort order for the results. This is only supported for a paged search.

descending=true | *false
Determines if the sorting according to **sortByAttributes** will be descending.

Note: The parameters `memberOf`, `searchAttributes`, and `identifier` are mutually exclusive. Paged search (resultsPerPage) only works for searchAttributes.

For the HTTP method POST:
This URI path operation creates a new user or group by posting a representation of the related profile. For details refer to the topic about the payload description. This URI path operation has no query parameter.

/um/users/profiles/*unique ID of user*
/um/groups/profiles/*unique ID of group*

For the HTTP method GET:
This URI path operation returns a representation of the user or group profile. For details refer to the topic about the payload description. This URI path operation has the following query parameter:

includeAttributes
The attributes contained in the profiles are limited to those specified in the comma-separated list provided by this attribute. By default, if you omit this parameter, all attributes that hold values are returned.

For the HTTP methods PUT or POST:
This URI path operation updates the user or group profile with the profile representation contained in the request body. Only the attributes provided in this representation are considered, therefore post only the attributes that you want to change. This URI path operation has the following query parameters:

update=*replace | merge | delete
This defines how the update is performed. Valid values are as follows:

replace
All attribute values provided in the update replace the existing ones. This is the default.

merge The new attribute values are merged with existing ones. This is only relevant for multi-value attributes.

delete The values of all attributes provided in the update are removed from the profile. Consequently, the actual attribute values given in the update are ignored.

For the HTTP method DELETE:
This URI path operation deletes the user or group. This URI path operation has no query parameter.

/um/groupmembership/*unique ID of user*
/um/groupmembership/*unique ID of group*

For the HTTP method GET:
This URI path operation returns the list of references to all group profiles of the groups of which the user or the group is a member. Refer to the URI path operations `/um/users/profiles/`*`unique ID of user`* and `/um/group/profiles/`*`unique ID of group`* listed previously. This is also called the membership list; for details refer to the topic about the payload description. This URI path operation has the following query parameters:

expandRefs=true|*false
If you set this to `true`, the complete profiles are embedded in the references. The default is `false`.

includeAttributes
The attributes contained in the profiles are limited to those specified in the comma-separated list provided by this attribute. By default, if you omit this parameter, the basic set of attributes is returned for users, or the minimum set of attributes is returned for groups.

showNested=true|*false
This parameter specifies whether nested groups are considered or not. If you set the parameter to `false`, only direct membership is evaluated. The default value is `false`.

For the HTTP methods PUT or POST:
This URI path operation updates the existing membership list for the user or group by the one that is posted. This URI path operation has the following query parameters:

update=*replace|merge|delete
This defines how the update is performed. Possible values are as follows:

replace
The complete membership list will be replaced by the one posted. This is the default.

merge The user or group are added to the groups contained in the posted membership list in addition to the existing group membership relations of the user or group.

delete The user or group will be removed from all the groups contained in the posted list only.

For the HTTP method DELETE:
This URI path operation deletes the membership list for the user or group; this means that it removes the user or group from all groups. This URI path operation has no query parameter.

Payload description:

The actual data that is processed by the remote REST service for PUMA that is the attributes and their values, user or group profiles, and membership lists, is

described by an XML schema document. This schema is normative for all kinds of input and output formats. Therefore, for representations that are not based on XML, such as JSON, you need to apply an appropriate transformation.

For the complete schema document, refer to the topic that contains the PUMA REST Service XML schema document.

The following sections describe the particular parts of the XML schema in detail.

Attributes and attribute values

The `attribute` element is used to represent either an attribute definition when it is used alone, or an instance of the attribute that includes one or more values when it is used inside a user or group profile. The attribute is identified by the mandatory `name` attribute and can optionally define its type and a flag that specifies whether multiple values are allowed. By convention, the values for the type attribute must be those data types that are defined in the XSD data types specification. For more information, see the section about data types. The attribute values are represented as separate elements called `attributeValue` that can contain arbitrary character data.

```
<xs:element name="attribute">
      <xs:complexType>
         <xs:sequence>
            <xs:element ref="attributeValue" minOccurs="0" maxOccurs="unbounded"/>
         </xs:sequence>
            <xs:attribute name="name" type="xs:string" use="required"/>
            <xs:attribute name="type" type="xs:string" use="optional"/>
            <xs:attribute name="multiValued" type="xs:boolean" use="optional" default="false"/>
      </xs:complexType>
   </xs:element>
<xs:element name="attributeValue" type="xs:string">
```

The following is an example of a stand-alone attribute definition that is represented in plain XML:

```
<um:attribute xmlns:um="um" name="ibm-hobby" type="xs:string" multiValued="true"/>
```

The usage of the `attribute` element for representing attribute values is shown in the next section.

Profile data

Profiles are represented in a `profile` element that needs to define the type of the profile as restricted to the values `user` or `group` in an attribute. Wrapped inside the `profile` element there can be a sequence of arbitrary length of `attribute` elements. In this case, these `attribute` elements must contain attribute value elements.

```
<xs:element name="profile">
    <xs:complexType>
        <xs:sequence>
            <xs:element ref="attribute" maxOccurs="unbounded"/>
        </xs:sequence>
        <xs:attribute name="type" type="profileType" use="required"/>
        <xs:attribute name="identifier" type="xs:string" use="optional"/>
    </xs:complexType>
</xs:element>
<xs:simpleType name="profileType">
    <xs:restriction base="xs:string">
        <xs:enumeration value="user"/>
        <xs:enumeration value="group"/>
    </xs:restriction>
</xs:simpleType>
```

The following is an example of a user profile according to this schema:

```
<um:profile type="user" identifier="uid=bob,o=defaultWIMFileBasedRealm">
    <um:attribute name="uid" type="xs:string" multiValued="false">
        <um:attributeValue>bob</um:attributeValue>
    </um:attribute>
    <um:attribute name="cn" type="xs:string" multiValued="false">
        <um:attributeValue>Bob</um:attributeValue>
    </um:attribute>
    <um:attribute name="ibm-hobby" type="xs:string" multiValued="true">
        <um:attributeValue>Running</um:attributeValue>
        <um:attributeValue>Baseball</um:attributeValue>
    </um:attribute>
</um:profile>
```

Group membership list

The groups membership list lists all groups of which a particular user or group is a member. The representation of the group membership list uses a special element `profileRef` that is used to represent a reference to a profile. This element contains a reference to the resource that is described by the profile; it can optionally also contain the complete profile element itself. This action is done by the mandatory `uri` attribute, which must contain the URL path of the profile, for example `/um/secure/groups/profiles/myGroupId`. The profile reference elements are then aggregated to a list within the `groupMembershipList` element. The list points to those groups of which the user or group that is defined by the resource URL is a member.

```
<xs:element name="profileRef">
    <xs:complexType>
        <xs:sequence>
            <xs:element ref="profile" minOccurs="0⌂" maxOccurs="1"/>
        </xs:sequence>
        <xs:attribute name="uri" type="xs:string" use="required"/>
    </xs:complexType>
</xs:element>
<xs:element name="groupMembershipList">
    <xs:complexType>
        <xs:sequence>
            <xs:element ref="profileRef" maxOccurs="unbounded" minOccurs="0"/>
        </xs:sequence>
    </xs:complexType>
</xs:element>
```

The following listing shows an example of a group membership list XML representation that is based on the schema:

```
<um:groupMembershipList>
    <um:profileRef uri="/wps/um/secure/groups/profiles/8eAeK . . . . . BQIMK5D1"/>
    <um:profileRef uri="/wps/um/secure/groups/profiles/8eAeK . . . . . FADFJABC"/>
</um:groupMembershipList>
```

```

Error codes:

If the operations described previously fail for some reason, the remote REST service for PUMA returns a subset of the HTTP error codes. They include a message with a detailed description of the error.

The following list gives the error codes that the remote REST service for PUMA can return, and typical situations in which each specific error code is returned.

400 - Bad Request
The input provided in the request body does not comply to the expected format. For example, this can be invalid XML in a posted profile.

401 - Unauthorized
Access control check during request processing failed.

403 - Forbidden
The operation that the client tries to perform is not possible. For example, this can be creating a user ID that already exists, setting attribute values for attributes that are not defined, or using mutually exclusive request parameters.

404 - Not Found
The URI does not match any of the defined URI paths or a variable part of a defined URI path does not denote a resource that exists.

405 - Method Not Allowed
The request addresses a defined URI, but uses an HTTP method that is not defined for this URI.

415 - Unsupported Media Type
The format specified in the mime-type URI parameter or accept headers is not supported.

Data types for attributes:

Data types for attributes belong to a subset of the XML Schema data type specification.

You can use the following of data types with the PUMA REST API:

xs:string
String value or string representation of an arbitrary object.

xs:long
Number of type Long.

xs:integer
Number of type Integer.

xs:double
Number of type Double.

xs:dateTime
A timestamp with this format: `yyyy-MM-dd'T'HH:mm:ss`

xs:anyURI
URI path to a resource defined by the remote REST service for PUMA, for example to reference a user profile. This can be an absolute URL that includes the server name or a URI that denotes the absolute path.

xs:hexBinary
A hex encoded binary string.

Note: The Puma REST API converts the preceding data type names to conform with the XML Schema Definition (XSD) language.

How the portal implements the remote PUMA REST service

The previous topics describe the general part of the remote REST service for PUMA Interface. This interface can be implemented by different providers that can be based on different backend systems or user repositories and provide their own input and output formats. The implementation of the interface described here is the one based on WebSphere Portal Express Version 8.5.

The implementation described here uses ATOM (refer to RFC 4287) and the ATOM Publishing Protocol as basic input and output format to wrap the resource representations described by the schema in the general part. Additionally, using the remote REST service for PUMA requires that you consider some special aspects described in this section.

"URL path segment for virtual portals" on page 2916
WebSphere Portal Express provides the concept of virtual portals that allows you to manage several separate portals within one portal installation. You can associate each of these virtual portals with a user realm and thereby limit the scope of users or groups that can access it to one realm of the underlying user repository.

"Identifiers used in the Portal Implementation" on page 2916
For the unique identifier in the URLs, the portal uses a string representation of the internal identifier that is considered to be opaque to the client. The identifier that is used for retrieval of users or groups, that is by either the `identifier` or the `memberOf` request parameters, is the unique security name that is associated to the security context in the WebSphere Application Server. The exact matching of the unique security name is part of the security configuration, but in most scenarios it matches the distinguished name (DN). The same identifier is of course also used for the `identifier` attribute in the profile element.

"Access Control Checks" on page 2916
The portal does not allow you to set permissions for attribute definitions. Therefore the remote REST service for PUMA allows requests to some operations only for authenticated users.

"Using ATOM/APP as input and output format" on page 2917
The remote REST service for PUMA uses the ATOM Publishing Protocol (APP) as the primary input and output format. It wraps the elements described by the schema document in the remote REST service for PUMA in appropriate ATOM feed or entry documents. Although this is the default input and output format, the client should specify the mime type `application/atom+xml` either in the `mime-type` request parameter or in the accept header. A more detailed description of how the APP maps to the RESTful interface and some examples are given here.

"Switch for tunneling of HTTP methods" on page 2920
The portal implementation allows you to simulate PUT and DELETE requests by tunneling, that is by using POST requests instead.

"HTTP caching" on page 2921
The remote REST service for PUMA sets the `Cache-Control` HTTP header in the response to `public` for resources that are served without authentication, and to `private` for URIs that require authentication.

"Context root and authentication mechanism" on page 2921
The remote REST service for PUMA is implemented as a servlet that runs as a separate enterprise application on the WebSphere Portal Express server.

"Lookup facility in the portal" on page 2921
For both convenience and alignment to other portal REST services, the portal remote REST service for PUMA offers a lookup facility. This is done by plugging a provider into a reusable lookup facility in the portal. This functionality allows you to retrieve particular URLs of the service by specifying an absolute URI as a parameter to the so-called lookup servlet addressed by `/wps/poc`.

URL path segment for virtual portals:

WebSphere Portal Express provides the concept of virtual portals that allows you to manage several separate portals within one portal installation. You can associate each of these virtual portals with a user realm and thereby limit the scope of users or groups that can access it to one realm of the underlying user repository.

To address this case, the portal remote REST service for PUMA allows you to specify a particular virtual portal for each operation. This operation is then limited to the user realm of that virtual portal. This applies to both of the following:

- The result of the operation. For example, search results are limited to the realm.
- Security checks. The user performing the operation must be member of the realm that is implicitly addressed.

The virtual portal information is represented by two additional path elements `/vp/`*`virtul_portal_url_mapping`* that follow the URL path element `/um` or, respectively, the `/um/secure` path element. When no particular virtual portal is specified, the implementation uses the default virtual portal. For example, if the portal installation defines a virtual portal with the URL mapping `sales` for the user realm SalesPersons, the URL `/wps/um/secure/vp/sales/users/profiles` returns the references to all user profiles in the SalesPersons user realm.

Identifiers used in the Portal Implementation:

For the unique identifier in the URLs, the portal uses a string representation of the internal identifier that is considered to be opaque to the client. The identifier that is used for retrieval of users or groups, that is by either the `identifier` or the `memberOf` request parameters, is the unique security name that is associated to the security context in the WebSphere Application Server. The exact matching of the unique security name is part of the security configuration, but in most scenarios it matches the distinguished name (DN). The same identifier is of course also used for the `identifier` attribute in the profile element.

Access Control Checks:

The portal does not allow you to set permissions for attribute definitions. Therefore the remote REST service for PUMA allows requests to some operations only for authenticated users.

The portal remote REST service for PUMA allows requests to the following operations only for authenticated users by using the `/um/secure` path element:

- `/um/attributes/users`
- `/um/attributes/users/`*`attribute name`*
- `/um/attributes/groups`
- `/um/attributes/groups/`*`attribute name`*

For all other operations, the implementation performs permission checks by using the corresponding Portal Access Control (PAC) settings for users and groups.

Using ATOM/APP as input and output format:

The remote REST service for PUMA uses the ATOM Publishing Protocol (APP) as the primary input and output format. It wraps the elements described by the schema document in the remote REST service for PUMA in appropriate ATOM feed or entry documents. Although this is the default input and output format, the client should specify the mime type `application/atom+xml` either in the `mime-type` request parameter or in the accept header. A more detailed description of how the APP maps to the RESTful interface and some examples are given here.

For details about the APP refer to the draft for the protocol on the internet.

Representing list results as ATOM feeds

All the REST service operations that return lists of resources return an ATOM feed document that represents each portal resource as a single ATOM entry. This applies to the GET cases for the operations `/um/attributes/users`, `/um/attributes/groups`, `/um/users/profiles`, and `/um/groups/profiles`. Depending on the value of the `expandRefs` parameter, the ATOM entries contain a `content` section that embeds the XML representation of the resource according to the schema defined in the interface.

Example 1: This example shows a server response to the `/um/secure/attributes/groups` URI path:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:xs="http://www.w3.org/2001/XMLSchema-datatypes"
           xmlns:um="http://www.ibm.com/xmlns/prod/websphere/um.xsd"
           xmlns:atom="http://www.w3.org/2005/Atom"
           xmlns:xhtml="http://www.w3.org/1999/xhtml">
    <atom:title>Available group attributes</atom:title>
    <atom:author>
        <atom:name>IBM WebSphere Portal</atom:name>
    </atom:author>
    <atom:link href="/wps/um/secure/attributes/groups" rel="self"/>
    <atom:id>um:secure/attributes/groups</atom:id>
    <atom:updated>2006-12-16T17:06:35.609Z</atom:updated>
    <atom:entry>
        <atom:title>cn</atom:title>
        <atom:link href="/wps/um/secure/attributes/groups/cn" rel="self"/>
        <atom:id>um:secure/attributes/groups/cn</atom:id>
        <atom:updated>2006-12-16T17:06:35.609Z</atom:updated>
    </atom:entry>
    <atom:entry>
        <atom:title>description</atom:title>
        <atom:link href="/wps/um/secure/attributes/groups/description" rel="self"/>
        <atom:id>um:secure/attributes/groups/description</atom:id>
        <atom:updated>2006-12-16T17:06:35.609Z</atom:updated>
    </atom:entry>
    <atom:entry>
        <atom:title>createTimestamp</atom:title>
        <atom:link href="/wps/um/secure/attributes/groups/createTimestamp" rel="self"/>
        <atom:id>um:secure/attributes/groups/createTimestamp</atom:id>
        <atom:updated>2006-12-16T17:06:35.609Z</atom:updated>
    </atom:entry>
    <atom:entry>
        <atom:title>modifyTimestamp</atom:title>
        <atom:link href="/wps/um/secure/attributes/groups/modifyTimestamp" rel="self"/>
        <atom:id>um:secure/attributes/groups/modifyTimestamp</atom:id>
        <atom:updated>2006-12-16T17:06:35.609Z</atom:updated>
    </atom:entry>
</atom:feed>
```

Note: The `atom:updated` does not contain any useful information, but it has to be added to comply to the ATOM specification.

Example 2: The same URI including the option to expand the references, that is /um/secure/attributes/groups?expandRefs=true, gives the following server response:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:xs="http://www.w3.org/2001/XMLSchema-datatypes"
           xmlns:um="http://www.ibm.com/xmlns/prod/websphere/um.xsd"
           xmlns:atom="http://www.w3.org/2005/Atom"
           xmlns:xhtml="http://www.w3.org/1999/xhtml">
    <atom:title>Available group attributes</atom:title>
    <atom:author>
        <atom:name>IBM WebSphere Portal</atom:name>
    </atom:author>
    <atom:link href="/wps/um/secure/attributes/groups?expandRefs=true" rel="self"/>
    <atom:id>um:secure/attributes/groups%3FexpandRefs%3Dtrue</atom:id>
    <atom:updated>2006-12-16T17:15:23.391Z</atom:updated>
    <atom:entry>
        <atom:title>cn</atom:title>
        <atom:link href="/wps/um/secure/attributes/groups/cn" rel="self"/>
        <atom:id>um:secure/attributes/groups/cn</atom:id>
        <atom:updated>2006-12-16T17:15:23.391Z</atom:updated>
        <atom:content type="application/xml">
            <um:attribute xmlns:um="um" name="cn"
                          type="xs:string" multiValued="false"/>
        </atom:content>
    </atom:entry>
    <atom:entry>
        <atom:title>description</atom:title>
        <atom:link href="/wps/um/secure/attributes/groups/description" rel="self"/>
        <atom:id>um:secure/attributes/groups/description</atom:id>
        <atom:updated>2006-12-16T17:15:23.391Z</atom:updated>
        <atom:content type="application/xml">
            <um:attribute xmlns:um="um" name="description"
                          type="xs:string" multiValued="true"/>
        </atom:content>
    </atom:entry>
    <atom:entry>
        <atom:title>createTimestamp</atom:title>
        <atom:link href="/wps/um/secure/attributes/groups/createTimestamp" rel="self"/>
        <atom:id>um:secure/attributes/groups/createTimestamp</atom:id>
        <atom:updated>2006-12-16T17:15:23.391Z</atom:updated>
        <atom:content type="application/xml">
            <um:attribute xmlns:um="um" name="createTimestamp"
                          type="xs:dateTime" multiValued="false"/>
        </atom:content>
    </atom:entry>
    <atom:entry>
        <atom:title>modifyTimestamp</atom:title>
        <atom:link href="/wps/um/secure/attributes/groups/modifyTimestamp" rel="self"/>
        <atom:id>um:secure/attributes/groups/modifyTimestamp</atom:id>
        <atom:updated>2006-12-16T17:15:23.391Z</atom:updated>
        <atom:content type="application/xml">
            <um:attribute xmlns:um="um" name="modifyTimestamp"
                          type="xs:dateTime" multiValued="false"/>
        </atom:content>
    </atom:entry>
</atom:feed>
```

Representing resources as ATOM entries

All particular resources are represented in an ATOM entry document. This applies to the GET cases for the operations /um/attributes/users/*attribute name*, /um/attributes/groups/*attribute name*, /um/currentuser/profile, /um/users/profiles/*unique_id_of_user*, /um/groups/profiles/*unique_id_of_group*, /um/groupmembership/*unique_id_of_user*, and /um/groupmembership/*unique_id_of_group*. This means that the XML structure is wrapped in the atom:content element of one atom:entry element. This way useful meta information, such as the link to the resource and an

ID can be returned together with the resource itself. Note that the group membership list is also treated as a single resource that contains the group membership information of one user or group.

The following example retrieves a user profile directly by using the ATOM based output. It shows a useful convenience feature of the implementation: as ATOM allows you to add several `atom:link` elements with certain types, the `related` link element can be used for a shortcut to the group membership URL of the same user. This shortcut is provided for user and group profiles and allows the client to directly follow this link instead of constructing the URL from static and dynamic parts.

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:entry xmlns:xs="http://www.w3.org/2001/XMLSchema-datatypes"
            xmlns:um="http://www.ibm.com/xmlns/prod/websphere/um.xsd"
            xmlns:atom="http://www.w3.org/2005/Atom">
   <atom:title>wpsadmin</atom:title>
   <atom:link href="/wps/um/secure/users/profiles/9eAe . . . K5D1" rel="self"/>
   <atom:link href="/wps/um/secure/groupmembership/9eA . . . K5D1" rel="related"/>
   <atom:id>um:secure/users/profiles/9eAeK2IIK9L59QKQ2 . . . K5D1</atom:id>
   <atom:updated>2006-12-16T17:34:04.406Z</atom:updated>
   <atom:content type="application/xml">
      <um:profile type="user" identifier="uid=wpsadmin,o=defaultWIMFileBasedRealm">
         <um:attribute name="uid" type="xs:string" multiValued="false">
            <um:attributeValue>wpsadmin</um:attributeValue>
         </um:attribute>
         <um:attribute name="cn" type="xs:string" multiValued="false">
            <um:attributeValue>wpsadmin</um:attributeValue>
         </um:attribute>
      </um:profile>
   </atom:content>
</atom:entry>
```

Result for a paged search

The result for a paged search will contain 3 openSearch elements, a link to the first and last page and if available links to previous and next page.

```

POST, PUT and DELETE cases

For the operations of the PUMA SPI REST Service interface that use one of the methods POST, PUT, or DELETE, you do not need to consider anything special from a client perspective when using the APP format. You can use the plain XML format as defined in the schema; you do not need to wrap it into ATOM elements when doing POSTs or PUTs of resources to the server. The client needs to make sure that the correct namespaces and syntax are used for the input that is posted to the server, as the server validates both the payload format defined in the `um.xsd` and the basic ATOM structures. This is not very strict, but elements that are not defined in the ATOM specification are rejected. The client should therefore check the response as follows:

- Successful POST operations to feeds return a response with status code `201 Created`, the `Location` header set to the URI of the new resource, and a representation of the `atom:entry` element that has been created. This is only the case for operations `/um/users/profiles` and `/um/groups/profiles`
- Successful PUT or DELETE operations return a status code of `200 OK`.

Related information:

http://ietfreport.isoc.org/all-ids/draft-ietf-atompub-protocol-11.txt

Switch for tunneling of HTTP methods:

The portal implementation allows you to simulate PUT and DELETE requests by tunneling, that is by using POST requests instead.

By default tunneling is disabled. If you want to enable it, for example because you want to disable PUT and DELETE requests in general, but allow equivalent operations for REST services provided by the portal, set the property `x-method-override.enabled` to the value `true` in the portal configuration service WP ConfigService Resource Environment Provider in the WebSphere Integrated Solutions Console. If you set the property `x-method-override.enabled` to `true` , then the Config Service considers the `x-method-override` request header, when a request comes in. Whether or not to send this header is a decision of the HTTP

client. Although the property name refers to only one replacement, the switch actually applies to both ways of request tunneling as described in the interface.

HTTP caching:

The remote REST service for PUMA sets the `Cache-Control` HTTP header in the response to `public` for resources that are served without authentication, and to `private` for URIs that require authentication.

The expiration time is defined by the `max-age` directive in the same header and can be configured as a number in seconds within the `wp.user.restservice.maxage` environment entry of the remote REST service for PUMA enterprise application. This is called **UserProfileRESTServlet** in the WebSphere Integrated Solutions Console. It defaults to the value `3600` seconds, that is equivalent to one hour.

Context root and authentication mechanism:

The remote REST service for PUMA is implemented as a servlet that runs as a separate enterprise application on the WebSphere Portal Express server.

The starting weight of the application has to be higher than the starting weight of the portal application (usually `wps.ear`) because it needs the portal run time during startup. This is set by the corresponding install and configuration tasks. By default the REST Service application defines the context root `/wps/um`, where the `/wps` part is equivalent to the general portal context path. The `/um` path element is considered to be fix as it is part of the URI path definitions in the RESTful interface.

Using the Portal context path as a prefix for the context root is a necessary prerequisite with regards to the default authentication method that is configured for the servlet, which reuses the application specific form based authentication mechanism implemented in the portal. This way, a request that needs authentication is redirected to the appropriate portal login page. After successful authentication, the portal login again redirects to the previous URL. As this requires a specific handling of the redirect on the client side, it is recommended that clients make sure that a security context exists already before calling operations that involve protected URLs. This is usually the case when running in a portal session context. Alternatively, you can configure the servlet for different authentication methods by changing the `web.xml` descriptor appropriately, for example, for basic or SSL client certificate authentication.

Lookup facility in the portal:

For both convenience and alignment to other portal REST services, the portal remote REST service for PUMA offers a lookup facility. This is done by plugging a provider into a reusable lookup facility in the portal. This functionality allows you to retrieve particular URLs of the service by specifying an absolute URI as a parameter to the so-called lookup servlet addressed by `/wps/poc`.

The absolute URIs for the remote REST service for PUMA can be constructed from the service URL paths or be taken from the `atom:id` elements of the ATOM feeds or entries. The URIs are completely UTF-8 encoded. When constructing a URI manually, you take the URI path after the element `/um/` without a leading slash, add `um:` as URI prefix, and encode the whole expression by using UTF-8. For example, the URL `/um/secure/users/profiles?searchAttributes=uid%3Dwps*` has the URI `um:secure/users/profiles%3FsearchAttributes%3Duid%3Dwps*`. You can then call the URL `/wps/poc?uri=um:secure/users/profiles%3FsearchAttributes`

%3Duid%3Dwps* and get redirected to the corresponding REST service URL. Or, when you use the verb=lookup parameter, which is mandatory for operations other than GET, get an ATOM feed with the service description such as the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:entry xmlns:atom="http://www.w3.org/2005/Atom" xmlns:xhtml="http://www.w3.org/1999/xhtml">
    <atom:author>
        <atom:name>IBM WebSphere Portal</atom:name>
    </atom:author>
    <atom:id>um:secure/users/profiles?searchAttributes=uid=wps*</atom:id>
    <atom:link href="/wps/um/secure/users/profiles?searchAttributes=uid=wps*"/>
    <atom:title>Remote PUMA REST service URI information</atom:title>
    <atom:updated>2006-12-19T19:21:37.562Z</atom:updated>
</atom:entry>
```

If you need the service description of several REST Service URLs, you can set the uri parameter multiple times by using different URIs, and the lookup servlet will aggregate the descriptions into one ATOM feed.

Portal Access Control interfaces

Portal Access Control provides interfaces for retrieving and modifying and access control information of portal resources, such as portlets or pages.

"Portal Access Control SPI"
The Portal Access Control (PAC) System Programming Interface (SPI) lets you directly retrieve and modify access control information for portal resources.

"Portal Access Control REST API" on page 2923
The Portal Access Control REST API lets you remotely access and modify access control information for resources through the HTTP protocol.

Portal Access Control SPI

The Portal Access Control (PAC) System Programming Interface (SPI) lets you directly retrieve and modify access control information for portal resources.

You can retrieve the following main service interfaces through the AccessControlHome interface.

You can use the **runtime model** of Portal Access Control to evaluate whether a user is allowed to perform a specific operation. For example, you can evaluate whether the user who triggered the request is allowed to do that.

com.ibm.portal.ac.AccessControlHome
Portal Access Control provides interfaces for retrieving and modifying and access control information of portal resources, such as portlets or pages.

com.ibm.portal.ac.AccessControlGlobalRuntimeModel
The AccessControlGlobalRuntimeModel provides read access to the current access control permissions on a resource that is registered at Portal Access Control.

com.ibm.portal.ac.AccessControlRuntimeModel
The AccessControlRuntimeModel provides read access to the current access control permissions on one specific resource.

You can use the **configuration model** to retrieve the hierarchy of protected resources, and also to retrieve and modify role assignments and configuration data such as role blocks.

com.ibm.portal.ac.AccessControlEnvironment
The AccessControlEnvironment provides some general information about the access control configuration, for example the available role types.

com.ibm.portal.ac.ManagedProtectedResource
The ManagedProtectedResource provides read access to the access control configuration of a resource that is registered at Portal Access Control.

com.ibm.portal.ac.ManagedProtectedResourceController
The ManagedProtectedResourceController provides write access to the access control configuration of a resource that is registered at Portal Access Control.

com.ibm.portal.ac.RoleData
The RoleData provides read access to the role data of a single resource, such as role assignments.

Note: For performance reasons, make requests of the form "Is user *x* allowed to perform operation *y* on resource *z* ?" by using AccessControlRuntimeModel or AccessControlGlobalRuntimeModel, rather than by asking for explicit role assignments using the RoleData interface.

com.ibm.portal.ac.RoleDataController
The RoleDataController provides write access to the role data of a single resource, such as role assignments.

com.ibm.portal.ac.ManagedProtectedResourceModel
The ManagedProtectedResource represents the hierarchical tree model of protected resources per database domain.

Examples of how these interfaces are used are provided in the accompanying Javadoc. The following example shows how to evaluate if a principal has view permissions on a resource:

```
Identifiable resource = ... ; // some resource, for example a portlet
Principal bob = ... ; // some principal, for example Bob
Context ctx = new InitialContext();
AccessControlHome home = (AccessControlHome) ctx.lookup(AccessControlHome.JNDI_NAME);
AccessControlEnvironment environment = home.getAccessControlEnvironment();
Permission permission = environment.getPermission(resource, RoleType.USER);
AccessControlGlobalRuntimeModel globalModel = home.getAccessControlGlobalRuntimeModel();
isAllowed = globalModel.hasPermission(bob, permission);
```

Portal Access Control REST API

The Portal Access Control REST API lets you remotely access and modify access control information for resources through the HTTP protocol.

The REST API for Portal Access Control provides the following URIs:

Member Feed
`ac:member:oid:<principalID>@role:<roleTypeName>@oid:<resourceID>`

Member Collection Feed
`ac:member:<roleTypeName>@oid:<resourceID>`

Role Feed
`ac:role:<roleTypeName>@oid:<resourceID>`

Role Collection Feed
`ac:role:oid:<resourceID>`

Resource Config Feed
`ac:resourceconfig:oid:<resourceID>`

Allowed Access Feed
`ac:access:oid:<resourceID>`

Notes:

- Member Collection Feed is defined as a collection.
- Role Collection Feed is defined as a collection.
- Member Collection Feed allows the HTTP method `POST`.
- The available `<roleTypeName>` are listed in the table in the topic Roles.

Supported HTTP methods

Table 454. Supported HTTP methods for feeds

Feed Name	GET method	POST method	PUT method	DELETE method
Member	405	405	405	Removes a member from a role.
Member Collection	Returns all members of a role.	Adds a principal to the specified role.	405	405
Role	Returns a role.	405	405	405
Role Collection	Returns all roles of a resource.	405	405	405
Resource Config	Returns a resource configuration.	405	Modifies the resource configuration.	405
Allowed Access	Returns all access levels that the current user has been granted or has inherited.	405	405	405

Common response elements

The following XML framework is returned for GET requests on each of the feeds. It contains the link to itself, the title of the feed, the ID of the feed, the feed URI, and the timestamp when the feed was created. For collection feeds, the top-level element is an `atom:feed` and `opensearch` elements are included. For the other feeds, the top-level element is an `atom:entry`.

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:xhtml="http://www.w3.org/1999/xhtml"
  xmlns:atom="http://www.w3.org/2005/Atom"
  xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
  xmlns:ac="http://www.ibm.com/xmlns/prod/lotus/access-control/v1.0"
  xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
  xmlns:opensearch="http://a9.com/-/spec/opensearch/1.1/"
  xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base"
  xml:base="http://localhost:10040/wps/mycontenthandler/!ut/p/digest!F4eOOrdKv7QXA2o0iUT9A/T9A
                /ac/member:User@oid:ibm.portal.Home">
  <atom:author>
    <atom:name>IBM WebSphere Portal/6.1.0.3</atom:name>
  </atom:author>
  <atom:title>MemberCollection</atom:title>
  <atom:id>ac:member:User@oid:ibm.portal.Home</atom:id>
  <atom:link href="/wps/mycontenthandler/!ut/p/digest!F4eOOrdKv7QXA2o0iUT9A/ac/member:User@oid:ibm.portal.Home"
            rel="self"
            type="application/atom+xml"/>
  <opensearch:startIndex>0</opensearch:startIndex>
  <opensearch:itemsPerPage>2147483647</opensearch:itemsPerPage>
  <opensearch:totalResults>0</opensearch:totalResults>
  <atom:updated>2009-10-01T06:03:51.850Z</atom:updated>
</atom:feed>
```

Common response elements for collection feeds

For collection feeds, the feed contains a list of `atom:entry` elements. Each entry includes the following additional information: the ID of the entry, the entry's URI, additional links, and a content element that contains the actual information.

```
<atom:entry>
  <atom:id>ac:member:oid:8eAe13RO6G4CL3TGMIPDKBQ6MGHE53P02OTDI3T26M14LRSA6PDE@role:User@oid:
          6_CGAH47L00GN960I4GOF1G510I3</atom:id>
  <atom:title>MemberCollection</atom:title>
  <atom:updated>2009-10-01T05:56:58.341Z</atom:updated>
  <atom:link href="/wps/mycontenthandler/!ut/p/digest!F4eOOrdKv7QXA2o0iU-T9A
                  /ac/member:oid:8eAe13RO6G4CL3TGMIPDKBQ6MGHE53P02OTDI3T26M14LRSA6PDE@role
   :User@oid:6_CGAH47L00GN960I4GOF1G510I3" rel="edit" type="application/atom+xml"/>
  <atom:content type="application/xml">
    <ac:member ac:id="8eAe13RO6G4CL3TGMIPDKBQ6MGHE53P02OTDI3T26M14LRSA6PDE"
               ac:DN="all authenticated portal users" ac:type="virtual"/>
  </atom:content>
</atom:entry>
```

URI variables and their ranges

<roleTypeName>
: Case-insensitive name of a defined role type; for example, Manager, EDitor, usEr.

<resourceID>
: `ObjectID` or `uniqueName` of a resource; for example, `ibm.portal.Home` or `8eAe13RO6G4CL3TGMIPDKBQ6MGHE53P02OTDI3T26M14LRSA6PDE`.

<principalID>
: `ObjectID` of a Principal (user or group); for example, `8eAe13RO6G4CL3TGMIPDKBQ6MGHE53P02OTDI3T26M14LRSA6PDE`.

Member feed and the DELETE method

URI: `ac:member:oid:<principalID>@role:<roleTypeName>@oid:<resourceID>`

Parameters: None.

The HTTP `DELETE` method:

- Deletes the given principal from the given `RoleType` on given resource.
- Equivalent Portal Access Control Java API:
  `accessControlHome.getRoleDataController(resourceID)`

  .
- Returns `200` if successful.
- Returns `404` if `resourceID` cannot be resolved.
- Returns `400` if:
  - `roleTypeName` is not applicable.
  - the according role does not exist.
  - `principalID` cannot be resolved.
  - the current user does not have sufficient access rights.

Member Collection feed and the GET method

URI: `ac:member:<roleTypeName>@oid:<resourceID>`

Parameters:

start-index=*n*
Specifies the *n-th* member of the role will be the first one in the result list.

max-results=*m*
Specifies that at most *m* members will be included.

The HTTP `GET` method:

- Provides all members mapped to a single role for a given resource.
- Equivalent Portal Access Control Java API: accessControlHome.getRoleData(resourceID).getMappedPrincipals(roleType)
- Returns `200` if successful.
- Returns `404` if `resourceID` cannot be resolved.
- Returns `400` if `roleTypeName` is not applicable.

The following is the result of the `GET` method. Each entry element in the member collection contains a single member element that specifies the member identity. The edit link can be used to remove the member from the role (DELETE on member feed).

```
<atom:entry ...>
...
<atom:title>MemberCollection</atom:title>
<atom:entry>
 <atom:id>ac:member:oid:8eAe13RO6G4CL3TGMIPDKBQ6MGHE53P02OTDI3T26M14LRSA6PDE@role:User@oid:
          6_CGAH47L00GN960I4GOF1G510I3</atom:id>
 <atom:title>MemberCollection</atom:title>
 <atom:updated>2009-10-01T05:56:58.341Z</atom:updated>
 <atom:link href="/wps/mycontenthandler/!ut/p/digest!F4eOOrdKv7QXA2o0iUT9A
                  /ac/member:oid:8eAe13RO6G4CL3TGMIPDKBQ6MGHE53P02OTDI3T26M14LRSA6PDE@role:
    Privileged%25252520User@oid:6_CGAH47L00GN960I4GOF1G510I3"
    rel="edit" type="application/atom+xml"/>
 <atom:content type="application/xml">
  <ac:member ac:id="8eAe13RO6G4CL3TGMIPDKBQ6MGHE53P02OTDI3T26M14LRSA6PDE"
             ac:DN="all authenticated portal users" ac:type="virtual"/>
 </atom:content>
</atom:entry>
```

Member Collection feed and the POST method

URI: `ac:member: <roleTypeName>@oid:<resourceID>`

Parameters: None.

The HTTP `POST` method:

- Adds the principal specified in the payload to the given `RoleType` on given resource.
- Equivalent Portal Access Control Java API:
  `accessControlHome.getRoleDataController(resourceID).addPrincipalsToRole(RoleType, Collection<Principal>)`
- Returns `201` if successful.
- Returns `404` if:
  - `resourceID` cannot be resolved.
  - the specified principal cannot be resolved from the distinguished name (DN) or email.
- Returns `400` if:
  - `roleTypeName` is not applicable.
  - specified principal cannot be resolved from `oid`.
  - the current user does not have sufficient access rights.

The `POST` payload for the Member Collection feed is as follows:

UID: ac:member: <roleTypeName>@oid:<resourceID>

The payload needs to include at least the following:

```
<atom:entry xmlns:atom="http://www.w3.org/2005/Atom">
  <atom:content type="application/xml">
    <ac:member xmlns:ac="http://www.ibm.com/xmlns/prod/lotus/access-control/v1.0"
                    ac:id="9eAe6BD86PGCHPD6JMCCG1D8MMG63JD0JM4C3BDAJMK66BC46O"/>
  </atom:content>
</atom:entry>
```

As an alternative to ac:id, which is used to identify a Principal using the ObjectID, you can use the following alternative identifiers:

ac:DN="uid=wpsadmin,o=defaultWIMFileBasedRealm" ac:type="user"
: Specifies the principal using the distinguished name. The type can be user, group or virtual (for virtual principals), where user is the default. Valid Virtual Principals are the ones defined in the following Javadoc: com.ibm.portal.um.PumaEnvironment.VirtualPrincipalNames and are currently **all authenticated portal users**, **all portal user groups**, and **anonymous portal user**.

ac:email="wpsadmin@de.ibm.com"
: Specifies users by their email addresses.

Role feed and the GET method

URI: ac:role:<roleTypeName>@oid:<resourceID>

Parameters:

resolve-membership
: Specify true or false. If true, then members are included. The default is false.

The HTTP GET method:

- Returns information about a single role available for given resource.
- Role is only available if at least one principal is mapped to it, otherwise returns 404.
- Equivalent Portal Access Control Java API: accessControlHome.getRoleData(resourceID).getRole(RoleType).
- Returns 200 if successful.
- Returns 404 if:
  - resourceID cannot be resolved.
  - the role for specified roleTypeName is not available.
- Returns 400 if roleTypeName is not applicable.

The following is the result of the GET method:

```
<atom:entry ...>
  ...
  <atom:title>Role</atom:title>
  <atom:id>ac:role:User@oid:myPage</atom:id>
  <atom:link href="/wps/mypoc/!ut/p/digest!TSVlGy5DI0S5vyp5i_yTw
                  /ac/role:User@oid:myPage?mode=download&amp;resolve-membership=true"
    rel="self" type="application/atom+xml"/>
  <atom:updated>2009-10-01T12:35:05.442Z</atom:updated>
  <atom:link ac:rel="members" href="/wps/mycontenthandler/!ut/p/digest!TSVlGy5DI0S5vyp5i_yTw
           /ac/member:User@oid:6_M8768B1A00FT20I480O8A53000?
   resolve-membership=true" rel="related" type="application/atom+xml"/>
 <atom:content type="application/xml">
  <ac:role ac:type="User">
   <ac:member
     ac:id="8eAeI9EE3J5C63C8JM064RD2JMG613C2MM4C6BP4MM072JD6MI17P9E03R86H1"ac:display-name="wpsadmins"
```

```
    ac:DN="cn=wpsadmins,o=defaultWIMFileBasedRealm" ac:type="group"/>
  </ac:role>
 </atom:content>
</atom:entry>
```

Role Collection feed and the GET method

URI: `ac:role:oid:<resourceID>`

Parameters:

`filter` Specify one of the following values:

`type=<roleTypeName>` to return the specified role, if available.

`inUse` to return available roles. This is the default value.

`all` to return all applicable role types.

`start-index=`*n*

Specifies that the *n-th* member of the role is the first one in the result list.

`max-results=`*m*

Specifies that at most *m* members are included.

URI: `ac:role:oid:<resourceID>`

The HTTP `GET` method:

- Provides information about all roles available for a given resource.
- A role is only available if at least one principal is mapped to it.
- Equivalent Portal Access Control Java API:
  `accessControlHome.getRoleData(resourceID).getRoles()`
- Returns `200` if successful.
- Returns `404` if `resourceID` cannot be resolved.
- Returns `400` if the specified `roleTypeName` is not applicable.

The following is the result of the `GET` method:

```
<atom:feed ...>
  ...
  <atom:title>RoleCollection</atom:title>
  <atom:id>ac:role:oid:myPage</atom:id>
  <atom:link href="/wps/mypoc/!ut/p/digest!TSVlGy5DI0S5vyp5i-yTw/ac/role:oid:myPage?mode=download"
        rel="self" type="application/atom+xml"/>
  <opensearch:startIndex>0</opensearch:startIndex>
  <opensearch:itemsPerPage>2147483647</opensearch:itemsPerPage>
  <opensearch:totalResults>1</opensearch:totalResults>
  <atom:updated>2009-10-01T12:46:16.509Z</atom:updated>
  <atom:entry>
  <atom:id>ac:role:User@oid:6_M8768B1A00FT20I480O8A53000</atom:id>
  <atom:title>RoleCollection</atom:title>
  <atom:updated>2009-10-01T12:46:16.509Z</atom:updated>
  <atom:link ac:rel="members" href="/wps/mycontenthandler/!ut/p/digest!TSVlGy5DI0S5vyp5i-yTw
            /ac/member:User@oid:6_M8768B1A00FT20I480O8A53000"
    rel="related" type="application/atom+xml"/>
  <atom:link href="/wps/mypoc/!ut/p/digest!TSVlGy5DI0S5vyp5i-yTw
                /ac/role:User@oid:6_M8768B1A00FT20I480O8A53000?mode=download"
    rel="self" type="application/atom+xml"/>
  <atom:content type="application/xml">
   <ac:role ac:type="User"/>
  </atom:content>
 </atom:entry>
</atom:feed>
```

Resource Config feed and the GET method

UID: `ac:resourceconfig:oid:<resourceID>`

Parameters: None.

The HTTP GET method:

- Provides configuration information on the following resources:
  - Owner
  - Role blocks
  - IsPrivate
- Equivalent Portal Access Control Java API:

  accessControlHome.getManagedProtectedResource(resourceID)
- Returns 200 if successful.
- Returns 404 if resourceID cannot be resolved.

The following is the result of the GET method:

```
<atom:entry ...>
 ...
 <atom:title>ResourceConfig</atom:title>
 <atom:id>ac:resourceconfig:oid:myPage</atom:id>
 <atom:link href="/wps/mycontenthandler/!ut/p/digest!TSVlGy5DI0S5vyp5i_yTw
                  /ac/resourceconfig:oid:myPage" rel="self" type="application/atom+xml"/>
 <atom:updated>2009-10-01T12:15:59.683Z</atom:updated>
 <atom:content type="application/xml">
  <ac:resource-config>
   <ac:ownerac:id="9eAePPC2JP8C2ROIJMG6M1D8JMG6PPD0JM0723P8JM06KPOC6IH66BOCMQC6N1"
      ac:display-name="wpsadmin"
      ac:DN="uid=wpsadmin,o=defaultWIMFileBasedRealm" ac:type="user"/>
   <ac:role-block ac:block-type="inheritance" ac:type="Privileged User"/>
   <ac:role-block ac:block-type="propagation" ac:type="Delegator"/>
  </ac:resource-config>
 </atom:content>
</atom:entry>
```

Resource Config feed and the PUT method

UID: ac:resourceconfig:oid:<resourceID>

Parameters:

mode Specify one of the following values:

merge to add role blocks to existing ones. The owner is changed if you specify this value.

update to replace existing role blocks and owners. The role blocks and owners are removed if you do not specify them. This is the default value.

The HTTP PUT method:

- Updates the following resource configurations:
  - Owner
  - Role blocks
- Equivalent Portal Access Control Java API:

  accessControlHome.getManagedProtectedResource(resourceID)
- Returns 200 if successful.
- Returns 404 if resourceID cannot be resolved.
- Returns 400 if the current user does not have sufficient access rights.

The PUT payload for the Resource Config feed is as follows:

URI: ac:resourceconfig:oid:<resourceID>

The payload must be as follows:

```
<atom:entry xmlns:atom="http://www.w3.org/2005/Atom"
      xmlns:ac="http://www.ibm.com/xmlns/prod/lotus/access-control/v1.0" >
  <atom:content type="application/xml">
    <ac:resource-config>
      <ac:owner ac:id="9eAe6BD86PGCHPD6JMCCG1D8MMG63JD0JM4C3BDAJMK6"/>
      <ac:role-block ac:block-type="inheritance" ac:type="MANAger"/>
      <ac:role-block ac:block-type="propagation" ac:type="Editor"/>
      <ac:role-block ac:block-type="propagation" ac:type="user"/>
    </ac:resource-config>
  </atom:content>
</atom:entry>
```

The owner and role-block elements are optional.

As an alternative to `ac:id`, which is used to identify the owner using the `ObjectID`, use the following alternative identifiers:

ac:DN="uid=wpsadmin,o=defaultWIMFileBasedRealm" ac:type="user"
: Specifies the principal using the distinguished name. The type can be user, group or virtual (for virtual principals), where user is the default.

ac:email="wpsadmin@de.ibm.com"
: Specifies users by their email addresses.

Allowed Access feed and the GET method

UID: `ac:access:oid:<resourceID>`

Parameters: None.

The HTTP `GET` method:

- Provides run time information on the resource for the current user as follows: All access levels that the current user has on the given resource.
- Equivalent Portal Access Control Java API: There is no 1:1 mapping to the Java API, however, the following API is called for all applicable `roleTypes`:

  ```
  accessControlHome.getAccessControlRuntimeModel(resourceID).hasPermission(roleType)
  ```
- Returns `200` if successful.
- Returns `404` if `resourceID` cannot be resolved.

The following is the result of the `GET` method:

```
<atom:entry...>
 ...
 <atom:title>allowed-access</atom:title>
 <atom:id>ac:access:oid:ibm.portal.Home</atom:id>
 <atom:link href="/wps/mycontenthandler/!ut/p/digest!TSVlGy5DI0S5vyp5i-yTw
                 /ac/access:oid:ibm.portal.Home" rel="self" type="application/atom+xml"/>
 <atom:updated>2009-10-01T12:55:16.620Z</atom:updated>
 <atom:content type="application/xml">
  <ac:allowed-access xmlns:ac="http://www.ibm.com/xmlns/prod/lotus/access-control/v1.0"
                     ac:user-owned="false">
   <ac:access-level ac:type="Administrator"/>
   <ac:access-level ac:type="Security Administrator"/>
   <ac:access-level ac:type="Delegator"/>
   <ac:access-level ac:type="Manager"/>
   <ac:access-level ac:type="Editor"/>
   <ac:access-level ac:type="Contributor"/>
   <ac:access-level ac:type="Privileged User"/>
   <ac:access-level ac:type="User"/>

```

Developing portlets

Get an overview of the process of creating portlets, learn about the concepts of the APIs used to develop portlets, and view the samples to get you started. Also, learn about integrating features such as single sign-on, cooperative sharing of information using the property broker, and migrating Struts applications to the portlet environment.

WebSphere Portal Express supports portlets written to the standard portlet API.

- If you are not an experienced Java developer...

  you can quickly integrate many of your existing resources into WebSphere Portal Express without developing your own portlets.
- If you have Java and servlet development experience but are new to portlet development...

  you should start by reading "Portlet concepts" on page 2932 and "Standard portlet API" on page 2934. When you are ready to start developing portlets, see Portlet creation basics for samples that demonstrate common features of the API.
- If you have experience with Struts applications...

  "Struts Portlet Framework" on page 2943 explains how to take an existing Struts application and convert it to a portlet.
- If you are already familiar with portlet development using either the standard portlet API...

  "Portlet communication" on page 3069 describes how you can enable portlets to share information with other portlets on the page, using the property broker service. "Collaborative Services API and the person tag" on page 3103 explains how you can integrate collaborative functionality into your portlets, such as online status, chat, and email.

Rational Application Developer includes tools designed to help you develop portlet applications for WebSphere Portal Express.

"Portlet concepts" on page 2932
Learn about portlets from a user's and an application developer's perspective. View a brief comparison between a portlet and a servlet and understand basic portlet concepts; know the effect of Java 2 security enablement on the operation of portlets that rely on certain privileges for processing.

"Standard portlet API" on page 2934
The Java Portlet Specification addresses the requirements of aggregation, personalization, presentation, and security for portlets running in a portal environment.

"Portlet services" on page 2937
Portlet services are used to provide common functionality to portlets. Each portlet service has its own service-specific interface for the functionality that it offers.

"Struts Portlet Framework" on page 2943
Learn how to write Struts applications that can be deployed in WebSphere Portal Express. Know special considerations when developing such applications and additional concepts, such as portlet modes, multiple device support, and portlet communication, that might need to be addressed by the Struts application.

"Web 2.0 user interface features" on page 2979
Learn about portal features that pertain to the Web 2.0 generation type of Web user interface.

Portlet concepts

Learn about portlets from a user's and an application developer's perspective. View a brief comparison between a portlet and a servlet and understand basic portlet concepts; know the effect of Java 2 security enablement on the operation of portlets that rely on certain privileges for processing.

Portlets are reusable Web modules that run on a portal server and provide access to Web-based content, applications, and other resources. Companies can create their own portlets or select portlets from a catalog of third-party portlets. Portlets are intended to be assembled into a larger portal page, with multiple instances of the same portlet displaying different data for each user.

From a user's perspective, a portlet is a window on a portal site that provides a specific service or information, for example, a calendar or news feed. From an application development perspective, portlets are pluggable Web modules that are designed to run inside a portlet container of a portal server.

The portlet container provides a run time environment in which portlets are instantiated, used, and finally destroyed. Portlets rely on the portal infrastructure to access user profile information, participate in window and action events, communicate with other portlets, access remote content, lookup credentials, and to store persistent data. The Portlet API provides standard interfaces for these functions. The portlet container is not a stand-alone container like the servlet container. Instead, it is implemented with the servlet container and reuses the functionality provided by the servlet container.

- The Java Portlet Specification API. This is based on javax.portlet interfaces. WebSphere Portal Express supports the Java Portlet Specifications 1.0 and 2.0, also known as JSR168 and JSR286.

You can place both types of portlets on portal pages. However, a portlet cannot mix classes and methods from both packages.

Each portlet on the page is responsible for providing its output in the form of markup fragments to be integrated into the portal page. The portal is responsible for providing the markup surrounding each portlet. In HTML, for example, the portal can provide markup that gives each portlet a title bar with minimize, maximize, help, and edit icons.

Portlets and the Servlet API

Portlets are special types of Web modules designed to run in the context of a portal. They are written to comply with a portlet API that is similar to the servlet API but addresses portal specific areas of concerns. In contrast to servlets, portlets may not send errors directly to browsers, forward requests, or write arbitrary markup to the output stream. Another difference compared to servlets is that portlets rely on specific features of the portal infrastructure, such as user profile information, storing and retrieving persistent settings, and getting client information.

Generally, portlets are administered more dynamically than servlets. Portlet applications consisting of several portlets can be installed and removed using the portal administration interface while the portal server is running. In a similar manner, the settings of a portlet can be changed by an administrator with appropriate access rights at any time without stopping/restarting the portal server Web application. Portlets can be created and deleted dynamically. For example, a clipping administration portlet can create new portlet instances whenever an administrator creates a new clipping.

Java 2 security

Enablement of Java 2 security on the portal server can affect the operation of portlets that rely on certain privileges for processing. If your portlet requires certain privileges, for example, access to the file system or to the network, you might need to package a `was.policy` file in the portlet WAR indicating which privileges are needed. Even more important, any privileges needed by the portlet should be documented for the administrator.

Related concepts:

"Java 2 security with WebSphere Portal Express" on page 1572
Java 2 (J2SE) security provides a policy-based, fine-grain access control mechanism that increases overall system integrity by checking for permissions before allowing access to certain protected system resources. J2SE security allows you to set up individual policy files that control the privileges assigned to individual code sources. If the code does not have the required permissions and still tries to execute a protected operation, the Java Access Controller will throw a corresponding security exception.

The Java Portlet Specification addresses the requirements of aggregation, personalization, presentation, and security for portlets running in a portal environment.

Standard portlet API

The Java Portlet Specification addresses the requirements of aggregation, personalization, presentation, and security for portlets running in a portal environment.

Version 1.0 of the Java Portlet Specification was approved by the Java Community Process in October 2003 as JSR 168. The purpose of the specification is to solve the problem of portlet compatibility between portal servers offered by different vendors. Version 2.0 of the Java Portlet Specification extended the capabilities to include coordination between portlets, resource serving, and other advanced features. The final version 2.0 was approved by the Java Community Process in March 2008 as JSR 286.

WebSphere Portal Express includes a portlet run time environment that supports portlets developed according to the Java Portlet Specification, hereafter called *standard portlets*.

With WebSphere Portal Express there are some IBM specific parameters for portlets available. For more information about these parameters refer to the topic *Deployment descriptors* under the section *Reserved parameter names*.

For portlets conforming to JSR 286, WebSphere Portal Express also includes support for two-phase rendering.

The following topics provide specific information about the implementation of the standard portlet API within WebSphere Portal Express.

"Using two-phase rendering with JSR 286 portlets" on page 2935
For portlets conforming to JSR 286, IBM WebSphere Portal Express includes support for two-phase rendering, which allows portlets to set cookies and the HTTP headers and to change the portal page title dynamically.

Introducing the Portlet Specification, Part 2

Using two-phase rendering with JSR 286 portlets

For portlets conforming to JSR 286, IBM WebSphere Portal Express includes support for two-phase rendering, which allows portlets to set cookies and the HTTP headers and to change the portal page title dynamically.

"Enabling two-phase rendering for a portlet"
By default, two-phase rendering is turned off. To enable two-phase rendering for a portlet, you must update the `portlet.xml` deployment descriptor for the portlet.

"Setting headers for a JSR 286 portlet" on page 2936
To set HTTP header information in your JSR 286 portlet, use the setProperty and addProperty methods of the PortletResponse.

"Setting cookies for a JSR 286 portlet" on page 2936
Although cookies can be set like any other HTTP header, the portlet API provides the addProperty convenience method on the PortletResponse for setting cookies.

"Modifying the HTML head section of a JSR 286 portlet" on page 2936
To write into the HTML head section of your JSR 286 portlet, for example, to change a page title, use the `addProperty` method on the `PortletResponse`.

"Setting portlet caching values for a JSR 286 portlet" on page 2937
You can dynamically modify portlet caching parameters for a JSR 286 portlet during the render phase.

Related reference:

"WSRP two-phase rendering" on page 1501
The WSRP Consumer and the WSRP Producer in the portal support two-phase rendering for JSR 286 portlets. Two-phase rendering allows a remote portlet to set headers and cookies and to modify the HTML head section.

Enabling two-phase rendering for a portlet:

By default, two-phase rendering is turned off. To enable two-phase rendering for a portlet, you must update the `portlet.xml` deployment descriptor for the portlet.

Procedure

Edit the `portlet.xml` file for the portlet. Add the following entry to the file:

```
<portlet>
    ...
    <container-runtime-option>
        <name>javax.portlet.renderHeaders</name>
        <value>true</value>
    </container-runtime-option>
</portlet>
```

Setting headers for a JSR 286 portlet:

To set HTTP header information in your JSR 286 portlet, use the setProperty and addProperty methods of the PortletResponse.

Procedure

Specify the appropriate method, depending on whether you want to overwrite or append key values.

- `setProperty(String key, String value)`: Overwrites all previous values for the given key.
- `addProperty(String key, String value)`: Attempts to append the key value.

When setting headers in the render lifecycle phase, portlets should set the header in the render headers part or simply override the GenericPortlet.doHeaders method to make sure the server's response headers have not already been committed. Note, however, that the delivery of HTTP headers to the client cannot be guaranteed, because other portlets on a page might override it or the setting of some header attributes might be against the portal's policy.

Setting cookies for a JSR 286 portlet:

Although cookies can be set like any other HTTP header, the portlet API provides the addProperty convenience method on the PortletResponse for setting cookies.

Procedure

Invoke the addProperty method to set cookies.

- PortletReponse.addProperty(javax.servlet.http.Cookie cookie)

Note: When setting cookies, you must invoke the addProperty method before the response headers are committed. This should occur no later than during the render headers sub phase of the render lifecycle phase.
Example:

```
protected void doHeaders(RenderRequest request, RenderResponse response)
{
    ...
    Cookie c = new Cookie("myCookieName", "myCookieValue");
    c.setPath(request.getContextPath());
    response.addProperty(c);
    ...
}
```

Modifying the HTML head section of a JSR 286 portlet:

To write into the HTML head section of your JSR 286 portlet, for example, to change a page title, use the `addProperty` method on the `PortletResponse`.

Procedure

Invoke the `addProperty` method to modify the HTML head section.

- `PortletReponse.addProperty(String key, org.w3c.dom.Element element)`

Note: When modifying the HTML head section, you must invoke the `addProperty` method before the response headers are committed. This should occur no later than during the render headers sub phase of the render lifecycle phase.

Example

Example:

```
protected void doHeaders(RenderRequest request, RenderResponse response)
{
 Element title = response.createElement("title");
        title.setTextContent("My Portal Page Title");
        response.addProperty(MimeResponse.MARKUP_HEAD_ELEMENT, title);
}
```

What to do next

If you add a script tag to the portlet head section, be sure to add text to the tag. If you do not add text, the script tag is not closed properly. Consider the following incorrect code sample from a `doHeader` :

```
String url = "/sample.js";
Element scriptElement = response.createElement(Tag.SCRIPT.toString());
scriptElement.setAttribute(Attribute.TYPE.toString(), "text/javascript");
scriptElement.setAttribute(Attribute.SRC.toString(), url);
response.addProperty(MimeResponse.MARKUP_HEAD_ELEMENT, scriptElement);
```

This generates a script tag in the header like as follows:

```
<script src="/sample.js" type="text/javascript" />
```

This causes rendering problems in Mozilla FireFox and other browsers.

The code needs to call `setTextContent` with a non-empty string as given in the fifth line of the following code sample:

```
String url = "/sample.js";
Element scriptElement = response.createElement(Tag.SCRIPT.toString());
scriptElement.setAttribute(Attribute.TYPE.toString(), "text/javascript");
scriptElement.setAttribute(Attribute.SRC.toString(), url);
scriptElement.setTextContent(" ");
response.addProperty(MimeResponse.MARKUP_HEAD_ELEMENT, scriptElement);
```

This generates a properly closed script tag in the header as follows:

```
<script src="/sample.js" type="text/javascript"> </script>
```

Setting portlet caching values for a JSR 286 portlet:

You can dynamically modify portlet caching parameters for a JSR 286 portlet during the render phase.

Procedure

Update the doHeaders call in the javax.portlet.CacheControl object to set the portlet caching parameters.
The following sample code sets the portlet's cache scope to private and the cache expiration time to a value of 30 seconds.

```
protected void doHeaders(RenderRequest request, RenderResponse response)
{
  response.getCacheControl().setExpirationTime(30);
  response.getCacheControl().setPublicScope(false);
}
```

Portlet services

Portlet services are used to provide common functionality to portlets. Each portlet service has its own service-specific interface for the functionality that it offers.

WebSphere Portal Express supports portlet services for both IBM portlets and standard portlets:

- Standard portlets use a JNDI lookup to retrieve a `PortletServiceHome` object, which is used to retrieve a portlet service implementation.
- IBM portlets retrieve portlet services using the PortletContext.getService() method.

A portlet service can be invoked only from within a portlet.

Portlet service interfaces used by standard portlets are different from those used by IBM portlets. You can write your own portlet service and register it in the portal, so that all portlets can use it. Various services may be implemented by different vendors, for example, a SearchService, LocationService, or a MailService. The following services are available with WebSphere Portal Express:

- ContentAccessService
- CredentialVaultService
- Model SPI services
- PumaHome
- DynamicUIManagementFactoryService

"Accessing portlet services"
Using an example, learn how a standard portlet can retrieve and use a sample portlet service. Accessing a portlet service requires a JNDI lookup for a PortletServiceHome. To use the portlet service, you retrieve a service object from the home, cast it to the service-specific interface and invoke service methods.

"Creating your own portlet service" on page 2939
Write a portlet service by defining the interface, writing the service implementation, making the service accessible, and registering the service.

Accessing portlet services

Using an example, learn how a standard portlet can retrieve and use a sample portlet service. Accessing a portlet service requires a JNDI lookup for a PortletServiceHome. To use the portlet service, you retrieve a service object from the home, cast it to the service-specific interface and invoke service methods.

This section describes how a portlet can invoke a portlet service. See "Portlet services" on page 2937 for a general overview of portlet services. The following example shows how a standard portlet can retrieve and use a sample portlet service. The service implementation and deployment is explained in "Creating your own portlet service" on page 2939.

Accessing a portlet service requires a JNDI lookup for a PortletServiceHome. As this is may be a rather expensive operation, you should do it in the init() method of the portlet and store the returned object in an instance variable:

```
import javax.portlet.*;
import com.ibm.portal.portlet.service.*;

private PortletServiceHome helloServiceHome = null;
...

public void init(PortletConfig config)
{
   javax.naming.Context ctx = new javax.naming.InitialContext();
   try {
       Object home =
             ctx.lookup("portletservice/sample.portletservice.HelloService");
```

```
        if (home != null)
                helloServiceHome = (PortletServiceHome) home;
    } catch(javax.naming.NameNotFoundException ex) {
    // we can do without the service, if it is not available
    config.getPortletContext().log("No hello service available");
    }
}
```

The example is written to gracefully handle a situation where the service is not available because the service is optional for the functionality of the portlet. If possible, you should write your portlets so that they are portable across portal installations, whether they support a given portlet service or not. Such portlets can still run on portals that have not support for portlet services at all and do not even provide the IBM-specifc PortletServiceHome class, because this class is only loaded when the service is actually registered in JNDI.

To use the portlet service, you retrieve a service object from the home, cast it to the service-specific interface and invoke service methods:

```
public void doView(RenderRequest request, RenderResponse response)
{
   if (helloServiceHome != null)
   {
      HelloService service =
            (HelloService) helloServiceHome.getPortletService(HelloService.class);
      service.sayHello(request, response);
   }

   //... do other stuff
}
```

Note that, while it is good practice to store the PortletServiceHome object in an instance variable, you must not store the actual service object, because references to service objects may not be held for longer than a single request.

- "Creating your own portlet service"

Creating your own portlet service

Write a portlet service by defining the interface, writing the service implementation, making the service accessible, and registering the service.

Writing a portlet service consists of four steps:

The service provider interfaces can be used to write portlet services for Standard portlets. The IBM Portlet API is no longer supported starting with WebSphere Portal Express Version 8.5.0. You must convert portlets based on the IBM Portlet API to the Standard Portlet API. Learn how to convert IBM Portlets to Standard API portlets.

Defining the interface

This step is not required if you want to implement your service against an existing interface. Defining a portlet service interface requires the same careful considerations as defining any public API interface. A portlet service interface must extend the `PortletService` interface defined in the `com.ibm.portal.portlet.service` package. The following is an example interface for the `HelloWorldService` .

```
package sample.portletservice;

import java.io.IOException;
import javax.portlet.RenderRequest;
import javax.portlet.RenderResponse;
import com.ibm.portal.portlet.service.PortletService;

public interface HelloService extends PortletService
{
    /** print a nice greeting */
    public void sayHello(RenderRequest request, RenderResponse response)
           throws IOException;
}
```

Figure 38. Extending the PortletService interface

Writing the service implementation

The service implementation must implement the `PortletServiceProvider` interface of the `com.ibm.portal.portlet.service.spi` package to be able to make use of the portlet service life cycle methods in addition to your service interface. The `PortletServiceConfig` parameter of the init() method allows you, for example, to access the configuration of the service (see "Registering the service" on page 2942 for more information).

```
package sample.portletservice;

import java.io.IOException;
import java.io.PrintWriter;
import java.util.prefs.Preferences;

import javax.portlet.RenderRequest;
import javax.portlet.RenderResponse;

import com.ibm.portal.portlet.service.spi.PortletServiceProvider;

public class HelloServiceImpl
    implements HelloService, PortletServiceProvider {

    private String message;

    // called by the portal when the service is initialized
    public void init(Preferences servicePreferences) {

        // read the message from the configuration, default is "Hello"
        message = servicePreferences.get("message", "Hello");
    }

    public void sayHello(RenderRequest request, RenderResponse response)
                throws IOException {
        String user = request.getRemoteUser();
        if (user == null)
            // no user logged in
            user = "Stranger";

        PrintWriter out = response.getWriter();
        out.print(message);
        out.print(", ");
        out.print(user);
    }

}
```

Figure 39. Implementing the PortletServiceProvider interface

Making the service accessible for IBM portlets

This step is optional. If you want your portlet service to be available for IBM portlets, you need to create an additional service interface that extends `org.apache.jetspeed.portlet.service.PortletService` and provides the same functionality.

```
package sample.portletservice;

import java.io.IOException;
import org.apache.jetspeed.portlet.PortletRequest;
import org.apache.jetspeed.portlet.PortletResponse;
import org.apache.jetspeed.portlet.service.PortletService;

public interface HelloServiceIBM extends PortletService {

    /** print a nice greeting */
    public void sayHello(PortletRequest request, PortletResponse response) throws IOException;

}
```

Figure 40. Extending the PortletService interface for IBM portlets

You can have a single implementation that is registered for both interfaces and implements both. If the service methods take arguments that are classes or interfaces from the portlet API, the method signatures are different for the two service interfaces. You can still use a common implementation for both interfaces by using the `APIConverterFactory` class of the `com.ibm.portal.portlet.apiconvert` package. This class includes methods that wrap objects from the IBM portlet API, such as `PortletRequest` and `PortletSession`, and implement the corresponding standard portlet API objects on the service side, so that you can re-use your service implementation for standard portlets.

```
package sample.portletservice;

import java.io.IOException;
import java.io.PrintWriter;
import java.util.prefs.Preferences;

import javax.portlet.RenderRequest;
import javax.portlet.RenderResponse;

import org.apache.jetspeed.portlet.PortletRequest;
import org.apache.jetspeed.portlet.PortletResponse;

import com.ibm.portal.portlet.apiconvert.APIConverterFactory;
import com.ibm.portal.portlet.service.spi.PortletServiceProvider;

public class HelloServiceImpl2
    implements HelloService, HelloServiceIBM, PortletServiceProvider {

    private String message;

    // called by the portal when the service is initialized
    public void init(Preferences servicePreferences) {

        // read the message from the configuration, default is "Hello"
        message = servicePreferences.get("message", "Hello");
    }

    public void sayHello(RenderRequest request, RenderResponse response)
                throws IOException {
        String user = request.getRemoteUser();
        if (user == null)
            // no user logged in
            user = "Stranger";

        PrintWriter out = response.getWriter();
        out.print(message);
        out.print(", ");
        out.print(user);
    }

    public void sayHello(PortletRequest request, PortletResponse response)
                throws IOException {
        sayHello (APIConverterFactory.getInstance().getRenderRequest(request),
            APIConverterFactory.getInstance().getRenderResponse(response));
    }

}
```

Figure 41. Using the APIConverterFactory class

Registering the service

1. Put all service interface and implementation classes into a JAR file.
2. Place the JAR file in the *wp_profile_root*/PortalServer/config directory.
3. Register the new portlet service with the WP PortletServiceRegistryService resource environment provider in the WebSphere Integrated Solutions Console.
   - Create an entry to register the implementation in the JNDI directory. The name for this entry is jndi.*service_interface* and the value is *service_implementation*. The fully qualified service interface name can then be used to lookup the service.
   - Optional: Provide configuration parameters for the implementation. The name for this entry is *service_implementation*.parameter and the value is the required parameter value.
4. Restart WebSphere Portal Express to activate the new settings.

In the following example, `HelloService` is the name of the portlet service, `HelloServiceIBM` is the name of the interface for IBM portlets, and the `message` configuration parameter is set with the value `Greetings`.

Note: The colon (:) used in previous versions of WebSphere Portal Express to designate JNDI entries with `jndi:` is not supported for resource environment providers. Use `jndi.` instead.
To register this portlet service, add the following property names and values to the `PortletServiceRegistryService`:

Property name	Value
`jndi.sample.portletservice.HelloService`	`sample.portletservice.HelloServiceImpl2`
`sample.portletservice.HelloServiceIBM`	`sample.portletservice.HelloServiceImpl2`
`sample.portletservice.HelloServiceImpl2.message`	`Greetings`

Tip: To check whether your service has been registered successfully, use the application server **`dumpNamespace`** tool. The following command, run from the *AppServer_root*`/bin` directory, lists all portlet service entries in JNDI:

```
dumpNamespace -port bootstrap_port -root server -startAt portletservice
```

Using the WebSphere Integrated Solutions Console, you can find the bootstrap port of your portal server in the "End Points" section of the settings for the server "WebSphere_Portal".

Struts Portlet Framework

Learn how to write Struts applications that can be deployed in WebSphere Portal Express. Know special considerations when developing such applications and additional concepts, such as portlet modes, multiple device support, and portlet communication, that might need to be addressed by the Struts application.

Struts is a popular open source project for implementing Web applications using a Model-View-Controller design pattern. Struts has an active development community and continues to evolve. The user community is equally active and many Web applications have been implemented using Struts. The Struts framework can be used to effectively design the Web application. The framework supports both large or small development teams as well as organizations that need to split the development work between specialists (for example, between user interface designers and programmers). The reasons that Struts has became popular for the servlet environment apply for portlets as well. This document introduces the Struts Portlet Framework, which adds support for writing Struts applications that can be deployed in WebSphere Portal Express.

Developers that have worked with Struts in the servlet environment should adapt easily to the Struts Portlet Framework. The packaging of a Struts portlet application is very similar to a Struts application in the servlet environment. However, WebSphere Portal Express also introduces additional concepts, such as portlet modes, multiple device support, and portlet communication, that might need to be addressed by the Struts application. This document provides information about special considerations when developing Struts applications for the portlet environment.

For more detailed information, you can find numerous sources available about Struts. The Struts website offers resources for developers, including a User Guide, Javadoc information, and the source code. There are also several excellent books on

Struts that are referenced from the Struts website. These references describe in detail the aspects of designing and implementing a Web application using Struts. For more information about Struts, see the link to the Struts Application Framework.

The Struts Portlet Framework ships several example WAR files, including source code, that demonstrate how to implement a Struts application in WebSphere Portal Express and also how to exploit portal features, such as portlet modes and device support. Throughout this documentation, source code from `SPFLegacyMailReader.war` and `SPFStandardMailer.war` is used to demonstrate the changes necessary to enable a Struts Web application to be deployed and run as a portlet. `SPFLegacyMailReader.war` is available on the WebSphere Portal Express Catalog.

The following subtopics describe the development of Struts applications in the portal environment.

"Changes to Struts application code" on page 2945
Learn about the main differences between a servlet-based Struts application and a Struts application created for the portal environment.

"Changes to Struts JSPs" on page 2955
The JSPs for Struts applications in the portal environment have to be modified to adapt to the way the portal server expects portlet URIs to be created. There are some changes to the tag library for HTML markup and additional tag libraries have been added to support cHTML and WML markup.

"Changes to configuration files" on page 2958
Struts Portlet Framework-specific init parameters were added so you can customize the Struts application for the portal environment. The portlet and web deployment descriptors require configurations specific to the Struts Portlet Framework. In addition, changes to the Struts configuration file must be made to specify a portal specific request processor as the controller.

"Supporting multiple Struts applications" on page 2972
Learn how web applications that allow packaging more than one Struts-based portlet in a single application can be created either using Struts modules or a namescoped servlet context.

"Create link tags in Struts" on page 2975
Get an overview of how to write tags to create links in a JSP in both a servlet and a portlet in Struts framework.

"Formatting XML documents with XSLT" on page 2976
Learn how a Struts application supports applying a style sheet to XML data.

"Static content in Struts" on page 2976
Portlet JSPs can link to the static content within the portlet's WAR directory structure by using the services of the portlet container to create portlet URIs from which the content can be referenced.

"Migrating existing Struts applications" on page 2977
Get an overview of how the existing Struts applications can be migrated using the Struts Portlet Framework so that these applications can be deployed in IBM WebSphere Portal Express.

The Struts Application Framework

Changes to Struts application code

Learn about the main differences between a servlet-based Struts application and a Struts application created for the portal environment.

Comparison of servlets and portlets

There are two main differences between the portlet and servlet environment that affects a Struts application in WebSphere Portal Express.

1. Action processing and rendering

   All servlet processing occurs during the service() method. The Struts rendering of the page is usually immediately preceded by action processing; they are essentially part of one step. The request and response object are passed to the service() method, which writes the resulting output to the response object. The servlet-based Struts RequestProcessor is designed to complete the Struts action processing and eventually forward, based on the URI, to a JSP or another Struts action.

   Portlet processing, however, is implemented in two phases, an event phase and a render phase. Action processing is performed prior to rendering the display view. Only the request object is passed to the portlet during the event phase. When a Struts application is migrated to the portlet environment, some of the information that was available during the event phase, namely the request parameters, is no longer available during the render phase. Additionally, since rendering methods, such as doView(), can be called when the portlet page is refreshed without a new event occurring for that portlet, all information required to render the page must be available every time that method is called.

   Note: The struts action is not invoked when moving between modes (view, edit, and configure). Only the service method is called (doView, doEdit) when switching modes. To cause the struts action to fire, place a call to that action in these methods.

   The Struts Portlet Framework provides a RequestProcessor that creates an IViewCommand. IViewCommand encapsulates the information so that the command object can be rendered at a later time, during the rendering method. IViewCommand and IViewCommandFactory are discussed in Saving information for rendering the view.

2. URI construction

URIs are constructed differently for portlets than for servlets. The portlet creates the URI programmatically using the PortletResponse object. The Struts Portlet Framework has modified the tags in Struts so that they create portal links. The Struts link tags behave the same as they do in the servlet environment, but the URL is a portlet URL and the Struts URL is passed as a parameter on the URL.

Saving information for rendering the view

A command pattern can be used to encapsulate the rendering of the view, and the information required during this rendering (See *Design Patterns: Elements of Reusable Object-Oriented Software* by Gamma, Helm, Johnson, and Vlissides for more information about the command design pattern). The pattern is implemented using the `IViewCommand` interface.

During the action processing, information needed to render the view needs to be saved, including the path to the page to be displayed. Also, for a JSP in a Struts application, the associated `ActionForm` is normally needed in order to complete the page. So, any `ActionForm` attributes need to be saved along with the path to the page to render. The attributes that are saved with a command should be limited because, since the action processing and view rendering steps involve separate requests, the command is saved in session. Since the session information may need to be serialized in a high availability environment, it is important to minimize the amount of data stored in the session wherever possible. Thus, the `ActionForm` is typically needed, this is saved by default.

In doView() processing, nothing needs to be known about the IViewCommand except that it should be executed. The execute method of the IViewCommand receives the request and response objects as parameters. As part of the processing, the previously saved attributes are populated into the request object that is passed in on the execute method.

Also, during the render phase, an execution context object (`ViewCommandExecutionContext`) is passed in on the execute call, which provides additional objects to help with the actual execution. You can save additional information with the view command and provide additional objects and information in the command execution context.

Note: For more information about `IViewCommand`, refer to the Javadoc documentation for the com.ibm.portal.struts.command package. The product Javadoc documentation is located at *`PortalServer_root`*`/doc/Javadoc/api_docs/` directory. Also see Using the command factory.

Updating ActionForm in the render phase

Some Struts applications may need to refresh the beans for the render phase every time the portlet renders. If the user is interacting with the portlet and clicking action links then the portlet will have an action phase and then followed by a render phase. The typical scenario is the case where an action phase does not precede the render phase. For example, if a user is interacting with another portlet on the page, then only that portlet has an action phase. The other portlets on the page may need to refresh the data to be rendered. The Struts action that implements the IStrutsPrepareRender action can read data from the model and update the ActionForm bean associated with the JSP through the information available through the ActionMapping. The page controller action is executed in the render phase of the portal server and therefore cannot change portlet state

or write to the model. It also cannot interact with other portlets using Property Broker or portlet messaging. The collaboration between portlets must occur during the action phase of the portal server.

The IStrutsPrepareRender interface is way to indicate that a Struts action should be called in the render phase of portal, for the specific task of refreshing the data to be displayed. When the Struts Portlet Framework Request Processor detects a Struts Action that implements the IStrutsPrepareRender in the action phase, the request processing is stopped and the ViewCommandFactory is called to create a WpsStrutsViewActionCommand object. The WpsStrutsViewActionCommand object is then executed in the render phase of the portal, at which time the request processor will be called again to execute the Struts action. A Struts action implementing IStrutsPrepareRender may forward to another Struts action that implements the Prepare-Render interface or to the JSP that renders the view. To see an example of how to use the IStrutsPrepareRender interface, see the Stock Quote portlet or Clock portlet. Both of these portlets are available for download from the WebSphere Portal Express Business Solutions Catalog.

Stock Portlet Sample:

The Stock Quote portlet is a Struts application that allows configuring companies in the edit portlet mode, and then the Stock Quotes for the portlet are displayed in the view mode. The quotes are supplied by a StockService, which returns random numbers, but the StockQuoteService could be replaced by a real service. The Stock Quote sample also uses a Struts Action that implements the IStrutsPrerpareRender so the stock quotes are refreshed even if a request phase does not precede the render phase.

```
public class RefreshAction extends Action implements IStrutsPrepareRender
{
  // ----------------------------------------------- Instance Variables
   /**
    * The Log instance for this application.
    */
    private Log log =
       LogFactory.getLog(this.getClass());

  // ------------------------------------------------ Public Methods
   /**
    * This action will refresh the stock quotes and then forwards to an
    * ActionForward for displaying the quotes.
    *
    * @param mapping The ActionMapping used to select this instance
    * @param form The optional ActionForm bean for this request (if any)
    * @param request The HTTP request we are processing
    * @param response The HTTP response we are creating
    *
    * @exception Exception if the application business logic throws
    *  an exception
    */
    public ActionForward execute(ActionMapping mapping,
                         ActionForm form,
                         HttpServletRequest request,
                         HttpServletResponse response)
           throws Exception
   {
      HttpSession httpSession = request.getSession();
        //-----------------------------------------------------------
        // Get the SubscribedNewsgroupsBean. This should have been
        // put in the session earlier
        //-----------------------------------------------------------
        SubscribedCompaniesBean subscribedCompaniesBean =
          ( SubscribedCompaniesBean )
            httpSession.getAttribute( Constants.SUBSCRIBED_COMPANIES );

        ActionForward actionForward = mapping.findForward("welcome");
```

```
        if ( subscribedCompaniesBean != null )
        {
          log.debug("Refresh quotes");

          Collection companies = subscribedCompaniesBean.getCcompanies();
          if ( companies != null )
          {
            StockQuoteService stockQuoteService =
                              new StockQuoteService();
            Iterator iterator = companies.iterator();
            while ( iterator.hasNext() )
            {
              CompanyBean companyBean = ( CompanyBean ) iterator.next();
              try
              {
                log.debug("Get quote for company " +
                                          companyBean.getSymbol() );
                float quote =
                      stockQuoteService.getQuote(companyBean.getSymbol());
                companyBean.setQuote( Float.toString( quote) );
              }
              catch ( Exception ex )
              {
                companyBean.setQuote( "---");
              }
              subscribedCompaniesBean.addCompany(companyBean.getName(),
                                                    companyBean );
            }
          }
        }
        return actionForward;
    }
}
```

Response object

During portlet action processing the response object is not available. The methods called during Struts processing expect both a request and response. To address the need for a response object, the Struts Portlet framework creates a temporary one. Other than for calling sendError(), you should not write to the response object. Instead your Action should return an ActionForward object and let the Struts RequestProcessor complete the doForward set.

sendError() processing

The typical Struts application has no need to access the response object during the Action processing. However, when an application checks and finds some state information invalid during action processing, it is not unusual for a Struts application to report the error using the response.sendError() method. The Struts Portlet Framework intercepts the calls to sendError() and saves the error information in the session. During the later view render phase, this error information is found, and the error information is displayed in lieu of displaying other content for the portlet.

Overriding Error Response Formatter

The Struts Portlet Framework provides default formatting for error responses. For standard portlets, the default error response formatter is `com.ibm.portal.struts.plugins.DefaultErrorResponseFormatter`. For IBM portlets, it is `com.ibm.wps.portlets.struts.plugins.DefaultErrorResponseFormatter`. This formatter can be overridden from within a Struts Plug-in. You can provide your own Plug-in which sets your own subclass of `DefaultErrorResponseFormatter`. The SPFLegacyPlugins.war and SPFStandardPlugins.war are examples of how to implement a custom error response formatter.

Saving information in a bean

A typical Struts application does not write directly to the response object and instead forwards to a JSP. The JSPs should not need access to the original event information, request parameters, which initially led to the current rendering. Instead, action processing should store information in a bean from which the JSP extracts the information. As long as the bean is available during the rendering, the rendering can be repeated. Since beans, such as `ActionForm`, are usually stored in the original request attributes, the request attributes from the original request processing must be saved in the iViewCommand and made available when doView() is invoked.

Forwards and redirects

Although you can write portlets using Struts, there are some aspects of the servlet environment that you cannot do in a Struts portlet. For example, Struts provides support for redirects and forwards to other servlets. These are provided because they are functions generally available to servlets. However, these capabilities are not available in portlets because WebSphere Portal Express does not support forwards or redirects.

The Struts `Action` object returns an ActionForward object, which contains a path to be either forwarded or redirected to. WebSphere Portal Express does not support forward operations because the response object has already been committed. If the path is not an action, include the page using the PortletContext.include() method. If the path is an action, then a forward to the Action is simulated. Forwards to other actions can be handled by recursively sending the new Action URI through the Struts base processing of an `Action`. Redirects are treated in the same way as a forward. This can be implemented using PortletApiUtils class. The following example demonstrates how to implement a forward to a Struts Action from an Action or a custom tag.

```
PortletApiUtils portletUtils = PortletApiUtils.getInstance();
if (portletUtils != null)
{
   portletUtils.forward( page, request );
}
else
{
   pageContext.forward( page, request );
}
```

The PortletApiUtils.getInstance() method is called to see if a PortletApiUtils instance is available. If a non null value is returned, then the execution is inside of WebSphere Portal. In this case, the portletApiUtils.foward() method is used instead of the PageContext.forward().

The issue with forwards affects tag handlers as well. In tag handlers, it is possible to access the PageContext object and invoke the forward method. An alternative method to the PageContext.forward() is available via the PortletApiUtils class that will provide a mechanism to emulate the forward functionality.

The tags in the PortalStrutsExample were modified to use the PortletApiUtil class instead of the `PageContext.forward`. The tags shipped with the Struts example are `CheckLogonTag`, `LinkSubscriptionTag`, and `LinkUserTag`. Here is a code sample of the change.

```
PortletApiUtils portletUtils = PortletApiUtils.getInstance();
if (portletUtils != null)
{
   // when run in a portlet use this execution path.
   Object pResponse = portletUtils.getPortletResponse( request );
   Object portletURI =
   portletUtils.createPortletURIWithStrutsURL(pResponse, url.toString() );
   // don't need to call response.encodeURL,
   // the portletURI.toString takes care of that.
   results.append(portletURI.toString() );
}
else
{
   // when run as a servlet, execute this path
   results.append(response.encodeURL(url.toString()));
}
```

If a forward is required in a JSP, then the logic forward tag is the suggested solution. The forward tag has been modified to use the PortletApiUtils forward implementation, and is the preferred method for a forward from a JSP. The PortletApiUtils can be obtained in a JSP through java code, but obtaining the Struts ModuleConfig to prefix the path is problematic. The logic forward tag handles these issues.

Customizing Commands

The section Comparison of servlets and portlets describes two phase processing of the portal server and the need for the `IViewCommand` objects that are created in the actionPerformed() phase. The Struts Portlet Framework ships several different commands that handle dynamic content, static content, XML data and error information from response.sendError(). This section describes some of the customizations that can be applied to a command, and also how to implement a command factory for creating new commands.

Struts View command

The Struts View command is the base class for commands in the Struts Portlet Framework.

- Standard portlets: com.ibm.portal.struts.command.StrutsViewCommand
- IBM portlets: com.ibm.wps.portlets.struts.WpsStrutsViewCommand

This class provides the foundation for saving the required information, including attributes, so the command can be rendered at a later time and multiple times. The Struts View command limits the number of attributes saved in the command object because these objects are saved in session. The command object needs to be available any time the portlet is refreshed so the command is saved in session. There is one command per portlet mode supported.

When the command object is created, Struts View command saves the request attributes that are configured to be saved. When the command is executed, it restores these attributes in the request object. An anticipated change to a command is the need for additional request attributes to be stored with the command. The Struts View command has two static methods that allow adding additional request attributes to save so this change can be made easily. The new attributes can be request attributes with a specific name, or attributes of a specific type.

If the rendering step requires additional attributes, then The Struts View command can be requested to save those attributes.

Struts View Jsp command

The Struts View Jsp command is the most commonly used command in the Struts Portlet Framework.

- Standard portlets: com.ibm.portal.struts.command.StrutsViewJspCommand
- IBM portlets: com.ibm.wps.portlets.struts.WpsStrutsViewJspCommand

The dynamic content rendered in the JSP most likely needs request attributes in the render step. The request attributes that are saved and made available in the render step are:

Attributes with the name

`Globals.MODULE_KEY`

`Globals.MESSAGES_KEY`

`Globals.ERROR_KEY`

Attributes of type

`ActionForm`

Adding request attributes stored with a command

The Struts application should call the Struts View command to add static methods before any `IViewCommand` objects are created. There are two ways to implement this customization of the Struts View command.

- Subclass `WpsStrutsPortlet` and implement the init() method. The `WpsStrutsPortlet` subclass then uses the following `WpsStrutsViewCommand` static methods.

  ```
  addAttributeNameToSave(String attributeName)
  addAttributeTypeToSave(Class attributeType)
  ```

- Use a Struts plug-in. The Struts plug-in is started when the configuration for the Struts module is read. The plug-in can be used to add the attributes that are needed by a command. Here is an example plug-in definition from the Struts configuration file.

  ```
  <plug-in
       className="com.ibm.struts.sample.plugins.ExampleAddAttributePlugin">
  </plug-in>
  ```

  Here is an example of the plug-in's init() method:

```
/**
 * Add attributes to save.
 *
 * @param config The ModuleConfig for our owning modules
 * @param servlet The ActionServlet
 *
 * @exception ServletException if we cannot configure
 * ourselves correctly
 */
public void init(ActionServlet actionServlet, ModuleConfig config)
throws ServletException
{
    // Call StrutsViewCommand.addAttributeNameToSave for each
    // request attribute we want to make available to the code
    // that renders our page. We can either specify the name
    // of the attribute or the class
    // type of attributes to save.
    StrutsViewCommand.addAttributeNameToSave("testAttribute");
}
```

Accessing request attributes

All request attributes that are set by the Struts action will be available when the WpsStrutsViewCommand is rendered the first time without the need to take these additional steps to save them. When a user interacts

with a portlet, this defines a single request and the same request object is available to the actionPerformed() method, where the Struts action is executed, and the service() method, where the rendering occurs. If the portlet is requested to refresh the view at a later time, the attributes might not be available. The refresh may be because the user is interacting with another portlet and the request object will not have the expected attributes. If the additional attributes are required during the refresh at a later time, then WpsStrutsViewCommand should be modified to save these attributes as described previously. Also, the rendering step should not rely directly on request parameters. Request parameters should be processed in the Action. However, request parameters can be saved automatically by Struts in the ActionForm. The ActionForm objects are available to the render phase.

Adding commands through the command factory

The Struts Portlet Framework uses the ViewCommandFactory object to create the IViewCommand objects for representing the view to render based on the given input information. The view command object typically contains the URL of the object (usually a JSP) creating the output for the portlet and other information needed for the rendering.

- For standard portlets, the default view command factory class is `com.ibm.portal.struts.plugins.ViewCommandFactory`.
- For IBM portlets, the default view command factory class is `com.ibm.wps.portlets.struts.plugins.ViewCommandFactory`.

The command object needs to contain the information to render the output properly. For a JSP within a Struts application, this is typically a form bean. It is possible that a particular portlet needs additional information in order to do the rendering. In such a case, you would need to add code to cause the additional information to be added to the command. The likely approach would be to override the saveAttributes() method in your subclass of the IViewCommand class. If the given URI (or perhaps type of URI) was one that would require additional information for rendering, then a new type of WpsStrutsViewCommand would need to be created which contained the needed information. The saveAttributes() method of this subclass of IViewCommand could then save the additional objects to be placed in the request object as attributes when the command was executed. To cause an existing request attribute to be saved, the saveAttribute method can be used to provide the request object and name of the attribute.

Note: The `SPFLegacyPlugins.war` and `SPFStandardPlugins.war` are examples of how to implement a custom ViewCommandFactory.

Controlling where commands are stored using the Command Manager Factory

The CommandManagerFactory allows a Struts application to specify where the IViewCommand objects are stored. The Command Manager is pluggable through the Command Manager Factory interface.

- Standard portlet container: The Command Factory plug-in is typically configured in the portlet deployment descriptor.
- IBM portlet container: The Command Factory plug-in is configured in the web deployment descriptor.

The default Command Manager Factory is the SessionCommandManagerFactory which stores the IViewCommands in the portlet session. The SessionCommandManagerFactory is the default command manager factory and recommended for portlets.

Note: The SPFLegacyCommandManager.war are examples of how to implement a custom CommandManagerFactory.

API enhancements

Ideally, portal-specific requirements should be minimized when writing Struts Applications. There are certain areas that need to be surfaced to the developer, like tag modifications and forwards. For those developing Struts applications specifically for the portlet environment, a class is provided to hide some of the servlet details that do not map well to execution in the portal server environment.

StrutsAction

The `StrutsAction` class provides an execute method that is passed portlet objects instead of servlet objects so a cast is not required to access portal-specific objects. The signatures for functions in the `StrutsAction` class are as follows:

Standard portlets

```
public ActionForward execute(ActionMapping mapping,
       ActionForm form, PortletRequest request) throws Exception;

public ActionForward execute(ActionMapping mapping,
                     ActionForm form, ActionRequest request,
                     ActionResponse response) throws Exception;

public ActionForward execute(ActionMapping mapping,
                     ActionForm form, RenderRequest request,
                     RenderResponse response) throws Exception;

public void sendError(ActionRequest request,
            int sc, String msg) throws IOException;

public void sendError(RenderRequest request,
            int sc, String msg) throws IOException;

public void sendError(ActionRequest request, int sc )
                                          throws IOException;

public void sendError(RenderRequest request,
                                  int sc ) throws IOException;
```

IBM portlets

```
public ActionForward execute(ActionMapping mapping,
                     ActionForm form, PortletRequest request)
                                       throws Exception;

public ActionForward execute(ActionMapping mapping,
                     ActionForm form, PortletRequest request,
                     PortletResponse response) throws Exception;

public void sendError(PortletRequest portletRequest,
                        int sc, String msg) throws IOException;

public void sendError(PortletRequest portletRequest,
                                  int sc) throws IOException;
```

LookupDispatchAction and DispatchAction

The `WpsLookupDispatchAction` and `WpsDispatchAction` classes offer the same functionality as their Jakarta `LookupDispatchAction` and `DispatchAction` counterparts.

- Standard portlets

  ```
  com.ibm.portal.struts.action.LookupDispatchAction
  com.ibm.portal.struts.action.DispatchAction
  ```

- IBM portlets

```
com.ibm.wps.struts.action.WpsLookupDispatchAction
com.ibm.wps.struts.action.WpsDispatchAction
```

`DispatchAction` extends `StrutsAction`, so the `StrutsAction` methods can be used for the sendError() implementation.

In the following getKeyMethodMap() example, the add and delete buttons each have their own methods for processing.

```
protected Map getKeyMethodMap() {
      Map map = new HashMap();
      map.put("button.add", "add");
      map.put("button.delete", "delete");
      return map;
  }
```

The `LookupDispatchAction` subclass implements the following two methods.

```
public ActionForward add(ActionMapping mapping,
                     ActionForm form, PortletRequest request )
                     throws IOException, ServletException {
      // do add
      return mapping.findForward("success");
  }
  public ActionForward delete(ActionMapping mapping,
                       ActionForm form, PortletRequest request )
                       throws IOException, ServletException {
 *      // do delete
 *      return mapping.findForward("success");
 *  }
 *
```

The Struts Portlet Framework implementation of `LookupDispatchAction` is not passed a response object and the request object is a `PortletRequest`. These two classes are a convenience for applications that are intended for the portal environment only.

Accessing portlet objects

There will be situations when a Struts Action needs to access objects in the Portlet API. For example, the Struts Action might need to access the PortletRequest object to get to PortletSettings or PortletPreferences, depending on the container. The PortletApiUtils should be used to obtain the PortletRequest object from the HttpServletRequest object.

```
PortletApiUtils portletUtils = PortletApiUtils.getUtilsInstance();

if (portletUtils != null)
{

   PortletRequest portletRequest = (PortletRequest)
   portletUtils.getPortletRequest( request );
}
```

The Struts Action class also makes the ActionServlet class available. When the Struts application is authored with the Struts Portlet Framework, the ActionServlet class is actually the `WPActionServlet`. For more information see the Javadoc documentation for:

- Standard portlet container: com.ibm.portal.struts.portlet.WpActionServlet class information.
- IBM portlet container: com.ibm.wps.portlet.struts.WpsActionServlet class information.

Sending a message

The Struts examples use the Property Broker for sending messages from one portlet to another.

The Struts Portlet Framework ships the SPFLegacyMultipleModules, and SPFStandardMultiplModules as examples of using the property broker and Struts Portlet Framework

Changes to Struts JSPs

The JSPs for Struts applications in the portal environment have to be modified to adapt to the way the portal server expects portlet URIs to be created. There are some changes to the tag library for HTML markup and additional tag libraries have been added to support cHTML and WML markup.

Creating portlet URIs

The Struts application paths, both to actions and to pages, must be sent and retrieved using portlet URIs. Portlet URIs have a specific format. A special API is used to generate the URI and add the required information to be passed to the portlet. If portlet URIs were not used, control would not get passed to the correct portlet. Thus, the portlet URIs must be used to get control passed to the correct portlet, with the additional path information needed by the Struts application made available. The Struts tags have been modified to automatically provide this needed functionality.

Struts Action mappings are defined in terms of paths. The name and location of page objects (for example, JSPs) are also defined using paths. Thus, although portlets have their own form of URI, it is still necessary to associate the Struts path with an action sent to a portlet and to retrieve that Struts path when the portlet action is handled. The Struts URI is passed as a parameter so the Struts request processor can process the action. If the link is not an action then the portlet processes the information and create the appropriate IViewCommand.

Typically a Struts application passes parameters on such a path using the query string on the HTTP URL. Often the actions containing these paths are generated from tags provided by Struts. The most obvious examples of these are the tags for the HTML elements `<link>` and `<form>`. For IBM Struts portlets, the **`urlType`** attribute must be included in the <html:form>, <html:link> and <html:rewrite> tags to support the different types of URIs. This attribute can take the following values:

- return - Creates a portlet return URL indicating the caller of the portlet. For example, this URL can be useful for creating a form action that can take a user back to view mode from edit mode.
- standard - Creates a standard portlet URL.

Examples:

<html:rewrite>

```
<link rel="stylesheet" type="text/css"
      href="<html:rewrite page='/assets/styles/base.css'/>">
```

<html:form> (Standard portlets)

```
<html:form action="/saveConfiguration.do" portletMode="view">
```

Style sheets

Many existing Struts application use the rewrite tag to create a link element for a cascading style sheet. This is not the documented intention of the rewrite tag, which is supposed to create the same path as the link tag without the <a> element. Since the Struts Portlet Framework had to modify how links are created, the rewrite tag required some customizations to be used to create link elements for style sheets. The rewrite tag will create the same path as the link tag, except when the page or forward reference is to a CSS file. In the case where a CSS file is referenced, the rewrite tag will use the Jakarta Struts implementation, which results in a path to the CSS file. Here are examples of how to create link elements for style sheets using the Struts Portlet Framework.

Using a forward

```
<link rel="stylesheet" type="text/css"
                       href="<html:rewrite forward='baseStyle'/>">
```

Using a page

```
<link rel="stylesheet" type="text/css"
                       href="<html:rewrite page='/basestyle.css'/>">
```

Using the portlet tags

```
<%@ taglib uri="/WEB-INF/tld/portlet.tld" prefix="api" %>
<api:init />
<link rel="stylesheet" type="text/css"
      href="<%= portletResponse.encodeURL( basestyle.css ) %>">
```

Markup support

The Struts tag library has been modified to support the additional markup languages supported by WebSphere Portal Express. For HTML, the tags that create links have been modified to support portlet URIs. See Creating portlet URIs for details. Also, be aware of the restrictions for HTML output described in “Markup guidelines” on page 3123.

There might be a cases where the JSPs for a Struts application need to run in both the servlet and portlet environment. For this reason, page level tags are implemented in tag libraries. The Struts application can use them in its JSPs, but the tags will not generate markup when executed within WebSphere Portal.

You should also refrain from setting color, and fonts. The portal server supports skins and themes that give the page a consistent look and feel. The JSP should be authored so it adheres to the conventions of the theme by using the appropriate style sheet.

Using the cHTML tags

The use of the cHTML tags is similar to the use of the HTML tags. The name of the cHTML tag library file is `struts-chtml.tld`. The following is an example of the cHTML taglib definition.

```
<%@ taglib uri="/WEB-INF/struts-chtml.tld" prefix="chtml" %>
```

Using the WML tags

The WML tags are a new addition for creating a user experience in WAP

devices. The use of the WML tags is similar to the use of the Struts HTML tags. Use the following directive to make these tags available to a JSP.

```
<%@ taglib uri="/WEB-INF/struts-wml.tld" prefix="wml" %>
```

The use of the WML tags provided with this distribution is similar to the use of Struts HTML tags. The name of the WML tag library file is `struts-wml.tld`. The following is an example of the WML version of `index.jsp` .

```
<%@ taglib uri="/WEB-INF/struts-bean.tld" prefix="bean" %>
<%@ taglib uri="/WEB-INF/struts-wml.tld" prefix="wml" %>
<%@ taglib uri="/WEB-INF/struts-logic.tld" prefix="logic" %>
<p>
<wml:link page="/editRegistration.do?action=Create">
   <bean:message key="index.registration"/>
</wml:link>
<br/>
<wml:link page="/logon.jsp">
   <bean:message key="index.logon"/>
</wml:link>
<br/>
<wml:link page="/tour.do">
   <bean:message key="index.tour"/>
</wml:link>
</p>
```

See General tips for portlet output and the WML markup guide for general guidelines about providing WML markup.

WML does not have a <form> element like HTML. Struts, however, uses the <form> tag for the scoping of parameters and supporting form beans. For that reason, the WML implementation also includes a <form> tag to support some of the Struts features in WML. The <form> tag in the WML taglib takes an action as an attribute. The following is an example of a form in WML.

```
<wml:form action="/logon">

<do type="options" label="send">

  <wml:go method="post">
    <postfield name="username" value="$username"/>
    <postfield name="password" value="$password"/>
  </wml:go>
</do>

<bean:message key="prompt.username"/><wml:text property="username"/>
<bean:message key="prompt.password"/>
<wml:password property="password" size="16" maxlength="16"/>

</p>

</wml:form>
```

Figure 42. Example form for WML

The JSPs for the HTML Struts example have been modified for the WML markup. This example also demonstrates the use of the WML taglib. These JSPs can be found in the `/wml/view` directory of the expanded `PortalStrutsExample.war` file.

The tags in the Struts portlet WML tag library can throw a `JspException` at run time. An error page can be declared using the `<%@ page %>` directive to

detect the exception and supply information about the error condition. The actual exception is passed as an attribute in the request object with the key `org.apache.struts.action.EXCEPTION`.

The following is a brief description of each tag. See Detailed descriptions of the Struts WML tags for more information.

Table 455. Summary of WML tags for Struts portlets

Tag	Description
<wml:cancel/>	Renders a WML `<postfield>` element with a value of `cancel`.
<wml:card/>	Renders a WML card element.
<wml:errors/>	Retrieves the set of error messages from the request object with the default key of `Action.ERROR_KEY` or the value specified by attribute name.
<wml:form/>	Does not render any markup, but it is used to scope beans and transactions.
<wml:go/>	Renders a WML <go> element.
<wml:head/>	Renders a WML <head> element with language attributes extracted from the user's current Locale object, if there is one.
<wml:link/>	Renders a WML <a> element as a hyperlink to the specified URL.
<wml:option/>	Renders a WML <option> element, representing one of the choices for an enclosing <select> element.
<wml:options/>	Renders a set of WML <option> elements, representing possible choices for a <select> element.
<wml:password/>	Renders a WML <input> element of type password, populated from the specified value or the specified property of the bean associated with our current form.
<wml:postfield/>	Renders a WML <postfield> element.
<wml:rewrite/>	Renders a request URI based on exactly the same rules as the link tag does, but without creating the <a> hyperlink.
<wml:select/>	Renders a WML <select> element, associated with a bean property specified by our attributes.
<wml:text/>	Renders a WML <input> element of type text, populated from the specified value or the specified property of the bean associated with our current form.
<wml:wml/>	Renders a <wml> element.

Changes to configuration files

Struts Portlet Framework-specific init parameters were added so you can customize the Struts application for the portal environment. The portlet and web deployment descriptors require configurations specific to the Struts Portlet Framework. In addition, changes to the Struts configuration file must be made to specify a portal specific request processor as the controller.

Configuring the Struts application for the IBM container

Most of the configuration for a Struts application is in the web deployment descriptor file (`web.xml`). The servlet class that is specified in the web deployment descriptor must be the portlet servlet. The class name is `WpsStrutsPortlet`. Here is an example definition.

```
<servlet id="Servlet_1">
    <servlet-name>MyStrutsApp</servlet-name>
    <servlet-class>com.ibm.wps.portlets.struts.WpsStrutsPortlet
    </servlet-class>
    ...
</servlet>
```

When subclassing WpsStrutsPortlet, you must designate the subclass name for <servlet-name/>. The servlet **`id`** must be suffixed with a unique ID to prevent conflicts with other portlets. See "Deployment descriptors" on page 3129 for more information.

Initialization parameters

The following is a list of names of the initialization parameters that can be configured in the web deployment descriptor for Struts portlets with the `<init-param>` element.

CommandManagerPlugin

This configuration parameter allows setting a pluggable CommandManager.

struts-servlet-mapping

Identifies a Struts action mapping so that paths that must be treated as Struts actions can be recognized. See Servlet mapping for further details.

ModuleSearchPath

Indicates the search path for Struts modules, default value is the markupName and mode. See Using modes for more information.

IncludesSearchPath

Indicates a more fine-tuned search path for including a file. If this value is not specified, then PortletContext.include() is used instead.

NamescopeServletContext

This allows the WpsStrutsPortlet to be defined in the web deployment descriptor more than once by namescoping the parameters in the servlet context.

NamescopeFormName
The default behavior is for the Struts form tag to namescope the name of the portlet. Setting this parameter to false will allow the behavior to be overridden.

UseGroupsForAccess
Configures the Struts portlet to use portal server group names as if they were role names. Struts uses roles to determine access to an `Action`. Set this parameter to **`true`** to configure the Struts application to use the portal's group names as if they were role names to emulate role-based access control.

UsePortalsLocale
This parameter allows a Struts application to override default behavior of using the portal's locale. If this parameter is set to false the Struts application can use the Request processor's processLocale method for controlling locale or set the locale in a Struts action; otherwise, it uses the portal's locale and also supports dynamic changes. The default value is true.

WelcomeFileSearchPath
This configuration parameter allows customizing the initial view page search.

Servlet mapping
In a portlet, you must use a servlet URL mapping for your portlet. So, one would typically use a path prefix servlet mapping similar to the following.

```
<servlet-mapping id="ServletMapping_1">
     <servlet-name>MyStrutsApp</servlet-name>
     <url-pattern>/Struts/*</url-pattern>
</servlet-mapping>
```

The typical Struts application uses an extension mapping. The Struts example uses extension mapping and it is expected that most Struts applications use the extension mapping "`*.do`". In the normal Struts case, this means that URIs ending in "`*.do`" are directed to the Struts servlet. Struts provides a single servlet that you can use (or subclass) for all of your Struts applications. When you want to cause control to be given to a Struts Action when a link is selected or form submitted, use the extension from the extension mapping, for example "`*.do`" on the URI so that the processing is routed to the Struts ActionServlet. Other URIs, such as those for JSPs, do not have this extension and, thus, would not be routed through the Action Servlet for processing.

A Struts application, which is itself a servlet application, also requires a servlet mapping. Although the Struts portlet already has a servlet mapping as shown previously, you still must identify what to use as a Struts action mapping so that paths that must be treated as Struts actions can be recognized. To specify the pseudo servlet mapping that is used by Struts, specify it as a servlet initialization parameter in the `web.xml` file, as follows:

```
 <init-param>
     <param-name>struts-servlet-mapping</param-name>
     <param-value>*.do</param-value>
 </init-param>
```

The Struts Portlet Framework supports the same servlet mappings modes as the servlet-based Struts application. However, the current Struts implementation supports extension mapping for the module implementation. Since the portal server implementation uses modules for the mode and markup support, use the extension mapping.

Configuring the Struts application for the standard portlet container

In the standard container the Struts application is configured in the portlet deployment descriptor. The portlet class and init parameters are specified in the portlet deployment description. In the standard container, the only configuration in the web deployment descriptor is the welcome file list and the tag library (taglib) elements. The portlet class that is specified in the portlet deployment descriptor must be the `com.ibm.portal.struts.portlet.StrutsPortlet` class or subclass.

```
<portlet>
  <portlet-class>com.ibm.portal.struts.portlet.StrutsPortlet</portlet-class>
</portlet>
```

If subclassing the `StrutsPortlet`, the subclass class name must be designated as the <portlet-class/>.

Initialization parameters

The following is a list of names of the initialization parameters that can be configured in the web deployment descriptor for Struts portlets, with the `<init-param>` element):

IncludesSearchPath
Indicates a more fine-tuned search path for including a file. If this value is not specified, then PortletContext.include() is used instead.

ModuleSearchPath
Indicates the search path for Struts modules, default value is the markupName and mode. See Support for multiple Struts applications for more information

NamescopeFormName
The default behavior is for the Struts form tag to namescope the name of the portlet. Setting this parameter to false allows the behavior to be overridden.

NamescopeServletContext
This allows the WpsStrutsPortlet to be defined in the web deployment descriptor more than once by namescoping the parameters in the servlet context.

struts-servlet-mapping
Identifies a Struts action mapping so that paths that must be treated as Struts actions can be recognized. See Servlet mapping for further details.

UseGroupsForAccess
Configures the Struts portlet to use portal server group names as if they were role names. Struts uses roles to determine access to an Action. However, WebSphere Portal V 4.2 does not support roles. Set this parameter to true to configure the Struts application to use the portal's group names as if they were role names to emulate role-based access control.

UsePortalsLocale
This parameter allows a Struts application to override default behavior of using the portal's locale. If this parameter is set to false, the Struts application can use the Request processor's processLocale method for controlling locale or set the locale in a Struts action. Otherwise, it uses the portal's locale and also supports dynamic changes. The default value is true.

WelcomeFileSearchPath
This configuration parameter allows customizing the initial view page search.

Setting an initial view

The Struts application must specify what the initial view is for the application. The typical way that the initial screen is specified is through the welcome file list. The Struts Portlet Framework supports the welcome file list configuration, and has some additional features. The servlet implementation of the welcome file list only supports JSP and HTML pages. The Struts Portlet Framework supports a JSP or HTML welcome file, and also allows a Struts action to be specified as the welcome file. See Example 1 for implementation details.

The alternative method allows Welcome files to be configured on a per portlet basis as a configuration parameter in the portlet deployment descriptor `portlet.xml`. The default search looks for the initial view file per portlet mode. The other feature in the Struts Portlet Framework is the support for modules. A unique welcome file must be configured for each module by specifying the application prefix. For example, to support the view mode for the markup WML, a welcome file `wml/view` can be specified. See Example 2 for implementation details.

```
<welcome-file-list>
  <welcome-file>index.jsp</welcome-file>
  <welcome-file>help/index.jsp</welcome-file>
  <welcome-file>wml/view/index.jsp</welcome-file>
</welcome-file-list>
```

Figure 43. Example 1: Welcome file list that is specified in the file `web.xml`

```
<portlet-preferences>
   <preference>
      <name>viewMode.page</name>
      <value>portlet1/welcome.jsp</value>
   </preference>
   <preference>
      <name>editMode.page</name>
      <value>html/edit/index.jsp</value>
   </preference>
</portlet-preferences>
```

Figure 44. Example 2: Welcome file list that is specified on a per portlet basis (standard portlets)

```
<config-param>
    <param-name>viewMode.page</param-name>
    <param-value>portlet1/welcome.jsp</param-value>
 </config-param>
 <config-param>
    <param-name>editMode.page</param-name>
    <param-value>portlet1/edit.jsp</param-value>
 </config-param>
```

Figure 45. Example 3: Welcome file list that is specified on a per portlet basis (IBM)

Note:

- A welcome file entry must be configured for each module. The welcome file entry is the initial screen that is shown when first switching to that module.
- The default Struts configuration, which has a "" prefix, is used any time a module prefix is not found.

Using modes

The Struts Portlet Framework is set up to use the mode and markup to find the Struts configuration. However, if you do not want to use a Struts application in one of the modes, the Struts portlet `(Wps)StrutsPortlet` must be subclassed. The appropriate service() method must be overridden to implement the wanted behavior. For example, if the developer wants a help mode that does not use a Struts application, then the doHelp() method must be implemented in a subclass.

Portlet modes can be supported by the Struts Portlet framework. The Struts Portlet Framework stores the IViewCommand objects on a per mode basis. That means that an application that supports view and edit mode has an IViewCommand object for view and edit mode. The welcome file list is typically used for the initial page when entering a mode.

The `SPFLegacyMultipleModules.war` example for the IBM container and the `SPFStandardMultipleModules.war` example for the standard portlet container demonstrate support for edit mode. The Module 1 portlet implements an edit mode wizard that steps through three screens. The example also demonstrates how to use a StrutsActionForward so that the IViewCommand object for the last page of the wizard can be marked for removal on a mode change. This allows the IViewCommand object for edit mode to be deleted when the user switches from edit mode back to view. The anticipated use is that the user is entering data in edit mode and the configuration data is submitted to be stored. The last page displays that the data has been successfully stored. The user then leaves edit mode with the skin. If the user goes back into edit mode, they do not want to see the message that the data was successfully stored. Since the command was deleted, the welcome file list entry can be used to start the wizard again. This feature also reduces the number of attributes that are stored in session.

```
<action path="/nextEditPage2"
        type="com.ibm.wps.struts.example.multipleapps.actions.ForwardAction">
        <forward className="com.ibm.wps.struts.action.StrutsActionForward"
                 name="success"
                 path="/edit3.jsp">
                <set-property property="removeOnModeChange"
                              value="true"/>
         </forward>
</action>
```

The Struts example application demonstrates support for help mode. A Struts configuration was added to the web deployment descriptor, `web.xml`, to demonstrate help mode. This mode is entered when the user clicks the help button for the Struts example portlet. The following code fragment from the web deployment descriptor demonstrates how to configure the struts-configuration to support help mode.

```
<init-param>
 <param-name>config/html/help</param-name>
 <param-value>/WEB-INF/html/help/struts-config.xml</param-value>
</init-param>
```

The search path that is set in the web deployment descriptor includes mode, which enables a separate Struts configuration for a mode.

```
<init-param>
 <param-name>ModuleSearchPath</param-name>
 <param-value>markupName, porletMode</param-value>
</init-param>
```

The welcome file list defines the welcome file for the help mode, as follows:

```
<welcome-file-list>
 <welcome-file>index.jsp</welcome-file>
 <welcome-file>html/help/index.jsp</welcome-file>
 <welcome-file>wml/view/index.jsp</welcome-file>
</welcome-file-list>
```

Support for devices

The Struts Portlet Framework's support of devices was flexible. The way the configuration and JSP files are placed in the directory structure must be tolerant of the devices that must be supported. Some applications can support HTML browsers and need a single Struts configuration file. Other applications can support multiple markups and locales but do not need to know specifics about the device itself, while other implementations need unique implementations for each of the supported devices.

Note: This support requires extension mapping. The prefix mapping supports only a single configuration file.

WebSphere Portal Express is designed to allow portlets to access information about the client device, such as locale and markup language supported with the Client interface. The Struts support for modes and markups was implemented by allowing a configuration parameter to specify the fields in the client object that are interesting. The Client object is treated like a bean, where the field value corresponds to a get method in the Client object. This allows developers to specify the fields in the Client object that are necessary to their device support.

Note: The standard portlet container does not have a Client object but the following fields are supported:

- markupName
- locale
- portletMode

There are two paths that can be specified for supporting modes and device types (clients). The first path is the search path, and that path is used to specify the module to use. The search path locates the appropriate Struts configuration to use and is the prefix that is used as the base directory for the necessary JSPs. The default search path is *markupName, portletMode*. This searches for a configuration that is based on the current markup and the portlet mode.

```
<init-param>
  <param-name>ModuleSearchPath</param-name>
  <param-value>markupName, portletMode</param-value>
</init-param>
```

For example, if a desktop browser is used and the user is in view mode, then the search path would be:

- html/view
- html
- "" (default configuration)

And if the Client object specified "wml" as the markupName then the search path would be:

- wml/view
- wml
- "" (default configuration)

The search path is checked against all of the prefixes for the ModuleConfig objects for a match. The modules are configured in the web deployment descriptor, `web.xml`, by specifying a prefix for a Struts configuration.

For example, a module for the WML markup in view mode would be configured by adding a configuration to the web deployment descriptor like:

```
<init-param>
   <param-name>config/wml/view</param-name>
   <param-value>/WEB-INF/wml/view/struts-config.xml</param-value>
</init-param>
```

If the `wml/view` module is selected, the corresponding JSPs are searched for under the `wml/view` directory of the Struts application WAR file.

This is a good start for separating the files for different markups and modes, but this granularity is probably not enough to deal with all available devices, or even locales. You can modify this search path to have a finer granularity. For example, you can create a unique module for every phone that they support.

The search path of markupName, portletMode, locale, manufacturer, model, and version can be used. This offers a fine-grained deployment of the JSPs. The problem with this approach is that most of the JSPs would probably be the same for each of the devices. There are probably a few that must be modified for each device, but this approach does not allow sharing.

This is why two paths are offered, search and include. The search path is used to find the module. This would be for applications that can use a common configuration, share actions, and some of the JSPs. The include path can then be used to look for specific implementations of the JSP and if not found, fall back to a common file.

Take the following include path for including JSPs that are dependent on the device.

```
<init-param>
   <param-name>IncludesSearchPath</param-name>
   <param-value>manufacturer, model, version</param-value>
</init-param>
```

This would search for the file relative to the module and then take the requested fields into account. If the search path found the `wml/view` module and the file `index.jsp` is requested, then the previous search path for an ACME T400 would be as follows:

- wml/view/Acme/T400/index.jsp
- wml/view/Acme/index.jsp
- wml/view/index.jsp

That version did not show up in the search. The default client configuration for the T400 did not have one defined. If one was configured later, then it would be used.

Portal aggregation is flexible in how the differences between devices are supported. The common features are supported through the search path; all WML devices in view mode in a locale. The subtitle differences between devices would be supported through the file search of the include path. The common versions of the JSPs would be at a root level, and specific files would be in subordinate directories.

The Struts example includes several tags, two of which required a minor change to support modules. The LinkSubscriptionTag and LinkUserTag tags had to be modified so that the current ModuleConfig's prefix had to be added to the computed URL.

Globalization support

The Struts Portlet Framework supports i18n by using resource bundles. Each Struts application can specify a message resource. The Java resource bundle implementation determines the resource bundle to use based on the locale and variant. The Struts application typically uses the message tag to include translated text from the application-supplied resource bundle.

```
<init-param>
  <param-name>IncludesSearchPath</param-name>
  <param-value>locale</param-value>
</init-param>
```

The Struts framework was designed to give the application control over locale by using a locale object that is set in session with a known key. The Struts RequestProcessor sets the locale object for each user during the processLocale() method. The processLocale() method sets the locale object using the key Globals.LOCALE_KEY if the feature is enabled through the Struts configuration file and the attribute was not already set in session.

A setting on the controller element that is available in the Struts configuration file controls the locale support in Struts. The support can be turned off, which stops the locale processing in the Request processor processLocale() method.

WebSphere Portal supports dynamic changes to the locale. Portlets must use the locale object that is obtained through the PortletRequest object for the locale setting. The Struts Portlet Framework sets the locale object in the session with the key Globals.LOCALE_KEY during the actionPerformed() and service() methods. The support is implemented by calling the (Wps)StrutsPortlet processLocale() method, which sets the locale object if one is not found or the locale is different from the one already in session. This assures that a portlet written using the Struts Portlet Framework uses the correct locale.

Locale support can also be customized. The (Wps)StrutsPortlet processLocale() method can be overridden for a customized implementation. The invocation of (Wps)StrutsPortlet processLocale() can also be stopped by adding the following init-parameter to the web deployment descriptor for the application.

```
<init-param>
  <param-name>UsePortalsLocale</param-name>
  <param-value>false</param-value>
</init-param>
```

However, in most cases the portlet must use the default implementation.

Using the IBM container

WebSphere Portal also provides an implementation to find globalized JSPs using the include() method on PortletContext. PortletContext inserts the locale into the path to locate the locale-specific JSP. For more information, see Generating markup for multiple devices, markups, and languages.

The Struts Application can be deployed to use the portal server's aggregation method to find globalized JSPs, instead of a resource bundle for each locale. The

Struts Portlet Framework uses the PortletContext.include() on the existing container to include JSP pages, so both methods of globalization are supported.

PortletContext.include() searches for locale-specific files by inserting the markup and locale name in the path. This behavior can be configured through an initialization parameter in the web deployment descriptor. An include search path can be specified that controls how the includes are located. For example, the default implementation would be markup, locale but can be changed to just locale if required. The mode and markup support may have been already configured to include markup, so this configuration allows the markup to not be needed a second time.

WML support

Because WebSphere Portal Express supports pervasive devices, such as WAP phones, the example was configured to support a generic WML device. Adding a Struts configuration for WML devices supports the view mode for a WML device. The following code fragment demonstrates how to set up the struts-configuration for the view mode for WML markup.

```
<init-param>
 <param-name>config/wml/view</param-name>
 <param-value>/WEB-INF/wml/view/struts-config.xml</param-value>
</init-param>
```

The search path that is set up in the web deployment descriptor, takes markup, mode, and locale into account. When a WAP device connects to a portal server, the markup is WML, and the mode is view. This example does not use the locale that is requested.

The welcome file list also defines the welcome file for the `wml/view` mode.

```
<welcome-file-list>
 <welcome-file>index.jsp</welcome-file>
 <welcome-file>html/help/index.jsp</welcome-file>
 <welcome-file>wml/view/index.jsp</welcome-file>
</welcome-file-list>
```

For more information about WML support in the Struts Portlet Framework, see "Changes to Struts JSPs" on page 2955.

Logging

The Struts Portlet Framework uses the Commons-Logging interface for a logging facility. The Struts Portlet Framework was supplied an implementation of the Commons-Logging Log interface that can be used to map the trace messages to the logging facility used by the portal server. This file is normally found in the *PortalServer_root*/log directory. Setting properties in the *wp_profile_root*/PortalServer/config/config/log.properties file enables trace logging. The trace string for tracing a Struts portlet application can be configured in `log.properties`. The trace string can be modified to add or remove classes. The entire trace string must be on one line in `log.properties`.

The logging in WebSphere Portal Express typically creates a logging object per class and the trace messages open the log class that the message is from. It is convenient to determine where a trace message originated from and also allows enabling the tracing on certain classes.

The typical trace string that is configured in the log.properties file for tracing a Struts application would be as the following examples (all on one line). This can be modified to add or remove classes.

IBM container:

```
traceString=
org.apache.struts.*=all:
com.ibm.wps.portlets.struts.*=all:
com.ibm.wps.struts.common.*=all:
com.ibm.wps.struts.base.*=all
```

Some of the Apache source uses a string to specify the class name and, in some cases, this string is not be a valid class. In those cases the class name in the trace message is com.ibm.wps.portlets.struts.logging.WpsStrutsTraceLogger. This package or class must be specified in the traceString to account for these occasions.

The log messages from Struts use the Portal Server's logging facility when logging is enabled. When this is the case, the log messages from Struts do not open the correct method name as part of the log message. There is a configuration parameter to enable correcting this problem, but this is an expensive operation. This feature is not required as much with the logging changes implemented in this release.

JSR-compliant container:

```
traceString=
org.apache.struts.*=all:
com.ibm.portal.struts.*=all:
com.ibm.wps.struts.common.*=all:
com.ibm.wps.struts.base.*=all
```

Customizing logging

The Struts Portlet Framework specifies the commons logging Log Factory in the META-INF/services directory. In the samples, the org.apache.commons.logging.LogFactory file specifies the default logger that the Struts Portlet Framework uses. The log factory class name is dependent on the WebSphere Portal Express container. The org.apache.commons.logging.LogFactory file can be edited to specify other commons log factories.

Using the default logging implementation class: Struts Portlet Framework 5.0.3 or later Struts Portlet Framework 5.0.3 and later no longer use the System property org.apache.commons.logging.LogFactory to specify the log factory class. The commons log factory can be specified either in the META-INF/services directory or the commons-logging.properties file that must be found through the class path. The suggested way to specify the commons log factory is to through the META-INF/services directory of the WAR file.

IBM container with a Struts Portlet Framework version prior to 5.0.3: Versions of the Struts Portlet Framework before SPF 5.0.3 set the logging implementation class with the System property org.apache.commons.logging.LogFactory. The portlet initialization method, init, in com.ibm.wps.portlets.struts.WpsStrutsPortlet calls the setCommonsLogFactory method.

```
public void setCommonsLogFactory()
{
   String methodName = "setCommonsLogFactory";
```

```
    s_traceLogger.text( WpsStrutsTraceLogger.TRACE, methodName,
                "Set common logging to use StrutsLogFactory" );
    System.setProperty( "org.apache.commons.logging.LogFactory",
                "com.ibm.wps.portlets.struts.logging.StrutsLogFactory");
}
```

Note: A portlet must not use this mechanism, as the system property affects other applications in the WebSphere Application Server. If an older version of the Struts Portlet Framework is used, first the WpsStrutsPortlet must be extended and the setCommonsLogFactory must be implemented to do nothing. Then modify the application to specify the commons log factory through the org.apache.commons.logging.LogFactory file in the `META-INF/services` directory of the application.

Struts Portlet Framework version 5.0.3 or later Log Factory's class name

Standard portlet container: org.apache.commons.logging.LogFactory

IBM portlet container: com.ibm.wps.portlets.struts.logging.StrutsLogFactory

Overriding the default logging implementation class

Struts portlet developers can override the default logging implementation class. Depending on the version of Struts, the implementation varies.

Struts Portlet Framework 5.0.3 or later There are two ways to customize the logger. The first and recommended option is to specify the log factory in the org.apache.commons.logging.LogFactory file in the `META-INF/services` directory. The Commons Logging implementation checks the `META-INF/services` directory before looking for the `commons-logging.properties` file in the class path to determine the class name of the LogFactory. The second option is to specify the `commons-logging.properties` file in the application's class path. The org.apache.commons.logging.LogFactory file can be updated to specify the required LogFactory.

Note: Version 5.0.3 of the Struts Portlet Framework used the `commons-logging.properties` file to specify the logger, and this file was packaged in the `wp.struts-commons-logging.jar`. Specifying the log factory in the `META-INF/services` directory takes precedent over the log factory specified in the `wp.struts-commons-logging.jar` file.

IBM container with a Struts Portlet Framework version prior to 5.0.3: To override the default logging implementation class, developers can extend com.ibm.wps.portlets.struts.WpsStrutsPortlet and override the setCommonsLogFactory method. The developer could remove the call to set the org.apache.commons.logging.LogFactory System property in setCommonsLogFactory, and create the file org.apache.commons.logging.LogFactory in the `META-INF/services` directory (or the file commons-logging.properties in the `WEB-INF/classes` directory of the application to determine the logging implementation class. The `META-INF/services` directory is the preferred method.

Note: The portlet web deployment descriptor will then need to be updated to specify the WpsStrutsPortlet subclass as the servlet class.

Logging conflict between new and old versions of Struts portlets

The JCL determines the logging implementation by first looking for the System property org.apache.commons.logging.LogFactory. If the System property has not been set, it then looks for the

org.apache.commons.logging.LogFactory file in the `META-INF/services` directory and then for commons-logging.properties in the classpath.

The value of the System property becomes available to all portlets once it is set, and this would determine the logging implementation class for the portlets on the page. There would be no effect on the logging if the default logging implementation is used by all portlets. However, if the logging implementation class for a portlet is set in a custom common-logging.properties file, it would be ignored. To overcome this, the developer would need to override the method, which sets the System property. See the section Overriding the default logging implementation class for more details.

Commons Logging JAR file

The WebSphere Application Server includes a version of the `commons-logging.jar` file and specifies the default commons logger to be the com.ibm.ws.commons.logging.TrLogFactory class. If the Struts portlet does not specify a log factory, then the default log factory of TrLogFactory is used. However, if the application includes a version of commons-logging, then a ClassCastException results. This release of the Struts Portlet Framework no longer includes `commons-logging.jar`, but instead uses the version that is included in the Application Server. Older applications can continue to use the `commons-logging.jar` file that is packaged with the Struts Portlet Framework if the application specifies a logger, which is the typical case.

Changes to the Struts configuration file

The Struts configuration that is used by Struts portlets references the 1.1 version of the DTD.

```
<!DOCTYPE struts-config PUBLIC
          "-//Apache Software Foundation//DTD Struts Configuration 1.1//EN"
          "http://jakarta.apache.org/struts/dtds/struts-config_1_1.dtd">
```

For the Struts Portlet Framework operate properly, the `RequestProcessor` must be configured. The `RequestProcessor` is responsible for the main function of processing a request. The default `RequestProcessor` can be overridden in the `struts-config.xml` with the controller element. In the `struts-config.xml`, the following portal server `RequestProcessor` must be specified:

Standard portlet container:

```
<controller
   processorClass="com.ibm.portal.struts.portlet.WpRequestProcessor">
</controller>
```

IBM portlet container:

```
<controller
   processorClass="com.ibm.wps.portlets.struts.WpsRequestProcessor">
</controller>
```

You can also extend the Struts RequestProcessor in order to extend the function of Struts. If you place the path to your RequestProcessor in the controller element in the struts-config file, your application does not work properly in the portlet environment. Instead, what you must do is have your RequestProcessor class extend the WpsRequestProcessor rather than the normal Struts RequestProcessor.

The following are the methods overridden in WpsRequestProcessor:

- processLocale
- processActionPerform()

- processActionForm()
- processActionForward()
- processPath()
- processRoles()
- processMapping()
- processValidate()
- doForward()
- doInclude()
- getMapping()

If you override any of the methods listed previously, you must make sure to start the super class version of the method from within your method.

There are existing Struts Extensions, which require you to use their RequestProcessor. Clearly, you cannot use their RequestProcessor and the WpsRequestProcessor at the same time. Instead, you must get the source to that RequestProcessor and following the approach described.

Tiles support

Struts integrates the Tiles package for creating views. A Tiles sample is included with the Struts Portlet Framework that demonstrates how to configure Tiles in the Struts Portlet Framework. Tiles requires a specific Request processor that is configured through a plug-in. The following is from the Struts configuration to show how to configure Tiles for a Struts application that is deployed in WebSphere Portal.

Standard portlet container:

```
<!-- add the Tiles plugin. -->
<plug-in className="com.ibm.portal.struts.plugins.WpTilesPlugin">
   <set-property property="definitions-config"
                 value="/WEB-INF/conf/tiles-def.xml"/>
   <set-property property="definitions-debug" value="2"/>
   <set-property property="definitions-parser-details" value="2"/>
   <set-property property="definitions-parser-validate" value="true"/>
</plug-in>
```

The Tiles plug-in requires that compatible request processor is configured in the controller element. The WpTilesPlugin was written to accept the default Struts RequestProcessor, WpStrutsRequestProcessor, or the WpTilesRequestProcessor.

IBM portlet container:

```
<!-- add the Tiles plugin. -->
<plug-in
   className="com.ibm.wps.portlets.struts.plugins.WpsStrutsTilesPlugin">
   <set-property property="definitions-config"
                 value="/WEB-INF/conf/tiles-def.xml"/>
   <set-property property="definitions-parser-details" value="2"/>
   <set-property property="definitions-parser-validate" value="true"/>
</plug-in>
```

The Tiles plug-in requires that compatible request processor is configured in the controller element. The WpsStrutsTilesPlugin was written to accept the default Struts RequestProcessor, WpsStrutsRequestProcessor, or the WpsStrutsTilesRequestProcessor.

Supporting multiple Struts applications

Learn how web applications that allow packaging more than one Struts-based portlet in a single application can be created either using Struts modules or a namescoped servlet context.

The Jakarta Struts Framework does not support configuring more than one Struts ActionServlet in the web deployment descriptor. This limitation occurs because there is only one servlet context per web application and the commons digester imports the Struts configuration into the servlet context. Struts stores the required information as attributes in the servlet context, and the information is retrieved by using globally defined key names. Struts will suffix these attribute names with the prefix of the Struts modules, so several Struts modules are supported in a single web application, but multiple Struts applications are not.

The Struts Portlet Framework is used to create Struts applications that are deployed in WebSphere Portal Express. This section discusses two techniques for creating web applications that allow packaging more than one Struts-based portlet in a single application. As stated, Jakarta Struts does not support declaring the Struts ActionServlet in the web deployment descriptor more than once. The Struts Portlet Framework has the same limitation because the servlet context is used when the Struts configuration is digested in the portal as well. However, the Struts Portlet Framework supports two ways that an application can be developed in order to implement multiple Struts-based portlets. The first technique uses a single Struts controller while defining a Struts module for each portlet in the application. The second technique uses a servlet context wrapper that namescopes the attributes stored in the servlet context, so each portlet can have its own namespace in the servlet context.

Note: Legacy portlets, such as `SPFLegacyMultipleServletContext.war` referenced here, are available for download from the WebSphere Portal Business Solutions Catalog.

Using Struts modules (IBM portlet container only)

One method of supporting multiple Struts portlets in a single war file is to define a Struts module for each portlet. The welcome file can be specified as a configuration parameter for each concrete portlet. This technique takes advantage of the fact that the Struts Portlet Framework uses the welcome file to set the Struts module. The prefix corresponding to the Struts module for a portlet is stored in the IViewCommand object. The IViewCommand object is retrieved for each portlet and the module prefix is used to select the module, so each portlet in the application will use the Struts module selected during the welcome file processing. Obviously, the portlet can then forward to other modules as well, but initially each portlet can have a unique configuration using the Struts module.

The Struts Portlet Framework controller, WpsStrutsPortlet, is defined as the servlet-class in the web deployment descriptor. The corresponding abstract portlet is then defined in the portlet deployment descriptor. The application can then define each concrete portlet, and specify a welcome file to use. The configuration for one of the concrete portlets is demonstrated as follows:

```
<concrete-portlet-app uid="wp.struts.legacy.examples.MultipleStrutsApp.1">
  <portlet-app-name>Struts Legacy Multiple Modules Application 1</portlet-app-name>
  <concrete-portlet href="#Portlet_1">
    <portlet-name>Struts Legacy Multiple Modules 1</portlet-name>
      <default-locale>en</default-locale>
      <language locale="en">
        <title>Struts Legacy Multiple Modules 1</title>
```

```
        <title-short>Struts Legacy Multiple Modules 1</title-short>
        <description>Struts Legacy Multiple Modules 1</description>
        <keywords>WPS, Struts, Legacy</keywords>
      </language>
      <config-param>
        <param-name>viewMode.page</param-name>
        <param-value>portlet1/welcome.jsp</param-value>
      </config-param>
      <config-param>
        <param-name>editMode.page</param-name>
        <param-value>portlet1/edit.jsp</param-value>
      </config-param>
  </concrete-portlet>
</concrete-portlet-app>
```

The application can configure a separate Struts module that maps to each portlet. This scheme is customizable and will support as many Struts modules as required. However, only one abstract portlet can be defined because there can only be one Struts-based servlet-class. All of the concrete portlets created from the one abstract portlet must share the abstract's portlet configuration. See the SPFLegacyMultipleModules example for more information.

Using a namescoped servlet context

Multiple Struts portlets in a single web application can also be supported by configuring the portlet to use a servlet context wrapper. The (Wps)StrutsPortlet class instantiates the WpsActionServlet object to digest the Struts configuration. The Wp(s)ActionServlet extends the Struts ActionServlet and uses the ActionServlet's `init` implementation to digest the configuration. The (Wps)StrutsPortlet object will invoke the init method of the Wp(s)ActionServlet to digest the configuration. Since the (Wps)StrutsPortlet instantiates the Wp(s)ActionServlet and calls the `init` method, the Struts Portlet Framework has the opportunity to provide a servlet context wrapper. If the application is configured to use the servlet context wrapper, then the Wp(s)ActionServlet will return the servlet context wrapper when the getServletContext method is invoked. The servlet context wrapper defines a namespace unique to the portlet and then stores the attributes in the real servlet context. The concept is similar to how Struts prefixes the attributes in the servlet context for the configuration of each Struts module.

Note: The Wp(s)ActionServlet should be used to obtain the servlet context wrapper when this technique is used. The servlet context obtained from the pageContext, for example, will not be the wrappered servlet context. The Wp(s)ActionServlet can be obtained from the request object using the Globals.ACTION_SERVLET_KEY.

For an IBM portlet container:

The WpsStrutsPortlet class, which is specified as the servlet class in the web deployment descriptor, can be defined multiple times when the NamescopeServletContext initialization parameter, `init-param`, is set to true.

```
<servlet id="wp.struts.legacy.examples.ServletContext.1">
  <servlet-name>StrutsLegacyMultipleServletContexts1</servlet-name>
  <servlet-class>
     com.ibm.wps.portlets.struts.WpsStrutsPortlet
  </servlet-class>
  <init-param>
    <param-name>config</param-name>
    <param-value>
```

```
      /WEB-INF/portlet1/struts-config.xml
    </param-value>
  </init-param>
  <init-param>
    <param-name>struts-servlet-mapping</param-name>
    <param-value>*.do</param-value>
  </init-param>
  <init-param>
    <param-name>NamescopeServletContext</param-name>
    <param-value>true</param-value>
  </init-param>
</servlet>
```

An abstract portlet for each servlet-class can then be defined in the portlet deployment descriptor.

```
<portlet id="Portlet_1"
         href="WEB-INF/web.xml#wp.struts.legacy.examples.ServletContext.1"
         major-version="1" minor-version="0">
  <portlet-name>
     Struts Legacy Multiple Servlet Contexts 1
  </portlet-name>
    <cache>
      <expires>0</expires>
      <shared>NO</shared>
    </cache>
    <allows>
      <maximized />
      <minimized />
    </allows>
    <supports>
      <markup name="html">
        <view />
        <edit />
      </markup>
    </supports>
  </portlet>
```

For a standard portlet container:

The StrutsPortlet class, which is specified as the portlet class in the portlet deployment descriptor, can be defined multiple times when the NamescopeServletContext initialization parameter, `init-param`, is set to true.

```
<portlet>
   <description xml:lang="en">
      Struts Standard Multiple Servlet Contexts 2
   </description>
   <portlet-name>
      Struts Standard Multiple Servlet Contexts 2
   </portlet-name>
   <display-name xml:lang="en">
      Struts Standard Multiple Servlet Contexts 2
   </display-name>
   <portlet-class>
      com.ibm.portal.struts.portlet.StrutsPortlet
   </portlet-class>
   <init-param>
      <name>config</name>
      <value>/WEB-INF/portlet2/struts-config.xml</value>
   </init-param>
   <init-param>
      <name>struts-servlet-mapping</name>
      <value>*.do</value>
   </init-param>
   <init-param>
      <name>NamescopeServletContext</name>
```

```
      <value>true</value>
   </init-param>
   ...
</portlet>
```

Each portlet is independent of the other Struts-based portlets. See the SPFLegacyMultipleServletContexts.war example for more information.

Create link tags in Struts

Get an overview of how to write tags to create links in a JSP in both a servlet and a portlet in Struts framework.

Tags that create links need to create links that are serviced by the portlet. The URL that is created because of the Struts processing needs to be passed as a parameter back to the portlet. There must be a common tag for both a servlet and a portlet. The following code sample demonstrates how to write a tag that can be used by a JSP in both a servlet and a portlet.

```
PortletApiUtils portletUtils = PortletApiUtils.getInstance();
if (portletUtils != null)
{
   Object pResponse = portletUtils.getPortletResponse((HttpServletRequest)
                                                    pageContext.getRequest());
   Object portletURI =
      portletUtils.createPortletURIWithStrutsURL(pResponse,
                   calculateURL());

   results.append(portletURI.toString() );
}
else
{
   // servlet environment
   results.append(calculateURL());
}
```

The else clause was the original statement for the servlet-only environment. An instance of PortletAPIUtils is initially obtained. In a non-portlet environment, this call would return null. The initialization of the Struts Portlet Framework support would set the instance of the PortletAPIUtils implementation. A PortletResponse object is obtained as an Object. The PortletURI is then created with a DefaultPortletAction and a parameter that contains the Struts path through the call to `createPortletURIWithStrutsURL`.

Creating links in a JSP

The preferred method of creating a link in a JSP is to use a tag. This method is the most convenient method to assure that the link is portal-aware and takes Struts Modules into account. The Struts module implementation requires that the link is prefixed with the ModuleConfig's prefix. A typical Struts tag implementation would include logic similar to the following sample.

```
ModuleConfig config =
  (ModuleConfig) pageContext.getRequest().getAttribute(Globals.MODULE_KEY);
if (config != null) {
  value.append(config.getPrefix());
}
```

There are times when a link needs to be created in a JSP by using Java code. The links that are created in a JSP must also prefix the `ModuleConfig` prefix so the links support Struts Modules. PortletApiUtils has a convenience method that can be used to prefix the URL that uses the `ModuleConfig`. The method is called `addModulePrefix`. The following snippet demonstrates creating a link in a JSP.

```
<%@ page language="java" import="com.ibm.wps.struts.common.PortletApiUtils"
%>

<%
  PortletApiUtils portletUtils = PortletApiUtils.getInstance();
%>

<%
    if (portletUtils != null)
   {
      String url = "/bean-write.jsp";
      // add the module prefix to the url
      url = portletUtils.addModulePrefix(url, request);
      Object portletURI = portletUtils.createPortletURIWithStrutsURL(request, url);
%>
  <a href="<%=portletURI.toString()%>"><bean:write></a>
<%
   }
%>
```

Formatting XML documents with XSLT

Learn how a Struts application supports applying a style sheet to XML data.

The typical way that a Struts application supports applying a style sheet to XML data is to implement a Struts Action that writes directly to the response object. The IStrutsPrepareRender interface allows implementing a Struts action that will be executed in the render phase of portal, and therefore will have a response object that can be written to. The SPFLegacyTransformation.war is an example of how to implement a Struts action in the Struts Portlet Framework that can apply a style sheet to an XML document.

Note: You can locate legacy portlets, such as SPFLegacyTransformation.war, from the IBM WebSphere Portal Express Catalog.

Static content in Struts

Portlet JSPs can link to the static content within the portlet's WAR directory structure by using the services of the portlet container to create portlet URIs from which the content can be referenced.

Portlet JSPs cannot link directly to static content within the portlet's WAR directory structure. Instead, they have to use the services of the portlet container to create portlet URIs from which the content can be referenced. Links within static pages (for example, HTML pages) also need to be converted into portlet URIs. The Struts Portlet Framework processes links to static content and converts them to the form of portlet URIs so that linked content is brought back into the portlet and displayed.

Creating a Home button for static content

When the Struts Portlet Framework is used to display static content, it can be difficult to navigate back through a number of screens to a location earlier in the browser history. To overcome this, you can add a `homeFromStatic` forward to your action mapping which references the static content. This causes a home button to be added to your static content. Pressing the home button causes the link specified by the `homeFromStatic` forward to be used.

As with any action mapping, it is possible also to use a global forward. Thus, if for all sequences of static pages it was required to use the same link for every home button, one could use a global forward:

```
<global-forwards>
  <forward name="homeFromStatic"     path="/index.jsp"/>
   ...
</global-forwards>
```

A `homeForStatic` forward can also be created for a specific ActionMapping:

```
<action path="/staticpage"
        type="org.apache.struts.actions.ForwardAction"
   parameter="/html/view/static.html">
   <forward   name="homeFromStatic"       path="/index.jsp"/>
</action>
```

The home button is not only placed on the first static content page, but on all pages generated by links resulting from that page. If no `homeFromStatic` forward is found with the action mapping which initiated the sequence of static content pages, and there is no global `homeFromStatic` forward either, the home button is not generated.

Migrating existing Struts applications

Get an overview of how the existing Struts applications can be migrated using the Struts Portlet Framework so that these applications can be deployed in IBM WebSphere Portal Express.

The Jakarta Struts distribution ships an example Struts application that demonstrates the features of Struts, including implementing Struts Actions, creating custom tags, using the Struts tag libraries, authoring JSPs, and form validation. The Struts Portlet Framework demo builds on this example by incorporating WebSphere Portal Express features, including support for help mode and WML markup. The Struts example required very few changes to enable it for the Struts Portlet Framework.

The file structure of the WAR file for a Struts Portlet Framework is the same as that used for a Struts servlet. The Struts application in the portal server is a WAR file just like it is in the servlet environment. The portlet WAR file has some additional JARS and other requirements, but the basis of the implementation is similar to the servlet application. See Creating a simple portlet for more information.

Migrating servlet-based Struts applications

Existing Struts applications can be migrated using the Struts Portlet Framework so the application can be deployed in WebSphere Portal. Since Struts is a framework there are many variations to how the application can be built with Struts. There are also numerous other frameworks that may also be incorporated into the Struts

application. The steps in this section can be used as a starting point for the migration effort, but may not cover all of the issues that can be encountered.

1. Make sure the existing Struts application has been built as a Struts 1.1 application. (See http://jakarta.apache.org/struts/.)
2. Check Struts Actions to see if the action writes directly to the response object. If it does then, the action must be modified to either return an ActionForward instead, or check to see if the IStrutsPrepareRender interface should be used.
3. The Web deployment descriptor must be updated to use the WpsStrutsPortlet as the servlet class instead of the ActionServlet. (See "Changes to configuration files" on page 2958.)
4. The servlet mapping for Struts actions must be specified as the struts-servlet-mapping init parameter. (See "Changes to configuration files" on page 2958.)
5. Create a `portlet.xml`. The `SPFLegacyMailReader.war` can be used as an example. (See "Deployment descriptors" on page 3129.)
6. Modify the `struts-config.xml` to specify the WpsRequestProcessor as the controller. (See "Changes to configuration files" on page 2958.)
7. Modify tags that use pageContext.forward() to use the PortletApiUtils forward. (See "Changes to Struts application code" on page 2945.)
8. Modify JSPs that use a forward to use the logic forward tag. (See "Changes to Struts JSPs" on page 2955.)
9. Modify JSPs as necessary to use the Struts tags for creating URLs, like the Struts Link and Form tags. (See "Changes to Struts JSPs" on page 2955).
10. The JAR files from the `WEB_INF/lib` directory of the `SPFLegacyBlank.war` must be used. These files are the Struts JARs and the required Struts Portlet Framework JARs.
11. The TLD files must be updated from the `WEB_INF/lib` directory of `SPFLegacyBlank.war`. Verify the taglib attributes and that the JSP correctly reference the TLD files. This has been a common source of problems when migrating existing applications.
12. The JSPs should be modified so they do not use html, head and body elements. All HTML output to the portal is written in the context of an HTML table cell.

Migrating servlet-based Struts applications to the Standard version

Existing Struts applications can be migrated using the Struts Portlet Framework so the application can be deployed in WebSphere Portal. Since Struts is a framework there are many variations to how the application can be built with Struts. There are also numerous other frameworks that may also be incorporated into the Struts application. The steps in this section can be used as a starting point for the migration effort, but may not cover all of the issues that can be encountered.

1. Make sure the existing Struts application has been built as a Struts 1.1 application. (See http://jakarta.apache.org/struts/.)
2. Check Struts Actions to see if the action writes directly to the response object. If it does then, the action must be modified to either return an ActionForward instead, or check to see if the IStrutsPrepareRender interface should be used.
3. The Web deployment descriptor must be updated to use the StrutsPortlet as the portlet class. Remove the servlet-class from the Web deployment descriptor, and specify the StrutsPortlet as the portlet class in the portlet deployment descriptor. (See Changes to the Web deployment descriptor.)

4. The servlet mapping for Struts actions must be specified as the struts-servlet-mapping init parameter. The portlets init parameters are specified in the portlet deployment descriptor.
5. Create a `portlet.xml`. The SPFStandardMailReader.war can be used as an example. (See Portlet deployment descriptor.)
6. Modify the `struts-config.xml` to specify the WpRequestProcessor as the controller. (See "Changes to the Struts configuration file" on page 2970.)
7. Modify tags that use pageContext.forward() to use the PortletApiUtils forward. (See "Forwards and redirects" on page 2949.) The following example illustrates the change in which the PortletApiUtils object is obtained:
   - Old: PortletApiUtils portletUtils = PortletApiUtils.getInstance();
   - New: PortletApiUtils portletUtils = PortletApiUtils.getUtilsInstance();
8. Modify JSPs that use a forward to use the logic forward tag.
9. Modify JSPs as necessary to use the Struts tags for creating URLs, like the Struts Link and Form tags. (See "Creating portlet URIs" on page 2955).
10. The JAR files from the `WEB_INF/lib` directory of the SPFStandardBlank.war must be used. These files are the Struts JARs and the required Struts Portlet Framework JARs.
11. The TLD files must be updated from the `WEB_INF/lib` directory of SPFStandardBlank.war. Verify the taglib attributes and that the JSP correctly reference the TLD files. This has been a common source of problems when migrating existing applications.
12. The JSPs should be modified so they do not use html, head and body elements. All HTML output to the portal is written in the context of an HTML table cell.

Web 2.0 user interface features

Learn about portal features that pertain to the Web 2.0 generation type of Web user interface.

Web technology has evolved towards a different direction. In the public this evolution has been named Web 2.0. This term does not describe a new type of technology, but has been used in a broad manner to describe a change to a more user centered focus. Among the benefits are improved customer and service orientation, increased user activities, easier communication and collaboration, better usability, faster performance, etc.

Within portal, the Web 2.0 features are implemented as follows:

- Client side portlet programming model: You can use the client side programming model for your portlets. You can do everything with the client side programming model that you can do with the server side portlet programming model. Additionally, the client side programming model has the following advantages:
  - Improved user experience by faster responses and performance, as many interactions are processed on the client side rather than on the server.
  - User customization of user profile, preferences, and changes to the portlet state are done locally, and therefore with a faster response time. A fragment that contains the customization is later sent to the server and saved.
  - The user experience is consistent between both client side aggregation and server side aggregation.
- Live text: You can use live text. Live text provides elements embedded in portal pages that become active in the browser and are enhanced with additional

functionality by JavaScript libraries. For example, if you include portal user IDs in your portlet output and mark them as live text, users can click these IDs in the browser and see a person info card or a menu that allows them to send a mail to the person. Live text has the following advantages:
  - Live text allows easier click to action.
  - You can adopt new portal content within your company more easily, as it is now easier to handle portal tags. For example, you can write tags and make them available centrally, and UI developers can reuse these tags for in their portlets for various purposes.
  - Content editors can add meaningful live text elements to portlets without requiring portlet development knowledge.
  - You can embed content from other sources, for example, from a HTTP or .NET server.
- REST services:
  - Portal offers many REST services, such as Layout model, Portlet model, Content model, Navigation model, Wire model, and User profile.
  - By the use of REST services you can write your own advanced Web application and build it with REST (Representational State Transfer) services that provide the XML request information.
  - REST services allow you to access portal models remotely for both read and write access. The Navigation model allows read access only; it is updated by changes made to the content model.
- Controller SPI: The Controller SPI is a public portal interface. It is not directly related to the Web 2.0 type of user experience, but it allows you to perform certain administrative tasks more easily.

"The client side portlet programming model"
You can use the client side programming model to make use of AJAX techniques in your standard API portlets.

"Outbound HTTP connection" on page 2984
Applications in your IBM WebSphere Portal Express and the related user activities can require outbound HTTP connections to remote computer systems. The outbound HTTP connection service provides an administration infrastructure with a central point of administration for all outbound HTTP connections that are defined in the portal environment.

"Live text for click-to-action" on page 3062
IBM WebSphere Portal Express supports a live text API for user controlled data transfer between components. With live text, a component on a page can declare sources and targets for data transfer. For example, this can be a portlet or a navigation element. When the user clicks on a source element, the portal displays a menu listing targets that match the selected source. When a menu item is selected, the portal invokes the corresponding target passing it the source data. This process is called Click-to-Action (C2A).

The client side portlet programming model

You can use the client side programming model to make use of AJAX techniques in your standard API portlets.

You can use the client side programming model for writing your portlets. You can do everything with the client side programming model that you can do with the server side portlet programming model. Additionally, the client side programming model has the following advantages:

- The client side portlet programming model works in both client side aggregation (CSA) and server side aggregation (SSA).

- Improved user experience by faster response and performance. Portlets that use the clients side programming model render faster, as the portal does not re-render the whole page, but only the aspects of the portlet that change.
- The client side programming model allows you to handle changes of the portlet mode and window state, preferences, and user customization of user profile locally. This provides a faster response time for the user. A fragment that contains the customization is later sent to the server and saved.
- Writing portlets to the client side programming model does not require deep Java knowledge. You can write such portlets as HTML code with css style sheets and JavaScript. They have few or no JSPs. Example scenarios for writing client side portlets are:
  - A user can add some markup to the portlet view by selecting options in a form.
  - Preference changes that a user makes to the portlet are applied immediately in the browser view without reloading the whole portlet. The preference change is later sent to the server and saved.
  - Access to the user profile on the client side.
  - Portlet mode changes are performed entirely on the client. Performance improves as no server-client communication is required.
  - The portlet can retrieve markup fragments from the server. The user does not notice this, as the ATOM feed format is hidden by the XMLPortletRequest implementation, similar to a XMLHttpRequest (XHR).
  - XSLT and XPath helper functions make it easier to handle XML feeds.

For the full description of the JavaScript interfaces refer to the Web 2.0 Javadoc documentation available on developerWorks.

"Getting started with the client-side programming model for portlets"
Getting started with the client-side programming Model requires a few updates to the portlet JSPs.

"Handling portlet preferences on the client" on page 2982
One of the most useful aspects of the client side programming model is the ability to read, modify, and save portlet preferences on the client.

"Changing portlet mode and window state on the client side" on page 2983
With the client-side programming model, you can handle portlet mode and window state changes entirely on the client, rather than requiring a full server-client roundtrip.

"JavaScript namespacing - observing good practice" on page 2984
The client side context of Web programming requires good namespacing.

Getting started with the client-side programming model for portlets:

Getting started with the client-side programming Model requires a few updates to the portlet JSPs.

Procedure

1. Add a reference for the client-side programming model tag library:
```
<%@ taglib uri="http://www.ibm.com/xmlns/prod/websphere/portal/v6.1/portlet-client-model"
    prefix="portlet-client-model" %>
```
2. Declare the modules of the client-side programming model that you want to use:
```
<portlet-client-model:init>
     <portlet-client-model:require module="ibm.portal.xml.*"/>
     <portlet-client-model:require module="ibm.portal.portlet.*"/>
</portlet-client-model:init>
```

For a complete list of modules for use with the client-side programming model refer to the public API documentation.

3. To be able to work with the client-side programming model in your portlets, use the object `ibm.portal.portlet.PortletWindow` as an entry point:

```
<script>
   dojo.addOnLoad(function() {
      <%=namespace%>_portletWindow = new ibm.portal.portlet.PortletWindow("<%=portletWindowID%>");
   });
</script>
```

Note: Use the tag `portlet-client-model:init` to create the scripting variable `portletWindowID` for use in the JSP. The following example shows how you can start an `XMLPortletRequest`:

```
<script>

function sendXPR( /*string*/url, /*Function*/callback, /*String*/errMsg ) {
   var xpr = <%=namespace%>_portletWindow.newXMLPortletRequest();
   var me = this;
   xpr.onreadystatechange = function () {
      if ( xpr.readyState == 4 ) {
         if ( xpr.status == 200 ) {
            callback( xpr.responseText );
         }
      else {
         <%=namespace%>_portletWindow.logError("The request failed!", errMsg );

         }
      }
   };
   xpr.open( "GET", url );
   xpr.send( null );
}
</script>
```

Handling portlet preferences on the client:

One of the most useful aspects of the client side programming model is the ability to read, modify, and save portlet preferences on the client.

About this task

The interface `ibm.portal.portlet.PortletPreferences` JavaScript mirrors its server side counterpart `javax.portlet.PortletPreferences` as closely as possible. For the full description of the JavaScript interfaces refer to the public API documentation.

The following code sample shows how you can retrieve and read the portlet preferences on the client:

```
<script>
    function <%=namespace%>_handleLoadPortletPreferences(portletWindow, status, portletPrefs) {
        if (status==ibm.portal.portlet.PortletWindow.STATUS_OK) {
            portletWindow.setAttribute("preferences", portletPrefs);
            alert("Preferences.getValue()\n"+portletPrefs.getValue("test"));
            var prefs = portletPrefs.getMap();
            var mapStr = "Preferences.getMap()\number of preferences: "+prefs.length + "\n";
            for (var i=0; i<prefs.length; i++) {
                mapStr += i+" - "+prefs[i].name+" - "+prefs[i].values+" - "+prefs[i].readonly + "\n";
            }
            alert(mapStr);
        }
        else { alert("error loading feed"); }
    }
    <%=namespace%>_portletWindow = new ibm.portal.portlet.PortletWindow("<%=portletWindowID%>");
    <%=namespace%>_portletWindow.getPortletPreferences(<%=namespace%>_handleLoadPortletPreferences);
</script>
```

For the full description of the JavaScript interfaces refer to the public API documentation.

Related information:

Changing portlet mode and window state on the client side:

With the client-side programming model, you can handle portlet mode and window state changes entirely on the client, rather than requiring a full server-client roundtrip.

About this task

In client-side aggregation, you can provide an event handler for changes of portlet mode and portlet window state. This handler gets called when a mode change or a window state change is triggered.

Note: This function is only supported in the portal CSA theme and the CSA skin. You can adapt the CSA theme and skin to write your own custom themes and skins to support this feature.
The return value of your handler determines whether the default action is run:

- A return value of `true` allows execution of the default action, in this case the portlet mode or window state change.
- A return value of `false` cancels the default action.

This action allows the portlet to handle these changes entirely on the client, with no server interaction.

You define the change handlers as follows:

- To define a portlet mode change handler, define a JavaScript function with the name `<portlet:namespace/>doPortletMode` in your portlet.
- To define a portlet window state change handler, define a function with the name `<portlet:namespace/>doWindowState`.

The CSA skin checks whether such a function is defined before it processes any portlet mode or window state changes. The handler function provides two arguments:

- The first argument is the required portlet mode or window state in string form.
- The second argument is the markup element that must be used to insert a mode-specific markup. This argument is necessary to support the inline modes that you see in the CSA version of the IBM portal skin.

Refer to the following example:

```
<portlet:namespace/>doPortletMode( portletMode, div ){
   var retVal = true;
   if ( portletMode == ibm.portal.portlet.PortletMode.VIEW ) {
      //do view mode here
      div.innerHTML = "...some view mode markup...";
      retVal = false;
   }
   return retVal;
   }
```

JavaScript namespacing - observing good practice:

The client side context of Web programming requires good namespacing.

About this task

When using the client side programming model for your portlets you need to apply good namespacing practices in JavaScript. This helps to avoid collisions in the page which can be timely and expensive to track down. The namespace need must be balanced with the performance advantage of moving all JavaScript into external JavaScript files that can be cached. An additional benefit is that this makes portlet JSPs much smaller. Refer to the following code sample of writing JavaScript for a portlet by the client side programming model:

`htmlEditor.js:`

```
if ( typeof( HTMLEditorController ) == "undefined" ) {
     var HTMLEditorController = function( namespace ) {
          this._namespace = namespace;
          this.getSaveForm = function () {
               return document.forms[ namespace + "saveForm" ]
          }
     }
}
```

`htmlEditor.jsp:`

```
var <%=namespace%>htmlController = new HTMLEditorController( "<%=namespace%>" );
```

Outbound HTTP connection

Applications in your IBM WebSphere Portal Express and the related user activities can require outbound HTTP connections to remote computer systems. The outbound HTTP connection service provides an administration infrastructure with a central point of administration for all outbound HTTP connections that are defined in the portal environment.

Advantages:

- The outbound HTTP connection service gives portal system administrators central control over outbound HTTP connections that are used.
- The outbound HTTP connection infrastructure provides functions for authentication and cookie handling.
- Application developers do not have to implement common HTTP connections support. For example, they do not need to write the handler code for various types of HTTP-based authentication, such as the following types:
  - Basic authentication
  - Form based authentication
  - Authentication through SSL tokens
  - SAML authentication.
- In WebSphere Portal Express Version 8.0 and earlier versions, outbound HTTP connections were accessible through the Ajax Proxy service. The Ajax Proxy service was configured by a configuration document named `proxy-config.xml`. You find this document in the `/WEB-INF` directory of the web module that uses the Ajax Proxy service. Starting with WebSphere Portal Express Version 8.5 and the new outbound connection service, the configuration of outbound HTTP connections is now part of the standard datastore-based portal configuration.

Outbound HTTP connections are created by application code to establish an HTTP connection to a remote system. For example, such application code can be part of portlets, portlet services, themes, servlet filters, or other items. A remote outbound HTTP connections can be called from different components. Examples:

- Code that runs in the context of a portlet
- Code that runs in the context of a servlet, for example, a servlet filter
- Code that runs on the portal server outside the context of a servlet request
- Code that runs on the client.

You can therefore establish outbound HTTP connections in the following different ways:

- Through the portlet-request based outbound HTTP connection service
- Through the servlet-request based outbound HTTP connection service
- Through the Ajax proxy.

The WebSphere Portal Express outbound HTTP connection includes the following components:

- A common outbound HTTP connection configuration infrastructure. This infrastructure provides base functions for managing the configuration of outbound HTTP connections.
- The outbound HTTP connection service. This service makes it possible to establish outbound HTTP connections from code that runs in the portal context.
- The HTTP proxy for Ajax application. This application provides an interface for accessing outbound HTTP connections by using an HTTP proxy channel.

The Ajax proxy and the outbound HTTP connection services use the same common configuration infrastructure.

You can use an outbound HTTP connection in the following two ways:

- Through the outbound HTTP connection service
- Through the Ajax Proxy, which is also known as the HTTP proxy for Ajax application.

The following image illustrates the two different ways to connect to a remote system by using outbound HTTP connections:

"The programming model for the outbound HTTP connection service" on page 2986
The outbound HTTP connection service can be used from the context of a servlet request service or from the context of a portlet request service. Here are some code examples.

"HTTP proxy for Ajax applications, also known as Ajax Proxy" on page 2989
One of the basic technologies that emerged in the context of the next generation web user interface is *Ajax* (Asynchronous JavaScript and XML). Using Ajax can increase the responsiveness and usability of your web applications.

"Configuring outbound HTTP connections" on page 2992
In WebSphere Portal Express Version 8.0 and earlier versions, outbound HTTP connections were accessible through the Ajax Proxy service. The Ajax Proxy service was configured by a configuration document named `proxy-config.xml`. You find this document in the `/WEB-INF` directory of the web module that uses the Ajax Proxy service. Starting with WebSphere Portal Express Version 8.5 and the new outbound connection service, the configuration of outbound HTTP connections is now part of the standard datastore-based portal configuration.

"Authenticating outbound HTTP connections" on page 3031
You can protect the access to the remote host by an authentication mechanism.

"Using dynamic elements in outbound HTTP connection settings" on page 3053
In some cases, it is useful to control configuration settings at run time. For example, an administrator might want to have the program decide at run time which policy rule is applied. In another scenario, parts of a policy rule configuration that are known only at run time must be included in the configuration.

"Using programmatic extensions for outbound HTTP connections" on page 3054
To extend the functions of an outbound connection, portal administrators can implement a custom outbound service filter.

"Migration" on page 3061
WebSphere Portal Express Version 8.5 provides a migration process for the change from the Ajax proxy of previous portal versions to the new outbound HTTP connection.

The programming model for the outbound HTTP connection service:

The outbound HTTP connection service can be used from the context of a servlet request service or from the context of a portlet request service. Here are some code examples.

The following example shows how to obtain the outbound HTTP connection service from the context of a portlet:

```
import javax.naming.Context;
import javax.naming.InitialContext;
import javax.naming.NamingException;
import javax.portlet.PortletRequest;
import javax.portlet.PortletResponse;
import com.ibm.portal.outbound.service.OutboundConnectionService;
import com.ibm.portal.outbound.service.OutboundConnectionServiceHome;
import com.ibm.portal.outbound.service.OutboundConnectionServiceException;

// obtain an Outbound HTTP connection service object (portlet context)

private OutboundConnectionService getService (PortletRequest p_request,
           PortletResponse p_response)
 throws  OutboundConnectionServiceException, NamingException
{

 Context ctx = new InitialContext();
 final OutboundConnectionServiceHome home = (OutboundConnectionServiceHome)
           ctx.lookup(OutboundConnectionServiceHome.JNDI_NAME);
      final OutboundConnectionService service =
          home.getOutboundConnectionService(p_request, p_response);
 return service;
}
```

In a different scenario, the code that calls the outbound HTTP connection service is part of a servlet. In this case, the method `getOutboundConnectionService ()` receives the servlet request and servlet response variable. See the following example:

```
import javax.naming.Context;
import javax.naming.InitialContext;
import javax.naming.NamingException;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;
import com.ibm.portal.outbound.service.OutboundConnectionService;
import com.ibm.portal.outbound.service.OutboundConnectionServiceHome;
import com.ibm.portal.outbound.service.OutboundConnectionServiceException;
...
```

```
// obtain an Outbound HTTP connection service object  (servlet context)
private OutboundConnectionService getService ( HttpServletRequest s_request,
       HttpServletResponse s_response)
 throws OutboundConnectionServiceException, NamingException
{

 Context ctx = new InitialContext();
 final OutboundConnectionServiceHome home = (OutboundConnectionServiceHome)
           ctx.lookup(OutboundConnectionServiceHome.JNDI_NAME);
      final OutboundConnectionService service =
          home.getOutboundConnectionService(p_request, p_response);
 return service;
}
```

Applications use the `createConnection()` method of the outbound HTTP connection service to open an outbound HTTP connection. The following code snippet connects to a URL resource through outbound HTTP connections and reads the content of the web page and writes it to a byte array output stream. See the following example:

```
import java.io.IOException;
import java.io.InputStream;
import java.io.ByteArrayOutputStream;
import java.net.HttpURLConnection;
import java.net.URL;
import com.ibm.portal.outbound.service.OutboundConnectionService;

...
/**
 * usage sample for GET requests using Outbound HTTP Connections
 * @param service the outbound HTTP connection service
 * @param theURL the remote URL
 * @param bos An object that receives the content of the GET request.
 * @return the HTTP status
 **/
private int doGet (OutboundConnectionService service,
                   URL theURL,
                   ByteArrayOutputStream bos)
    throws OutboundConnectionServiceException, IOException
{
    // obtain a connection object
    HttpURLConnection connection = createConnection(theURL);
    try {
       // Submit the URL connection to the remote host.
       connection.connect();

       // read the returned content:
       InputStream is = (InputStream)connection.getContent();
       int byt = is.read();
       while (byt >= 0) {
          bos.write(byt);
          byt = is.read();
       }
  int status = connection.getStatus();
       return status;
    } finally {
       connection.disconnect();
       bos.close();
    }
}
```

The following code snippet connects to a URL resource through outbound HTTP connections and submits a POST request:

```
import java.io.IOException;
import java.io.InputStream;
import java.io.ByteArrayOutputStream;
import java.net.HttpURLConnection;
import java.net.URL;
import com.ibm.portal.outbound.service.OutboundConnectionService;

...
/**
 * usage sample for POST requests using Outbound HTTP Connections
 * @param service the outbound HTTP connection service
 * @param theURL the remote URL
 * @param postData the POST data.
 * @param bos An object that receives the content of the GET request.
 * @return the HTTP status
 **/
private int doPost (OutboundConnectionService service,
                    URL theURL,
                    byte[] postData,
                    ByteArrayOutputStream bos)
    throws OutboundConnectionServiceException, IOException
{
    // obtain a connection object
    HttpURLConnection connection = createConnection(theURL);
    try {
       // write the POST data
       OutputStream os = connection.getOutputStream();
       os.write(postData, 0, postData.length);
       os.close();

       // Submit the URL connection to the remote host.
       connection.connect();

       // read the returned content:
       InputStream is = (InputStream)connection.getContent();
       int byt = is.read();
       while (byt >= 0) {
          bos.write(byt);
          byt = is.read();
       }
  int status = connection.getStatus();
       return status;
    } finally {
       connection.disconnect();
       bos.close();
    }
}
```

The following code snippet obtains an outbound connection service and requests the content of the URL www.ibm.com:

```
ByteArrayOutputStrream bos = new ByteArrayOutputStream();

OutboundConnectionService ocs = getService (request, response);
int status = doGet(ocs, new URL("http.//www.ibm.com"), bos);
if (status >= 400) {
    System.err.println("Remote connection failed with HTTP status "+status);
} else {
    byte[] da = bos.toByteArray();
    String first = da.length > 10 ? new String(da,0,da.length) : new String(da);
    System.out.println("The content starts with "+first);
}
```

HTTP proxy for Ajax applications, also known as Ajax Proxy:

One of the basic technologies that emerged in the context of the next generation web user interface is *Ajax* (Asynchronous JavaScript and XML). Using Ajax can increase the responsiveness and usability of your web applications.

Ajax enables web pages to load data or markup fragments from a server by using asynchronous requests. These requests are processed in the background. Therefore, they do not interfere with the web page that is displayed in the browser. When you use Ajax, your web application exchanges only small amounts of data between the server and the client. Therefore, it refreshes only small parts of the markup. Therefore, Ajax is also useful for developing portlets and for building mashups, that is, aggregating content from various different sources into a uniform user experience. For example, such content can consist of RSS or Atom feeds or other data that is retrieved from external REST services.

To prevent cross-site scripting attacks in such web applications, browsers introduced the so called same-origin policy. This policy prevents client side scripts, in particular JavaScript, from loading content from an origin that has a different protocol, domain name, or port. To overcome this restriction, some browser vendors offer solutions that are based on signed scripts. However, using a signed script does not mean that a script can be trusted. Another disadvantage of these browser-specific solutions is that they rely on the user to configure the browser accordingly.

The solution that IBM WebSphere Portal Express offers is based on a server-side HTTP proxy. This proxy is named the HTTP Proxy for Ajax Applications, or also known as the Ajax Proxy. The underlying security model allows administrators to restrict access to trusted origins in a flexible way. The Ajax Proxy can be used for developing themes, skins, static pages, or portlets. The following sections explain how to use and configure the Ajax proxy.

"The programming model for using the AJAX proxy"
View information on using the proxy when programming portlets.

The programming model for using the AJAX proxy:

View information on using the proxy when programming portlets.

The programming model specifies the following:

- How you make requests, that is how you format URLs that address the proxy
- How the proxy reacts in specific cases, for example in case of an error.

Note: The proxy does not rewrite URLs that are part of the received content, because the proxy does not know the semantics of the content that it fetches. Consequently, AJAX applications that use the proxy need to generate proxy URLs by themselves.

"URL format and examples" on page 2990
The proxy can be addressed via URLs that comply with the REST-based URL format given here.

"AJAX proxy status codes" on page 2990
The AJAX proxy responds to requests by defined status codes. Possible errors that can occur in the proxy are mapped to the corresponding HTTP status codes.

"Using the AJAX proxy in portlets" on page 2991
Here is how you use the AJAX proxy in portlets.

URL format and examples:

The proxy can be addressed via URLs that comply with the REST-based URL format given here.

This format is as follows:

```
<protocol>://<portal-domain>/<proxyurl>/<protocol>/<host>%3a<port>/<url>?<query>
```

The proxy URL carries the target URL in its path information part. Depending on the context path mapping in the proxy configuration, the target URL can be an absolute or relative URL.

Examples: Refer to the following sample proxy URLs. They show how you can load a URL via the proxy depending on the context path mapping in the proxy configuration.

```
URL: http://www.ibm.com/developerworks/news/dw_dwtp.rss
Context path mapping (from proxy-config.xml): <mapping contextpath="/proxy" url="*"/>
Proxy URL: http://myportal.com:10040/wps/proxy/http/www.ibm.com/developerworks/news/dw_dwtp.rss

URL: http://myotherportal.com:1234/sitemap
Context path mapping (from proxy-config.xml): <mapping contextpath="/proxy" url="*"/>
Proxy URL: http://myportal.com:10040/wps/proxy/http/myotherportal.com%3a1234/sitemap

URL: http://www-01.ibm.com/software/swnews/swnews.nsf/swnewsrss?openview&RestrictToCategory=lotus
Context path mapping (from proxy-config.xml): <mapping contextpath="/ibmsoftwarenews"
        url="http://www-01.ibm.com/software/swnews/"/>
Proxy URL: http://myportal.com:10040/wps/ibmsoftwarenews/swnews.nsf/swnewsrss?openview&RestrictToCategory=lotus
```

AJAX proxy status codes:

The AJAX proxy responds to requests by defined status codes. Possible errors that can occur in the proxy are mapped to the corresponding HTTP status codes.

By default, the AJAX proxy does not forward an HTTP status code that it receives from the target host. Only 2xx and 3xx status codes are directly forwarded to the client. If the proxy receives an 4xx error code, it will always return a 404 'Not Found' error instead. You can change this behavior by using the `forward-http-errors` configuration parameter. For more details about this parameter refer to the topic about General configuration parameters.

The proxy returns its response with one of the following status codes:

200 OK
: This code indicates that the request was accepted by the proxy and that the target server returned a response with a status code 200. This means that the request complied with one of the access policies that you specified in the proxy configuration.

400 Bad Request
: The proxy returns this code if the syntax of the request was incorrect.

403 Forbidden
: The proxy returns this code in either of the following two cases:
  - The request was not accepted by the proxy, that is the proxy found no matching access policy that grants access to the target server.
  - Basic authentication failed.

404 Not found
: This code indicates that the proxy accepted the request, but the target server either returned status code 404 itself or a different 4xx error code.

302 Found
This code indicates that the authentication was successful.

Using the AJAX proxy in portlets:

Here is how you use the AJAX proxy in portlets.

The easiest way to create proxy URLs in a portlet is to register the AJAX proxy servlet in the `web.xml` file of the portlet. This allows you to create the base proxy URL by using the portlet API, whereas you append the target URL according to the URL format specified in the section about the URL format. The class name of the proxy servlet is `com.ibm.wps.proxy.servlet.ProxyServlet`. For more details refer to the sample `web.xml` file.

If you want the proxy to be able to access resources that require authentication, specify a second servlet mapping that is associated with a security constraint. In the sample, only authenticated users can access proxy URLs that match the URL pattern `/myproxy/*`.

Note: You must associate the user roles that you specify in the `web.xml` file with the user roles of the portal server. You can do this by creating the corresponding role mappings for the respective application in the WebSphere Integrated Solutions Console.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" ...>
   ...
   <servlet>
      <servlet-name>ProxyServlet</servlet-name>
      <servlet-class>com.ibm.wps.proxy.servlet.ProxyServlet</servlet-class>
   </servlet>
   ...
   <servlet-mapping>
      <servlet-name>ProxyServlet</servlet-name>
      <url-pattern>/proxy/*</url-pattern>
   </servlet-mapping>
   <servlet-mapping>
      <servlet-name>ProxyServlet</servlet-name>
      <url-pattern>/myproxy/*</url-pattern>
   </servlet-mapping>
   ...
   <security-constraint id="SecurityConstraint_1">
      <web-resource-collection id="WebResourceCollection_1">
         <web-resource-name/>
         <url-pattern>/myproxy/*</url-pattern>
         <http-method>GET</http-method>
         <http-method>POST</http-method>
         <http-method>PUT</http-method>
         <http-method>HEAD</http-method>
      </web-resource-collection>
      <auth-constraint id="AuthConstraint_1">

```

Registering the proxy servlet in the Web deployment descriptor of a portlet does not imply that the portlet is based on an application specific configuration. If no `proxy-config.xml` file is provided with the portlet, the proxy servlet uses the global proxy configuration instead. The only constraint that you need to consider is that for each servlet mapping, a corresponding context path mapping must exist in the proxy configuration. This can be either in the global or in the application specific configuration. For details on how to configure the AJAX proxy refer to the section about AJAX proxy configuration.

Configuring outbound HTTP connections:

In WebSphere Portal Express Version 8.0 and earlier versions, outbound HTTP connections were accessible through the Ajax Proxy service. The Ajax Proxy service was configured by a configuration document named `proxy-config.xml`. You find this document in the `/WEB-INF` directory of the web module that uses the Ajax Proxy service. Starting with WebSphere Portal Express Version 8.5 and the new outbound connection service, the configuration of outbound HTTP connections is now part of the standard datastore-based portal configuration.

About this task

For more detailed information, read the following topics.

"Configuration structure"
The Outbound Connection Service Configuration model has the following structure.

"XML format for outbound HTTP connection configuration settings" on page 3000
To export or import the outbound HTTP Connections configuration, you use an XML file with a specific schema.

"Administration tools for configuring outbound HTTP connections" on page 3012
Portal system administrators can administer the outbound HTTP connection configuration in one of two ways: either by using configuration tasks, or by using the portal Model and Controller SPIs.

"Sample administration tasks" on page 3023
Here you find some procedures for running administration tasks on the outbound HTTP connection settings. These tasks use the portal configuration engine interface.

Configuration structure:

The Outbound Connection Service Configuration model has the following structure.

For more detailed information about the configuration structure of the outbound connection service, read the following topics. Examples follow in later topics.

"Outbound connection profile" on page 2993
The outbound connection profile contains the elements of the configuration model. The following profiles can exist.

"Policy mappings" on page 2994
When an outbound HTTP connection is established through the outbound connection service, the caller can specify the mapping context in an optional parameter.

"Policy rules" on page 2994
Policy rules define handling rules for outbound HTTP connections. Policy rules are identified by a URL pattern. When an outbound HTTP connection is opened, the portal compares the URL of that outbound HTTP connection against the URL pattern of the policy rule and handles the URL accordingly.

"Cookie rules" on page 2995
Cookie rules define handling rules for cookies that you use in the context of an outbound HTTP connection.

"Policy variables" on page 2997
You can use policy variables to resolve tokens of the form `{$Variable_name}` that can appear in the URL pattern setting of a proxy rule or in metadata.

Outbound connection profile:

The outbound connection profile contains the elements of the configuration model. The following profiles can exist.

System profile
This profile is reserved for configuration settings that are used by the system internally. A portal configuration contains exactly one system profile.

Global profile
This profile contains all global configuration settings. These settings are maintained by the portal administrator. In contrast to settings in application-scoped profiles, the policy mappings, proxy rules, and cookie rules that are defined in the global profile are available to all applications that use the outbound connection service. A portal configuration contains zero or one global profile.

Application-scoped profiles
Application scoped profile settings are valid within the scope of a specific web module. The application for which this profile is scoped is determined by the context root of the web module deployment descriptor. For example, if the deployment descriptor of the web module `bannerad.war` contains the context root setting `/wps/PA_Banner_Ad`, the application-scope profile must contain only `/wps/PA_Banner_Ad` as a scope reference.

An outbound connection profile item contains the application scope reference setting:

application scope reference
This setting is `null` for the system profile and for the global profile. For application-scoped profiles, the scope reference identifies the application to which this profile belongs. The scope reference contains the context root setting of the application. You can locate this information by either of the following ways:

- If the referenced application is a portlet application, proceed as follows:
  1. Log in to the portal by using the portal administrator user ID.
  2. Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.

3. In the **Manage Web Modules** portlet, click **Select Web Module Properties** for the requested web module. The web module properties view lists the context root. For example, this context root can be `/wps/PA_Banner_Ad`.

- By alternative, you can determine the context root of an application by using the WebSphere Integrated Solutions Console. Proceed as follows:
  1. Select the enterprise application that you want to refer to.
  2. Click **View Deployment Descriptor**.
  3. Locate the context-root tag.
  4. Take the value of this tag as scope reference value.

Policy mappings:

When an outbound HTTP connection is established through the outbound connection service, the caller can specify the mapping context in an optional parameter.

Policy mappings have the following two purposes:

- The policy mapping is the container of the policy rules that define the characteristics of the outbound connections.
- If the outbound connection is accessed through the Ajax proxy, the policy mapping defines the connection settings for the Ajax proxy.

The following code sample shows how you create an outbound connection service by using the policy mapping context path `/mycontext`:

```
String theMappingContextPath = "/mycontext";

OutboundConnectionServiceHome home = (OutboundConnectionServiceHome)
          ctx.lookup("portal:service/model/OutboundConnectionService");
OutboundConnectionService connectionService = home.getOutboundConnectionService
          (request, Response, theMappingContextPath);
```

If the connection is established through the Ajax proxy, the mapping context root is used as context root for the proxy:

```
http://localhost:10039/wps/mycontext/(...encoded remote url ...);
```

An outbound connection profile contains at least one policy mapping item. This item is created when the outbound connection profile element is created. This default policy mapping does not have a context path. Therefore, policy rules that are defined in the default policy mapping are always accessible to outbound HTTP connection filters, independent of the context for which the connection was created. In the previous example, the following policy rules are available for the connection:

- The policy rules that are defined at the Policy Mapping with the context path `/mycontext`.
- The policy rules that are defined at the default policy mapping.

Policy rules:

Policy rules define handling rules for outbound HTTP connections. Policy rules are identified by a URL pattern. When an outbound HTTP connection is opened, the portal compares the URL of that outbound HTTP connection against the URL pattern of the policy rule and handles the URL accordingly.

A policy rule contains the following settings:

URL pattern:
Policy rules are identified by their URL patterns. If an outbound HTTP connection to a certain URL is connected, the outbound HTTP connection service checks the URL patterns of all policy rule items in the accessible policy mappings. The policy rule with the URL pattern that matches best is selected.

basicAuth
This flag indicates whether the connection that is defined by this policy rule is protected by basic authentication. If you set this key to `true`, the connection is protected by basic authentication. If you set it to `false`, the connection is not protected by basic authentication.

active This flag indicates whether this rule is active or not.

A set of allowed methods:
A policy rule can contain a set of allowed HTTP methods. This list restricts the HTTP methods for the URL connection. For example, if you specify `Get, Post` as the set of allowed methods, then only GET and POST requests are permitted for the URLs that this policy rule controls. If a policy rule does not contain a list of allowed methods, then all HTTP methods are permitted.

A set of mime types:
A policy rule can contain a set of mime types. They restrict the allowed mime type of the content that is received. For example, if you specify the set `text/html, text/plain`, it restricts outbound HTTP connections to content that is either plain text or HTML output. If you specify no list of supported mime types, then outbound HTTP connections are not restricted to certain mime types.

A set of Headers:
A policy rule can restrict the outbound connection to a set of request headers that are allowed for the remote connection.

A custom chain of URL connection filters:
To add an outbound HTTP connection that provides custom function, you can add a chain of custom URL connection filters. The outbound HTTP connection service provides a filter API. Programmers can use this API to write filters that are called whenever an outbound HTTP connection is opened. For more information, read *Program extensions for outbound HTTP connections*.

Related tasks:

"Using programmatic extensions for outbound HTTP connections" on page 3054
To extend the functions of an outbound connection, portal administrators can implement a custom outbound service filter.

Cookie rules:

Cookie rules define handling rules for cookies that you use in the context of an outbound HTTP connection.

Cookies are set by the remote server by using the `Set-Cookie:` response header setting. The cookie rules determine the handling of a created cookie. The cookie rule defines how this cookie is treated. Cookie rule definitions are owned by policy rules. Each policy rule defines individually how to handle cookies that are set in outbound HTTP connections.

A Cookie Rule contains the following settings:

cookie names
Use this setting to specify a set of wildcard expressions that contain names or name patterns of cookies. For example, the cookie rule with the name `LtpaToken*` applies to both LtpaToken and LtpaToken2. A cookie rule is owned by a proxy rule. Therefore, a cookie rule is applied if both of the following conditions apply:

- The owning proxy rule is applied.
- The cookie name matches with the wildcard expression.

cookie handling
Use this setting to define how the outbound HTTP connection service handles remote cookies. The outbound HTTP connection service can handle cookies in the following ways:

block This value is the default value. Cookies that you define as blocked cookies are filtered out: They are not returned in the response header of the outbound HTTP connection.

store in session
Cookies are stored in a cookie store that is placed in the local HTTP session.

store in request
Cookies are stored in a cookie store that is placed in the local HTTP request.

passthru
Cookies of the handling type `passthru` are copied into the response header of the connection of the Ajax proxy. The domain and cookie path of the cookie that is passed through are converted to the domain and path of the Ajax proxy servlet. The handling type `passthru` takes effect only if the outbound connection is established through the Ajax proxy.

wrap If you use cookies of the handling type `passthru`, they can conflict with local cookies, for example LtpaToken, LtpaToken2, or JSESSIONID cookies. In this case, you can use the handling type `wrap`. Cookies of handling type `wrap` are handled like cookies in `passthru` mode, but additionally, the cookie name is transformed.

cookie scope
This setting defines the owner of this cookie. A cookie can be associated with the following scopes:

user The cookie is scoped to the current user.

application
The cookie is scoped to the application that calls the outbound HTTP connection service.

system
The cookie is not scoped at all.

cookie transformations
This setting defines a programming interface. Application developers can use it to implement a custom cookie transformation handler. The custom extension code is called at the following two occasions:

1. Before the remote HTTP connection writes the request header to the remote connection

2. When the response header of the remote HTTP connection is evaluated.

   The custom transformation handler can modify the name, value, domain, and path of the cookie that is assigned with the custom transformation handler. For more information, read *Using custom cookie transformation handlers*.

Related tasks:

"Using custom cookie transformation handlers" on page 3059
You can use custom cookie transformation handlers to allow custom program extensions to get programmatic control over the outbound HTTP connection.

Policy variables:

You can use policy variables to resolve tokens of the form `{$Variable_name}` that can appear in the URL pattern setting of a proxy rule or in metadata.

Policy variables are used in the `urlPattern` setting of a proxy rule item, or in a metadata section. There are two types of policy variables:

Endpoint variables

Endpoint variables define a single-value variable. They are typically used to define a specific backend host. When application developers use endpoint variables, they can write a policy rule so that it extracts those parts of the URL pattern in a variable that are specific to the current portal environment. Example:

1. The portlet developer defines a proxy rule with the following URL pattern setting: `{$my_server}/mymail*`. This means that the resulting URL pattern is the value of the policy variable, appended with the path `/mymail`.
2. The portal system administrator defines the value `http://www.the-remote-system.com` for the variable `my_server`. Therefore, the URL pattern of the policy rule is `http://www.the-remote-system.com/mymail`.

The benefit of this technique is that you can divide a URL pattern into parts that are owned by the portlet developer and parts that are owned by the portal system administrator. Therefore, the portlet developer can define a policy rule without knowing the concrete host name of the backend system to which the outbound connection is established.

Dynamic policy variables

Dynamic policy variables can have more than one value. The purpose of this variable type is to define dynamic parts of the URL pattern without having to specify a policy rule more than once. Example:

- A policy rule URL pattern has the following URL pattern setting: `http://localhost/wps/{$my_dynamic_policy}/Main/*`.
- The variable `my_dynamic_policy` is associated with the values `portal` and `myportal`.

As a result, the policy rule applies to URLs that start with `http://localhost/wps/portal/Main/` or `http://localhost/wps/myportal/Main/`. The purpose of this technique is to make one policy rule available for multiple URL patterns that can contain dynamic parts.

For hints and tips for working with policy variables and setting them, read the following topic.

"Setting policy variables" on page 2998
You can set policy variables in different ways.

Setting policy variables:

You can set policy variables in different ways.

- You can set a policy variable in the portal WP Configuration Service Resource Environment Provider (REP) properties. This method is the preferred method to place global settings independent from the policies that refer to them.
- You can set a policy variable in the outbound HTTP connection configuration. This method is the preferred way for values or selections that are closely related with the policy rule.
- You can set a policy variable at run time. To do so, you use a URL query string parameter. Use this method if your policy contains dynamic elements that you want to define at run time.

For more details about these methods, read the following sections.

Setting policy variable values in the Resource Environment Provider properties

You can set policy variables in the portal WP Configuration Service Resource Environment Provider (REP) properties. You do so in the custom properties section of the WebSphere Integrated Solutions Console. For more information about setting properties in the portal configuration services, read Setting service configuration properties.

The portal matches policy variables based on the following custom property name scheme:

`wp.proxy.config.urlreplacement.`*`variable_name`*`.suffix`

The partial strings of the naming scheme have the following meanings:

`wp.proxy.config.urlreplacement`
This prefix identifies the property for defining a dynamic policy replacement value.

`variable_name`
This variable identifies the target dynamic policy variable that is used in the outbound HTTP connection configuration.

`suffix`
This suffix represents a string of your choice. If there is more than one key, this string makes the key unique among all replacement keys that refer to the same dynamic policy replacement variable.

Example: The following policy of an outbound HTTP connection configuration references the dynamic policy variable `my_remote_hosts`:

```
<policy url="http://{$my_remote_host}/*" >
     <actions>
     <method>GET</method>
     </actions>
</policy>
```

To attach this policy to outbound requests to URLs that match one of the URL patterns `http://www.some.server.com` or `http://some.other.server.com`, you can add the following two custom properties to the WP Configuration Service REP:

```
wp.proxy.config.urlreplacement.my_remote_host.1=http://www.some.server.com
wp.proxy.config.urlreplacement.my_remote_host.2=http://some.other.server.com
```

Notes: Dynamic policy values that are defined in the WP Configuration Service REP properties are not scoped. Therefore, such dynamic policy variables can be

used both by policies that are set in the global configuration profile and by policies that are set in an application-scoped profile.

Note: For configuration changes in the WP Configuration Service REP properties to take effect, restart IBM WebSphere Application Server.

Setting policy variables in the outbound HTTP connection configuration

As an administrator, you can define policy variables directly in the Outbound HTTP Connection configuration. Example:

```
<variables>
     <dynamic-policy name="my_path">
          <value>wps/portal</value>
          <value>wps/contenthandler</value>
     </dynamic-policy>
</variables>
...
<policy url="http://www.myremotesite.com/{$my_path}/*" >
     <actions>
     <method>GET</method>
     </actions>
</policy>
```

In this example, the policy variable `my_path` is defined in the outbound HTTP connection configuration. The variable is scoped to the configuration profile, in which the variable was defined:

- If the variable is defined in the global configuration, the variable can be referenced by policies or metadata settings of the global configuration.
- If the variable is defined in an application-scoped configuration, the variable can be referenced by policies or metadata settings of the same application-scoped profile.

To create, modify, or delete configuration-based policy variables, use the administration tools of the outbound HTTP connection services. For more detailed information, read Administration tools for configuring outbound HTTP connections.

Setting policy variables at run time

There are also cases where an application developer wants to set the policy variable directly by the application. Example: An application wants to choose the credential slot ID of an authenticated HTTP connection. For these scenarios, the outbound HTTP connection infrastructure provides a means to specify policy variables at run time. There are two ways to define policy variables for runtime resolution:

- The policy variable is defined as a dynamic-policy variable.
- The policy variable is defined as an endpoint variable. Its value is empty. At run time, the client sets the policy variable value. The value is not validated.

Security note: Define runtime policy variables carefully. Run time policy variables can have a security impact.
Example: The portal administrator wants to define two different user credentials for an outbound HTTP connection to the URL `http://www.myremotehost.com/test`. The user wants to select the credentials when the connection is created. A configuration defines the following policy variable:

```
name=SLOTID
type=Dynamic Policy
Values= MySlot2, MySlot33
```

The variable is referenced by the Credential Vault slot description that is defined in the metadata section of a policy mapping `/myproxy` as illustrated later:

```
metadata name:  paa.slotid
metadata value: {$SLOTID}
```

At run time, the client submits the following request at the Ajax proxy:

```
HTTP://localhost/wps/myproxy/www.myremotehost.com/test?SLOTID=MySlot2
```

At run time, the authentication filter of the outbound HTTP connection server reads the metadata `paa.slotid`. By doing so, it obtains the slot ID for the credentials that you want to be used for the outbound HTTP connection. The value of `paa.slotid` is mapped to the policy variable `SLOTID`. The client that called the connection defined a slot ID value `MySlot2`, which is in the valid set of policy variables.

"Administration tools for configuring outbound HTTP connections" on page 3012
Portal system administrators can administer the outbound HTTP connection configuration in one of two ways: either by using configuration tasks, or by using the portal Model and Controller SPIs.

XML format for outbound HTTP connection configuration settings:

To export or import the outbound HTTP Connections configuration, you use an XML file with a specific schema.

Example of a `proxy-config.xml` file

The following example is a sample outbound HTTP connection configuration script. It shows the schema for XML scripts that you can use to export or import the outbound HTTP Connections configuration.

```
<?xml version="1.0" encoding="UTF-8"?>
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
    <variables>
        <dynamic-policy name="default_policy">
           <value>http://www.ibm.com/*</value>
           <value>http://www-3.ibm.com/*</value>
        </dynamic-policy>
    </variables>
    <mapping contextpath="/proxy" url="*" name="proxy"/>
    <mapping contextpath="/myproxy" url="*" name="myproxy">
       <policy url="http://www.test-server.com/*" name="ibm1">
           <actions>
              <method>GET</method>
           </actions>
     <cookie-rule name="my.application.cookie">
        <cookie>TestCookie</cookie>
              <scope>user</scope>
           <handling>store-session</handling>
     </cookie-rule>
        </policy>
```

```
    </mapping>
    <policy url="{$default_policy}" name="default">
        <actions>
            <method>GET</method>
            <method>HEAD</method>
        </actions>
    </policy>

    <meta-data>
        <name>socket-timeout</name>
        <value>10000</value>
    </meta-data>
</proxy-rules>
```

"XML schema of outbound HTTP connection configuration script"
An outbound connection configuration script file needs to conform to the following XML schema.

"Description of the outbound HTTP connection configuration script" on page 3003
The configuration settings of an outbound HTTP connection configuration script are described here.

XML schema of outbound HTTP connection configuration script:

An outbound connection configuration script file needs to conform to the following XML schema.

```
<?xml version="1.0" encoding="UTF-8"?>

```

Description of the outbound HTTP connection configuration script:

The configuration settings of an outbound HTTP connection configuration script are described here.

proxy-rules

The `proxy-rules` setting is the root of a configuration profile. The configuration profile for which the script is applied is specified in the configuration task that is run against this script. The `proxy-rules` setting can contain the following subsettings:

variables

Use the `variables` setting to specify endpoint variables or dynamic policy variables. Variables are used in the URL attribute of the policy setting, or they are used in a variable value. For more details about how to use variables, read *Variables*.

mapping

Use the `mapping` setting to map incoming requests to a target URL, based on their context path. Therefore, each mapping must specify a `contextpath` attribute and optionally a `url` attribute. Optionally, mappings can declare policy settings that represent mapping specific access policies. For more details about how to use mappings, read *Context path mappings*. Mappings contain a name attribute that gives an administrative name for this mapping. This attribute is used by administrative tasks to identify the mapping for update tasks or delete tasks.

policy

Use the `policy` setting to define an access policy for a specific URL pattern. A proxy configuration can contain multiple policy definitions. If no policy is specified at all, the portal denies all incoming requests. For more details about policies, read *Access policies*.

ipfilter

Use `ipfilter` setting to define one or more IP patterns. You can use these IP filter patterns to either grant or deny a particular IP address or a set of addresses access to the Ajax proxy. For more details about IP filtering rules, read *IP filtering*.

meta-data

Use the `meta-data` setting to specify general configuration properties of the proxy, for example HTTP-related parameters. Each `meta-data` setting must have a `name` and a `value`. To get a list of configuration parameters that are available in the portal, read *General configuration parameters by metadata*.

"Variables"
Variables settings define variables that are used in other sections of the configuration.

"Context path mapping" on page 3005
You use a context path mapping to map a specific context path to a specific target URL. The proxy resolves context path mappings before it applies the matching access policy.

"Policies" on page 3006
Each `policy` setting defines an access policy for a URL pattern. You specify the pattern by using the **`url`** attribute. A **`url`** attribute can be either a URL, or the wildcard character, or URL part that ends with the wildcard character "*". The following are examples for url attribute values: `http://localhost/index.html` `*http://www.ibm.com/developerWorks/*`.

"IP filtering" on page 3007
You can use `ipfilter` settings to declare IP filtering rules and to either grant or deny a client access to the Ajax proxy.

"Configuration metadata for outbound HTTP connections" on page 3008
You can add general proxy configuration parameters to the file `proxy-config.xml` by using `meta-data` settings.

"Cookie rule" on page 3011
You can use cookie rules to determine how you want the cookie to be handled.

Related concepts:

"The programming model for the outbound HTTP connection service" on page 2986
The outbound HTTP connection service can be used from the context of a servlet request service or from the context of a portlet request service. Here are some code examples.

Variables:

Variables settings define variables that are used in other sections of the configuration.

There are two types of variable settings, endpoint variables and dynamic-policy variables:

endpoint variables

Endpoint variables define a single endpoint. For example, this endpoint can be the host name of a remote server. You specify the value of an endpoint in the content of an endpoint variable.

dynamic-policy variables

Dynamic-policy variables can have multiple values. Dynamic-policy variables contain one or more value elements. All of these value elements apply to the variable.

The following example illustrates the usage of an endpoint variable:

```
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
     <variables>
          <endpoint name="the_remote_host">www.myremotehost.com</endpoint>
     </variables>
     <policy url="http://{$the_remote_host}/*" name="endpoint_sample">
          <actions><method>GET</method></actions>
     </policy>
</proxy-rules>
```

The following example shows the usage of a dynamic policy variable. The policy that is defined in this example applies to the following URL patterns:

- `http://www.myremotehost.com/*`
- `http://w3.myremotehost.com/*`
- `https://www.myremotehost.com/*`
- `https://w3.myremotehost.com/*`

```
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
     <variables>
          <dynamic-policy name="my_prot_selector">
               <value>http</value>
               <value>https</value>
          </dynamic-policy>

          <dynamic-policy name="the_remote_host">
               <value>www.myremotehost.com</value>
               <value>w3.myremotehost.com</value>
          </dynamic-policy>
     </variables>
     <policy url="{my_prot_selector}://{$the_remote_host}/*" name="dyn_policy_example">
          <actions><method>GET</method></actions>
     </policy>
</proxy-rules>
```

Context path mapping:

You use a context path mapping to map a specific context path to a specific target URL. The proxy resolves context path mappings before it applies the matching access policy.

To work with context path mappings, you work with the `mapping` setting. An example `mapping` setting can look as follows:

```
<mapping contextpath="/ibmproducts" url="http://www.ibm.com/products"/>
```

It maps requests that contain the context path `/ibmproducts` to the URL `http://www.ibm.com/products`. As a result, the incoming proxy URL is `http://myportal.com/wps/ibmproducts/us/en`, the proxy forwards the request to `http://www.ibm.com/products/us/en`. For more details about the proxy URL format and the usage of context path mappings, read *The programming model for the outbound HTTP connection service*.

You can also define generic context path mappings that are not tied to a specific URL pattern. You do so by specifying the asterisk as a wildcard: `url="*"`. Example:

```
<mapping contextpath="/proxy" url="*"></mapping>
```

However, if your application must connect to only a few external systems, for example to one external REST service that provides the application data, it is better to use a specific context path mapping.

Note: The current servlet-based implementation of the proxy requires a corresponding servlet mapping for each defined `mapping` setting. You define the servlet mapping in the file `web.xml`. The servlet mapping maps all requests that address the specified context path to the proxy servlet. If you apply this rule to the previous examples, there must be a servlet mapping for either of the context paths `"/ibmproducts"` or `"/proxy"` that references the proxy servlet.

Policies:

Each `policy` setting defines an access policy for a URL pattern. You specify the pattern by using the **`url`** attribute. A **`url`** attribute can be either a URL, or the wildcard character, or URL part that ends with the wildcard character "*". The following are examples for url attribute values: `http://localhost/index.html` `*http://www.ibm.com/developerWorks/*`.

The following example shows a simple policy:

```
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
     <policy name="SamplePolicy" url="http://www.myremotehost.com/*">
          <actions><method>GET</method></actions>
     </policy>
</policy-rules>
```

For each incoming request, the proxy applies the policy with the best URL match. If the proxy finds a policy, it applies this policy to the outbound connection. If the proxy finds no matching policy, the proxy rejects the request. Mappings can optionally declare `policy` setting that represents mapping-specific access policies.

A `policy` setting can have a `name` attribute that identifies this policy for administrative tasks. If this attribute is not set, the portal sets a unique administrative name for it. The administrative name must be unique for all policies that have the same parent `mapping` setting or parent `proxy-rules` setting.

To enable Basic Authentication for a policy, you can set the attribute `basic-auth-support` to `true`.

A `policy` setting can have the subsettings that are shown in the following list. Specify the subsettings in the same order in the configuration file `proxy-config.xml` as in the list:

actions

This setting is mandatory. Use it to define the list of HTTP methods that can be used to access resources in the target domain. These methods are `GET`, `HEAD`, `POST`, `PUT`, and `DELETE`. The proxy denies requests that use HTTP methods that are not on this list. Specify each HTTP method by using a separate `method` setting. The following example shows a policy that supports the methods DELETE, GET, HEAD, POST, and PUT:

```
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
     <policy name="SamplePolicy_supporting_all_methods" url="http://www.myremotehost.com/*">
          <actions>
```

```
                <method>GET</method>
                <method>HEAD</method>
                <method>POST</method>
                <method>PUT</method>
                <method>DELETE</method>
            </actions>
        </policy>
</policy-rules>
```

headers

This setting is optional. Use it to define the list of header names that you want the proxy to forward to the target domain. The header names can include wildcard characters. If you specify no header names for the policy, the proxy by default forwards headers that match the following name expressions: `Cache-Control`, `Pragma`, `User-Agent`, `Accept*`, `Host`, and `Content*`. Specify each header name by using a separate `header` setting.

Note: The value `Cookies` is not allowed. Instead, use the `cookie-rules` setting to specify the cookie forwarding behavior for the policy.
The following example shows a policy that supports the `X-Method-Override` header:

```
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
     <policy name="SamplePolicy_custom_header_added" url="http://www.myremotehost.com/*">
          <actions><method>GET</method></actions>

          <headers>
               <header>X-Method-Override</header>
          </headers>
     </policy>
</proxy-rules>
```

mime-types

This setting is optional. Use it to specify the list of accepted mime types. The mime types refer to the response that the proxy receives from the target server. If you specify at least one mime type, the proxy accepts only responses with a `Content-Type` response header that matches one of the specified mime types. If you specify no mime type, the proxy accepts all responses. Specify each mime type by using a separate `mime-type` setting. Servers might append the character encoding to the mime type. Therefore, it can be useful to use wildcard characters when you specify mime types. For example, if you specify `text/html*`, the proxy also accepts responses with the Content-Type `text/html; charset=utf-8`. The following example shows a policy that uses mime type filtering:

```
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
     <policy name="SamplePolicy_filtered_mimetype" url="http://www.myremotehost.com/*">
          <actions><method>GET</method></actions>

          <mime-types>
               <mime-type>text/plain</mime-type>
          </mime-types>
     </policy>
</proxy-rules>
```

IP filtering:

You can use `ipfilter` settings to declare IP filtering rules and to either grant or deny a client access to the Ajax proxy.

You can use `allow` settings to grant access to a particular IP address or set of addresses. By alternative, you can use `deny` settings to deny access to a particular IP address or set of addresses.

The `allow` and `deny` settings support the following value formats:

- Net address and bit number. Example: `192.0.0.0/24`

- Net address and NetMask. Example: `192.0.0.0/255.255.255.0`
- Specific IP address. Example `192.168.0.1`
- Specific IP address with wildcards. Example `192.168.*.1`

Note: If you declare multiple `ipfilter` settings in the proxy configuration, the proxy processes them by the sequence in which you specify them. As a result, the last matching rule always takes effect, regardless of the previous rules.
The following example makes the policies in the `/myproxy` mapping accessible only to clients that have an IP address in the specified range:

```
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
     <mapping contextPath="/myproxy" url="*">
          <policy name="SamplePolicy" url="http://www.myremotehost.com/*">
               <actions><method>GET</method></actions>
          </policy>
          <ipfilter>
               <allow>192.168.1.*</allow>
          </ipfilter>
     </mapping>
</policy-rules>
```

Configuration metadata for outbound HTTP connections:

You can add general proxy configuration parameters to the file `proxy-config.xml` by using `meta-data` settings.

You can specify all of these parameters within a `proxy-rules` or `mapping` setting.

HTTP connection handling parameters:

Use the following configuration parameters to determine how the proxy handles the HTTP connection:

`socket-timeout`

Use this parameter to define the default socket timeout in milliseconds. The socket timeout determines how long the proxy server waits for data after it successfully establishes a connection with the target server. The default value is 20 seconds. A timeout value of zero means that a timeout is not applied.

`retries`

Use this parameter to define the number of retries that you want the proxy to do if it cannot establish a connection with the target server. The default value is 2 retries.

`max-total-connections`

Use this parameter to define the maximum number of HTTP connections that the proxy can open to connect to arbitrary target hosts. The default value is 100 connections.

`max-connections-per-host`

Use this parameter to define the number of HTTP connections that the proxy can open to connect to a specific host. The default value is 50 connections per host.

User Agent identifier:

Use the following configuration parameter to redefine the user agent parameter:

`user-agent`

Use this parameter to specify the user agent identifier that you want to be used for the outbound connection.

Control Redirection:

Use the following configuration parameter to specify the reaction on an HTTP redirect status (HTTP status 302):

follow-redirects

Set this parameter to `true` if the caller wants an HTTP redirect status to be resolved automatically, that is, the connection is reestablished to the redirection URL. Set this parameter to `false` if no automated redirection is required. In that case, the proxy returns an HTTP status 302 to the caller. If you do not set this parameter, then the default reaction on a 302 HTTP status depends on the HTTP request method:

- For all requests of `HEAD` and `GET`, the portal follows the HTTP redirection.
- For all other request methods, the portal does not follow the HTTP redirection.

Deactivate policy rules, mappings, or custom connection filters:

A policy rule, a mapping, or a custom connection filter can be set to be deactivated. In this case, the disabled policy rule or mapping remains in the configuration, but does not take effect at run time. Ensure that you use the metadata setting to control the activation state of a policy rule or mapping:

active

Valid values are `false` and `true`:

true This is the default value. If you set this parameter to `true`, the policy rule is in effect.

false If you want the policy rule to be deactivated, set the `active` parameter to the value `false`.

Security parameters:

Use the following configuration parameters to specify security-related settings of the proxy. You can also define these security-related parameters within `policy` settings.

unsigned_ssl_certificate_support

Valid values are `false` and `true`:

true If you set this parameter to `true`, the proxy connects to any HTTPS URL that is allowed by the policy, regardless of whether it trusts the specified host. This is the default value.

false If you set this parameter to `false`, the proxy connects only to HTTPS URLs that it trusts.

forward-http-errors

This parameter defines whether the proxy forwards extra HTTP error codes to the client. Valid values are `false` and `true`:

false This value is the default value. It means that only 2*xx* and 3*xx* status codes are forwarded, whereas 4*xx* error codes are automatically mapped to a `404 'Not Found'` error.

true If you set the `forward-http-errors` parameter to `true`, the proxy forwards every status code, even if it represents an error code.

forward-credentials-from-vault
This parameter defines whether user credentials that are retrieved from the credential vault of the portal can be forwarded to the specified target host by using an HTTP authorization request header. Valid values are `false` and `true`:

false This is the default value. If you set this parameter to `false`, the proxy does not forward credentials.

true If you set this parameter to `true`, the proxy forwards credentials.

xhr-authentication-support
This parameter defines whether HTTP BASIC user credential challenges from the external service are rewritten. Valid values are `false` and `true`:

false This value is the default value. If you set this parameter to `false`, the proxy does not change the `WWW-Authenticate` HTTP header, and the user is prompted for credentials.

true If you set this parameter to `true`, the browser does not ask the user to provide credentials. Instead, the client-side code can handle that challenge. In detail, the proxy changes the value of the HTTP header `WWW-Authenticate` from `BASIC` to `XHRBASIC`.

Configuring a Boundary (pass-through) Proxy:
Use the following configuration parameters to make connections through a boundary (pass-through) proxy:

passthru_host
This parameter defines the host name of the pass-through proxy.

passthru_port
This parameter defines the port of the pass-through proxy.

passthru_realm
This parameter is optional. It defines the authentication realm of the pass-through proxy.

passthru_username
This parameter is optional. It defines the user name for the pass-through proxy.

passthru_password
This parameter is optional. It defines the password for the pass-through proxy.

The following example shows a typical metadata setting:

```
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
     <policy url="http://www.myremotehost.com/*" name="SamplePolicy">
          <actions><method>GET</method></actions>
     </policy>

     <meta-data>
          <name>socket-timeout</name>
          <value>10000</value>
     </meta-data>
     <meta-data>
          <name>retries</name>
          <value>2</value>
     </meta-data>
     <meta-data>
          <name>max-connections-per-host</name>
```

```
        <value>50</value>
    </meta-data>
    <meta-data>
        <name>max-total-connections</name>
    <value>100</value>
    </meta-data>
</proxy-rules>
```

Cookie rule:

You can use cookie rules to determine how you want the cookie to be handled.

The following options are available:

- The cookie can be made visible for the client that calls the outbound HTTP connection.
- The cookie can be wrapped in another cookie.
- The cookie can be stored in either of the following types of cookie store:
  - A cookie store that is scoped for the session
  - A cookie store that is scoped for the request

To configure your cookie rules, use the following attributes:

cookie
This attribute is required. You can specify multiple `cookie` attributes. `cookie` attributes contain a wildcard expression of a cookie name for which this cookie rule applies.

scope This attribute is optional. The `scope` attribute denotes the scope for which the cookie is shared. The following scope values are valid:

user This value is the default value. It defines that the cookie is scoped to the user that receives the cookie from the remote server.

system
This value defines the cookie as shared. That means that all clients of an outbound connection that establish a connection use the same cookie.

application
This value determines that the cookie is scoped to the application from which the outbound connection is established.

handling
This attribute is optional. It determines how to proceed with cookies that are defined by the remote server in outbound HTTP connections: The following handling values are valid:

passthru
This value is the default value. It leaves the cookie unchanged. The cookie is returned to the user of the outbound HTTP connection. It is up to the caller of the outbound HTTP connection to handle this cookie.

wrap This value wraps this cookie in another cookie. If you specify this value, the transformation rules define the characteristics of this transformation.

block This value blocks this cookie. If the cookie is set by the caller of the outbound HTTP connection, the cookie is not sent to the remote host. In the same manner, cookies that are set by the remote system are not received at the outbound HTTP connection.

store-in-request
This value stores the cookie in a cookie store during the HTTP request. Cookies that are set by the remote host are filtered out by the cookie handling filter. When the next HTTP connections are made, the stored cookies are added to the request header of this request.

store-in-session
This value stores the cookie in a cookie store during the HTTP session. Cookies that are set by the remote host are filtered out by the cookie handling filter. When the next HTTP connections are made, the stored cookies are added to the request header of this request.

The following example shows a cookie rule that contains a cookie rule for LTPA tokens, an application cookie that is named `app_cookie`, and a further cookie that is named `another_cookie`. By these cookie rules, the LTPA token is saved in a cookie store, and the two cookies `app_cookie` and `another_cookie` are passed through the proxy to the client.

```
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
     <policy name="SamplePolicy" url="http://www.myremotehost.com/*">
          <actions><method>GET</method></actions>
          <cookie-rule name="my_sso_tokens">
               <cookie>LtpaToken*</cookie>
               <handling>store-in-session</handling>
          </cookie-rule>
          <cookie-rule name="my_application_cookies">
               <cookie>app_cookie</cookie>
               <cookie>another_cookie</cookie>
               <handling>passthru</handling>
          </cookie-rule>
     </policy>
</proxy-rules>
```

Administration tools for configuring outbound HTTP connections:

Portal system administrators can administer the outbound HTTP connection configuration in one of two ways: either by using configuration tasks, or by using the portal Model and Controller SPIs.

"Configuring outbound HTTP connections by using configuration tasks" on page 3013
Programmers can create, read, update, or delete settings of the outbound HTTP connection by using the appropriate portal configuration engine tasks.

"Configuring outbound HTTP connections by using the Model Controller SPI" on page 3019
To query and administer the outbound HTTP connection, you can also use the model controller SPI.

Related concepts:

"Model SPI overview" on page 2858
Models provide information that is needed by WebSphere Portal Express to perform tasks such as content aggregation or building navigation to browse the aggregated content. The information that is aggregated is represented through models that can be accessed programmatically by using the Model SPI (read-only). The information of a model is usually persistent (stored in a database) but can also be transient (computed and stored only in memory). Models can be represented by using a tree structure (nodes have a parent-child relationship), a list structure, or a selection structure (a selected element in a tree structure).

"Controller SPI " on page 2883
You can use the Controller SPI for portal administration. It allows you to modify portal resources. It enhances the read-only portal Model SPI by adding writable aspects.

Configuring outbound HTTP connections by using configuration tasks:

Programmers can create, read, update, or delete settings of the outbound HTTP connection by using the appropriate portal configuration engine tasks.

About this task

The portal provides the following configuration tasks for these tasks:

```
create-outbound-http-connection-config
read-outbound-http-connection-config
update-outbound-http-connection-config
delete-outbound-http-connection-config
clean-outbound-http-connection-config
```

For more information about how to work with outbound HTTP connection configuration settings, read the following topics. They also provide information about to work with application-scoped configuration settings.

"Creating an outbound HTTP connection configuration profile" on page 3014
This configuration task creates an outbound HTTP connection configuration profile by using the settings that you specify in an XML document. Use this task if you want to initially create outbound HTTP settings for your configuration. You can create a global configuration or an application-scoped configuration.

"Reading an outbound HTTP connection configuration profile" on page 3015
This configuration task reads an outbound HTTP connection configuration and exports it to an XML document. System administrators can use this document to update the configuration of an outbound HTTP connection. You can read a global configuration or an application-scoped configuration.

"Updating an outbound HTTP connection configuration profile" on page 3016
This configuration task updates the configuration profile settings of the outbound HTTP connection with the settings that are specified in an XML document. Use this task to manage existing outbound HTTP settings of your configuration. You can update a global configuration or an application-scoped configuration.

"Deleting outbound HTTP connection configuration settings" on page 3017
This configuration task deletes configuration settings for an outbound HTTP connection. It deletes the settings that are specified in an XML document. You can delete settings of the global configuration or of an application-scoped configuration.

"Clearing an outbound HTTP connection configuration profile" on page 3018
This configuration task clears the complete configuration profile for an outbound HTTP connection. It deletes all settings of an outbound HTTP connection profile. Whereas the `delete-outbound-http-connection-config` configuration task deletes only those configuration settings that are listed in the specified XML document, this task purges the entire HTTP connection configuration profile.

Creating an outbound HTTP connection configuration profile:

This configuration task creates an outbound HTTP connection configuration profile by using the settings that you specify in an XML document. Use this task if you want to initially create outbound HTTP settings for your configuration. You can create a global configuration or an application-scoped configuration.

About this task

The configuration task creates the specified configuration settings if they do not exist. In contrast to the configuration task **update-outbound-http-connection-config**, this task leaves existing configuration settings unchanged. The syntax of the configuration task differs, depending on whether you want to create the settings for a global configuration or for an application-scoped configuration.

Creating the global outbound HTTP connection profile:
About this task

To create outbound HTTP connection settings for the global configuration, use the following syntax:

IBM i

```
ConfigEngine.sh create-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
```

Linux

```
./ConfigEngine.sh create-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
```

Windows

```
ConfigEngine.bat create-outbound-http-connection-config -DConfigFileName=your_path\config_file.xml
```

`your_path/config_file.xml` is the absolute path name of the XML document that contains the configuration settings for the outbound HTTP connection infrastructure that you want to add.

For more information, see Adding an outbound connection policy.

Creating an application-scoped outbound HTTP connection profile:
About this task

To create outbound HTTP connection settings for an application-scoped configuration, use the following syntax:

IBM i

```
ConfigEngine.sh create-outbound-http-connection-config   -DConfigFileName=your_path/config_file.xml
                                                         -DApplicationScopeRef=scoperef
```

Linux

```
./ConfigEngine.sh create-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
                                                         -DApplicationScopeRef=scoperef
```

Windows

```
ConfigEngine.bat create-outbound-http-connection-config  -DConfigFileName=your_path\config_file.xml
                                                         -DApplicationScopeRef=scoperef
```

`your_path/config_file.xml` is the absolute path name of the XML document that contains the configuration settings for the outbound HTTP connection infrastructure that you want to add.

`scoperef` is the context root of the application to which the configuration settings are scoped. To obtain the scope reference, proceed as follows:

1. Access the WebSphere Integrated Solutions Console.
2. Select the enterprise application for which the outbound HTTP connection is scoped.
3. Click **View Deployment Descriptor**.
4. Locate the value of the `context root` tag.

An example context root is `/PA_Banner_Ad`.

Reading an outbound HTTP connection configuration profile:

This configuration task reads an outbound HTTP connection configuration and exports it to an XML document. System administrators can use this document to update the configuration of an outbound HTTP connection. You can read a global configuration or an application-scoped configuration.

About this task

To update an outbound HTTP connection configuration, you first create the XML document by using use the configuration task `read-outbound-http-connection-config`. Then, you modify the document as required and update the outbound HTTP connection configuration by using the configuration task `update-outbound-http-connection-config`.

The syntax of the configuration task differs, depending on whether you want to read the settings for a global configuration or for an application-scoped configuration.

Reading the global outbound HTTP connection profile:
About this task

To read the outbound HTTP connection settings for the global configuration, use the following syntax:

IBM i

```
ConfigEngine.sh read-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
```

Linux

```
./ConfigEngine.sh read-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
```

Windows

```
ConfigEngine.bat read-outbound-http-connection-config -DConfigFileName=your_path\config_file.xml
```

`your_path/config_file.xml` is the absolute path name of the XML document to which you want the configuration settings to be written.

Reading an application-scoped outbound HTTP connection profile:
About this task

To read the outbound HTTP connection settings for an application-scoped configuration, use the following syntax:

IBM i

```
ConfigEngine.sh read-outbound-http-connection-config   -DConfigFileName=your_path/config_file.xml
                                                       -DApplicationScopeRef=scoperef
```

Linux

```
./ConfigEngine.sh read-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
                                                       -DApplicationScopeRef=scoperef
```

Windows

```
ConfigEngine.bat read-outbound-http-connection-config  -DConfigFileName=your_path\config_file.xml
                                                       -DApplicationScopeRef=scoperef
```

`your_path/config_file.xml` is the absolute path name of the XML document to which you want the configuration settings to be written.

`scoperef` is the context root of the application to which the configuration settings are scoped. To obtain the scope reference, proceed as follows:

1. Access the WebSphere Integrated Solutions Console.
2. Select the enterprise application for which the outbound HTTP connection is scoped.
3. Click **View Deployment Descriptor**.
4. Locate the value of the `context root` tag.

An example context root is `/PA_Banner_Ad`.

Updating an outbound HTTP connection configuration profile:

This configuration task updates the configuration profile settings of the outbound HTTP connection with the settings that are specified in an XML document. Use this task to manage existing outbound HTTP settings of your configuration. You can update a global configuration or an application-scoped configuration.

About this task

The configuration task updates the specified configuration settings. It creates the specified configuration settings if they do not exist.

The syntax of the configuration task differs, depending on whether you want to update the settings for a global configuration or for an application-scoped configuration.

To update an outbound HTTP connection configuration, you use the configuration tasks `read-outbound-http-connection-config` and `update-outbound-http-connection-config`.

Procedure

1. Run the configuration task `read-outbound-http-connection-config`. It exports the outbound HTTP connection configuration to an XML document.
2. Update the XML document that resulted from the previous step as appropriate.
3. To apply your updates to the configuration, you use the configuration task `update-outbound-http-connection-config`.

Updating the global outbound HTTP connection profile:
About this task

To update the outbound HTTP connection settings for the global configuration, use the following syntax:

IBM i

```
ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
```

Linux

```
./ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
```

Windows

```
ConfigEngine.bat update-outbound-http-connection-config -DConfigFileName=your_path\config_file.xml
```

`your_path/config_file.xml` is the absolute path name of the XML document that contains the configuration settings for the outbound HTTP connection infrastructure that you want to update.

Updating an application-scoped outbound HTTP connection profile:
About this task

To update the outbound HTTP connection settings for an application-scoped configuration, use the following syntax:

IBM i

```
ConfigEngine.sh update-outbound-http-connection-config   -DConfigFileName=your_path/config_file.xml
                                                         -DApplicationScopeRef=scoperef
```

Linux

```
./ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
                                                         -DApplicationScopeRef=scoperef
```

Windows

```
ConfigEngine.bat update-outbound-http-connection-config  -DConfigFileName=your_path\config_file.xml
                                                         -DApplicationScopeRef=scoperef
```

`your_path/config_file.xml` is the absolute path name of the XML document that contains the configuration settings for the outbound HTTP connection infrastructure that you want to update.

`scoperef` is the context root of the application to which the configuration settings are scoped. To obtain the scope reference, proceed as follows:

1. Access the WebSphere Integrated Solutions Console.
2. Select the enterprise application for which the outbound HTTP connection is scoped.
3. Click **View Deployment Descriptor**.
4. Locate the value of the `context root` tag.

An example context root is `/PA_Banner_Ad`.

Deleting outbound HTTP connection configuration settings:

This configuration task deletes configuration settings for an outbound HTTP connection. It deletes the settings that are specified in an XML document. You can delete settings of the global configuration or of an application-scoped configuration.

About this task

The task deletes the outbound HTTP connection configuration settings as specified in an XML document. You specify the settings that you want to delete in the XML document. The task tries to remove all items that are defined in the XML document. If an item contains dependent data that is not explicitly listed in this document, then the configuration setting is not deleted. The syntax of the configuration task differs, depending on whether you want to delete the settings for the global configuration or for an application-scoped configuration.

Deleting global outbound HTTP connection settings:
About this task

To delete global configuration settings for an outbound HTTP connection, use the following syntax:

IBM i

```
ConfigEngine.sh delete-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
```

Linux

```
./ConfigEngine.sh delete-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
```

Windows

```
ConfigEngine.bat delete-outbound-http-connection-config -DConfigFileName=your_path\config_file.xml
```

`your_path/config_file.xml` is the absolute path name of the XML document that contains the configuration settings for the outbound HTTP connection infrastructure that you want to delete.

Deleting application-scoped outbound HTTP connection settings:
About this task

To delete application-scoped configuration settings for an outbound HTTP connection, use the following syntax:

IBM i

```
ConfigEngine.sh delete-outbound-http-connection-config   -DConfigFileName=your_path/config_file.xml
                                                         -DApplicationScopeRef=scoperef
```

Linux

```
./ConfigEngine.sh delete-outbound-http-connection-config -DConfigFileName=your_path/config_file.xml
                                                         -DApplicationScopeRef=scoperef
```

Windows

```
ConfigEngine.bat delete-outbound-http-connection-config  -DConfigFileName=your_path\config_file.xml
                                                         -DApplicationScopeRef=scoperef
```

`your_path/config_file.xml` is the absolute path name of the XML document that contains the configuration settings for the outbound HTTP connection infrastructure that you want to delete.

`scoperef` is the context root of the application to which the configuration settings are scoped. To obtain the scope reference, proceed as follows:

1. Access the WebSphere Integrated Solutions Console.
2. Select the enterprise application for which the outbound HTTP connection is scoped.
3. Click **View Deployment Descriptor**.
4. Locate the value of the `context root` tag.

An example context root is `/PA_Banner_Ad`.

Clearing an outbound HTTP connection configuration profile:

This configuration task clears the complete configuration profile for an outbound HTTP connection. It deletes all settings of an outbound HTTP connection profile. Whereas the `delete-outbound-http-connection-config` configuration task deletes only those configuration settings that are listed in the specified XML document, this task purges the entire HTTP connection configuration profile.

About this task

The syntax of the configuration task differs, depending on whether you want to clear the settings for the global configuration or for an application-scoped configuration. If you specify no application scope reference, the task deletes the global outbound HTTP connections profile. Otherwise, the task deletes the

application-scoped profile that you identify by the `scoperef` parameter. The configuration task deletes all settings from that specified profile.

Clearing the global outbound HTTP connection profile:
About this task

To clear all settings of the global configuration for an outbound HTTP connection, use the following syntax:

IBM i

```
ConfigEngine.sh clean-outbound-http-connection-config -DOutboundProfileType=global
```

Linux

```
./ConfigEngine.sh clean-outbound-http-connection-config -DOutboundProfileType=global
```

Windows

```
ConfigEngine.bat clean-outbound-http-connection-config -DOutboundProfileType=global
```

Clearing an application-scoped outbound HTTP connection profile:
About this task

To clear all settings of an application-scoped configuration for an outbound HTTP connection, use the following syntax:

IBM i

```
ConfigEngine.sh clean-outbound-http-connection-config   -DOutboundProfileType=scoped
                                                        -DApplicationScopeRef=scoperef
```

Linux

```
./ConfigEngine.sh clean-outbound-http-connection-config -DOutboundProfileType=scoped
                                                        -DApplicationScopeRef=scoperef
```

Windows

```
ConfigEngine.bat clean-outbound-http-connection-config  -DOutboundProfileType=scoped
                                                        -DApplicationScopeRef=scoperef
```

`scoperef` is the context root of the application to which the configuration settings are scoped. To obtain the scope reference, proceed as follows:

1. Access the WebSphere Integrated Solutions Console.
2. Select the enterprise application for which the outbound HTTP connection is scoped.
3. Click **View Deployment Descriptor**.
4. Locate the value of the `context root` tag.

An example context root is `/PA_Banner_Ad`.

Configuring outbound HTTP connections by using the Model Controller SPI:

To query and administer the outbound HTTP connection, you can also use the model controller SPI.

About this task

The information that is given here provides a brief introduction only. For a complete reference about this SPI, read the outbound HTTP connection Javadoc.

1. "Obtaining the Model SPI" on page 3020
   You can obtain the home object for the outbound HTTP connection configuration model by using JNDI lookup.

2. "Obtaining the Controller SPI"
   The Outbound HTTP Connection configuration model SPI grants read access to the configuration only. You can make updates to the outbound HTTP connection configuration model by using the Controller SPI.
3. "Viewing the configuration settings of the outbound HTTP connection" on page 3021
   WebSphere Portal Express provides several interfaces that you can use to retrieve configuration settings: `OutboundConnectionProfile`, `PolicyMapping`, `PolicyRule`, `CookieRule`, and `PolicyVariable`.
4. "Modifying configuration settings of the outbound HTTP connection" on page 3022
   You can change configuration settings of the outbound HTTP connection by using the following interfaces: `ModifiableOutboundConnectionProfile`, `ModifiablePolicyMapping`, `ModifiablePolicyRule`, `ModifiableCookieRule`, and `ModifiablePolicyVariable`.
5. "Creating and deleting configuration settings of the outbound HTTP connection" on page 3022
   The controller object also provides methods for creating or deleting configuration settings.

Obtaining the Model SPI:

You can obtain the home object for the outbound HTTP connection configuration model by using JNDI lookup.

About this task

Here is a sample code snippet:

```
import com.ibm.portal.outbound.config.*;
...

javax.naming.Context ctx = new javax.naming.InitialContext();
OutboundConnectionModelHome home = (OutboundConnectionModelHome)
            ctx.lookup("portal:service/model/OutboundConnectionModel");
OutboundConnectionModel model = home.getOutboundConnectionModelProvider().
                                GetOutboundConnectionModel();
```

The code that calls the SPI must run in the context of the portal server.

Related concepts:

"Model SPI overview" on page 2858
Models provide information that is needed by WebSphere Portal Express to perform tasks such as content aggregation or building navigation to browse the aggregated content. The information that is aggregated is represented through models that can be accessed programmatically by using the Model SPI (read-only). The information of a model is usually persistent (stored in a database) but can also be transient (computed and stored only in memory). Models can be represented by using a tree structure (nodes have a parent-child relationship), a list structure, or a selection structure (a selected element in a tree structure).

Obtaining the Controller SPI:

The Outbound HTTP Connection configuration model SPI grants read access to the configuration only. You can make updates to the outbound HTTP connection configuration model by using the Controller SPI.

About this task

Here is a sample code snippet:

```
import com.ibm.portal.outbound.config.*;
...
OutboundConnectionModel model; // refer to the previous example for information
                               // about how to instantiate this model
...

javax.naming.Context ctx = new javax.naming.InitialContext();
OutboundConnectionModelControllerHome chome = (OutboundConnectionModelControllerHome)
    ctx.lookup("portal:service/model/OutboundConnectionModelController");
OutboundConnectionModelController ctrl =
    home.getOutboundConnectionModelControllerProvider().getOutboundConnectionModelController(model);
```

The code that calls the SPI must run in the context of the portal server. Note that access to the Controller SPI is only possible for users who have administrative rights.

Locating configuration items: You can access configuration items by using `Locator` interfaces that are provided by the Outbound Connection Model. The following locators are defined at the model SPI: `OutboundConnectionProfileLocator`, `PolicyMappingLocator`, `PolicyRuleLocator` `CookieRuleLocator`, and `PolicyVariableLocator`. The following example shows how to locate configuration items using various locators:

```
import com.ibm.portal.outbound.config.*;

OutboundConnectionModel model; // refer to previous examples, how to instantiate this model
...

// Locate the global outbound HTTP connection profile:
OutboundConnectionProfile profile = model.getProfileLocator().findGlobalProfile();

// Locate the mapping that is assigned with the context path "/proxy":
PolicyMapping mapping = model.getPolicyMappingLocator(profile).findByContextPath("/proxy")

// Locate a policy rule that resides in the selected mapping and has a the following URL pattern:
PolicyRule rule = model.getPolicyRuleLocator(mapping).findByUrlPattern("http://localhost:9092/*");

// Collect a list of cookie rules that reside in the selected policy rule and start with the
// cookie name "myCookie". The items are collected in the list "filteredCookies":

List<CookieRule> filteredCookies = new ArrayList<CookieRule>();
model.getCookieRuleLocator(rule).collectAllMatching(
   new PatternMatcher<CookieRule>() {
 public int getMatchValue (CookieRule candidate) {
    return (candidate.getCookieNames()[0].startsWith("myCookie")) ? 1 : 0;
 }
   },filteredCookies);

// Locate a policy variable by its name:
PolicyVariable pvar = model.getPolicyVariableLocator(globalProfile).findByName("the.policy.var");
```

Related concepts:

"Controller SPI " on page 2883
You can use the Controller SPI for portal administration. It allows you to modify portal resources. It enhances the read-only portal Model SPI by adding writable aspects.

Viewing the configuration settings of the outbound HTTP connection:

WebSphere Portal Express provides several interfaces that you can use to retrieve configuration settings: `OutboundConnectionProfile`, `PolicyMapping`, `PolicyRule`, `CookieRule`, and `PolicyVariable`.

About this task

For a complete reference of the functions that these interfaces provide, read the Javadoc API. The following code example shows how you can retrieve configuration settings of a policy variable:

```
PolicyVariable pvar;// refer to previous examples, how to instantiate this policy variable

System.out.println ("The policy variable is "+pvar.getName()+", the type is "+pvar.getType());
if (pvar.getType() == VariableType.Endpoint) {
   System.out.println("The value is "+pvar.getEndpointValue());
} else {
   System.out.println("The values are:\n");
   for (String svalue : pvar.getDynamicPolicyValues()) {
       System.out.println(svalue);
   }
}
```

Modifying configuration settings of the outbound HTTP connection:

You can change configuration settings of the outbound HTTP connection by using the following interfaces: `ModifiableOutboundConnectionProfile`, `ModifiablePolicyMapping`, `ModifiablePolicyRule`, `ModifiableCookieRule`, and `ModifiablePolicyVariable`.

About this task

You can access these interfaces by using the method `OutboundConnectionModelController.getModifiableNode()`. Changes that you make are not immediately applied at the data backend. You must confirm the changes. The following code example illustrates how you can modify configuration settings:

```
OutboundConnectionModel model; // For information about how to instantiate this model
                               // refer to the previous examples.
OutboundConnectionModelController ctrl; // For information about how to instantiate this
                                        // controller, refer to the previous examples.
PolicyRule rule;// Refer to previous examples, how to instantiate this policy rule
System.out.println("The original URL pattern of the PolicyRule is "+rule.getUrlPattern());

// Get the Modifiable.. interface for the selected Policy rule. Change the URL pattern setting.
ModifiablePolicyRule mrule = (ModifiablePolicyRule)ctrl.getModifiableNode(rule);
mrule.setUrlPattern("http://localhost:9091/*");

// Apply the changes.
ctrl.commit();
System.out.println("The URL pattern of the PolicyRule is now "+rule.getUrlPattern());
```

Creating and deleting configuration settings of the outbound HTTP connection:

The controller object also provides methods for creating or deleting configuration settings.

About this task

You can create new items by using the `CreationContext` interface. This interface provides the controller with the mandatory initialization data. The following creation contexts are available: `OutboundConnectionProfileCreationContext`, `PolicyMappingCreationContext`, `PolicyRuleCreationContext`, `CookieRuleCreationContext`, and `PolicyVariableCreationContext`. You can implement the creation contexts either by a custom application or by the singleton class `OutboundConnectionCreationContextBuidlerFactory`.

The following code example shows how you create a new policy rule, and how you delete another policy rule:

```
OutboundConnectionModel model; // Refer to previous examples, how to instantiate this model.
OutboundConnectionModelController ctrl; // Refer to previous example, how to instantiate this.
PolicyRule rule;// Refer to previous examples, how to instantiate this policy rule.

// This singleton can be used to produce CreationContext objects.
OutboundConnectionCreationContextBuilderFactory ccf =
     OutboundConnectionCreationContextBuilderFactory.getInstance();

// Create a new policy rule.
CreationContext cc = ccf.getPolicyRuleCreationContext(mapping, "rule2", "www.testme.com/test2*");
ModifiablePolicyRule mrule2 = (ModifiablePolicyRule) ctrl.create(ModifiablePolicyRule.class, cc);

// Delete the policy rule.
ctrl.delete(rule);

ctrl.commit(); // Apply the changes.
```

Sample administration tasks:

Here you find some procedures for running administration tasks on the outbound HTTP connection settings. These tasks use the portal configuration engine interface.

"Adding an outbound connection policy"
To add a policy to the outbound HTTP connection configuration, follow the procedure that is given here.

"Listing all available configuration profiles" on page 3026
To create a file that contains all profiles that are registered at the outbound HTTP connection configuration, follow the procedure that is given here.

"Modifying outbound HTTP connection policy settings" on page 3027
To modify the settings of an existing outbound HTTP connection policy, follow the procedure that is given here.

"Removing an outbound HTTP connection policy" on page 3028
To delete an outbound HTTP connection policy, you can use different options. Some of them are described here.

"Exporting a configuration profile to a file" on page 3029
To create a backup of a specific outbound HTTP connection profile, use the procedure given here.

"Importing a configuration profile from a file" on page 3030
To restore all policies and settings for a given application scoped profile, use the import procedure given here. For example, you can use this procedure to restore a specific connection profile configuration that you backed up previously.

Adding an outbound connection policy:

To add a policy to the outbound HTTP connection configuration, follow the procedure that is given here.

Procedure

1. Decide whether you want to create a global or application-scoped policy. You can place the policy in the global profile, or in an application-scoped profile:
   - Policies that are stored in the global profile are not linked to a specific application. For details about application scoping, see *Using the Ajax proxy in portlets*.
   - Policies that are stored in an application-scoped profile are visible in the scope of the application that is associated with the profile. The connection is effective only in the scope of that application, with the following consequences:

- If the remote connection is opened through the Ajax proxy, the caller must use the Ajax proxy URL that is registered in the web module. Application-scoped policies are not visible to the Ajax proxy servlet of IBM WebSphere Portal Express.
- If the remote connection is opened through the outbound connection service, the policy is only visible if the code runs in the web module for which the profile is scoped.

2. Decide the mapping for which you want the policy to apply. The policy mapping determines the entry point of the Ajax proxy. For example, the WebSphere Portal Express Ajax proxy servlet provides the following mapping points:
   - `/proxy` is for unauthenticated access. With this mapping point, an HTTP client can access the remote content without further authentication at the portal server.
   - `/myproxy` is for authenticated access. With this mapping point, the HTTP client must authenticate before it can access the remote resource through the Ajax proxy.

   Furthermore, you can also place the policy into the default mapping. Policies that are stored in the default mapping are accessible through all servlet entry points. Usually, policies for remote URLs that have security sensitive content are stored under the `/myproxy` mapping. Otherwise, it is good practice to store the policy in the default mapping. For more information, see *Policy Mappings*.
3. Open one of the following XML templates in a text editor. Here is a template for a policy in the `/myproxy` mapping:

```
<?xml version="1.0" encoding="UTF-8"?>
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">

   <variables>
      <dynamic-policy name="MY_ADMINISTRATIVE_NAME.url">
         <value>MY_URL_PATTERN</value>
         <!-- Step 5: add additional URL patterns here, if you want to -->
      </dynamic-policy>
   <variables>

   <mapping contextpath="/myproxy"  url="*">
      <policy name="MY_ADMINISTRATIVE_NAME" url="{$MY_ADMINISTRATIVE_NAME.url}" >
         <actions>
            <method>GET</method>
            <method>POST</method>
            <!-- Step 6: add or remove HTTP methods here -->
         </actions>

         <!-- uncomment the cookie-rule section if required
         <cookie-rule name="MY_ADMINISTRATIVE_NAME.cookies.1">
            <cookie>my_cookie_name</cookie>
            <scope>user</scope>
            <handling>store-in-session</handling>
         </cookie-rule>
         -->

         <!--Step 7: uncomment this section if you require an authenticated remote connection.
            Change the metadata setting according to the type of authentication
            that you want to established.

         <meta-data>
            <name>hpaa.authtype</name>
            <value>http-basic</value>
         </meta-data>
         <meta-data>
            <name>hpaa.slotid</name>
            <value>MY_ADMINISTRATIVE_NAME.credentials</value>
         </meta-data>
         <meta-data>
            <name>forward-credentials-from-vault</name>
            <value>true</value>
         </meta-data>
         -->
```

```
      </policy>
   </mapping>

</proxy-rules>
```

Here is a template for a policy in the default mapping:

```
<policy name="MY_ADMINISTRATIVE_NAME" url="{$MY_ADMINISTRATIVE_NAME.url}" >
   <actions>
      <method>GET</method>
      <method>POST</method>
      <!-- Step 6: add or remove HTTP methods here -->
   </actions>

   <!-- uncomment the cookie-rule section if required
   <cookie-rule name="MY_ADMINISTRATIVE_NAME.cookies.1">
      <cookie>my_cookie_name</cookie>
         <scope>user</scope>
         <handling>store-in-session</handling>
      </cookie-rule>
   -->

   <!--Step 7: uncomment this section if you require an authenticated remote connection.
   Change the metadata setting according to the type of authentication that should be
   established.

   <meta-data>
      <name>hpaa.authtype</name>
      <value>http-basic</value>
   </meta-data>

   <meta-data>
      <name>hpaa.slotid</name>
      <value>MY_ADMINISTRATIVE_NAME.credentials</value>
   </meta-data>

   <meta-data>
      <name>forward-credentials-from-vault</name>
      <value>true</value>
   </meta-data>
   -->
</policy>
```

You can apply all following steps to the templates given in this step.

4. Determine an administrative name for the policy. This administrative name helps administrators to identify the policy later. For example, you can use `policy_01`. Locate all occurrences of `MY_ADMINISTRATIVE_NAME` and replace this string with the administrative name that you determined (example: `policy_01`).
5. Define a URL pattern to which you want the policy to apply. Replace `MY_URL_PATTERN` with the URL pattern to which you want this policy to apply. For example, set the URL pattern to `http://http://www.ibm.com/us/en/*`.
6. Determine the HTTP methods for which you want to make proxy requests possible. In most cases, the HTTP methods GET and POST are required. If you require a different set of supported methods, you can manage the list in the `<actions>` list of the template. Manage the `<actions>` section according to your requirements.
7. Determine the authentication method that is required to establish the remote connection. The remote host might restrict the access to the URL. If you want the remote connection to be an authenticated connection, add the metadata settings that are required for the authentication type. Also, for certain authentications extra user credentials are referenced. Make sure that the Credential Vault contains the user credentials that are referenced in the authentication settings. For details, read *Authenticating outbound HTTP connections*.
8. Save the XML document to a file. For example, save the document to the file `/tmp/create_policy.xml`.
9. Deploy the policy at the configuration profile that you selected in an earlier step.

- If you want the policy to be active globally, start the following portal configuration engine task:
  - Linux :

    ```
    ./ConfigEngine.sh update-outbound-http-connection-config
                      -DConfigFileName=/tmp/create_policy.xml
    ```

  - IBM i:

    ```
    ConfigEngine.sh   update-outbound-http-connection-config
                      -DConfigFileName=/tmp/create_policy.xml
    ```

  - Windows:

    ```
    ConfigEngine.bat  update-outbound-http-connection-config
                      -DConfigFileName=/tmp/create_policy.xml
    ```

- If you want the policy to be active in the scope of a web module only, start the following portal configuration engine task. This example scopes the policy to the web module Banner AD:
  - Linux :

    ```
    ./ConfigEngine.sh update-outbound-http-connection-config
                      -DConfigFileName=/tmp/create_policy.xml
                      -DApplicationScopeRef=/PA_Banner_Ad
    ```

  - IBM i:

    ```
    ConfigEngine.sh   update-outbound-http-connection-config
                      -DConfigFileName=/tmp/create_policy.xml
                      -DApplicationScopeRef=/PA_Banner_Ad
    ```

  - Windows:

    ```
    ConfigEngine.bat  update-outbound-http-connection-config
                      -DConfigFileName=/tmp/create_policy.xml
                      -DApplicationScopeRef=/PA_Banner_Ad
    ```

The policy was now added to the configuration. It is ready to use.

Related tasks:

"Authenticating outbound HTTP connections" on page 3031
You can protect the access to the remote host by an authentication mechanism.

Related reference:

"Using the AJAX proxy in portlets" on page 2991
Here is how you use the AJAX proxy in portlets.

"Policy mappings" on page 2994
When an outbound HTTP connection is established through the outbound connection service, the caller can specify the mapping context in an optional parameter.

Listing all available configuration profiles:

To create a file that contains all profiles that are registered at the outbound HTTP connection configuration, follow the procedure that is given here.

Procedure

Start the following portal configuration engine task:

- Linux :

  ```
  ./ConfigEngine.sh list-outbound-http-connection-profiles
                    -DListFileName=/tmp/list.xml
  ```

- IBM i:

  ```
  ConfigEngine.sh   list-outbound-http-connection-profiles
                    -DListFileName=/tmp/list.xml
  ```

- Windows:

```
ConfigEngine.bat  list-outbound-http-connection-profiles
                  -DListFileName=/tmp/list.xml
```

The task returns a list of all installed profiles. Example:

```
profile: OutboundProfileType=system
profile: OutboundProfileType=global
profile: OutboundProfileType=scoped ApplicationScopeRef=PA_Search_Center
```

Modifying outbound HTTP connection policy settings:

To modify the settings of an existing outbound HTTP connection policy, follow the procedure that is given here.

Procedure

1. Export the configuration to a file:
   - If the policy resides in the global configuration, start the following portal configuration engine task:
     - Linux :

       ```
       ./ConfigEngine.sh  read-outbound-http-connection-config
                         -DConfigFileName=/tmp/the_global_configuration.xml
       ```

     - IBM i:

       ```
       ConfigEngine.sh    read-outbound-http-connection-config
                         -DConfigFileName=/tmp/the_global_configuration.xml
       ```

     - Windows:

       ```
       ConfigEngine.bat   read-outbound-http-connection-config
                         -DConfigFileName=/tmp/the_global_configuration.xml
       ```

   - If the policy resides in the application-scoped configuration, proceed as follows:
     a. Determine the name of the application scope. To obtain this name, start the procedure for listing all available configuration profiles.
     b. Start the following configuration engine task:
        - Linux :

          ```
          ./ConfigEngine.sh read-outbound-http-connection-config
                            -DConfigFileName=/tmp/the_scoped_configuration.xml
                            -DApplicationScopeRef=THE_APPLICATION_SCOPE
          ```

        - IBM i:

          ```
          ConfigEngine.sh   read-outbound-http-connection-config
                            -DConfigFileName=/tmp/the_scoped_configuration.xml
                            -DApplicationScopeRef=THE_APPLICATION_SCOPE
          ```

        - Windows:

          ```
          ConfigEngine.bat  read-outbound-http-connection-config
                            -DConfigFileName=/tmp/the_scoped_configuration.xml
                            -DApplicationScopeRef=THE_APPLICATION_SCOPE
          ```

        where *THE_APPLICATION_SCOPE* is the name of the application scope.
2. Edit either of the files `/tmp/the_global_configuration.xml` or `/tmp/the_scoped_configuration.xml` by using a text editor or an XML editor. The configuration file contains all policies, mappings, and metadata settings that are defined.
3. Apply the changes from the previous step at the outbound HTTP connection configuration:
   - If the profile was exported from the global configuration, start the following portal configuration engine task:

– Linux :

```
./ConfigEngine.sh update-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_global_configuration.xml
```

– IBM i:

```
ConfigEngine.sh   update-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_global_configuration.xml
```

– Windows:

```
ConfigEngine.bat  update-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_global_configuration.xml
```

- If the profile was exported from an application-scoped configuration, start the following portal configuration engine task:
  – Linux :

```
./ConfigEngine.sh update-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_scoped_configuration.xml
                  -DApplicationScopeRef=THE_APPLICATION_SCOPE
```

  – IBM i:

```
ConfigEngine.sh   update-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_scoped_configuration.xml
                  -DApplicationScopeRef=THE_APPLICATION_SCOPE
```

  – Windows:

```
ConfigEngine.bat  update-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_scoped_configuration.xml
                  -DApplicationScopeRef=THE_APPLICATION_SCOPE
```

  where *THE_APPLICATION_SCOPE* is the name of the application scope.

Removing an outbound HTTP connection policy:

To delete an outbound HTTP connection policy, you can use different options. Some of them are described here.

About this task

To remove an outbound HTTP connection policy, proceed as follows:

Procedure

1. Export the configuration from which you want to delete the policies to a file. For details, read *Exporting a configuration profile from a file*.
2. Edit the file by using a file editor or an XML editor.
3. Locate all policies that you want to delete and remove them from the file.
4. Restore the configuration by using the modified file. For details, read *Importing a configuration profile from a file*.

Removing all policies of a configuration profile:
About this task

To remove all policies from a configuration profile, proceed as follows:

Procedure

1. Determine the name of the application scope for which you want to delete its outbound HTTP Connection profile. To obtain this name, use the procedure under *Listing all available configuration profiles*.
2. Start the following portal configuration engine task:
   - Linux :

```
./ConfigEngine.sh clean-outbound-http-connection-config
                  -DApplicationScopeRef=THE_APPLICATION_SCOPE
```

- IBM i:

```
ConfigEngine.sh   clean-outbound-http-connection-config
                  -DApplicationScopeRef=THE_APPLICATION_SCOPE
```

- Windows:

```
ConfigEngine.bat  clean-outbound-http-connection-config
                  -DApplicationScopeRef=THE_APPLICATION_SCOPE
```

where THE_APPLICATION_SCOPE is the name of the application scope.

Note: To remove the global configuration, you can also use the configuration task clean-outbound-http-connection-config instead. However, it is good practise to review the current content of the global configuration profile before you delete its content. To do so, follow the procedure for *Removing an Outbound HTTP Connection Policy* earlier in this topic.

Exporting a configuration profile to a file:

To create a backup of a specific outbound HTTP connection profile, use the procedure given here.

Procedure

Export the configuration to a file.

- To export the global configuration, start the following portal configuration engine task:
  - Linux :

```
./ConfigEngine.sh read-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_global_configuration.xml
```

  - IBM i:

```
ConfigEngine.sh   read-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_global_configuration.xml
```

  - Windows:

```
ConfigEngine.bat  read-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_global_configuration.xml
```

  The output file /tmp/the_global_configuration.xml contains an XML export of the global configuration profile.
- To run an application scoped profile, proceed as follows:
  1. Determine the name of the application scope. To get this name, follow the procedure under *Listing all available configuration profiles*.
  2. Start the following portal configuration engine task:
     - Linux :

```
./ConfigEngine.sh read-outbound-http-connection-config
                    -DConfigFileName=/tmp/the_scoped_configuration.xml
                    -DApplicationScopeRef=THE_APPLICATION_SCOPE
```

     - IBM i:

```
ConfigEngine.sh   read-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_scoped_configuration.xml
                  -DApplicationScopeRef=THE_APPLICATION_SCOPE
```

     - Windows:

```
ConfigEngine.bat  read-outbound-http-connection-config
                  -DConfigFileName=/tmp/the_scoped_configuration.xml
                  -DApplicationScopeRef=THE_APPLICATION_SCOPE
```

where THE_APPLICATION_SCOPE is the name of the application scope.

The output file /tmp/the_scoped_configuration.xml contains an XML export of the application-scoped configuration profile.

Importing a configuration profile from a file:

To restore all policies and settings for a given application scoped profile, use the import procedure given here. For example, you can use this procedure to restore a specific connection profile configuration that you backed up previously.

About this task

The following procedure assumes that the configuration that you want to restore was saved in a file /tmp/configuration.xml .

Procedure

1. Optional: If you want to restore the global configuration, skip this step. Determine the name of the application scope for which you want to restore its outbound HTTP connection profile. To obtain this name, follow the procedure given under *Listing all available configuration profiles*.
2. Start the appropriate portal configuration engine task, depending on whether you want to restore the global configuration or an application-scoped configuration:
   - To restore the global configuration, run the following configuration engine tasks:
     - Linux :

       ```
       ./ConfigEngine.sh clean-outbound-http-connection-config
                         -DOutboundProfileType=global
       ./ConfigEngine.sh update-outbound-http-connection-config
                         -DConfigFileName=/tmp/configuration.xml
       ```

     - IBM i:

       ```
       ConfigEngine.sh   clean-outbound-http-connection-config
                         -DOutboundProfileType=global
       ConfigEngine.sh   update-outbound-http-connection-config
                         -DConfigFileName=/tmp/configuration.xml
       ```

     - Windows:

       ```
       ConfigEngine.bat  clean-outbound-http-connection-config
                         -DOutboundProfileType=global
       ConfigEngine.bat  update-outbound-http-connection-config
                         -DConfigFileName=/tmp/configuration.xml
       ```

   - To restore an application-scoped configuration, run the following configuration engine tasks:
     - Linux :

       ```
       ./ConfigEngine.sh clean-outbound-http-connection-config
                         -DapplicationScopeRef=THE_APPLICATION_SCOPE
       ./ConfigEngine.sh update-outbound-http-connection-config
                         -DapplicationScopeRef=THE_APPLICATION_SCOPE
                         -DConfigFileName=/tmp/configuration.xml
       ```

     - IBM i:

       ```
       ConfigEngine.sh   clean-outbound-http-connection-config
                         -DapplicationScopeRef=THE_APPLICATION_SCOPE
       ConfigEngine.sh   update-outbound-http-connection-config
                         -DapplicationScopeRef=THE_APPLICATION_SCOPE
                         -DConfigFileName=/tmp/configuration.xml
       ```

     - Windows:

```
ConfigEngine.bat  clean-outbound-http-connection-config
                  -DapplicationScopeRef=THE_APPLICATION_SCOPE
ConfigEngine.bat  update-outbound-http-connection-config
                  -DapplicationScopeRef=THE_APPLICATION_SCOPE
                  -DConfigFileName=/tmp/configuration.xml
```

- where THE_APPLICATION_SCOPE is the name of the application scope.

Authenticating outbound HTTP connections:

You can protect the access to the remote host by an authentication mechanism.

About this task

For several authentication mechanisms, the outbound HTTP connection infrastructure provides an internal authentication support. By this support, the outbound HTTP connection service can handle the authentication protocol that is run by built-in authentication handlers. The outbound HTTP connection service supports the following authentication types:

- HTTP basic authentication
- HTTP digest authentication
- SPNEGO authentication
- Single Sign-On (SSO) by using LTPA tokens
- Form-based authentication.

"Providing user credentials for authenticated connections" on page 3032
Several authentication handlers require that user credentials are presented in the authentication process. For example, the HTTP basic authentication handler requires such user credentials. Before the outbound connection can be used, these user credentials are set in the Credential Vault.

"Establishing a basic authenticated HTTP connection" on page 3032
To establish an HTTP connection with basic authentication, you enable an outbound connection policy for HTTP basic authentication.

"Establishing a digest authenticated HTTP connection" on page 3033
To establish an HTTP connection with digest authentication, you enable an outbound connection policy for HTTP digest authentication.

"Establishing a form-based authenticated HTTP connection" on page 3034
To establish an HTTP connection with form-based authentication, you enable an outbound connection policy for form-based authentication.

"Establishing SSO connections through LTPA token" on page 3035
To establish a Single Sign-On (SSO) connection through LTPA token, you enable an outbound connection policy for the SSO connection through LTPA token.

"Establishing SSO connections through SPNEGO token" on page 3036
To establish a Single Sign-On (SSO) connection through SPNEGO token, you enable an outbound connection policy for the SSO connection through SPNEGO token.

CF03 "Establishing SSO connections through SAML 2.0 tokens" on page 3036
It is possible to establish outbound HTTP connections to remote resources that are authenticated by using the SAML 2.0 protocol. Outbound HTTP connections take care of the communication with the Identity provider (IDP) to get an authenticated connection by using SAML tokens. The SAML Authentication handler uses the HTTP POST binding protocol of the SAML specification. Therefore, it is required that both the Identity Provider and the Service Provider support the HTTP POST binding, if they are used by Outbound HTTP Connections for authentication.

Providing user credentials for authenticated connections:

Several authentication handlers require that user credentials are presented in the authentication process. For example, the HTTP basic authentication handler requires such user credentials. Before the outbound connection can be used, these user credentials are set in the Credential Vault.

About this task

For details about setting and storing credentials in the Credential vault, read the information about *Credential vault*.

The outbound HTTP connection configuration references the credentials by the slot name.

The following example procedure creates a simple credential with user ID and password in the Credential Vault:

Procedure

1. Access WebSphere Portal Express as a portal administrator.
2. Click the **Administration menu** icon. Then, click **Access** > **Credential Vault**. The Credential Vault management portlet is shown.
3. Select **Add a Vault slot**. The window for creating a vault slot is shown.
4. Choose a Vault slot name, and select the slot and vault segment to where it belongs.
5. Set the Vault slot as **Shared**, and set the user ID and password for the remote user.

Results

You created a credential with user ID and password in the Credential Vault.

Related concepts:

"Credential Vault" on page 1523
The Credential Vault is a service that stores credentials that allow portlets to log in to applications outside the realm on behalf of the user. It manages multiple identities for portlets and users.

Establishing a basic authenticated HTTP connection:

To establish an HTTP connection with basic authentication, you enable an outbound connection policy for HTTP basic authentication.

About this task

The policy rule settings in the following example code snippet enable an outbound connection policy for HTTP basic authentication. The example assumes that the connection `http://the_remote_server.com/basic-auth-protected/` is a remote site that is protected by basic authentication.

```
<policy url="http://the_remote_server.com/basic-auth-protected/*"
     basic-auth-support="true">
     <meta-data>
          <name>hpaa.authtype</name>
          <value>http-basic</value>
     </meta-data>
     <meta-data>
```

```
          <name>hpaa.slotid</name>
          <value>OutboundConnectionCredentials</value>
     </meta-data>
     <meta-data>
          <name>forward-credentials-from-vault</name>
          <value>true</value>
     </meta-data>
</policy>
```

The meanings of the settings are as follows:

- The policy attribute `basic-auth-support` enables the authentication filter.
- The value of the metadata parameter `hpaa.authtype` specifies the authentication type as HTTP basic authentication.
- The value of `hpaa.slotid` specifies the slot ID of the credential vault. For instructions about how to provide the user credentials of the remote connection, read *Providing user credentials for authenticated connections*.
- The metadata setting `forward-credentials-from-vault` specifies that the credentials of the basic authentication are gathered from the Credential Vault.
- You can use the parameter `hpaa.piid` to specify the portlet instance ID for which the credential slot is defined. This parameter is optional.

Establishing a digest authenticated HTTP connection:

To establish an HTTP connection with digest authentication, you enable an outbound connection policy for HTTP digest authentication.

About this task

The settings in the following example code snippet enable an outbound connection policy for HTTP digest authentication. The example assumes that the connection `http://the_remote_server.com/digest-auth-protected/` is a remote site that is protected by digest authentication.

```
<policy url="http://the_remote_server.com/basic-auth-protected/*"
     digest-auth-support="true">
     <meta-data>
          <name>hpaa.authtype</name>
          <value>http-digest</value>
     </meta-data>
     <meta-data>
          <name>hpaa.slotid</name>
          <value>OutboundConnectionCredentials</value>
     </meta-data>
     <meta-data>
          <name>forward-credentials-from-vault</name>
          <value>true</value>
     </meta-data>
</policy>
```

- The policy attribute `basic-auth-support` enables the authentication filter.
- The value of the metadata parameter `hpaa.authtype` specifies the authentication type as HTTP digest authentication.
- The value of `hpaa.slotid` specifies the slot ID of the credential vault. For instructions about how to provide the user credentials of the remote connection, read *Providing user credentials for authenticated connections*.
- The metadata setting `forward-credentials-from-vault` specifies that the credentials of the digest authentication are gathered from the Credential Vault.
- You can use the parameter `hpaa.piid` to specify the portlet instance ID for which the credential slot is defined. This parameter is optional.

Establishing a form-based authenticated HTTP connection:

To establish an HTTP connection with form-based authentication, you enable an outbound connection policy for form-based authentication.

About this task

The settings in the following example code snippet enable an outbound connection policy for form-based authentication. The example assumes that the site http://*the_remote_server*.com/login-form-protected/ is protected by a form-based authentication. The form is submitted by an action URL https://*the_remote_server*.com/doLogin.php.

```
<policy url="http://the_remote_server.com/login-form-protected/*" >
     <meta-data>
          <name>hpaa.authtype</name>
          <value>form</value>
     </meta-data>
     <meta-data>
          <name>hpaa.slotid</name>
          <value>OutboundConnectionCredentials</value>
     </meta-data>
     <meta-data>
          <name>forward-credentials-from-vault</name>
          <value>true</value>
     </meta-data>
     <meta-data>
          <name>form-action-url</name>
          <value>https://the_remote_server.com/doLogin.php</value>
     </meta-data>
     <meta-data>
          <name>form-field-name-user</name>
          <value>user_id</value>
     </meta-data>
     <meta-data>
          <name>form-field-name-password</name>
          <value>user_id_password</value>
     </meta-data>
     <meta-data>
          <name>form-additional-fields</name>
          <value>param1=value1,param2=value2</value>
          </meta-data>
     <meta-data>
          <name>form-session-cookies</name>
          <value>sessioncookie1,sessioncookie2</value>
     </meta-data>
</policy>
```

Set the following metadata parameters as required:

hpaa.slotid
Use this parameter to specify the slot ID of the credential vault. For information about how to provide the user credentials of the remote connection, read *Providing user credentials for authenticated connections*.

forward-credentials-from-vault
Use this parameter to specify that the credentials of the form-based authentication are gathered from the Credential Vault.

form-action-url
Use this parameter to specify the URL to which the form data is submitted.

form-field-name-user
Use this parameter to specify the ID of the HTML <input> tag that contains the user ID. In the previous example, the specified value is user_id.

form-field-name-password
Use this parameter to specify the ID of the HTML <input> tag that contains the password. In the previous example, the specified value is user_id_password.

form-additional-fields
Use this parameter to specify the names of the additional HTML input elements that are present in the form. In the previous example, the specified elements are param1=value1 and param2=value2.

form-session-cookies
Use this parameter to specify the names of the session cookies that are received from the remote server as part of Set-Cookie headers when the form is submitted and the authentication is successful. In the previous example, the specified cookies are sessioncookie1 and sessioncookie2.

Establishing SSO connections through LTPA token:

To establish a Single Sign-On (SSO) connection through LTPA token, you enable an outbound connection policy for the SSO connection through LTPA token.

About this task

The settings in the following example code snippet enable an SSO outbound connection policy through LTPA token. The example assumes that the connection http://the_remote_server.com/sso-protected/ is a remote site that is protected by an LTPA token.

```
<policy url="http://the_remote_server.com/sso-protected/*"
     basic-auth-support="true">
     <meta-data>
          <name>hpaa.authtype</name>
          <value>ltpa</value>
     </meta-data>
     <meta-data>
          <name>hpaa.slotid</name>
          <value>OutboundConnectionCredentials</value>
     </meta-data>
     <meta-data>
          <name>forward-credentials-from-vault</name>
          <value>true</value>
     </meta-data>
</policy>
```

- The policy attribute basic-auth-support enables the authentication filter.
- The value of the metadata parameter hpaa.authtype specifies the authentication type as SSO authentication by using LTPA tokens.
- The value of hpaa.slotid specifies the slot ID of the credential vault. For instructions about how to provide the user credentials of the remote connection, read *Providing user credentials for authenticated connections*. The slot ID identifies the Credential Vault slot for the user subject for which the LTPA tokens are used.
- The metadata setting forward-credentials-from-vault specifies that the credentials of the SSO authentication are gathered from the Credential Vault.

Related tasks:

"Providing user credentials for authenticated connections" on page 3032
Several authentication handlers require that user credentials are presented in the authentication process. For example, the HTTP basic authentication handler requires such user credentials. Before the outbound connection can be used, these user credentials are set in the Credential Vault.

Establishing SSO connections through SPNEGO token:

To establish a Single Sign-On (SSO) connection through SPNEGO token, you enable an outbound connection policy for the SSO connection through SPNEGO token.

The settings in the following example code snippet enable an SSO outbound connection policy through SPNEGO token. The example assumes that the connection `http://the_remote_server.com/sso-protected/` is a remote site that is protected by an SPNEGO token.

```
<policy url="http://the_remote_server.com/sso-protected/*"
     basic-auth-support="true">
     <meta-data>
          <name>hpaa.authtype</name>
          <value>spnego</value>
     </meta-data>
</policy>
```

- The policy attribute `basic-auth-support` enables the authentication filter.
- The value of the metadata parameter `hpaa.authtype` specifies the authentication type as SSO authentication by using SPNEGO tokens.

Establishing SSO connections through SAML 2.0 tokens:

It is possible to establish outbound HTTP connections to remote resources that are authenticated by using the SAML 2.0 protocol. Outbound HTTP connections take care of the communication with the Identity provider (IDP) to get an authenticated connection by using SAML tokens. The SAML Authentication handler uses the HTTP POST binding protocol of the SAML specification. Therefore, it is required that both the Identity Provider and the Service Provider support the HTTP POST binding, if they are used by Outbound HTTP Connections for authentication.

An outbound HTTP connection is activated by setting the metadata **`SSO_SAML_20_IDP`** at the connection policy or policy mapping. The value of this metadata setting is a symbolic name for the Identity provider that establishes the connection. This name is used as a prefix for another set of metadata that define the settings of the Identity provider as the following example illustrates:

```
<mapping contextpath="/myproxy" url="*">
 <policy url="http://www.myremotesite.com/RESOURCE*" >
  ...
  <!-- the following meta data setting activates the connection        -->
  <!-- for SSO connections via SAML. The symbolic name of the Identity -->
  <!-- Provider is MySampleIdentityProvider                -->
  <meta-data>
   <name>SSO_SAML20_IDP</name>
   <value>MySampleIdentityProvider</value>
  </meta-data>
 </policy>

 <!-- a second policy that establishes a SSO connection via this IDP -->
 <policy url="http://www.myremotesite.com/ANOTHER*" > <!-- another policy -->
  ...
  <meta-data>
   <name>SSO_SAML20_IDP</name>
```

```
   <value>MySampleIdentityProvider</value>
  </meta-data>
 </policy>

 <!-- the settings of the Identity provider MySampleIdentityProvider -->
 <!-- In this  example, the identity provider settings are saved in the meta data -->
 <!-- is scoped to the policy mapping "/myportal".                                 -->
 <meta-data>
  <name>MySampleIdentityProvider.IDP_HOST</name>
  <value>www.the-identity-provider.com</value>
 </meta-data>
 <meta-data>
  <name>MySampleIdentityProvider.IDP_PARAM_NAME.1</name>
  <value>SAMLRquest</value>
 </meta-data>
 <meta-data>
  <name>MySampleIdentityProvider.IDP_PARAM_VALUE.1</name>
  <value>request</value>
 </meta-data>

</mapping>
```

CF03 "Configuration settings for SAML authenticated connections"
To enable a connection policy for SAML-based authentication, the following settings must be defined in the metadata section of the policy, the policy mapping, or the default mapping.

Configuration settings for SAML authenticated connections:

To enable a connection policy for SAML-based authentication, the following settings must be defined in the metadata section of the policy, the policy mapping, or the default mapping.

SSO_SAML20_IDP

The unique name of the Identity Provider, for example, *IdpName*. This metadata enables the policy for SAML-based authentication and is used to locate the Identity Provider settings. This metadata is required to support SAML-based authentication. Refer to the following example:

```
<meta-data>
 <name>SSO_SAML20_IDP</name>
 <value>IdpName</value>
</meta-data>
```

Important: For the remaining settings, *IdpName* refers to the name of the Identity Provider that you specified in the **SSO_SAML20_IDP** setting.

IdpName.IDP_HOST

The host name or IP address of the identity provider. This setting is required. Refer to the following example:

```
<meta-data>
 <name>IdpName.IDP_HOST</name>
 <value>www.mytfim.org</value>
</meta-data>
```

IdpName.IDP_PROTOCOL

This setting defines how the Identity Provider is connected and has two possible values, either `http` or `https`. Refer to the following example:

```
<meta-data>
 <name>IdpName.IDP_PROTOCOL</name>
 <value>https</value>
</meta-data>
```

IdpName.IDP_PORT

This setting defines the TCP port that is used for the Identity Provider connection. The default value is 80. Refer to the following example:

```
<meta-data>
 <name>IdpName.IDP_PORT</name>
 <value>9443</value>
</meta-data>
```

IdpName.IDP_URI

The URI of the Identity Provider service to which the SAML authentication is submitted. If this metadata setting is not defined, the connection uses the default URI `/SAML2/SSO/POST`. Refer to the following example:

```
<meta-data>
 <name>IdpName.IDP_URI</name>
 <value>/idp/saml20/post</value>
</meta-data>
```

IdpName.IDP_TIMEOUT

The timeout value of the connection to the Identity Provider. If this metadata setting is not defined, the connection timeout is 60 seconds. Refer to the following example:

```
<meta-data>
 <name>IdpName.IDP_TIMEOUT</name>
 <value>120</value> <!-- wait 2 minutes -->
</meta-data>
```

CF05 **IdpName.IDP_AUTH_TOKEN_SOURCE**

Optional parameter that determines from where the authentication tokens for the IDP are taken. The default value is `ltpa`. The SAML authentication protocol begins with a request to the Identity provider. This request contains an authentication token, used to identify the caller at the Identity provider. The **IdpName.IDP_AUTH_TOKEN_SOURCE** parameter determines where this authentication token is taken from. Currently, two values are enabled:

ltpa If the value `ltpa` is defined, then the Ajax proxy creates an LTPA token from the user subject of the Ajax proxy connection. This LTPA token is submitted to the Identity provider to authenticate the IDP request. For most authentication scenarios that are based on Tivoli Federated Identity Manager, the `ltpa` setting is the preferred one.

cookies

If the value `cookies` is defined, then the Ajax proxy uses authentication cookies from the local connection to authenticate the IDP request. The authentication cookie names are defined in the **IdpName.IDP_AUTH_TOKEN.n** metadata settings.

Refer to the following example:

```
<meta-data>
 <name>IdpName.IDP_AUTH_TOKEN_SOURCE</name>
 <value>cookies</value>
<! -- take cookie list from IDP_AUTH_TOKEN_COOKIE.n as authentication tokens -->
</meta-data>
```

IdpName.PARAM_NAME.n and IdpName.PARAM_VALUE.n

IdpName.PARAM_NAME.n is the name of a URL query parameter to the Identity Provider. Use this setting with **IdpName.PARAM_VALUE.n**, which defines the value of a URL query parameter to the Identity Provider. For both settings, *n* is a counter beginning with 1. Refer to the following example:

```
<meta-data>
 <name>IdpName.PARAM_NAME.1</name>
 <value>RequestBinding</value>
</meta-data>
<meta-data>
 <name>IdpName.PARAM_VALUE.1</name>
 <value>HTTPPost</value>
</meta-data>
```

IdpName.IDP_AUTH_COOKIE.n

The name of the authentication cookie, where *n* is a counter beginning with 1. If this metadata setting is not defined, the default authentication cookie is SAML20. Refer to the following example:

```
<meta-data>
 <name>IdpName.IDP_AUTH_COOKIE.1</name>
 <value>SAML20</value>
</meta-data>
<meta-data>
 <name>IdpName.IDP_AUTH_COOKIE.2</name>
 <value>another_cookie</value>
</meta-data>
```

CF05 **IdpName.IDP_AUTH_TOKEN_COOKIE.n**

The name of the authentication cookie that is used to authenticate against the Identity Provider to start the SAML authentication protocol. This metadata is only effective if the metadata **IdpName.IDP_AUTH_TOKEN_SOURCE** is set to cookies. Otherwise, the settings are ignored. The following example defines the authentication cookies MSISAuthenticated, MSISAuth, and MSISAuth1.

```
<meta-data>
 <name>IdpName.IDP_AUTH_TOKEN_COOKIE.1</name>
 <value>MSISAuthenticated</value>
</meta-data>
<meta-data>
 <name>IdpName.IDP_AUTH_TOKEN_COOKIE.2</name>
 <value>MSISAuth</value>
</meta-data>
<meta-data>
 <name>IdpName.IDP_AUTH_TOKEN_COOKIE.3</name>
 <value>MSISAuth1</value>
</meta-data>
```

Finding the Identity Provider login URL and the Partner URL (TFIM):

In order to establish an SSO connection through Tivoli Federated Identity Manager, you must specify the Identity Provider login URL and the Partner URL. Learn how to find these values from the Tivoli Federated Identity Manager configuration if you do not already know them. If you know these values already, skip this step.

About this task

The following values are needed from the Tivoli Federated Identity Manager configuration in order to establish an SSO connection through Tivoli Federated Identity Manager:

The Identity Provider login URL
The login URL of the Identity Provider service.

The Partner URL
The URL of the federation partner.

The following steps describe how to obtain the Identity Provider login URL and the Partner URL from the Tivoli Federated Identity Manager configuration by using the Tivoli Federated Identity Manager admin console.

Procedure

1. Log in to the WebSphere Integrated Solutions Console of the Tivoli Federated Identity Manager server.
2. Click **Tivoli Federated Identity Manager** > **Configure Federated Single Sign-on** > **Federations**. The panel shows a list of Identity Providers.
3. Select the Identity Provider that you want to use for the SSO connection.

   Note: This Identity Provider must have a single sign-on protocol **SAML 2.0** and the role of this federation must be **Identity Provider**.
4. Click **Properties...**.
5. Select the value of the field **Single Sign-on Service URL**. Use this value as the Identity Provider service URL for your Tivoli Federated Identity Manager configuration.
6. Click **Cancel**.
7. Click **View Partners...**.
8. Select the Partner that you want to use for the SAML connection.
9. Click **Properties...**.
10. Select the value of the field **Provider ID**. Use this value as the Partner URL for your Tivoli Federated Identity Manager configuration.
11. Click **Cancel**.

Creating Identity Provider settings at the Outbound Connection Service configuration (TFIM):

Certain metadata settings such as the Identity Provider URL and the Partner URL are required to use Tivoli Federated Identity Manager Identity Provider for SSO connections through SAML 2.0 authentication protocol.

About this task

The following metadata values are required to define a Tivoli Federated Identity Manager Identity Provider, where *IdpName* is the unique name of the Identity Provider:

***IdpName*.IDP_PROTOCOL**
The protocol part of the Identity Provider login URL. Replace the value *my_idp_prot* with the value of the protocol part of the Identity Provider login URL, either `http` or `https`.

***IdpName*.IDP_HOST**
The host name part of the Identity Provider login URL. Replace the value *my_idp_host* with the Identity Provider login URL host name.

***IdpName*.IDP_PORT**
The port number of the Identity Provider login URL. Replace the value *my_idp_port* with the value of the Identity provider login URL port.

***IdpName*.IDP_URI**
The URL path of the Identity Provider login URL. Replace the value *my_idp_uri* with the path of the Identity Provider login URL.

***IdpName*.IDP_AUTH_COOKIE.1 and *IdpName*.IDP_AUTH_COOKIE.2**
Authentication tokens that are created by the federation partner.

***IdpName*.PARAM_NAME.1 and *IdpName*.PARAM_VALUE.1**
This setting selects the SAML 2.0 binding. Specify `HTTPPost` as the value.

***IdpName*.PARAM_NAME.2 and *IdpName*.PARAM_VALUE.2**
The partner URL. Replace the value *my_partner_url* with the URL of the partner that runs the Service Provider service.

***IdpName*.PARAM_NAME.3 and *IdpName*.PARAM_VALUE.3**
Defines the format of the name ID field. Specify `Email` as the value.

The following `XML` example creates the Identity Provider settings for Tivoli Federated Identity Manager at the Outbound Connection Service Configuration and uses the following values:

- The Identity Provider name is `tfim101`.
- The Identity Provider login URL is `https://idp.example.com/sps/myfederation/saml20/login`.
- The Partner URL is `https://sp.example.com/sps/myfederation/saml20/v2_0`.

Change these values according to your configuration.

Procedure

1. Create an `XML` document like the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">
 <variables>
  <!--  replace values with the IdP login URL and the partner URL -->
  <endpoint name="tfim101.idp_prot">https</endpoint>
  <endpoint name="tfim101.idp_host">idp.example.com</endpoint>
  <endpoint name="tfim101.idp_port">443</endpoint>
  <endpoint name="tfim101.idp_uri">/sps/myfederation/saml20/login</endpoint>
  <endpoint name="tfim101.partner_url">https://sp.example.com/sps/myfederation/saml20/v2_0</endpo
 </variables>
 <meta-data>
  <name>tfim101.IDP_PROTOCOL</name>
  <value>my_idp_prot</value>
 </meta-data>
 <meta-data>
  <name>tfim101.IDP_HOST</name>
  <value>my_idp_host</value>
 </meta-data>
 <meta-data>
  <name>tfim101.IDP_PORT</name>
  <value>my_idp_port</value>
 </meta-data>
 <meta-data>
  <name>tfim101.IDP_URI</name>
```

```
 <value>my_idp_uri</value>
</meta-data>
<meta-data>
 <name>tfim101.PARAM_NAME.1</name>
 <value>RequestBinding</value>
</meta-data>
<meta-data>
 <name>tfim101.PARAM_VALUE.1</name>
 <value>HTTPPost</value>
</meta-data>
<meta-data>
 <name>tfim101.PARAM_NAME.2</name>
 <value>PartnerId</value>
</meta-data>
<meta-data>
 <name>tfim101.PARAM_VALUE.2</name>
 <value>my_partner_url</value>
</meta-data>
<meta-data>
 <name>tfim101.PARAM_NAME.3</name>
 <value>NameIdFormat</value>
</meta-data>
<meta-data>
 <name>tfim101.PARAM_VALUE.3</name>
 <value>Email</value>
</metadata>
<meta-data>
 <name>tfim101.IDP_AUTH_COOKIE.1</name>
 <value>LtpaToken</value>
</meta-data>
<meta-data>
 <name>tfim101.IDP_AUTH_COOKIE.2</name>
 <value>LtpaToken2</value>
</meta-data>
</proxy-rules>
```

2. After you save the XML file, run the ConfigEngine task **update-outbound-http-connection-config** to apply the Identity Provider settings at the global configuration profile.
   - AIX, HP-UX, Linux, Solaris: `./ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`
   - IBM i: `ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`
   - Windows: `ConfigEngine.bat update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`

   where *XML_file* is the file path to the XML file.

Defining policy rules for the remote connection (TFIM):

Learn about how to create a policy rule for the SSO connection. Creating a policy rule is required to use the SSO connection for the Identity Provider that you registered.

About this task

The metadata setting **SSO_SAML20_IDP** enables the policy for SSO authentication by using SAML. Replace the default value, in this case, *tfim101* with the unique Identity Provider name.

Procedure

1. To create a policy rule for a remote connection that uses a Tivoli Federated Identity Manager Identity Provider, create an XML document like the following example:

   Notes:

   - The following example creates a policy for an SSO connection to http://www.my_remote_site.com, which is controlled by the Tivoli Federated Identity Manager Identity Provider.
   - The example includes the optional definition of a cookie handling rule **store-in-session** for the authentication tokens LtpaToken and LtpaToken2. This setting saves the authentication tokens of the remote connection in the cookie store. When a URL to the remote site is requested again, the Outbound HTTP connection service establishes an authenticated HTTP connection by using the saved authentication tokens. Reestablishing the SAML authentication procedure is therefore not needed.

```
<?xml version="1.0" encoding="UTF-8"?>
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">

  <mapping contextpath="/myproxy" url="*">

   <policy name="pol_tfim101" url="http://www.my_remote_site.com/*" >
    <actions>
     <method>GET</method>
     <method>POST</method>
    </actions>
    <cookie-rule name="co_tfim101">
     <cookie>LtpaToken</cookie>
     <cookie>LtpaToken2</cookie>
     <scope>user</scope>
     <handling>store-in-session</handling>
    </cookie-rule>
    <meta-data>
     <name>SSO_SAML20_IDP</name>
     <value>tfim101</value>
    </meta-data>
   </policy>
  </mapping>
</proxy-rules>
```

2. After you save the XML file, run the ConfigEngine task **update-outbound-http-connection-config** to apply the policy settings to the configuration profile:
   - AIX, HP-UX, Linux, Solaris: `./ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`
   - IBM i: `ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`
   - Windows: `ConfigEngine.bat update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`

   where *XML_file* is the file path to the XML file.

Adding the Java Authentication and Authorization Service (JAAS) login module to the Tivoli Federated Identity Manager (TFIM) server:

The Java Authentication and Authorization Service (JAAS) login module is available as a plug-in. This plug-in sets the email address of the logged in user within the security context so that the email address can be used within Tivoli Federated Identity Manager.

The local Tivoli Federated Identity Manager server creates SAML tickets to interact with SmartCloud for Social Business. You can identify the user in those tickets by their email address. The default mapping rules in Tivoli Federated Identity Manager enable access to attributes within the security context of a user. It is not possible to use the email address of the user that is currently logged in. Instead of custom programming, WebSphere Portal Express provides a Java Authentication and Authorization Service (JAAS) login module implementation that must be added to your Tivoli Federated Identity Manager system. The JAAS plug-in accesses the user's email address and inserts it into the Authorization Token, so the email address can be used within the standard mapping rules. Because the plug-in uses VMM API calls to obtain the email address, the Federated Repository type needs to be configured on your Tivoli Federated Identity Manager system. The following WebSphere Application Server JAAS login modules must be enabled before you enable the plug-in:

- **`com.ibm.ws.security.server.lm.ltpaLoginModule`**
- **`com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule`**

The preceding modules are enabled by default.

If these prerequisites are not met in your environment, or you have another way of obtaining the email address that is not stored in your User Repository, you can implement your own JAAS plug-in by using the developerWorks guidelines. For more information, see the developerWorks article *Developing a custom Java module* in the related links.

CF03 "Configuring the Java Authentication and Authorization Service (JAAS) login module"
The behavior of the JAAS login module is configurable. If you change the attribute name for the security context, make sure to adjust the mapping rule accordingly.

CF03 "Tivoli Federated Identity Manager (TFIM) mapping for the Java Authentication and Authorization Service (JAAS) login module" on page 3047
By default, the JAAS plug-in reads a user's email address from the VMM attribute with the name `mail`. The JAAS plug-in sets the `mail` attribute in the security context. If you change the name of the attribute in the security context, update the following mapping rule accordingly.

Developing a custom Java module

Configuring the Java Authentication and Authorization Service (JAAS) login module:

The behavior of the JAAS login module is configurable. If you change the attribute name for the security context, make sure to adjust the mapping rule accordingly.

Before you begin

- Verify that the following WebSphere Application Server JAAS login modules are enabled:
  - **com.ibm.ws.security.server.lm.ltpaLoginModule**
  - **com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule**
- Copy the JAAS plug-in to the `AppServer\lib\ext` directory of your Tivoli Federated Identity Manager installation. If your Tivoli Federated Identity Manager is clustered, complete this step on the Deployment Manager and all cluster nodes. The JAAS plug-in file is named `wp.auth.jaas` and is available in the `PortalServer/base` directory.

About this task

Copying the JAAS plug-in to the `AppServer` directory prevents the plug-in from being updated during a portal installation update. If fixes are available, make sure to update the portal installation and then replace the existing `JAR` files in the Tivoli Federated Identity Manager installations with the new `JAR` files.

Procedure

- To configure the plug-in by using the default settings, complete the following steps:
  1. Open a wsadmin shell.
  2. Run the following command:

```
$AdminTask configureLoginModule { -loginType system
      -loginEntryAlias WEB_INBOUND -loginModule com.ibm.wps.auth.jaas.EnrichAttributeLoginModu
      -useLoginModuleProxy true -authStrategy OPTIONAL  -newModule true }
$AdminConfig save
```

  3. Exit wsadmin and restart the server.
- To configure the plug-in by using an alternative VMM attribute name for the email address, complete the following steps.
  1. Open a wsadmin shell.
  2. Run the following command:

```
$AdminTask configureLoginModule { -loginType system
      -loginEntryAlias WEB_INBOUND -loginModule com.ibm.wps.auth.jaas.EnrichAttributeLoginModu
      -useLoginModuleProxy true -authStrategy OPTIONAL  -customProperties
      {"vmm_email_attribute_name=internet_mail"} -newModule true }
$AdminConfig save
```

     Where *internet_mail* is the alternative VMM attribute name for the email address.
  3. Exit wsadmin and restart the server.
- To configure the plug-in by using an alternative attribute name for the security context, complete the following steps:
  1. Open a wsadmin shell.
  2. Run the following command:

```
$AdminTask configureLoginModule { -loginType system
      -loginEntryAlias WEB_INBOUND -loginModule com.ibm.wps.auth.jaas.EnrichAttributeLoginModu
      -useLoginModuleProxy true -authStrategy OPTIONAL  -customProperties
      {"context_email_attribute_name=email"} -newModule true }
$AdminConfig save
```

     Where *email* is the alternative attribute name for the security context.
  3. Exit wsadmin and restart the server.

- To configure the plug-in by using an alternative VMM attribute name for the email address and an alternative attribute name for the security context, complete the following steps:
  1. Open a wsadmin shell.
  2. Run the following command:

```
$AdminTask configureLoginModule
        { -loginType system -loginEntryAlias WEB_INBOUND -loginModule
        com.ibm.wps.auth.jaas.EnrichAttributeLoginModule -useLoginModuleProxy true -authStra
        OPTIONAL  -customProperties {"vmm_email_attribute_name=internet_mail",
        "context_email_attribute_name=email"} -newModule true }
$AdminConfig save
```

     Where *internet_mail* is the alternative VMM attribute name for the email address and *email* is the alternative attribute name for the security context.
  3. Exit wsadmin and restart the server.
- To remove the plug-in, complete the following steps:
  1. Open a wsadmin shell.
  2. Run the following command:

```
$AdminTask
        unconfigureLoginModule { -loginType application -loginEntryAlias Portal_LTPA -loginM
        com.ibm.wps.auth.jaas.EnrichAttributeLoginModule }
$AdminConfig save
```

  3. Exit wsadmin and restart the server.

Tivoli Federated Identity Manager (TFIM) mapping for the Java Authentication and Authorization Service (JAAS) login module:

By default, the JAAS plug-in reads a user's email address from the VMM attribute with the name `mail`. The JAAS plug-in sets the `mail` attribute in the security context. If you change the name of the attribute in the security context, update the following mapping rule accordingly.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
xmlns:xalan="http://xml.apache.org/xalan"
version="1.0"
xmlns:mapping-ext="com.tivoli.am.fim.trustserver.sts.utilities.IDMappingExtUtils"
extension-element-prefixes="mapping-ext"
xmlns:stsuuser="urn:ibm:names:ITFIM:1.0:stsuuser">
        <xsl:strip-space elements="*" />
        <xsl:output method="xml" version="1.0" encoding="utf-8" indent="yes" />
        <!-- Initially we start with a copy of the document. -->
        <xsl:template match="@* | node()">
            <xsl:copy>
               <xsl:apply-templates select="@* | node()" />
            </xsl:copy>
        </xsl:template>

        <!-- This will replace the principal name with the user's email. -->
        <xsl:template
        match="//stsuuser:Principal/stsuuser:Attribute[@name='name']">
            <stsuuser:Attribute name="name" type="urn:oasis:names:tc:SAML:1.1:nameid-format:emailA
            <stsuuser:Value>
               <xsl:value-of select="//stsuuser:AttributeList/stsuuser:Attribute[@name='mail']/sts
            </stsuuser:Value>
            </stsuuser:Attribute>
        </xsl:template>
</xsl:stylesheet>
```

Configuration settings for Active Directory Federation Services (ADFS):

Creating a generic SAML 2.0 federation with a new or existing domain

Finding the Identity Provider login URL and the Partner URL (ADFS):

To establish a single sign-on (SSO) connection through Active Directory Federation Services (ADFS), you must specify the Identity Provider login URL and the Partner URL. Learn how to find these values from the ADFS configuration if you do not already know them. If you know these values already, skip this step.

About this task

The following steps describe how to obtain the Identity Provider target URL to directly initiate an IDP login flow on ADFS to a specific partner.

Procedure

1. Open the ADFS Management on the ADFS server.
2. Go to **Relying Party Trusts** and select the target partner.
3. Click **Properties...**
4. Click the **Identifiers** tab and copy the **Relying party identifier**.
5. Using a browser, log in to the web interface of the ADFS server that is provided by Internet Information Services (IIS). For example, go to the following URL: `https://<host>:<port>/adfs/ls/IdpInitiatedSignOn.aspx?loginToRp=<partnerUrl>`, where *<partnerUrl>* is the value of the **Relying party identifier** that you copied in the previous step.

Results

The federation flow starts automatically after you log in to the IIS-provided web interface of the ADFS server.

Adding cookie handling to the Active Directory Federation Services (ADFS) server:

The Internet Information Services (IIS) server as a part of the ADFS configuration sets up the ADFS cookies by default on a specific path and a specific host. To use these cookies for single sign-on (SSO) between the portal server and the ADFS server, the cookies need to flow on requests to the portal server as well. The cookie domain and cookie path must be changed.

Procedure

- To change the cookie domain, open the `web.CONF` of the IIS ADFS module and add the following:

```
<configuration>

...

<system.web>

...

<httpCookies domain="your_domain" httpOnlyCookies="false" requireSSL="false" />

...
```

- To change the cookie path, an **outboundRule** on IIS is needed. To support this **outboundRule** via the IIS Management console, Application Request Routing (ARR) is needed. This enhancement creates an **outboundRule** like the following example:

```
<rewrite>
<outboundRules>
<remove name="ChangeCookiePath" />
<rule name="ChangeCookiePath">
<match serverVariable="RESPONSE_Set_Cookie" pattern="^(.*; path=/)adfs/ls" />
<conditions />
<action type="Rewrite" value="{R:1}" />
</rule>
</outboundRules>
</rewrite>
```

Creating Identity Provider settings at the Outbound Connection Service configuration (ADFS):

Certain metadata settings such as the ADFS cookies, the Identity Provider URL, and the Partner URL are required to define a single sign-on (SSO) connection through Active Directory Federation Services (ADFS).

About this task

The following metadata values are required to define an ADFS Identity Provider, where *IdpName* is the unique name of the Identity Provider:

***IdpName*.IDP_PROTOCOL**
: The protocol part of the Identity Provider login URL. Replace the value *my_idp_prot* with the value of the protocol part of the Identity Provider login URL, either `http` or `https`.

***IdpName*.IDP_HOST**
: The host name part of the Identity Provider login URL. Replace the value *my_idp_host* with the Identity Provider login URL host name.

***IdpName*.IDP_PORT**
: The port number of the Identity Provider login URL. Replace the value *my_idp_port* with the value of the Identity provider login URL port.

***IdpName*.IDP_URI**
: The URL path of the Identity Provider login URL. Replace the value *my_idp_uri* with the path of the Identity Provider login URL.

***IdpName*.IDP_AUTH_COOKIE.1**
: Authentication token that is created by the federation partner. The default value is `SamlSession`.

***IdpName*.IDP_AUTH_TOKEN_SOURCE**
: Determines where the AJAX proxy obtains the IDP authentication tokens. The IDP authentication tokens are the cookies that are required to authenticate the connection with the Identity Provider. By default, the AJAX procy creates an LTPA token from the user subject and uses this LTPA token to authenticate the connection with the Identity Provider. Because the ADFS Identity Provider does not support an LTPA-based authentication, set the value of this parameter to `cookies`. This setting lets the AJAX proxy use the authentication tokens that are defined in the metadata settings **`IdpName.IDP_AUTH_TOKEN_COOKIE.n`**.

***IdpName*.IDP_AUTH_TOKEN_COOKIE.n**
: The authentication tokens that are required for authenticating against the Identity Provider. In the example that follows, the cookies *`MSISAuth`*, *`MSISAuth1`*, and *`MSISAuthenticated`* are defined.

***IdpName*.PARAM_NAME.1 and *IdpName*.PARAM_VALUE.1**
This setting defines the partner URL. Replace the value *idp_name_partner_url* with the URL of the partner that runs the Service Provider service.

The following XML example creates the Identity Provider settings for an Active Directory Federation Services connection at the Outbound Connection Service Configuration and uses the following values:

- The Identity Provider name is *adfs01*.
- The Identity Provider login URL is *https://idp.example.com/sps/myfederation/saml20/login*.
- The Partner URL is *https://sp.example.com/sps/myfederation/saml20/v2_0*.
- The ADFS authentication cookies are *MSISAuth*, *MSISAuth1*, and *MSISAuthenticated*.

Change these values according to your configuration.

Procedure

1. Create an XML document like the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0
 <variables>
  <!--  replace values with the IdP login URL and the partner URL -->
  <endpoint name="adfs01.idp_prot">https</endpoint>
  <endpoint name="adfs01.idp_host">idp.example.com</endpoint>
  <endpoint name="adfs01.idp_port">443</endpoint>
  <endpoint name="adfs01.idp_uri">/adfs/ls/IdpInitiatedSignOn.asp</endpoint>
  <endpoint name="adfs01.partner_url">https://sp.example.com/sps/myfederation/saml20/v2_0</end
 </variables>
 <meta-data>
  <name>adfs01.IDP_PROTOCOL</name>
  <value>my_idp_prot</value>
 </meta-data>
 <meta-data>
  <name>adfs01.IDP_HOST</name>
  <value>my_idp_host</value>
 </meta-data>
 <meta-data>
  <name>adfs01.IDP_PORT</name>
  <value>my_idp_port</value>
 </meta-data>
 <meta-data>
  <name>adfs01.IDP_URI</name>
  <value>my_idp_uri</value>
 </meta-data>
 <meta-data>
  <name>adfs01.PARAM_NAME.1</name>
  <value>LoginToRp</value>
 </meta-data>
 <meta-data>
  <name>adfs01.PARAM_VALUE.1</name>
  <value>idp_name_partner_url</value>
 </meta-data>
 <meta-data>
  <name>adfs01.IDP_AUTH_TOKEN_SOURCE</name>
  <value>cookies</value>
 </meta-data>
 <meta-data>
  <name>adfs01.IDP_AUTH_TOKEN_COOKIE.1</name>
  <value>MSISAuth</value>
 </meta-data>
```

```
 <meta-data>
  <name>adfs01.IDP_AUTH_TOKEN_COOKIE.2</name>
  <value>MSISAuth1</value>
 </meta-data>
 <meta-data>
  <name>adfs01.IDP_AUTH_TOKEN_COOKIE.3</name>
  <value>MSISAuthenticated</value>
 </metadata>
 <meta-data>
  <name>adfs01.IDP_AUTH_COOKIE.1</name>
  <value>SamlSession</value>
 </meta-data>
</proxy-rules>
```

2. After you save the XML file, run the ConfigEngine task **update-outbound-http-connection-config** to apply the Identity Provider settings at the global configuration profile.
   - AIX, HP-UX, Linux, Solaris: `./ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`
   - IBM i: `ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`
   - Windows: `ConfigEngine.bat update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`

   where *XML_file* is the file path to the XML file.

Defining policy rules for the remote connection (ADFS):

Learn about how to create a policy rule for the SSO connection. Creating a policy rule is required to use the SSO connection for the Identity Provider that you registered.

About this task

The metadata setting **SSO_SAML20_IDP** enables the policy for SSO authentication by using SAML. Replace the default value, in this case, *adfs01* with the unique Identity Provider name.

Procedure

1. To create a policy rule for a remote connection that uses an Active Directory Federation Services (ADFS) Identity Provider, create an XML document like the following example:

   Note: The following example creates a policy for an SSO connection to http://www.my_remote_site.com, which is controlled by ADFS.

```
<?xml version="1.0" encoding="UTF-8"?>
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0">

  <mapping contextpath="/myproxy" url="*">

   <policy name="pol_adfs01" url="http://www.my_remote_site.com/*" >
    <actions>
     <method>GET</method>
     <method>POST</method>
    </actions>
    <cookie-rule name="co_adfs01">
     <cookie>LtpaToken</cookie>
     <cookie>LtpaToken2</cookie>
     <scope>user</scope>
```

```
        <handling>store-in-session</handling>
       </cookie-rule>
       <meta-data>
        <name>SSO_SAML20_IDP</name>
        <value>adfs01</value>
       </meta-data>
      </policy>
     </mapping>
    </proxy-rules>
```

2. After you save the XML file, run the ConfigEngine task **update-outbound-http-connection-config** to apply the policy settings to the configuration profile:
   - AIX, HP-UX, Linux, Solaris: `./ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`
   - IBM i: `ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`
   - Windows: `ConfigEngine.bat update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`

   Where *XML_file* is the file path to the XML file.

Using dynamic elements in outbound HTTP connection settings:

In some cases, it is useful to control configuration settings at run time. For example, an administrator might want to have the program decide at run time which policy rule is applied. In another scenario, parts of a policy rule configuration that are known only at run time must be included in the configuration.

About this task

Enabling and disabling policy rules: Administrators can use the metadata parameter `active` to enable or disable the policy rule to which the metadata belongs. Instead of setting a static metadata value to `true` or `false`, the administrator can set a variable token. The following example uses this feature to disable policy mappings. For more details, read the information about *deactivate policy rules, mappings, or custom connection filters* under *Description of the outbound HTTP connection configuration script*.

Example

The following example deactivates multiple policy rules, depending on a single policy variable:

```
<proxy-rules ...>
     <variables>
          <endpoint name="am_i_active">false</endpoint>
     <variables>
     <mapping contextPath="/theproxy">
          <policy url="http://the_remote_server.com/*">
               ...
               <meta-data>
                    <name>active</name>
                    <value>{$am_i_active}</value>
               </meta-data>
          </policy>
          <policy url="http://another_remote_server.com/*">
               ...
               <meta-data>
                    <name>active</name>
```

```
                    <value>{$am_i_active}</value>
                </meta-data>
            </policy>
        </mapping>

</policy-rules>
```

In some cases, the decision whether the policy rules is active or inactive can be made only at run time. In this case, the policy variable must be passed to the Ajax proxy as a URL parameter. The following example shows the configuration:

```
<proxy-rules ...>
     <mapping contextPath="/theproxy">
          <policy url="http://the_remote_server.com/*">
               ...
               <meta-data>
                    <name>active</name>
                    <value>{$active_a}</value>
               </meta-data>
          </policy>
          <policy url="http://the_remote_server.com/*">
               ...
               <meta-data>
                    <name>active</name>
                    <value>{$active_b}</value>
               </meta-data>
          </policy>
     </mapping>
</policy-rules>
```

The following example activates the first rule and deactivates the second rule:

```
http://localhost/wps/theproxy/http/the_remote_server.com/main.html?active_a=true&active_b=false
```

Using programmatic extensions for outbound HTTP connections:

To extend the functions of an outbound connection, portal administrators can implement a custom outbound service filter.

About this task

For example, such access can be required in the following cases:

- A portal administrator wants to open an outbound HTTP connection to a back end system that requires a specific HTTP request header setting.
- A portal administrator wants to feed a third-party site analysis program with information about an outbound HTTP connection. In this case, the outbound connections service calls custom code whenever the outbound connection is opened to the specific remote site. The custom code feeds the third-party site analysis program with the information about the remote connection.

  "Custom outbound service filters" on page 3055
  Custom outbound service filters provide a plug point for application developers. They can use these filters to add custom function to the processing logic of a policy.

  "Using custom cookie transformation handlers" on page 3059
  You can use custom cookie transformation handlers to allow custom program extensions to get programmatic control over the outbound HTTP connection.

Custom outbound service filters:

Custom outbound service filters provide a plug point for application developers. They can use these filters to add custom function to the processing logic of a policy.

"Implementing a custom outbound connection service filter"
Application developers can implement a custom outbound connection service filter.

"Registering a custom outbound connection service filter" on page 3056
For a custom outbound connection filter to take effect, you must register it.

"Configuration settings for custom outbound connection filters" on page 3057
The configuration of a custom outbound connection filter definition includes a metadata section. Developers can use it as a store for filter-specific customization data.

"Built-in configuration settings for custom outbound connection filters" on page 3059
The following built-in metadata setting for custom connection filter is defined.

Implementing a custom outbound connection service filter:

Application developers can implement a custom outbound connection service filter.

About this task

Custom outbound connection service filters must implement the interface `com.ibm.mashups.proxy.ext.OutboundServiceFilter`. They are instantiated from a factory class `com.ibm.mashups.proxy.ext.OutboundServiceFilterFactory`.

The following listing is an example of a custom outbound service filter:

```
package sample.test.filters;

import com.ibm.mashups.proxy.Context;
import com.ibm.mashups.proxy.configuration.AjaxProxyConfiguration;
import com.ibm.mashups.proxy.ext.ConnectionStatusEvent;
import com.ibm.mashups.proxy.ext.FlowControl;
import com.ibm.mashups.proxy.ext.OutboundServiceFilter;
import com.ibm.mashups.proxy.ext.OutboundServiceFilterFactory;

public class MyFilterFactory implements OutboundServiceFilterFactory {

    /**
      * This method is called whenever an outbound HTTP conenction
      * is opened for a url for which this custom filter
      * is defined in its configuration settings.
      * The method receives the URL of the outbound connection,
      * the proxy configuration, and the runtime context.
      * The method must return a filter object that implements the
      * OutboundServiceFilter interface.
      */
      @Override
      public OutboundServiceFilter newOutboundServiceFilter(URL url,
                        AjaxProxyConfiguration proxyConfig,
                        Map<String,String> metadata,
                        Context runtimeCtx) throws IOException {
            return new MyCustomFilter();
      }
}

public class MyCustomFilter implements OutboundServiceFilter {
     /*
```

```
 * This method is called for outbound HTTP connections
 * for which this filter has been configured.
 * The method receives the HttpURLConnection object
 * that connects against the remote server.
 * The method is called immediately before the connect() method
 * is called against that HttpURLConnection object. This means that
 * the implementation of this method can retrieve or modify the setup
 * parameters and the general request properties of this connection objects.
 * The filter can abend the connection, by invoking errorHandler.setError()
 * or errorHandler.setRedirect().
 */
 @Override
 public void preConnect(HttpURLConnection urlConnection,
                        FlowControl errorHandler)
 {
     // implement your custom code here.
 }
/*
 * This method is called for outbound HTTP connections for that this
 * filter has been configured.
 * The method receives the HttpURLConnection object that has connected
 * against the remote server.
 * The method is called immediately after connect() method is called
 * against that HttpURLConnection object, which means, the implementation
 * of this method is allowed to retrieve or modify the response header
 * fields and the remote content.
 * The filter can abend the connection, by invoking errorHandler.setError()
 *or errorHandler.setRedirect().
 */
 @Override
 public void postConnect(HttpURLConnection urlConnection,
              Map<String, List<String>> modifiableResponseHeaders,
               FlowControl errorHandler) {

     // implement your custom code here.
 }

 /**
  * This method is called whenever the outbound connection service ran
  * into an error. The method receives an eventData object that
  * contains information about the problem that occurred, such as the name,
  * the id and the parameter array of a resource bundle that contains the
  * error message which describes the problem, as well as information about
  * the failing http connection.
  * The filter can use this method to override the error handling, by
  * invoking  by invoking errorHandler.setError() or
  * errorHandler.setRedirect(). For example, the error handler can
  * override the error message or override the HTTP status of the
  * outbound connection.
  */
 @Override
 public void handleError(ConnectionStatusEvent eventData,
                   FlowControl errorHandler) {
     // implement your custom code here.
 }
```

Make sure that the filter class can be loaded at run time. For example, place the class file in the `/WEB-INF/lib` directory of the web module that contains the code that establishes the outbound HTTP connection.

Registering a custom outbound connection service filter:

For a custom outbound connection filter to take effect, you must register it.

About this task

Custom connection filters for outbound HTTP connections are defined at a policy setting. The following XML snippet shows how you register a custom connection filter at a policy setting:

```
<policy url="http://the_remote_server.com/path/*" >
    <actions>
        <method>GET</method>
    </actions>
    <filter-chain>
        <filter-factory>
            <classname>sample.test.filters.MyFilterFactory
            </classname>
        </filter-factory>
    </filter-chain>
</policy>
```

The `<filter-chain>` section contains a list of class names that denote the factory class for custom HTTP connection filters. The outbound connection service loads and runs the filters in the order in which they appear in the configuration.

Configuration settings for custom outbound connection filters:

The configuration of a custom outbound connection filter definition includes a metadata section. Developers can use it as a store for filter-specific customization data.

Example: A developer implemented a custom filter named `MyUserAgentRedirectionFilter`. The developer uses the filter to cause a redirect to a different URL if the user agent matches with a user agent pattern. You must define the user agent pattern and the redirection URL in the configuration. The following code snippet illustrates how the filter factory fetches settings for the redirection URL and the user agent patterns from the configuration. The sample code snippet assumes that the configuration setting for the user agent pattern is in a metadata setting with the name `my_user_agent`, and the redirection URL is in a metadata setting with the name `my_redirection_url`.

```
public class MyUserAgentRedirectionFilterFactory implements OutboundServiceFilterFactory {

    @Override
    public OutboundServiceFilter newOutboundServiceFilter(URL url,
                AjaxProxyConfiguration proxyConfig,
                Map<String,String> metadata,
                Context runtimeCtx) throws IOException {

        // fetch the settings from the filter configuration.
        String redirection_url = metadata.get("my_redirection_url");
        String  ua_pattern = metadata.get("my_user_agent");
        return new MyCustomFilter(url, ua_patterns);
    }
}
```

The following outbound connection filter code sample checks whether the user agent string of the current outbound connection matches with the pattern that is defined in the configuration:

```
public class MyUserAgentRedirectionFilter implements OutboundServiceFilter {

    private final String redirectionUrl;
    private final String pattern;

    public  MyUserAgentRedirectionFilter(String url, String ua_pattern) {
        redirectionUrl = url;
        patterns = ua_patterns;
    }
```

```
    @Override
    public void preConnect(HttpURLConnection conn, FlowControl ctrl)
    {
        String userAgentString = conn.getRequestProperty("User-Agent");
        if (this.shoudRedirect(userAgentString)) {
            ctrl.setRedirect(redirectionUrl);
        }
    }

    @Override
    public void postConnect(HttpURLConnection conn,
                Map<String, List<String>> modifiableResponseHeaders,
                FlowControl ctrl) { }

    @Override
    public void handleError(ConnectionStatusEvent eventData,
                FlowControl ctrl) { }

    // helper method: check if this filter should apply.
    // returns true if the given user agent matches with the given pattern

    private boolean shouldRedirect(String ua) {
        return Pattern.compile(pattern).matcher(ua).matches();
    }
}
```

Finally, you provide the configuration. In the example scenario, you want to use the user agent redirection filter to redirect outbound HTTP requests to the remote host `http://www.my_remote_server.com/` if the client runs on an android device or iPhone device. You want outbound requests that are submitted from android devices to be redirected to `http://android.my_remote_server.com/index.html`, and requests from an iPhone device to be redirected to `http://iphone.my_remote_server.com/index.html`. The following configuration snippet gives an example:

```
<policy url="http://www.my_remote_server.com/*" >
   <actions>
      <method>GET</method>
   </actions>
   <filter-chain>
      <filter-factory>
         <classname>sample.test.filters.MyUserAgentRedirectionFilterFactory</classname>
       <meta-data>
            <name>my_redirection_url</name>
            <value>http://iphone.my_remote_server.com/index.html</value>
         </meta-data>
         <meta-data>
            <name>my_user_agents</name>
            <value>.*iPhone.*</value>
         </meta-data>
      </filter-factory>

      <filter-factory>
         <classname>sample.test.filters.MyUserAgentRedirectionFilterFactory</classname>
       <meta-data>
            <name>my_redirection_url</name>
            <value>http://android.my_remote_server.com/index.html</value>
         </meta-data>
         <meta-data>
            <name>my_user_agents</name>
            <value>.*Android.*Mobile.*</value>
         </meta-data>
      </filter-factory>
   </filter-chain>
</policy>
```

Built-in configuration settings for custom outbound connection filters:

The following built-in metadata setting for custom connection filter is defined.

active The built-in metadata setting `active` activates or deactivates a custom connection filter. If you want to disable the connection filter but keep the definition in the configuration, set this flag to `false`. Example: The portal administrator wants to temporarily disable the redirection handling of a connection filter.

```
<filter-chain>
    <filter-factory>
        <classname>sample.test.filters.MyUserAgentRedirectionFilterFactory
        </classname>
        <meta-data>
            <name>my_redirection_url</name>
            <value>http://iphone.my_remote_server.com/index.html</value>
        </meta-data>
        <meta-data>
            <name>my_user_agents</name>
            <value>.*iPhone.*</value>
        </meta-data>
        <meta-data>
            <name>active</name>
            <value>false</value>
        </meta-data>
    </filter-factory>
</filter-chain>
```

Using custom cookie transformation handlers:

You can use custom cookie transformation handlers to allow custom program extensions to get programmatic control over the outbound HTTP connection.

About this task

You define custom cookie transformation handlers in a cookie rule. The interface provides two methods for getting programmatic control in the following two phases of the outbound HTTP connection:

- Before the HTTP request header is sent to the remote connection. The transformation handler receives a cookie that applies to the cookie rule.
- After the response header is read. The transformation handler receives a cookie that was set in a `Set-Cookie` header definition.

Application developers can use a custom cookie transformation handler to modify the name, path, domain, or value of the affected cookie, or to produce analytic or statistical information about the cookie.

"Implementing a custom cookie transformation filter"
Application developers can implement a custom cookie transformation filter.

"Registering a custom cookie transformation filter" on page 3061
For a custom cookie transformation filter to take effect, you must register it.

Implementing a custom cookie transformation filter:

Application developers can implement a custom cookie transformation filter.

About this task

To do so, they must provide an implementation of the interfaces `com.ibm.mashups.proxy.ext.CookieTransformer` and

com.ibm.mashups.proxy.ext.CookieTransformerFactory. The factory class creates and returns an instance of the cookie transformer object. The following sample code uses the cookie transformation filter to write the name and value of a certain cookie to a log. The sample code uses System.err as a Writer object.

```
package test.sample;
import com.ibm.mashups.proxy.ext.CookieTransformer;
import com.ibm.mashups.proxy.ext.CookieTransformerFactory;

public class SampleCookieXformerFactory implements CookieTransformerFactory {
 /**
  * Produce and return a new CookieTransformer instance.
  * @param url is the URL for which the cookie transformer is to be opened.
       * @param the metadata that are associated with the transformer object.
       * @return CookieTransformer the custom cookie transformation handler.
         * Must not be null.
         */
 @Override
 public CookieTransformer newCookieTransformer(URL url,
                                  Map<String, String> metadata) {
     return new SampleCookieTransformer (url);
 }
}

package test.sample;
import com.ibm.mashups.proxy.ext.CookieTransformer;
import com.ibm.mashups.proxy.ext.CookieTransformerFactory;
/**
 * The custom cookie transformation handler logs ingoing and outgoing
 * cookies, for which the cookie transformer handler was defined.
 *
 */
public class SampleCookieTransformer implements CookieTransformer (

 // sample code: use System.err as output stream.
 private PrintStream getWriter () {
           return System.err;
 }

 private URL theURL;

        /**
         * Initialize a sample cookie transformation handler.
         * @param url the URL for which the outbound connection was opened.
         **/
        public SampleCookieTransformer (URL url) {
     this.theURL = url;
        }

    /**
     * Process an outgoing cookie.
     * This method is called before the outbound HTTP connection is submitted
     * to the remote host.
     * The sample code writes the name and value of the cookie and the URL
     * to which the connection was submitted to a PrintStream writer.
     * @param cookie the cookie instance.
     */
 @Override
 public void transformOutbound(HttpCookie cookie) {
            getWriter().println (Cookie "+cookie.getName() +" sent to URL
                                 "+theURL+". value="+cookie.getValue());
        }

    /**
     * Process an ingoing cookie.
```

```
     * This method is called after an HTTP response header was read.
     * The response header contains a Set-Cookie statement for a cookie
     * to which this connection handler applies.
     * The sample code writes the name and value of the affected cookie
     * and the URL from where the cookie was set to a PrintStream writer.
     * @param cookie the cookie instance.
     */
 @Override
 public void transformInbound(HttpCookie cookie) {
     getWriter().println (Cookie "+cookie.getName() +" received from URL
                               "+theURL+". value="+cookie.getValue());
        }

}
```

A custom cookie transformation handler is an extension of the outbound HTTP connection service. Therefore, the extension handler code must be accessible by the class loader of the WebSphere Application Server on which WebSphere Portal Express runs. For example, place the code in the following directory:

- Linux: *PortalServer_root*/shared/app
- IBM i: *PortalServer_root*/shared/app
- Windows: *PortalServer_root*\shared\app

Registering a custom cookie transformation filter:

For a custom cookie transformation filter to take effect, you must register it.

About this task

You define custom cookie transformation handlers at a cookie rule. The following xml snippet shows how you register a custom cookie transformation filter:

```
<cookie-rule>
    <cookie>TransformationCookie</cookie>
    <handling>store-in-session</handling>
    <transformation>
        <classname>test.sample.SampleCookieXformerFactory</classname>
    </transformation>
</cookie-rule>
```

The `transformation` section contains a class name that specifies the factory class for custom cookie transformation filters.

Migration:

WebSphere Portal Express Version 8.5 provides a migration process for the change from the Ajax proxy of previous portal versions to the new outbound HTTP connection.

If you upgrade your WebSphere Portal Express from a previous version to Version 8.5, the outbound HTTP connection infrastructure attempts to migrate existing Ajax proxy configuration settings to the outbound HTTP connection service configuration. It moves all settings from the Ajax proxy configuration into database settings for the outbound HTTP connection service. This migration takes place as follows:

Migration of global configuration settings:
In previous WebSphere Portal Express versions, global proxy configuration settings were in the `proxy-config.xml` file of the Ajax Proxy Configuration web module. The outbound HTTP connections infrastructure migrates

global proxy configuration settings when the portal Version 8.5 outbound HTTP connection service is accessed for the first time after the portal upgrade. The global configuration settings are updated in the system configuration profile.

Migration of customized global configuration settings:
In previous WebSphere Portal Express versions, custom global proxy configuration settings were in the WP Configuration Service Resource Environment Provider (REP) property named `proxy.config.file`. The outbound HTTP connections infrastructure migrates these custom global configuration settings when the portal Version 8.5 outbound HTTP connection service is accessed for the first time after the portal upgrade. Custom global configuration settings are updated into the global configuration profile.

Migration of application-specific proxy configurations
Application-specific configurations are imported into the outbound HTTP connection configuration when the web module for the application is deployed. The deployment program scans for the file `/WEB-INF/proxy-config.xml`. If this file exists, the migration program creates a scoped configuration profile that relates to the web module that is created.

Important: In previous WebSphere Portal Express versions, the `proxy-config.xml` file held the configuration of the Ajax proxy. Changes that you make to this file became effective when you restarted the web module. In contrast, the outbound HTTP connection infrastructure makes only the necessary updates to the `proxy-config.xml` file. Changes to this file do not become effective until one of the following events occur:

- For global or customized global configuration settings: The outbound HTTP connection service is started for the first time after the portal upgrade.
- For application-specific proxy configurations: The web module that contains the `proxy-config.xml` is deployed.
- One of the portal configuration tasks `create-outbound-http-connection-config` or `update-outbound-http-connection-config` is started.

Related tasks:

"Configuring outbound HTTP connections by using configuration tasks" on page 3013
Programmers can create, read, update, or delete settings of the outbound HTTP connection by using the appropriate portal configuration engine tasks.

Live text for click-to-action

IBM WebSphere Portal Express supports a live text API for user controlled data transfer between components. With live text, a component on a page can declare sources and targets for data transfer. For example, this can be a portlet or a navigation element. When the user clicks on a source element, the portal displays a menu listing targets that match the selected source. When a menu item is selected, the portal invokes the corresponding target passing it the source data. This process is called Click-to-Action (C2A).

Both sources and targets are specified by HTML markup that apply live text elements. This means that the HTML markup contains special attributes that marks the HTML fragment as a click-to-action tag.

- Sources of click-to-action menus provide a data item that is potentially relevant for other components on the page. The data item has an associated type name that is used to determine the targets that can handle this data item.

- Targets specify the type name that they are interested in and a display title for the click-to-action menu item that represents the target entry. They provide a handler for the received data either as JavaScript code or as a server-side URL to which the data is sent when the menu item is selected.

As both sources and targets are defined by live text elements, all components that contribute HTML markup to a page can provide sources and targets. This includes IBM portlets, JSR standard portlets, and theme and skin components, as well as WCM content or Web clippings. Portlets can register their portlet action or render URLs as server-side targets, but you can also define targets within one portal page that point to another page or even to a Common Gateway Interface (CGI) handler outside the portal.

Click-to-action treats all source data as unstructured text. You can encode any information in the source value, but the target handler is responsible for decoding the received data appropriately.

Click-to-action also integrates with the server side portlet communication programming model: If a portlet provides the following server side communication targets, they will automatically be made available for click-to-action on all pages that contain the portlet:

- Portlet events declared by a JSR 286 portlet in `portlet.xml` with a payload type of `java.lang.String`.
- Cooperative portlet actions declared by JSR 168 portlets in a WSDL deployment descriptor with an input property of class `java.lang.String`.

Therefore portlets that use these declarations do not need to generate semantic tagging markup for click-to-action targets.

Administrators can turn off the automatic generation of click-to-action targets by specifying a portlet preference `com.ibm.portal.c2a.target.generation = false`.

"Live text formats"
Application of live text elements to sources and targets is based on special HTML classes that are attached to elements of the HTML markup.

"Integrating click-to-action targets with the person menu" on page 3066
Target actions for live text based click-to-action can also integrate with the person menus that are generated for hCard microformats found in the page markup.

"Relation to cooperative portlet wiring" on page 3066
You can use both live text elements and cooperative portlet wires to exchange data between portlets on a page.

"Comparison of the new features with click-to-action in IBM portlets" on page 3067
The user experience of live text elements based click-to-action is similar to that of the click-to-action JSP tags that are available for IBM portlets.

Live text formats:

Application of live text elements to sources and targets is based on special HTML classes that are attached to elements of the HTML markup.

Note: The class attribute can be attached to any HTML element and that it can have multiple values, which are separated by spaces. Therefore, you can annotate any HTML element in your output with a click-to-action class, even if it has already a class attribute for CSS formatting.

Sources for Live text are span () or division ( ) elements that are annotated with a c2a:source class. Targets are HTML form (<form>) elements that are annotated with a c2a:target class. Both sources and targets have mandatory and optional properties. These properties are provided by annotated subelements of the main source or target tag. The property value is the entire content of the annotated property element with leading and trailing white spaces removed Example:

```
<b class="c2a:value">
    johndoe@acme.com
</b>
```

represents a c2a:value property with the value johndoe@acme.com. In many cases some of the source or target content is only relevant for the click-to-action framework but not for the user. In such cases, you might want to hide that part of the source or target content from rendering. To do this action, use the HTML attribute style="display:none".

Source tag

The source tag must be an HTML span () or division ( ) elements that are annotated with a c2a:source class. The properties of a source tag are as follows:

Table 456. Source tag properties

Property	Content	Mandatory
c2a:typename	Namespaced type name that describes the format and semantics of the data that is provided.	Yes
c2a:value	Actual data that is passed to the target operation.	Yes
c2a:anchor	Optional anchor point that you can use for displaying the **Click-to-action** hover menu. If you do not specify this property, the content of the property c2a:value is used as the default.	No
c2a:display	Markup that is inserted as a header into the menu that is generated for the source.	No

When the portal finds one or more matching targets for a source tag, the c2a:anchor subelement is marked as an active click-to-action source. And hovering over the element displays a click-to-action menu trigger. You can control the way that source anchors are displayed in the browser by the CSS file styles.css that is located under the directory c:\IBM\WebSphere\PortalServer\ui\wp.tagging.liveobject\semTagEar\Live_Object\Framework.ear\Live_Object_Framework.war\ui. The decoration for elements that offer a hover menu is defined by the following styles by default:

```
.hasHover { border-bottom: 1px dotted #306bc4; }
img.hasHover { padding:1px; border:1px dotted #306bc4; }
```

The value of the property c2a:typename is used to match sources to targets. This value can have an XML namespace associated to avoid unintended type name clashes. As plain HTML does not support the use of standard XML namespaces and namespace prefixes, a namespaced name is represented as namespaceURI#localPart.

Source tag example:

```
<div class="c2a:source someotherclass">
    <span class="c2a:typename"
          style="display:none">http://www.ibm.com/xmlns/prod/datatype#email822</span>
    <p>some content that is not relevant to click-to-action, also to make clear
```

```
       that property elements do not have to be direct children
        <b class="c2a:value">johndoe@acme.com</b>
    </p>
    <img class="c2a:anchor" src="c2aHoverTrigger.jpg" />
    <p class="c2a:display" style="display:none;">
        <b><c>This is a sample click-to-action source</c></b><br>
        <b><c>You can add an optional header to your action menu</c></b>
  </p>
</div>
```

Target tag

The target tag must be an HTML form (<form>) that is annotated with a c2a:target class. The properties of a target tag are as follows:

Table 457. Target tag properties

Property	Content	Mandatory
c2a:typename	Namespaced type name that describes the format and semantics of the data that is expected.	Yes
c2a:action-label	The string that you want to be displayed for the operation in the click-to-action menu.	Yes
c2a:action-param	This property must be an HTML input (<input>) element, designates the place where the data is passed.	No

When the portal finds one or more matching targets for a source tag, the c2a:anchor subelement is marked as an active click-to-action source. And hovering over the element displays a click-to-action menu trigger. You can control the way that source anchors are displayed in the browser by the CSS file styles.css that is located under the directory c:\IBM\WebSphere\PortalServer\ui\wp.tagging.liveobject\semTagEar\Live_Object\Framework.ear\Live_Object_Framework.war\ui. The decoration for elements that offer a hover menu is defined by the following styles by default:

```
.hasHover { border-bottom: 1px dotted #306bc4; }
img.hasHover { padding:1px; border:1px dotted #306bc4; }
```

When a target is selected from a click-to-action menu, the corresponding HTML form is processed as if a user submitted it. The input field that was annotated as c2a:action-param is filled with the source data. Then, JavaScript onsubmit handlers are started, and finally the portal sends the form to its target URL. The target URL must point to the server-side target for click-to-action. If you want to implement a client-side click-to-action handler, use an onsubmit handler on the form. The JavaScript handler can retrieve the form and the input value from the page Document Object Model (DOM). But for convenience, the source data is also passed in the global variable window.ibm.portal.c2a.event.value.

Target tag example for a server-side handler:

```
<FORM class="c2a:target" action="/myapp/do.something">
    <span class="c2a:typename"> http://www.ibm.com/xmlns/prod/datatype#email822</span>
    <p class="c2a:action-label">Show inbox</p>
       Email: <input type="text" class="c2a:action-param" name="someInputName">
    <input type="submit">
</FORM>
```

Target tag example for a client-side handler:

```
<FORM class="c2a:target" onsubmit="doSomething(this);return false"
      action="javascript:void(0)" style="display:none">
    <span class="c2a:typename"> http://www.ibm.com/xmlns/prod/datatype#email822</span>
    <p class="c2a:action-label">Show inbox</p>
    <input type="text" class="c2a:action-param" name="someInputName">
</FORM>
```

Integrating click-to-action targets with the person menu:

Target actions for live text based click-to-action can also integrate with the person menus that are generated for hCard microformats found in the page markup.

Target actions that you want to be displayed in a person menu need to declare the special type name as follows:

`http://www.ibm.com/xmlns/prod/websphere/portal/v6.1/livetext#hcard`

Unlike normal click-to-action sources, the person data that is available in the person menu is complex structured information. Therefore the value of the variable `window.ibm.portal.c2a.event.value` is not a string, but a JavaScript object with multiple nested properties that represent available information about the person. Refer to the person tag documentation about available attributes. The value that is passed in a target input field annotated with `c2a:action-param` is a string representation of this object in JavaScript Object Notation (JSON) format.

If you want target actions to receive only individual fields of the person record, you can indicate this by appending the field selector to the type name. For example, a target action that is declared with the following type name will receive only the `email.internet` nested property of the person record.

`http://www.ibm.com/xmlns/prod/websphere/portal/v6.1/livetext#hcard.email.internet`

If the specified field is not available for a given source, then the target action is not displayed in the person menu.

Relation to cooperative portlet wiring:

You can use both live text elements and cooperative portlet wires to exchange data between portlets on a page.

However, the execution flow for both methods is different:

Flow for cooperative portlet wiring:

1. The source portlet renders an action link.
2. The user clicks a link to execute the source portlet action.
3. The source portlet action is executed on the server, producing the source data and triggering the wires.
4. The wires fire target portlet actions that are executed with the source data.

Flow for click-to-action

1. The source portlet renders a source HTML tag that contains the source data.
2. The user clicks on the source element to open a menu and selects the target action from the menu
3. The source data is sent to the server where a target portlet action is executed with the source data.

The following table lists differences that will help you decide which method for data exchange is appropriate for your application:

Table 458. Comparing click-to-action to portlet wires

Click to action	Portlet wires	
Is based on dynamic presence of targets on a page.	Is based on static administrator-defined wires.	
Triggers a single target selected from a menu.	Triggers all defined targets that have been wired up.	
Can only handle string data.	Can pass complex data types.	

Notes:

1. You can write portlets that support both methods; any portlet action declared in a cooperative portlet WSDL that defines an input parameter is available as a target for both click-to-action and portlet wiring. For sources, you can add a preference that lets the administrator control whether click-to-action live text should be emitted, as demonstrated by the cooperative portlet JSR shipping example.
2. You can also combine both methods: a target action that is triggered by click-to-action can have wires attached that will propagate to other portlet actions on the server within the same request. consequently, a single click-to-action menu selection can trigger multiple portlet actions on the server.

Related concepts:

"Portlet communication" on page 3069
IBM WebSphere Portal Express supports multiple ways for portlets to exchange or share information.

Comparison of the new features with click-to-action in IBM portlets:

The user experience of live text elements based click-to-action is similar to that of the click-to-action JSP tags that are available for IBM portlets.

However, the underlying technologies are different, and the functional possibilities of live text go beyond click-to-action JSP tags. This results in important distinctions:

Table 459. Comparison of the new features to existing click-to-action

	New: Live text for click-to-action	Click-to-action JSP tags for IBM portets
How sources and targets are declared.	Sources and targets can be declared by any HTML fragment on a page, including portlets, theme components or simple HTML clippings. JSR portlet actions declared in a cooperative portlet WSDL are automatically registered as targets.	Sources and targets can only be declared within IBM portlets. Sources are declared by using JSP tags and targets are declared with a cooperative portlet WSDL.
How targets are handled	Targets can register client side (Javascript) or server side (FORM submission) handlers for click-to-action.	Target actions are always handled with a server call.

Table 459. Comparison of the new features to existing click-to-action (continued)

	New: Live text for click-to-action	**Click-to-action JSP tags for IBM portets**
Where menu contents are computed	Menu contents are computed on the client when the user clicks on a source. This results in improved performance and smaller markup size.	Menu contents are computed on the server when the JSP tags are rendered.
Whether menus can be customized	Menu appearance can be customized for each source by specifying a HTML menu head.	Menu appearance cannot be customized.
Whether cross-page actions are possible	Sources and targets must be defined on the same page. Target URLs can lead to a different page in the portal when they are selected.	Cross-page actions can be selected from sources on all pages.
Whether multiple targets are allowed	Only a single target is available for one user action.	Source data can be distributed to multiple targets with a single click.
Whether portlet wiring is supported	No wiring support is available.	Users can automate actions by pressing **Ctrl** and clicking on a menu item.

Client-side aggregation reference

Refer to programming model guidelines for client-side mode or server-side mode.

"Programming model guidelines for server-side mode"
Learn which widgets you can use in server-side mode and how to adapt widgets for server-side mode.

Programming model guidelines for server-side mode

Learn which widgets you can use in server-side mode and how to adapt widgets for server-side mode.

Widgets you can use in server-side mode

In general, all widgets programmed against the iWidget specification can be rendered in server side mode. However, a key difference to client side rendering is that full page refreshes happen frequently and not only if a user action triggers them explicitly. For example, each time a user triggers a portlet action, this results in a full page refresh that fetches the updated page from the server. This also means that the document object model (DOM) is regenerated as a result of a standard user interaction. Therefore, to write a widget that works in server side mode, apply the guidelines listed in the following:

- State always needs to be stored using onNavState changed events and not by storing it in the dom. Otherwise it is gone after a page refresh.

Furthermore, some of the predefined events that the iWidget specification specifies behave slightly different when you use them in server side rendering mode:

- `onRefreshNeeded`: This event is not sent after a page refresh.

- `onSizeChanged`: This event is only sent if the skin used with it supports it.
- `onNewWire`:
  - This event can be sent by a client side user interface component for widgets on the same page.
  - This event is not sent if the wire model of the page was changed externally.
  - This event is not sent after a page refresh.
- `onRemoveWire`:
  - This event can be sent by a client side user interface component for widgets on the same page.
  - This event is not sent if the wire model of the page was changed externally.
  - This event is not sent after a page refresh.

Options of interactions between widgets and portlets

iWidgets cannot:

- Send events to JSR168 or JSR286 portlets.
- Receive events from JSR168 or JSR286 portlets.
- Share render parameters with JSR286 portlets.

iWidgets can:

- Send events to and receive events from other iWidgets.
- Share render parameters with other iWidgets on the same page by using shared item sets.

Portlet communication

IBM WebSphere Portal Express supports multiple ways for portlets to exchange or share information.

Select the topic about the programming technique that is most appropriate for your application requirements from the following links.

"Public render parameters" on page 3070
Public render parameters allow JSR 286 portlets to share navigational state information. They are specially useful for coordinating the multiple navigation or viewer portlets that display different information items that are all related to the same parameter name. The portal stores all portlet render parameters, including public render parameters, as an encoded part of the current portal URL. Therefore, public render parameters are correctly preserved by typical browser navigation actions such as the Back button and bookmarking.

"Advanced URL generation for data exchange" on page 3072
For data exchange, IBM WebSphere Portal Express supports cross-portlet links

"Standard portlets publish and subscribe mechanisms" on page 3074
Both JSR 168 and 286 portlets provide communication capabilities that enable you to pass information from one portlet to another. For JSR 286 portlets, these capabilities are included in the JSR 286 standard. For JSR 168 portlets, an extension defined by IBM provides these capabilities. Portlet developers define these capabilities. Portal administrators then determine whether or not these capabilities are used to pass information between portlets.

"Known issues and restrictions related to standard portlets publish and subscribe mechanisms" on page 3094
Review this information for a list of known issues and restrictions with portlet communication.

"Special purpose techniques for data exchange" on page 3095
IBM WebSphere Portal Express supports special purpose techniques for data exchange.

"URL generation in WebSphere Portal" on page 2835
Generating Portal URLs correctly is one of the most important tasks in programming a WebSphere Portal Express based application. There are several programming tools and techniques available for generating WebSphere Portal Express URLs in custom code. The following section introduces the programming tools available and discusses when it is most appropriate to use each of the tools.

"Struts Portlet Framework" on page 2943
Learn how to write Struts applications that can be deployed in WebSphere Portal Express. Know special considerations when developing such applications and additional concepts, such as portlet modes, multiple device support, and portlet communication, that might need to be addressed by the Struts application.

Public render parameters

Public render parameters allow JSR 286 portlets to share navigational state information. They are specially useful for coordinating the multiple navigation or viewer portlets that display different information items that are all related to the same parameter name. The portal stores all portlet render parameters, including public render parameters, as an encoded part of the current portal URL. Therefore, public render parameters are correctly preserved by typical browser navigation actions such as the Back button and bookmarking.

Notes:

- Public render parameters are generated between JSR portlets during the render phase and not the action phase. For more information, see *JSR 286 portlet events based communications* in the related links.
- You can set shared render parameters as well as private render parameters during URL generation by using the state API. For more information, see *Advanced URL generation for data exchange*.
- Public render parameters can also be shared with remote portlets by using the WSRP V 2.0 protocol.
- Information about render parameters is normally encoded into the URL. Therefore their names and values should be as short as possible in order to not exceed the URL length restrictions set by your browser.

"JSR 286 portlet events based communications" on page 3075
Portlet events provide a powerful and flexible publish/subscribe mechanism for communication between JSR 286 portlets. They can be used to exchange complex data between portlets and to trigger portlet activity such as updates to back end systems. In the portal, they can also interoperate with other communication mechanisms such as Cooperative portlets and click-to-action.

Concepts of the Java Portlet Specification 2.0: Programming details for public render parameters are defined in the Java Portlet Specification 2.0. They are read as request parameters and set in render URLs or on an ActionResponse. For most purposes, public render parameters behave exactly like "normal" or private render parameters. The only difference is that the parameter identifier is explicitly declared by the programmer in the `portlet.xml` deployment descriptor, along with one or more namespaced public names. As a result, a portal can decide which parameters of two portlets must map to the same information.

Here is an example declaration in the deployment descriptor:

```
<portlet-app xmlns:x="http://acme.com/portlet">
   <portlet>
      ...
      <supported-public-render-parameter>custID</supported-public-render-parameter>
   </portlet>
   <public-render-parameter>
      <identifier>custID</identifier>
      <qname>x:customerID</qname>
   </public-render-parameter>
</portlet-app>
```

This snippet declares a public render parameter that is accessed with the parameter key `custID`. Here is an example code snippet for reading the parameter:

```
String customerID = renderRequest.getParameter("custID");
```

The parameter is shared with the global name, which consists of the namespace and the localname, and the `customerID` in the namespace `http://acme.com/portlet`. Therefore, if another portlet declares a parameter with the same global name - regardless of the local identifier that it uses - that parameter can be mapped to the same data by the portal.

Portlets can declare globalized display names and descriptions for public render parameters in the application resource bundle. However, WebSphere Portal Express Version 8.5 does not have a user interface that requires this information for display.

How to control parameter sharing in the portal: The portal implements the sharing of parameters by placing them in scopes: Two or more public render parameters from different portlets are mapped to the same data in the portlet URL, if and only if both of the following conditions apply:

- The parameters declare the same global name that includes the namespace.
- The parameters are placed in the same scope.

The default scope for all public parameters is the global scope. Therefore, all public parameters with the same global name are shared by all portlets across all pages.

For some use cases, it can be required to limit parameter sharing. For example, this case can occur if you have two pairs of navigator or viewer portlets on two different pages, where each pair must be coordinated. However, the pairs must not interfere across pages so that the navigator on the first page does not influence the viewer on the second page. For such cases, the portal makes it possible to limit the

sharing scope for public render parameters on a page basis. The parameter sharing scope for a page is controlled by a page parameter `param.sharing.scope`. You can set it from the **Page Properties** view under **Advanced options** > **I want to set parameters**. If you set a value for this parameter, portlets on the page share their public render parameters only with other portlets on the same page or on pages with the same scope.

If you want to prevent all render parameters that are used on a page from being shared with other pages, you can set the parameter `param.sharing.scope` to the reserved value `ibm.portal.sharing.scope.page`. Specifying this value produces the same result as using the unique object ID of the page, as generated internally by the portal, for the value of the `param.sharing.scope` parameter.

How to set the scope for specific public render parameters: The setting `param.sharing.scope` mentioned earlier sets the scope for all public render parameters. In addition, it is also possible to set the scope for specific public render parameters. The WebSphere Portal Express template pages use this approach. For example, the Basic page template specifies the following parameters:

```
<parameter
   name="param.sharing.scope.{http://www.ibm.com/xmlns/prod/datatype/content/resource-collections}"
   type="string" update="set"><![CDATA[ibm.portal.sharing.scope.page]]></parameter>
<parameter
   name="param.sharing.scope.{http://www.ibm.com/xmlns/prod/datatype/content}"
   type="string" update="set"><![CDATA[ibm.portal.sharing.scope.page]]></parameter>
<parameter
   name="param.sharing.scope.{http://www.ibm.com/xmlns/prod/websphere/portal/v7.0/portal-contextual-portal}"
   type="string" update="set"><![CDATA[ibm.portal.sharing.scope.page]]></parameter>
<parameter
   name="param.sharing.scope.{http://www.ibm.com/xmlns/prod/websphere/portal/v8.0/portal-contextual-portal}"
   type="string" update="set"><![CDATA[ibm.portal.sharing.scope.page]]></parameter>
<parameter
   name="param.sharing.scope.{http://www.ibm.com/xmlns/prod/websphere/portal/publicparams}path-info"
   type="string" update="set"><![CDATA[ibm.portal.sharing.scope.page]]></parameter>
```

This snippet from a template sets the page scope for all public render parameters that are contained in the following name spaces:

`http://www.ibm.com/xmlns/prod/datatype/content/resource-collections`
`http://www.ibm.com/xmlns/prod/datatype/content`
`http://www.ibm.com/xmlns/prod/websphere/portal/v7.0/portal-contextualportal`
`http://www.ibm.com/xmlns/prod/websphere/portal/v8.0/portal-contextualportal`

It also sets the scope for the `path-info` parameter that is defined in the namespace

`http://www.ibm.com/xmlns/prod/websphere/portal/publicparams`

Limitations: The following are known limitations to public render parameters:

1. The sharing scope always applies to all parameters of all portlets on a page. You currently cannot control sharing of public render parameters at a more granular level than the page level.
2. The optional `<alias>` elements of public render parameter declarations are ignored. Currently, sharing of public render parameters is only controlled by the `<name>` or `<qname>` elements of the parameter declarations

Advanced URL generation for data exchange

For data exchange, IBM WebSphere Portal Express supports cross-portlet links

Cross-portlet links work for both IBM and JSR portlets. They use the state API to generate a URL that points to a render parameter of a specific portlet. With the advanced URL generation APIs for portlets, you can have a portlet create a link that points to another portlet, possibly even on a different page, and pass data to that portlet. If it is at all possible, use the publish/subscribe methods. Use explicit

cross-portlet links only where other techniques are not applicable. For example, this can be for communication between IBM and JSR portlets.

For details, refer to the documentation about the portalRenderURL tag and the PortalURLGenerationService. Such links can also be created from a theme JSP that uses the portal URL generation tag.

For advanced use cases that require more control over the generated URLs, you can also use the portal state API.

If the pure render parameter approach is not applicable, generating URLs and transporting the data to be communicated is suggested. There are three options available: JSP tag URL generation, PortalURLGenerationService, and state API-based URL generation.

JSP tag URL generation
This approach is only supported for JSR portlets and allows the user to generate URLS that transport information from within portlet JSPs. For more information, see *JSP tags for standard portlets* in the related links.

PortalURLGenerationService based URL generation
Use this service to generate render URLs to other portlets. For more information, see *Interface PortalURLGenerationService* in the related links. This option might be available only if specific portlets are targeted and if render URLs need to be created for the target portlets in question. For more information, see *Leveraging WebSphere Portal V6 programming model: Part 2. Advanced URL generation in themes and portlets* in the related links.

State API-based link generation
Generating state API-based URLs allows the transfer of data to portlets developed by using the JSR168 API or JSR286 API. State API-based link generation is the most powerful way of modifying the navigational state and thus share information between portlets. In addition to the portlet state aspects such as portlet mode and window state, state API-based link generation also enables you to set private or public render parameters for one or multiple portlets. For more information, see *Leveraging WebSphere Portal V6 programming model: Part 2. Advanced URL generation in themes and portlets*.

Notes:

- To set private render parameters for a given portlet, request the PortletAccessorController from the PortletAccessorFactory. For more information, see *Interface PortletAccessorController* in the related links.
- To modify shared state information such as public render parameters for JSR286 portlets, you can also request the SharedStateAccessorController from the PortletAccessorFactory. For more information, see *Interface SharedStateAccessorController* in the related links.
- So far, the URLs being generated modify navigational state information only and do not carry any action semantic, which is necessary to modify the persistent backend state. PortletTargetAccessorController is available from the PortletAccessorFactory and enables the targeting of a specific portlet's processAction method. PortletTargetAccessorController triggers a processAction on the specific target portlet that the generated URL points to.
- Standard portlets provide powerful publish and subscribe mechanisms for exchanging information through an action phase invoked between portlets.

During the invocation, portlets can exchange complex data and trigger portlet activity such as updates to back-end systems.

Interface PortalURLGenerationService

Leveraging WebSphere Portal V6 programming model: Part 2. Advanced URL generation in themes and portlets

Interface PortletAccessorController

Interface SharedStateAccessorController

Standard portlets publish and subscribe mechanisms

Both JSR 168 and 286 portlets provide communication capabilities that enable you to pass information from one portlet to another. For JSR 286 portlets, these capabilities are included in the JSR 286 standard. For JSR 168 portlets, an extension defined by IBM provides these capabilities. Portlet developers define these capabilities. Portal administrators then determine whether or not these capabilities are used to pass information between portlets.

"Define portlet communication capabilities"
Standard portlets provide powerful publish and subscribe mechanisms for exchanging information by using an action such as semantic invocation. These mechanisms can be used to exchange complex data between portlets and to trigger portlet activity such as updates to back-end systems.

"Triggering communication" on page 3090
These communication methods are based on directed communication links that pass information from a source portlet to a target portlet.

Define portlet communication capabilities:

Standard portlets provide powerful publish and subscribe mechanisms for exchanging information by using an action such as semantic invocation. These mechanisms can be used to exchange complex data between portlets and to trigger portlet activity such as updates to back-end systems.

"JSR 286 portlet events based communications"
Portlet events provide a powerful and flexible publish/subscribe mechanism for communication between JSR 286 portlets. They can be used to exchange complex data between portlets and to trigger portlet activity such as updates to back end systems. In the portal, they can also interoperate with other communication mechanisms such as Cooperative portlets and click-to-action.

"JSR 168 IBM extension for cooperative portlets" on page 3077
Cooperative portlets represent an IBM specific API for publish/subscribe communication between portlets.

"Interoperability between JSR 286 portlet events and JSR 168 cooperative portlets" on page 3087
By concept, cooperative portlets are similar to JSR 286 portlet events. Both concepts describe publish/subscribe communication patterns that are based on typed information that is published and received by portlets and propagated via communication links.

JSR 286 portlet events based communications:

Portlet events provide a powerful and flexible publish/subscribe mechanism for communication between JSR 286 portlets. They can be used to exchange complex data between portlets and to trigger portlet activity such as updates to back end systems. In the portal, they can also interoperate with other communication mechanisms such as Cooperative portlets and click-to-action.

For more information about the portal event distribution mechanism, read the section about the portal *Event broker*.

Concepts of the Java Portlet Specification 2.0

Programming details for portlet events are defined in the Java Portlet Specification 2.0. Portlets can publish events by using the `response.setEvent()` call and receive events in the `processEvent` method. The `GenericPortlet` class provides a default event handling mechanism that dispatches events based on the `@ProcessEvent` annotation.

As a portlet programmer, declare all events that a portlet can publish or receive in the `portlet.xml` deployment descriptor.

Example declaration in the deployment descriptor:

```
<portlet-app xmlns:x="http://acme.com/portlet"
             xmlns:std="http://somestandardsbody.org/interop-events">
    <portlet>
        ...
        <supported-processing-event>
            <qname>x:address.showForUpdate</qname>
        </supported-processing-event>
        <supported-publishing-event>
            <qname>x:address.updated</qname>
        </supported-publishing-event>
    </portlet>
    <event-definition>
        <qname>x:address.showForUpdate</qname>
        <alias>std:address</alias>
        <value-type>com.acme.portlets.common.Address</value-type>
    </event-definition>
    <event-definition>
        <qname>x:address.updated</qname>
```

```
        <alias>std:address</alias>
        <value-type>com.acme.portlets.common.Address</value-type>
    </event-definition>
</portlet-app>
```

This declares a publishing and a processing event with a Java payloads of class `com.acme.portlets.common.Address` and global names `address.showForUpdate` and `address.updated` in the namespace `http://acme.com/portlet`. In addition, the alias `address` in the namespace `http://somestandardsbody.org/interop-events` of some presumed standardization organization indicates that these events are compatible with any events of another portlet that has the same alias and can therefore work with input or output values of the provided address type. Here is a coding example:

```
public class MyPortlet extends GenericPortlet {
    public static String NAMESPACE = "http://acme.com/portlet";

    @ProcessAction(name="address.updated")
    public void addressUpdated(ActionRequest request, ActionResponse response) {
      ...
      Address myAddress = ...;
      response.setEvent(new QName(NAMESPACE, "address.updated"), myAddress);
    }
    @ProcessEvent(name="address.showForUpdate")
    public void addressUpdated(EventRequest request, EventResponse response) {
      Address myAddress = (Address) request.getEvent();
      ...
    }
```

Controlling event distribution in the portal

The Java Portlet Specification intentionally leaves open how events are passed between portlets, but only specifies how they are published and received. In IBM WebSphere Portal Express Version 8.5, event distribution is based on the same event broker and wiring techniques that are used to connect cooperative portlets. That means that when you place a portlet on a page, it will initially not be able to publish or receive any events. You must use the portlet wiring tool link to connect the events declared by the portlet to outputs or inputs of other portlets.

Portlets can declare localized display names and descriptions for portlet events in the application resource bundle. Provide at least a display name, as the portlet wiring tool needs this information to display event sources and targets properly.

The portlet `EventDistributionService` provides the option to have user interface elements displayed dependent on whether a given event is wired to targets or not. The wiring information provided by this portlet service is available for all requests in which the property `com.ibm.portal.portlet.Constants.FEATURE_EVENT_DISTRIBUTION_SERVICE` is set and available. For incoming WSRP requests this property is not available.

Support for complex event types

As noted previously, portlet events support complex Java types as payloads. The Java Portlet Specification requires that such payload classes support Java serialization as well as XML serialization by using Java XML Binding (JAXB) annotations. The portal supports transfer of such payloads between portlets, even if they are deployed in different WAR files. However, if the payload class is packaged as part of the portlet WAR file, it is necessary to serialize and deserialize values during the transport because both portlets use different class loaders, which will result in less than optimal run time performance.

To obtain optimal performance for transferring complex Java payloads, at the cost of a more complicated deployment process, remove the payload classes from the WAR file and deploy them in a class loader that is shared by both portlets. You can do this by using the IBM WebSphere Application Server shared libraries, or by placing the shared classes in the *wp_profile_root*/PortalServer/config directory.

Related concepts:

"Public render parameters" on page 3070
Public render parameters allow JSR 286 portlets to share navigational state information. They are specially useful for coordinating the multiple navigation or viewer portlets that display different information items that are all related to the same parameter name. The portal stores all portlet render parameters, including public render parameters, as an encoded part of the current portal URL. Therefore, public render parameters are correctly preserved by typical browser navigation actions such as the Back button and bookmarking.

JSR 168 IBM extension for cooperative portlets:

Cooperative portlets represent an IBM specific API for publish/subscribe communication between portlets.

You can use cooperative portlet support with either IBM or JSR 168 portlets, but you cannot use it for communication between portlets of different API types.

For development of new portlets, use the standards based JSR 286 portlet events instead. They provide equivalent and compatible functionality. For more information about moving from cooperative portlets to JSR 286 events, refer to the documentation about interoperability between events and cooperative portlets.

"Cooperative portlets overview"
Cooperative portlets communicate by using properties that are produced and consumed by portlet actions. Each action on a portlet can be associated with a single input property and zero or more output properties. An additional WSDL deployment descriptor defines which portlet actions are enabled for communication. It also provides information about how the property value is transferred to or from the action, for example as a request attribute or a JSR 168 render parameter.

"Cooperative portlet programming model" on page 3078
View information on how properties and actions are registered, how properties are generated and received, and some available APIs.

"Packaging, deploying and compiling cooperative portlets" on page 3079
When packaging, deploying, and compiling cooperative portlets, refer to these considerations on aspects of the process such as creating deployment descriptors and packaging the WAR file.

"WSDL reference for cooperative portlets" on page 3081
WSDL is often used in the context of web services, in order to define interfaces implemented by a web service. The elements in the WSDL used by click-to-action are described, along with extensions to the <binding> element and the WSDL Extensions schema.

Cooperative portlets overview:

Cooperative portlets communicate by using properties that are produced and consumed by portlet actions. Each action on a portlet can be associated with a single input property and zero or more output properties. An additional WSDL deployment descriptor defines which portlet actions are enabled for

communication. It also provides information about how the property value is transferred to or from the action, for example as a request attribute or a JSR 168 render parameter.

This means that cooperative portlets do not require extra APIs for communication, but can use the same interfaces that handle normal action processing. Action processing in a target portlet often does not actually need to distinguish between an action initiated by a portlet URL and an action initiated by the transfer of a property value from another portlet.

Note: Cooperative portlet WSDLs are not evaluated for JSR 286 portlets, and therefore JSR 286 portlets do not support this model of re-using portlet actions for portlet communication.

For more detailed information about the cooperative portlet programming model refer to the documentation about the cooperative portlet programming model. For more information about how to declare actions and properties in cooperative portlet WSDL descriptors.

Packaging considerations for cooperative portlets

When you write cooperative portlets, you need to observe some special guidelines for packaging and deployment descriptors. In the case of standard portlets, the function of the wrapper is provided through a portlet filter, and no extra run time code has to be included in the portlet WAR file.

Cooperative portlet programming model:

View information on how properties and actions are registered, how properties are generated and received, and some available APIs.

Registering properties and actions

The declarative method can be used with standard portlets and is the only registration implementation supported for standard portlets.

Declarative (WSDL). Target portlets associate their actions with an input property which has been declared as an XML type. The actions are declared using WSDL, with a custom binding extension which specifies the mapping from the abstract action declaration to the actual action implementation. WSDL is a language used to define collections of abstract operations, together with the input and output parameters (called `parts` in WSDL) for each operation.

Associated with each action is zero or one input parameters and zero or more output parameters. Each input or output parameter is associated with exactly one property. Each property is associated with an XML type. The input property's type is used for matching the action to output properties which are produced by portlets. The output parameters are produced as a result of executing the action, and can be wired to other actions subject to the type matching constraint mentioned previously.

Generating property values

Action bindings

The WSDL custom binding extension provides mapping information from the abstract operation declaration to the actual action implemented by the portlet. The custom binding extension defines how information is delivered

to the action implementation and received from the action implementation. Actions can generate output properties to transfer information, and the binding used in the implementation must match the parameter binding declared in the WSDL file.

Receiving property values

Action bindings

Action bindings may also be used to receive property values. The bindings used to provide the property values to the action implementation will match the input parameter bindings specified in the WSDL file.

Advanced programmatic APIs

For standard portlets, the property broker provides additional APIs to give developers more control over inter-portlet communication. The following functionality can be implemented using the programmatic APIs:

-
  - Activate or deactivate actions for a session. Only active actions can be triggered through wires or through Click-to-Action menus.
  - Determine if a property is wired, and if it is a cross-page wire. It can also determine if the wire is actually active (the target action is active). This knowledge may be used to render links for triggering wired actions.

Note: Both sources and targets must register their input and output properties and actions for wire creation to be possible.

The following package define the programmatic APIs provided by the property broker: com.ibm.portal.propertybroker.service.PropertyBrokerService (this is an interface).

Packaging, deploying and compiling cooperative portlets:

When packaging, deploying, and compiling cooperative portlets, refer to these considerations on aspects of the process such as creating deployment descriptors and packaging the WAR file.

Creating the deployment descriptors

A WAR must have a `web.xml` and a `portlet.xml` file in order to comply with J2EE specifications. For standard portlets, `web.xml` needs to contain only servlet information, not portlet information. If the standard portlet does not contain servlets, `web.xml` must still be present, though the content of the file will be empty.

The `portlet.xml` file must specify the location of the WSDL file associated with each portlet. To achieve this, you must modify `portlet.xml` to add a configuration parameter to each concrete portlet that exposes actions to the property broker through the WSDL file.

- Standard portlet examples

  Sample `web.xml` file for standard portlet with empty content:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE web-app PUBLIC "-//Sun Microsystems, Inc.//DTD Web Application 2.3//EN"
                         "http://java.sun.com/dtd/web-app_2_3.dtd">
<web-app>
    <display-name>Shipping Portlets - Standard Version</display-name>
</web-app>
```

Sample standard portlet.xml file

```
<?xml version="1.0"?>
<portlet-app
   xmlns="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd"
   version="1.0"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd
                       http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd">
    <portlet>
        <description xml:lang="en">
           Displays details for a particular order
        </description>
        <portlet-name>StandardOrderDetail</portlet-name>
        <display-name xml:lang="en">Standard Order Detail</display-name>
        <portlet-class>
           com.ibm.wps.portlets.shipping.OrderDetailPortlet
        </portlet-class>
        <expiration-cache>3600</expiration-cache>
        <supports>
            <mime-type>text/html</mime-type>
        </supports>
        <supported-locale>en</supported-locale>
        <resource-bundle>nls.StandardOrderDetail</resource-bundle>
        <portlet-preferences>
            <preference>
                <name>
                   com.ibm.portal.propertybroker.wsdllocation
                </name>
                <value>/wsdl/OrderDetail.wsdl</value>
            </preference>
            <preference>
                <name>com.ibm.portal.context.enable</name>
                <value>true</value>
            </preference>
        </portlet-preferences>
    </portlet>

 ...

</portlet-app>
```

Note: For standard portlets, you must use a special <preference> entry to specify the application portlet class.

```
<portlet-preferences>
   <preference>
      <name>com.ibm.portal.propertybroker.wsdllocation</name>
      <value>/wsdl/OrderDetail.wsdl</value>
   </preference>
</portlet-preferences>
```

WAR file considerations

Once the code and deployment changes have been made for using the property broker, additional libraries and files must be packaged along with the application. After you package the WAR file, it is ready to be installed. Use the following table to package the files in the correct location.

Table 460. Files to package and their correct location

Portlet type	Standard portlets
File name	WSDL file
Path	relative to the root of the WAR file or an absolute URL

Additional considerations for compiling

If you are using your own development environment, make sure to add the `wp.propertybroker.standard.api.jar` file to your class path for standard portlets. These JAR files can be found in the *PortalServer_root*`/base/wp.propertybroker.standard.api/shared/app` directory. For other JAR file requirements, read Creating a simple portlet.

WSDL reference for cooperative portlets:

WSDL is often used in the context of web services, in order to define interfaces implemented by a web service. The elements in the WSDL used by click-to-action are described, along with extensions to the `<binding>` element and the WSDL Extensions schema.

Usually, a SOAP binding is used to specify the concrete realization of the interface by a web service which supports the SOAP protocol. The following shows how Click-to-Action uses some of the elements in the WSDL document. The extensions to the <binding> element are described and the complete schema for WSDL Extensions is provided.

- **<types>**

  For cooperative portlets, this declares the data type of the data to be transferred. The data type is declared using XML Schema Datatypes (XSD, see the XSD specification). There may be multiple types defined in the document.

  The following shows a declaration for the TrackingIDType:

  ```
  <types>
    <xsd:simpleType name="TrackingIDType">
      <xsd:restriction base="xsd:string">
      </xsd:restriction>
    </xsd:simpleType>
  </types>
  ```

- **<message>**

  Input messages can contain only one part.

- **<operation>**

  Provides an abstract definition of a Click-to-Action operation. Note the restriction on input messages mentioned previously.

- **<portType>**

  Defines an abstract collection of operations. The operations must be defined in the document. One operation corresponds to each action on the Click-to-Action enabled portlet. Only actions that are to be enabled for Click-to-Action should be declared.

- **<binding>**

  The binding element is extended to associate portlet actions with operations. For each operation, the portlet action name must be provided. The portlet action name may be specified using the **name** attribute of the action tag in the binding section of the WSDL file. If it is omitted, the **name** attribute from the operation tag is used as the portlet action name.

  For each operation parameter, the action parameter name must be provided. The portlet parameter name may be specified using the **name** attribute of the parameter tag in the binding section of the WSDL file. If it is omitted, the **name** attribute of the part tag associated with the param tag is used as the portlet parameter name.

Further, the **boundTo** attribute may be used to specify where the parameter will be bound. Choices are request-parameter, request-attribute, session-attribute, or action-attribute.

The <binding> element includes cooperative portlet extensions, which are described in Extensions to the <binding> element.

If you are familiar with WSDL, you might notice that the service section (enclosed by the <service> element in WSDL) is not used in the C2A action declaration file. This is because the file is associated with a specific portlet implementing the operations defined in the file through external means (an entry in the portlet.xml file associated with the portlet).

Extensions to the <binding> element

The <binding> element has been extended to support cooperative portlets. Each extension element is prefixed with `portlet:`, which refers to the C2A namespace, `http://www.ibm.com/wps/c2a`. The `portlet:` prefix is used to identify the extension elements in this section, but a different name may be used for the prefix as long as it refers to the C2A namespace. See WSDL Extension Schema

- <portlet:binding>

  This must be the first child element of the WSDL <binding> element. Its presence identifies the section as a C2A binding extension for portlet action invocation. The element has the following attribute.

  – **style**

    Deprecated. Specifying `style="struts"` indicates that Struts actions are being declared. Instead, you should use `type=struts` on the <portlet:action> element for this purpose.

- <portlet:action>

  This must be the first child element of any WSDL <operation> element in the binding section. It contains the following attributes:

  – **name**

    the portlet action name. If this is omitted, the name of the associated operation element is used as the portlet action name.

  – **caption**

    a short string about the action suitable for displaying in the portlet user interface. For translated captions, indicate in dotted format the name of the key in the resource bundles from which the caption is to be obtained.

  – **type**

    Indicates one of the following values:

    - **default** indicates a DefaultPortletAction object is used. This object is deprecated but still supported for migration purposes.
    - **simple** indicates a simple portlet action String is used.
    - **struts** indicates a Struts action is used.
    - **standard** indicates a standard (JSR) portlet action is used.
    - **standard-struts** indicates a struts action is used with a standard (JSR) portlet.

  – **actionNameParameter**

    (Standard only) The name of the request parameter which will be used to supply the action name.

  – **description**

a text description of the action. For translated descriptions, indicate in dotted format the name of the key in the resource bundles from which the description is to be obtained.

– **activeOnStartup**

Indicate either "true" or "false". If false, the action must be programmatically activated in each session. If true (default), the action is active as soon as the portlet is initialized.

– **selectOnMultipleMatch**

In the case that multiple actions match based on the data type for the portlet, this attribute can be used to indicate which action to trigger. Multiple matching actions can occur when a user broadcasts an action on a source. If not specified, the default is false. In the case where no single action is set to true, the data is not delivered to the target.

In the following example from `TrackingC2A.wsdl`, There are two actions declared: trackingDetails and routingDetails. **selectOnMultipleMatch** is used to indicate that the trackingDetails should be used in the case of a multiple match.

```
<binding name="TrackingBinding" type="tns:Tracking_Service">
   <portlet:binding/>
   <operation name="trackingDetails">
      <portlet:action caption="Tracking Details"
               description="Get tracking details for specified tracking id"
               selectOnMultipleMatch="true"/>
      <input>
          <portlet:param name="trackingId" partname="trackingId"/>
      </input>
      <output>
          <portlet:param name="customerName" partname="custName"
                         boundTo="session"/>
      </output>
   </operation>
   <operation name="routingDetails">
      <portlet:action caption="Routing Details"
               description="Get routing details for specified tracking id"/>
      <input>
          <portlet:param name="trackingId" partname="trackingId"/>
      </input>
   </operation>
</binding>
```

- <constant:param>

  This is used to set the value returned by the `getConstantParameters` method of the action. Each constant parameter will be bound as a request parameter with the specified name and value when the action is invoked. More than one constant parameter can be specified.

  – **name**

  the name of the parameter.

  – **value**

  specifies the parameter value.

  The following shows an example for using the constant parameter.

  ```
  <portlet:constant-params>
       <portlet:constant-param name="defaultMonth" value="January"/>
    </portlet:constant-params>
  ```

- <portlet:param>

  This must appear as a child element in the <input> or <output> subelements of the <operation> element in the binding. It specifies the parameters consumed (if enclosed in the <input> element) or produced (if enclosed in the <output>

element) by the portlet action. At present, we restrict the number of parameters consumed to at most one. The number of parameters produced can be any number. It has the following attributes:

- **name**

  the name of the parameter. If omitted, the name attribute value of the part element is used as the parameter name.

- **partname**

  refers to a part element of the input or output for the operation. It may be omitted if the input or output has a single part.

- **boundTo**

  specifies where the parameter value is bound. Currently, this attribute can specify one of the following values only:

  - `request-parameter` : This specifies that the value is bound as a parameter in the PortletRequest object. This is the default value if the boundTo attribute is omitted. Note that for output parameters, a different value should usually be specified as the default PortletRequest implementation provided by WebSphere Portal Express does not allow parameters to be set during action processing.
  - `request-attribute` : This specifies that the value is bound as an attribute in the PortletRequest object.
  - `session` : This specifies that the value is bound to the PortletSession object.
  - `action` : This specifies that the value is bound to a portlet action.
  - `render-parameter:` (JSR only) This specifies that the value is bound as a render parameter in the ActionResponse (output parameters only).

- **presentIfNullValue**

  specifies is null values for the parameter are significant for the purposes of wired action invocation. Value can be either "true" or "false", with "false" being the default. If "true", the presence of the parameter will cause the wired action to be invoked even if the value of the parameter is null. If "false", the presence of the parameter will cause the wired action to be invoked only if the parameter value is not null. Can be specified for either input or output parameters (i.e, the treatment of null parameter values can be controlled at either the source or the target).

WSDL Extension Schema

The following is the schema for the extensibility elements introduced for the portlet action invocation using Click-to-Action. Lines have been broken to allow viewing on the printed page.

```
<?xml version="1.0" encoding="UTF-8" ?>
<xsd:schema xmlns="http://www.w3.org/2001/XMLSchema"
               xmlns:xsd="http://www.w3.org/2001/XMLSchema"
               targetNamespace="http://www.ibm.com/wps/c2a"
               xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
               xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
               xsi:schemaLocation="http://schemas.xmlsoap.org/wsdl/
                                   http://schemas.xmlsoap.org/wsdl/
                                   http://www.w3.org/2001/XMLSchema
                                   http://www.w3.org/2001/XMLSchema.xsd"
               xmlns:portlet="http://www.ibm.com/wps/c2a">
   <!-- The binding  element indicates that the binding section
        contains custom extensions describing a mapping of operations to
        portlet actions. This must be placed within a WSDL
        binding element. -->
<element name="binding" type="portlet:bindingType"/>
```

```
<complexType name="bindingType">
   <!-- DEPRECATED, retained for compatibility with version 4. Use the
   type attribute with the action element instead. Set value to be
   "struts" for a portlet implemented using the struts framework. -->
   <attribute name="style" type="string" use="optional"/>
</complexType>
<!-- The action element is used to provide all the information
  about the portlet action necessary for the property broker to
  invoke it. This must be placed within an wsdl:operation element
  in the wsdl:binding section. -->
<element name="action" type="portlet:actionType"/>
<complexType name="actionType">
    <sequence>
        <!-- The constant-params element is used to provide constant
             parameters associated with the action. These are bound
             as request parameters when the action is invoked -->
        <element name="constant-params" type="portlet:constantParamsType"
             minOccurs="0" maxOccurs="1"/>
        </sequence>
         <!-- The name of the action.
              Will be set as the portlet action name.
              If omitted, the name of the corresponding operation
              element will be used as the action name. -->
        <attribute name="name" type="string" use="optional"/>
        <!-- The type of the action. Currently recognized values
             are default, simple, struts, and standard,
             with default being the default.
             The values specify whether the legacy DefaultPortletAction,
             legacy simple portlet action, legacy portlet
             struts action, or standard (JSR-168) portlet
             action mechanism is used to invoke the portlet action.
             The use of DefaultPortletAction is
             deprecated, and the default is set to this
             value for backwards compatibility.-->
        <attribute name="type" type="string" use="optional"
           default="default"/>
        <!-- A short name for  the action which is displayed to the
          user.If a message resource file is
          provided for the portlet,
          the value is used as a key to retrieve a translated string -->
        <attribute name="caption" type="string" use="optional"/>
        <!-- A description for  the action which is
             displayed to the user.
             If a message resource file is provided for the portlet, the
             value is used as a key to retrieve a translated string -->
        <attribute name="description" type="string" use="optional"/>
        <!-- If more than one portlet action can simultaneously process
             a property value, only those with the
             invokeOnMultipleMatch attribute
             set to true will be invoked -->
        <attribute name="selectOnMultipleMatch" type="boolean"
           use="optional" default="false"/>
        <!-- If the activeOnStartup attribute is true,
             the action may be selected for invocation
             at any time unless  programmatically
             deactivated on a per-session basis.
             If the activeOnStartup is false, the action may not be
             selected for invocation, unless
             programmatically activated on a per-session basis -->
        <attribute name="activeOnStartup" type="boolean"
           use="optional" default="true"/>
        <!-- The actionNameParameter attribute is used to specify
             the name of a request parameter whose value will carry
             the action name. It is recommended that all actions of
             a portlet use the same value of this parameter. This is
             used to identify the specific action which is being executed
             on the portlet, as the processAction method in JSR 168
```

```
          does not explicitly pass any information identifying the
          action. If this attribute is omitted, the
          actionNameParameter value defaults to
          com.ibm.portal.propertybroker.action -->
     <attribute name="actionNameParameter" type="string"
        use="optional"
        default="com.ibm.portal.propertybroker.action"/>
</complexType>
<complexType name="constantParamsType">

     action invocation. If omitted, the partname is used.
     This name will also be set as the name of the
     corresponding property. -->
     <attribute name="name" type="string" use="optional"/>
     <!-- The name of the corresponding part. May be omitted only if
          there is a single parameter for the action,
          in which case it will be inferred from
          the associated operation definition -->
     <attribute name="partname" type="string" use="optional"/>
     <!-- Where to place the parameter prior to invoking the action
          (in case of in parameters), or where to look for it
          after invoking the action (in case of out parameters).
          request-attribute, request-parameter, session are
          allowed for both standard and legacy portlets. A value of
          action is allowed for legacy portlets only, and a value
          of render-parameter is allowed for standard portlets only
     -->
     <attribute name="boundTo" type="string"
      default="request-parameter"/>
     <!-- If the parameter is found but its value is null, this attribute
     determines if the parameter is deemed to be present for brokered
     communication purposes. If the value is set to true, the parameter
     is deemed to be present and the null value will be propagated. The
     default is false.
     -->
     <attribute name="presentIfNullValue" type="string"
      default="false" use="optional"/>
```

```
        <!-- The java class for the parameter.
             The default is java.lang.String.
             If a non-default value is provided, it will be
             used in conjunction with type and namespace to
             restrict matches
        -->
        <attribute name="class" type="string"
         default="java.lang.String"/>
        <!-- A short name for the parameter which is displayed
             to the user. If a message resource file is
             provided for the portlet,
             the value is used as a key to retrieve a
             translated string -->
        <attribute name="caption" type="string" use="optional"/>
        <!-- A description for  the parameter which is displayed to the
             user. If a message resource file is provided for the
             portlet, the value is used as a key to retrieve a
             translated string -->
        <attribute name="description" type="string" use="optional"/>
    </complexType>
</xsd:schema>
```

Interoperability between JSR 286 portlet events and JSR 168 cooperative portlets:

By concept, cooperative portlets are similar to JSR 286 portlet events. Both concepts describe publish/subscribe communication patterns that are based on typed information that is published and received by portlets and propagated via communication links.

Because the concepts are quite similar, the portal supports data exchange between JSR 168 cooperative portlets and JSR 286 portlets that support events. This means that you can extend an existing setup using JSR 168 cooperative portlets with new JSR 286 portlets and that you can smoothly migrate individual cooperative portlets to the new API without losing communication possibilities.

The following table lists the similarities:

Table 461. Similarities between events and cooperative portlets

Aspect of similarity	Cooperative portlets	JSR 286 events
Event declaration	in a WSDL deployment descriptor	as part of `portlet.xml`
Sending data	as a side effect of action processing, for example by setting a request attribute that is declared as an output property	by using the portlet API `setEvent()` call on an action or event response
Receiving data	as a portlet action with input properties, for example, request parameters	by using the portlet API `processEvent()` callback

Writing interoperable portlets

In both models, portlets declare their external inputs and outputs so that they can be matched for communication. The outputs and inputs are matched based on an XML qualified name, which is associated with an XML namespace to make it globally unique. For JSR 286 portlets, the matching information is denoted by the event name while for cooperative portlets, the matching is based on XML data

type declared or referenced in the WSDL. In addition, inputs and outputs carry data that has a specific Java language data type.

Consequently, it is possible to connect a cooperative portlet action to a JSR 286 processing event if these two conditions are met:

- The XML type name of the action's output property matches the name or an alias of the processing event.
- The Java type of the output property is the same as the Java type of the procesing event payload.

You can connect JSR 286 publishing event to a cooperative portlet action if these two conditions are met:

- The name or an alias of the publishing event matches the XML type name of the action's input property.
- The Java type of the publishing event payload is the same as the Java type of the input property.

These rules also have the following implications:

- A JSR 286 event without an associated Java type (no `<value-type>` declaration) cannot be connected with a cooperative portlet.
- Exchanged data types must be primitive types or they must be Java and JAXB serializable (because JSR 286 requires this) and deployed in a shared class loader (because cooperative portlets do not support cross-class loader marshalling).

Example for migrating deployment descriptors

The following cooperative portlet WSDL declares a portlet action **OrdersForMonth** that takes a month name as input and produces an order ID and a customer ID as outputs.

```
   <definitions name="OrderDetail_Service"
  xmlns="http://schemas.xmlsoap.org/wsdl/"
  targetNamespace="http://www.ibm.com/wps/c2a/examples/shipping"
  xmlns:shipping="http://www.ibm.com/wps/c2a/examples/shipping"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">
<types>
  <xsd:schema targetNamespace="http://www.ibm.com/wps/c2a/examples/shipping">
    <xsd:simpleType name="MonthType">
      <xsd:restriction base="xsd:string"/>

    </xsd:simpleType>
    <xsd:simpleType name="OrderIDType">

      <xsd:restriction base="xsd:string"/>

    </xsd:simpleType>
    <xsd:simpleType name="CustomerIDType">

      <xsd:restriction base="xsd:string"/>

    </xsd:simpleType>
  </xsd:schema>
</types>
<message name="OrderMonthRequest">
  <part name="order_month" type="shipping:MonthType"/>
</message>
<message name="OrderMonthResponse">
  <part name="order_Id" type="shipping:OrderIDType"/>
  <part name="customer_Id" type="shipping:CustomerIDType"/>
</message>
<portType name="OrderMonth_Service">
  <operation name="order_Month">
     <input message="shipping:OrderMonthRequest"/>
     <output message="shipping:OrderMonthResponse"/>
  </operation>
</portType>
```

```
<binding name="OrderMonthBinding" type="shipping:OrderMonth_Service">
  <portlet:binding/>
  <operation name="order_Month">
    <portlet:action name="OrdersForMonth" type="standard"/>
    <input>
      <portlet:param name="month" partname="order_month" class="java.lang.String"/>
    </input>
    <output>
      <portlet:param name="orderId" partname="order_Id"/>
      <portlet:param name="customerId" partname="customer_Id"/>
    </output>
  </operation>
</binding>
</definitions>
```

The containing portlet can be converted to a JSR 286 portlet that exposes the same external behavior. Each action that has an input property becomes a processing event that can be sent to the portlet. Each output property of an action becomes a publishing event that can be emitted by the portlet. The wiring behavior can be maintained by declaring an alias for each event that has the same name as the WSDL data type of the corresponding input or output parameter: For example, the `customerId.published` event declares an alias `shipping:CustomerIDType` so that it can be wired to any processing event or portlet action that takes a customer ID as input.

```
<portlet-app xmlns="http://java.sun.com/xml/ns/portlet/portlet-app_2_0.xsd"
xmlns:shipping="http://www.ibm.com/wps/c2a/examples/shipping"
version="1.0">
<portlet ...>
...
   <supported-processing-event>
      <qname>shipping:OrdersForMonth</qname>
   </supported-processing-event>
   <supported-publishing-event>
      <qname>shipping:orderId.published</qname>
   </supported-publishing-event>
   <supported-publishing-event>
      <qname>shipping:customerId.published</qname>
   </supported-publishing-event>
</portlet>
<event-definition>
  <qname>shipping:OrdersForMonth</qname>
  <alias>shipping:MonthType</name>
  <value-type>java.lang.String</value-type>
</event-definition>
<event-definition>
  <qname>shipping:orderId.published</qname>
  <alias>shipping:OrderIDType</name>
  <value-type>java.lang.String</value-type>
</event-definition>
<event-definition>
  <qname>shipping:customerId.published</qname>
  <alias>shipping:CustomerIDType</name>
  <value-type>java.lang.String</value-type>
</event-definition>
</portet-app>
```

Note:

- The fact that the cooperative portlet properties use `java.lang.String` as data type and that the corresponding events must be declared with `<value-type>java.lang.String` depends only on the `class="java.lang.String"` attribute of the <portlet:param>WSDL element. If no class attribute is present, `java.lang.String` is also used as default value. The XML type declarations in the WSDL are not used to determine the Java type of a property.
- The declaration of cooperative portlet actions does not allow multiple input parameters. Actions or events that require multiple inputs must instead be declared with a single compound input property or event payload that combines all required data.

Triggering communication:

These communication methods are based on directed communication links that pass information from a source portlet to a target portlet.

The portlet programmer defines which information a portlet can send or receive in order to participate in the communication. At run time data is passed by an event broker component across communication links that are created by portal administrators or portal users. When data is sent across a link, the target portlet is explicitly invoked to process the received information and can perform arbitrary updates as a side-effect. This is called the push model. Previously cached markup is discarded as a result of receiving an event.

Message-based communication allows more programmatic and administrative control than shared state, but also creates more overhead. If you need to coordinate many portlets and create many connections, consider using shared state instead.

"Communication with persistent wires"
You can use portlet wires for communication between portlets. Portlet wires are persistent data links.

"Communication with dynamic menus" on page 3092
You can use dynamic menus for communication between portlets.

"Runtime behavior" on page 3092
The portal event broker subsystem provides support for inter-portlet communication with active notifications using portlet events or the cooperative programming model.

Communication with persistent wires:

You can use portlet wires for communication between portlets. Portlet wires are persistent data links.

The following two communication techniques are based on persistent portlet wires. You have to configure the wires in a separate step before the portlets can communicate:

Portlet events

This supports JSR 286 portlets only. The Java Portlet Specification 2.0 defines a model for communication by publishing and subscribing based on portlet events. This model is supported in WebSphere Portal Express Version 8.5. Portlet events can have complex objects as payload, if they provide an XML binding. With portlet events, WebSphere Portal Express Version 8.5 also supports communication links between remote (WSRP V2.0) portlets.

Cooperative portlets

Only JSR 286 portlets support this communication technique. WebSphere Portal Express Version 8.5 still supports the IBM specific cooperative portlet programming API that was provided by previous releases and is known as the Property Broker. However, if you develop new portlets, use the portlet events based on the JSR 286 standard instead. It provides equivalent and compatible functionality. For more information about moving from cooperative portlets to JSR 286 events, refer to Interoperability between events and cooperative portlets.

Note that you can create communication links in both directions between JSR 286 portlets and JSR 168 portlets by using the cooperative portlet API. However, that API does not support communication links between IBM and JSR 168 portlets.

"Portlet wires"
Portlet Wires are used to direct the information flow between portlets that communicate using JSR 286 Portlet events or the WebSphere Portal Cooperative portlets API.

Portlet wires:

Portlet Wires are used to direct the information flow between portlets that communicate using JSR 286 Portlet events or the WebSphere Portal Cooperative portlets API.

A wire connects a JSR 286 publishing event or an output property of a cooperative portlet to a JSR 286 processing event or a cooperative portlet action of another portlet. When the source portlet fires an event or produces a property, and that source event or property has outgoing wires, the information is propagated to the target portlet(s). At the same time the corresponding handler code, `processAction` or `processEvent` is invoked. Conversely, if an event is produced that is not wired to any targets, the event is simply discarded.

Creating wires is a part of page administration and requires appropriate access permissions. It is separated from the portlet development or deployment process, so that the portlet developer does not need to know the actual structure of inter-portlet communication. Communicating portlets can be developed independent of each other, as long as they agree on the same data type and semantics for data exchange. Wires between portlets are usually created by using the portlet wiring tool. It is available as a tab in the Edit Page user interface.

Creating wires: You can create wires only between portlets of the same API type, either standard API or IBM API based; for communication between IBM and Standards-based portlets, you need to use other means, such as cross page links. However, you can create wires between JSR 168 portlets and JSR 286 portlets, This allows you a smooth upgrade from the proprietary collaborative portlet API to the new standard based portlet events.

To create a wire between two portlets, the output that the source portlet declares must match the input that the target portlet declares. This match can be on either of the following two levels:

1. The XML name that describes the semantic content of the data:
   a. For JSR 286 events this is represented by the event names declared in `portlet.xml`.
   b. For collaborative portlets, this is represented by the XML name of the property type declared in the collaborative portlet WSDL.
2. The actual Java class representation of the data.

By default, the wiring tool requires a match of the semantic XML name. To avoid the requirement for a coordinated global namespace, JSR 286 portlets can declare multiple alias names for an event. This allows a portlet to connect to multiple other portlets that use different naming conventions. If the semantic XML name in the portlet section of the `portlet.xml` ends with a period (.), it works as a wildcard character. You can use it to match other semantic XML names defined in the portlet application section of the `portlet.xml` that have the same prefix. This

matching scheme can be useful for handling a group of similar portlet events that have the same payload format in a uniform way.

In a case where you know that two portlets are using the same data format but have declared different XML names, for example, for common formats such as email addresses, you can switch to matching on payload type, which allows you to create wires between sources and targets regardless of the XML semantic name. This can also be useful for very generic target portlets that can accept any string as input.

In addition to the portlet wiring tool, you can also create wires by using the portal configuration interface (XmlAccess). Note that this interface does not perform any consistency checks on declared output or input data. Of course, the option to create a wire does not necessarily mean that the portlets will communicate as expected. For example, if the portlets make different assumptions about the format of the payload, this leads to run time exceptions when the wire is executed.

Remote portlet support: The portal also allows you to create wires between remote portlets that use the WSRP 2.0 protocol for event transfer. You can wire remote portlets that have been integrated into the portal and placed on portal pages, even if they were consumed from different Producers. You can also wire remote portlets to local standard based portlets.

Payload data for remote events is transported as XML content. Therefore local portlets that want to communicate with remote portlets must either declare event payloads with appropriate XML serialization definitions by using the Java XML Binding framework (JAXB) or process the raw XML strings. If the remote portlet Producer is also a WebSphere Portal Express Version 8.5 or another JSR 286 compliant portal and local and remote portlets are using the same JAXB definitions, the correct XML translations happens automatically.

Communication with dynamic menus:

You can use dynamic menus for communication between portlets.

The following two communication techniques are based on dynamically generated menus that allow portal users to select a target destination for displayed data at run time:

Live text based click-to-action
: This technique works for JSR 168 and JSR 286 portlets only. The portal supports client side creation of dynamic action menus based on live text. This means that source data items on a portal page can be tagged with semantic HTML to serve as menu anchors. You can provide tagged source data by any type of HTML fragment on a page. This includes portlets, themes, or external content inside a rendering portlet. You can also define targets by using semantic HTML. In addition to such targets explicitly coded in HTML, the portal makes portlet events or cooperative portlet actions for portlets on the page automatically available as targets.

Runtime behavior:

The portal event broker subsystem provides support for inter-portlet communication with active notifications using portlet events or the cooperative programming model.

The event broker is based on a loosely coupled publish/subscribe communication model: participating portlets declare the messages or data types that they can publish and consume, but do not need to know about the actual communication structure.

Depending on the programming model that you use, sources and targets are defined and implemented in a different way (refer to the documentation about interoperability between events and cooperative portlets), but on the level of concepts described here, they are treated the same way.

Note: The following explanations apply to standard based portlets.

How messages are distributed between portlets is determined by portlet wires that are defined as part of page editing. Portlet wires link a defined output of one portlet on a page to a defined input of another portlet on the same page or on a different page.

The wiring step is separate from portlet development and deployment. This allows independent development of source and target portlets, as long as both portlets use common data types and semantics for information exchange. Portlets can operate stand-alone, and, as partner portlets for the communication are added by editing pages, they can exchange information and react in a coordinated manner, and thereby improve the user experience. Conversely, as portlets are removed, the remaining portlets still work correctly.

Action/event and render phases: The processing cycle of a portal request is divided into an action/event phase which processes user input and a render phase which generates markup output. The activity of the event broker subsystem occurs during the action/event phase. Event processing is usually initiated by a portlet action that is encoded in the current request URL. For example, this can be a portlet action URL, or a URL generated by a click-to-action menu. For requests that do not require portlet activity, but just produce output, the action/event phase can be skipped entirely.

If the request specifies a portlet action, that action will be run and may itself publish output, either as a JSR 286 event or as a cooperative portlet property. If that output is wired to the input of one or more other portlets, a call to the processing methods of these portlets is put into the event queue. When the first portlet action is completed, the next event is taken from the queue and the target portlet is invoked. In the course of the event processing, the target portlet can trigger further communication calls that are then also queued. This process repeats until the queue is empty.

This allows the synchronization of multiple portlets within a single request-response cycle. For example, in a context of a customer order for some goods, all of the following can happen:

1. Transfer of the order ID to the Order Details portlet.
2. This first step also triggers the transfer of the tracking ID for the order to the Tracking Details portlet
3. The Tracking details portlet in turn triggers the transfer of the customer name that is associated with the order to the Customer Details portlet.
4. Consequently, all three portlets display information that pertains to the same customer order.

To avoid infinite loops, event distribution will also stop when a maximum limit of portlet calls is reached; this is considered an error situation and should be avoided.

Note: Event processing is completely sequential and never nested within one client request; each target event or action is fully processed before the next one is invoked. The portal guarantees that the order in which events are delivered to a single target preserves the order in which the events were published. However, for performance reasons, events for different targets may be re-ordered to minimize context switches.

Cross-page communication: Wires can link source output from a portlet on one page to target events of other portlets on different pages. All targets, whether on the same page or on different pages, are processed within the action/event phase of one request cycle. A redirect to the target page can be sent only after the entire action/event phase has been completed. For details about wiring and cross-page wires, refer to the documentation about portlet wires.

Note: This behavior implies that the target portlet that receives event or action calls from a cross-page wire can be on a different page than the current page. In other words the "current page" at execution time can be different from the page that contains the target portlet. Portlet code that relies on retrieving programmatic information about the current page context during the action/event phase should be prepared to handle this case.

Known issues and restrictions related to standard portlets publish and subscribe mechanisms

Review this information for a list of known issues and restrictions with portlet communication.

The following known issues and restrictions exist with portlet communication.

- The pop-up menu functionality requires browsers with JavaScript on the client.
- Complex Java types can only be transferred between portlets if they are deployed in a shared class loader. Use basic Java types, such as `java.lang.String` or `java.util.HashMap` for compound data. Custom classes must be installed in a IBM WebSphere Application Server shared library available to both portlets or must be directly installed into the directory *`wp_profile_root`*`/PortalServer/config`.

  Note: JSR 286 events with XML bindings allow you to transfer complex data types between portlets in different class loaders. However, to avoid the performance penalty incurred by XML serialization, follow the previous recommendations.
- When you import sample Struts WAR files including the file `pbstrutsExample.war` into Rational Application Developer Version 6, it reports broken links. You can ignore this warning message.
- Rational Application Developer lists WS-I warnings for wsdl:binding errors. WS-I compliance warning messages will be displayed in the Problems view for Click-to-Action enabled portlets. You can ignore them in the Click-to-Action WSDL resources. To prevent these warning messages from being displayed, follow these steps:
  1. Select **Window**, then **Preferences**, then **Workbench**, and then **Capabilities**.
  2. Expand **Web Service Developer** and ensure that **Web Services Development** is selected.
  3. Click **Apply**.
  4. Select **Window**, then **Preferences**, then **Web Services**, and then **WS-I Compliance**.
  5. Set the compliance levels to **Ignore** compliance.

6. Click **Apply**.

Important: To remove the compliance warnings from the Problems view open the project's pop-up menu in the Project Explorer and select Run Validation.

- If multiple cross-page wires marked with the `switch page` flag are triggered at the same time, all wire targets are invoked. However, the target page to which a user gets directed cannot be predicted unambiguously.
- Cross-page wires for standard portlets are executed before redirecting to the target page. Therefore cross-page target portlets must not assume that they are executed on the target page.
- Wires created on a root page do not apply to derived pages that you create by referencing the root page. While such pages do inherit the content of the original page, this inheritance does not apply to wires; you have to explicitly create the wires for the derived page.
- Cooperative Java Server Faces (JSF) portlets that you developed by using older versions of Rational Application Developer Version 6 can contain code that does not work with IBM WebSphere Portal Express Version 8.5. If this occurs, replace the file `jsf-portlet.jar` in the failing WAR file with the version in the latest fix pack level.
- Cooperative portlet action declarations with multiple input parameters configured in the WSDL file are not supported.

Special purpose techniques for data exchange

IBM WebSphere Portal Express supports special purpose techniques for data exchange.

Cookies

The Java Portlet Specification 2.0 adds support for portlets to read and set HTTP cookies. You can share cookies between portlets and other Web applications to track information about the current browser interaction without requiring a server side session and without consuming server resources.

Custom JavaScript data exchange

As portlets are Web components inside an HTML page, you can use any client side techniques to read, write or exchange data within the markup that your portlet provides. This includes sharing data via the page document object model (DOM) or use of client side JavaScript code or libraries.

http://www-128.ibm.com/developerworks/websphere/library/techarticles/0612_behl/0612_behl.html

http://www-128.ibm.com/developerworks/websphere/library/techarticles/0603_behl/0603_behl.html

Shared portlet sessions

The following communication methods are based on shared state between multiple portlets. This means that two or more portlets read and write to the same data.

There is no direction imposed for the data flow. Portlets are not explicitly called to receive data, but receive data updates implicitly when they read shared information that has been updated (pull model).

The portal supports the following methods for portlet communication based on shared state:

Portlet session sharing
This applies to JSR standard API portlets only. All standard portlets and servlets that are deployed within the same Web application have access to the same Web module HTTP session. Portlet session attributes are normally namespaced per portlet window to avoid accidential collisions, but it is possible to access attributes at the actual HTTP session level by using the `PortletSession.APPLICATION_SCOPE` constant. Portlets that rely on shared session attributes need to be developed and deployed together in a single WAR file.

Public render parameters
This applies to JSR 286 standard API portlets only. The Java Portlet Specification 2.0 for JSR 286 allows portlets to share navigational state information that is stored as render parameters. This method of data sharing is especially useful for coordinating the view state of multiple portlets that display different information items that are all related to the same parameter name, such as a **`customerID`**. In this case, the parameter should be represented as a shared render parameter. Shared render parameters are defined per portlet in the portlet application's `portlet.xml`. A similar common scenario is the coordination between a navigator and a viewer portlet. Public render parameters provide a simple programming model and allow bookmarking of the shared state and **Back** button support. Public render parameters can also be shared with remote portlets via the WSRP V 2.0 protocol. This is supported by IBM WebSphere Portal Express Version 8.5 and later versions.

Note: Information about render parameters is normally encoded into the URL. Therefore their names and values should be as short as possible in order to not exceed the URL length restrictions that many browsers have.

Dynamic user interfaces

Learn about dynamic user interfaces that include dynamic pages, dynamic portlets, dynamic UI configuration, dynamic UI properties, and shared dynamic UIs. Get an overview of how to develop a dynamic UI configuration.

Dynamic user interfaces, or *dynamic UIs*, are portlets or pages that are dynamically created based on the definition of an existing page or portlet definition. A dynamic UI can be launched only by a portlet using the Dynamic UI Manager API. Because of its dynamic nature, the interface is not persisted in the portal database and has a maximum lifetime of the user's session with the portal. The interface can also be closed prior to the end of the session either programmatically or by the user.

Dynamic UIs are suited for applications in which users might need to have several instances of a page or portlet open for multitasking. Consider the travel request scenario in business process integration as an example. If several marketing representatives need to travel to a conference, their manager would receive multiple travel requests. With static pages, the manager must complete one request before proceeding to the next one. Using dynamic UIs, the manager can open several requests simultaneously and navigate between these and other pages in the portal. Business process integration is an example of a *dynamic UI configuration*.

Dynamic pages and portlets contain many of the same properties as static pages and portlets. For example, the user can navigate between static and dynamic

pages, or change the window state of a dynamic portlet. However, dynamic UIs are not stored in the portal database, so they have less impact on server performance. Therefore, dynamic UIs cannot be administered. For example, you cannot view or update a dynamic page using **Manage Pages** or assign a unique name to a dynamic portlet or page.

A dynamic UI is independent of its point of origin. For example, if a portlet launches a dynamic page, the launched page is maintained even if the originating portlet or page is deleted. A dynamic UI is a copy of a page or portlet definition at the time the instance is created and is not affected by subsequent changes to the definition. By default, the dynamic UI acquires the title and description of its page or portlet definition. However, it is possible to programmatically overwrite the title and description when the dynamic UI is launched.

Dynamic pages

A dynamic page is an instance of an existing static page, called a *page definition*. The page definition serves as a template from which all dynamic instances are created. Users must have view rights to the page definition in order to open a dynamic instance of that page. The page definition can be created by the administrator using XMLAccess or **Manage Pages**. The dynamic page copies the layout and content (containers, portlets, and wires) and portlet preferences provided by the page definition. Changes to the page definition do not affect the layout or content of dynamic pages that have already been launched. The layout and content of the dynamic page instance cannot be customized.

When a portlet launches a dynamic page, the new page instance appears in the navigation under a node created just for containing dynamic pages. This node is called an *extension node*. An example of an extension node is the container for task pages for business process integration. A single portal can have multiple extension nodes, one for each dynamic UI configuration. However, extension nodes are intended to hold only dynamic pages. Static nodes added under the content topology of an extension node are not visible. Dynamic pages are not visible to anonymous users, even if anonymous users have view rights to the page definition.

When a dynamic page is closed which a user currently has selected, the user is automatically redirected to another open dynamic page in the same configuration. If no sibling page exists, the redirection is determined by one of the following.

1. The page indicated by the setDefaultRedirectPage() method of the DynamicUIManagementFactoryService interface.
2. If setDefaultRedirectPage() is not used, the user is redirected to the page indicated by the defaultRedirectPage property in the `DynamicUIManagerFactoryServiceImpl`. This property is prefixed by the unique name of the extension node for the dynamic UI configuration. For example, two dynamic UI configurations could set this property as follows.

   ```
   my.dynui.config.test1.defaultRedirectPage=page1.unique.name
   my.dynui.config.test2.defaultRedirectPage=page2.unique.name
   ```

3. If the defaultRedirectPage property is not set, the user is redirected to the extension node for the configuration.

In most cases the page definition should be hidden from users by placing it in a sub tree of the content hierarchy that is not accessible by the portal navigation. In the business process configuration, for example, task page definitions are created under a **Task Page Definitions** node that is accessible only to the administrator.

Dynamic portlets

Dynamic portlets include portlets on a dynamic page and portlets that are dynamically added to the page. Dynamic portlets can receive properties from the portlet that launches the dynamic UI. The task processing portlet, which is a component of business process integration, is an example of a dynamic portlet.

When a portlet is dynamically added to an existing dynamic page, it is added to special containers that have been designated as launch areas. Each dynamic portlet that is added to the page is placed in the column with the least number of portlets. If all of the content of a dynamic page is locked, any attempt to launch a dynamic portlet on that page throws an `AddUIElementException`.

Note:

- It is possible for a user to access edit mode for a dynamic portlet. However, the preferences are not preserved (cannot be persisted).
- For a user to launch a dynamic portlet, the user must have view rights to the portlet definition from which the dynamic portlet would be launched.
- Dynamic portlets cannot be moved on a dynamic page.

Dynamic UI configuration

A dynamic UI configuration includes the settings and software components of a portal that support different application frameworks for dynamic UI. For example, a portal site can take advantage of the configuration provided by business process integration as well as support another dynamic UI configuration for a different purpose. The launching portlet can invoke a specific dynamic UI configuration by the unique name assigned to its extension node. Dynamic pages are assigned to the extension node for the configuration for which it is created.

Dynamic UI properties

Upon launch, a portlet can pass properties to a dynamic UI using the property broker API. Properties can be set during or after launching the dynamic UI. The purpose of these properties is to convey any information to the target portlets needed to fulfill their task, for example, a calendar entry to be processed or a document to be opened.

Properties passed to a dynamic page are available to all portlets on the page. Properties passed to a dynamic portlet are available only for that portlet. However, the dynamic portlets must declare their intention to receive dynamic properties using a preference setting in their descriptor. For example, in a business process configuration, the My Tasks portlets sends the TaskID, ReturnPageID. and TaskUIHandle properties to the dynamic page. The task processing portlet sets the **`com.ibm.portal.pagecontext.enable`** preference to `true` so that it will receive these properties. For IBM portlets, this is set as a configuration parameter. Also, IBM portlets must modify the servlet class entry of the `web.xml` file, specifying the com.ibm.wps.pb.wrapper.PortletWrapper class.

If page properties are set multiple times before the context is delivered, only the latest parameter set is distributed to the portlets on the target page.

Shared dynamic UIs

A *shared dynamic UI* is a dynamic page or dynamic portlet in which only one shared instance can exist for a user at a given time. A portlet can explicitly launch a shared portlet or shared page using the addSharedPage() or addSharedPortlet() methods. When a shared dynamic UI instance already exists, it is reused. If not, a new instance is created and marked as either the shared portlet for a given page, or the shared page for a dynamic UI instance.

If a dynamic UI is launched as shared, subsequent launching of the UI using the non-shared methods (addPortlet() and addPage()) creates a new instance. To ensure the same shared instance is used, the launching portlet must consistently use the shared methods.

The scope of a shared portlet or shared page instance is restricted to a dynamic UI configuration. This means, for example, that a portlet can add a shared dynamic page in dynamic UI configuration A. When another portlet also tries to create a shared instance in dynamic UI configuration B, a new one is created.

"Overview: Developing a dynamic UI configuration"

Overview: Developing a dynamic UI configuration

Get an overview of the main tasks involved in creating a dynamic UI configuration.

About this task

The following describes a general overview of the main tasks involved in creating a dynamic UI configuration.

- Planning
- Creating the extension node for containing dynamic pages
- Developing the portlet definition for dynamic portlets
- Developing the page definition for dynamic pages
- Developing the dynamic UI launching portlet
- Providing controls for closing dynamic UIs.
- Testing the configuration
- Deploying the configuration

Note: Only standard portlets can launch dynamic UIs. IBM portlets, however, can be launched as dynamic portlets and receive properties. Standard portlets can also launch dynamic pages that contain a mixture of standard and IBM portlets.

Procedure

1. Planning. Determine the requirements of the dynamic UI configuration. The following are some of the questions that can help you in the planning process.
   - What is the layout of the page definition?
   - Should the page definitions be viewable by users? If not, where in the portal topology should they be placed?
   - Where should the extension node be placed in the portal topology?
   - What information needs to be passed to each dynamic UI? How will the portlets use that information?

- How will the UI be closed? Should you use tags to allow the user to close dynamic pages and dynamic portlets? If not, is it the responsibility of the calling portlet or a dynamic portlet to close the UI?

2. Creating the extension node for dynamic pages.
   a. Create the page to be used for containing dynamic UIs.
   b. Assign a unique name to the node. To do this, use the Unique names portlet.
   c. Open a command prompt.
   d. Change to the *wp_profile_root*/ConfigEngine directory.
   e. Run the following configuration task:
      - Linux: `./ConfigEngine.sh action-enable-page-as-extension-node-wp.dynamicui.config -DPageUniqueName=`*`pageUniqueName`* `[-DVirtualPortalContext=`*`virtualPortalContext`*`]`
      - IBM i: `ConfigEngine.sh action-enable-page-as-extension-node-wp.dynamicui.config -DPageUniqueName=`*`pageUniqueName`* `[-DVirtualPortalContext=`*`virtualPortalContext`*`]`
      - Windows: `ConfigEngine.sh action-enable-page-as-extension-node-wp.dynamicui.config -DPageUniqueName=`*`pageUniqueName`* `[-DVirtualPortalContext=`*`virtualPortalContext`*`]`

      where *pageUniqueName* is the unique name of the extension node and *virtualPortalContext* is the context of the virtual portal that the specified page is part of. The `-DVirtualPortalContext` flag is needed only in the case where a virtual portal is used. This command designates the page as an extension node. If you subsequently need to remove the extension node designation, run the command using the `action-disable-page-as-extension-node-wp.dynamicui.config` task.

3. Developing the portlet definition for dynamic portlets. Any existing portlet can be used as the definition for a dynamic portlet. For standard portlets, be sure to set the ID attribute for the `<portlet-app/>` element in `portlet.xml`. The launching portlet uses this value, plus the `<portlet-name/>`, to obtain the object ID of the portlet definition. For IBM portlets, the uid attribute of the `<portlet-app/>` element is used. Determine what properties need to be passed to the portlet.

   Portlet deployment descriptor considerations

   To receive portlet properties, the **`com.ibm.portal.context.enable`** preference parameter must be set in the `portlet.xml` with a value of `true`. By default, this value is set to false.

   - For standard portlets:

```
<portlet-preferences>

   ...
    <preference>
    <name>com.ibm.portal.context.enable</name>
    <value>true</value>
   </preference>
   ...
</portlet-preferences>
```

   - For IBM portlets

```
...
   <config-param>
      <param-name>com.ibm.portal.context.enable</param-name>
      <param-value>true</param-value>
   </config-param>
...
```

Additionally, you must also modify the file `web.xml` for IBM portlets to receive portlet properties. The servlet class entry should specify the com.ibm.wps.pb.wrapper.PortletWrapper class. See"Packaging, deploying and compiling cooperative portlets" on page 3079 for more information and an example.

Considerations for retrieving context

Standard portlets receive page properties on the processAction() method using the com.ibm.portal.context request attribute. The value of this attribute is a Map storing the context entries. Each property value is obtained by name. The name and value of each property value is determined by the requirements of your dynamic UI configuration. Use the following code sample to get a value for the property with the name **propertyName**:

```
public void processAction (ActionRequest request, ActionResponse response)
            throws PortletException, java.io.IOException
{

   // perform application specific action handling
   ...

   // perform page context processing

   String specialAction = request.getParameter("com.ibm.portal.action");

   if (specialAction != null &&
       specialAction.equals("com.ibm.portal.context.receive"))
   {
      //this indicates context was passed to the launched page
      java.util.Map contextMap = (java.util.Map)
                    request.getAttribute("com.ibm.portal.context");

      Object propertyValue =  (Object) contextMap.get(<propertyName>);

      portletSession.setAttribute(<propertyName>, propertyValue);

   }

}
```

IBM portlets must implement the PropertyListener interface that provides the setProperties() method, which provides the page properties as an array of PropertyValue objects.In this sample, a loop is used to scan the array for the task properties.

```
public void setProperties(PortletRequest request, PropertyValue contextArray[])
{

   Object propertyValue;

   for (int i = 0; i < contextArray.length; i++)
   {
      String propertyName = contextArray[i].getProperty().getName();

      if(propertyName.equals(<propertyName>))
      {
         propertyValue = (Object)contextArray[i].getValue();
      }

   }

   request.getSession().setAttribute(<propertyName>, propertyValue);

}
```

IBM portlet considerations

To receive portlet properties, the **com.ibm.portal.context.enable** configuration parameter is specified in the portlet.xml. This parameter plays the same functional role as the standard portlet preference. Additionally, you must also modify the `web.xml` file to receive portlet properties. The servlet class entry should specify the com.ibm.wps.pb.wrapper.PortletWrapper class. See the "Packaging, deploying and compiling cooperative portlets" on page 3079 section for more information.

4. Developing the page definition for dynamic pages.
   a. Create the layout and content of the page definition from which dynamic pages are launched. For development purposes, you can use Manage Pages as you work with the visual layout.
   b. Assign a unique name to the page using the Unique names portlet. The portlet uses this name to lookup the object ID of the page definition.
5. Developing the dynamic UI launching portlet
   a. Using JNDI lookup, obtain a reference to the required portlet services.

```
private DynamicUIManagementFactoryService dynamicUIManagerFactoryService;
private RedirectURLGeneratorFactoryService redirectService;
PropertyFactory propertyFactory;
...

// Obtain a reference to the Dynamic UI Management Factory service
PortletServiceHome dynamicUIManagerFactoryServiceHome = (PortletServiceHome)
   ctx.lookup("portletservice/com.ibm.portal.portlet.service.dynamicui.DynamicUIManagementFactoryService");
dynamicUIManagerFactoryService = (DynamicUIManagementFactoryService)
   dynamicUIManagerFactoryServiceHome.getPortletService(DynamicUIManagementFactoryService.class);

// Obtain a reference to the property factory
PortletServiceHome serviceHome = (PortletServiceHome)
   ctx.lookup("portletservice/com.ibm.portal.propertybroker.service.PropertyFactory");
   propertyFactory =
     (PropertyFactory)serviceHome.getPortletService(com.ibm.portal.propertybroker.service.PropertyFactory.class);

// If the dynamic UI should be displayed immediately upon launch,
// obtain a reference to the RedirectURLGeneratorFactory service
   PortletServiceHome redirectServiceHome = (PortletServiceHome)
      ctx.lookup("portletservice/com.ibm.portal.portlet.service.state.RedirectURLGeneratorFactoryService");
   redirectService = (RedirectURLGeneratorFactoryService)
   redirectServiceHome.getPortletService(RedirectURLGeneratorFactoryService.class);
```

   b. Obtain the object ID of the page definition or portlet definition. This can be done using either a unique name (for a page or portlet definition) or portlet name + portlet-app ID (portlet definition only).

Using a unique name:

```
Context ctx = new InitialContext();

...

Name uniqueName = new CompositeName("portal:uniquename");

uniqueName.add(yourUniqueName);
ObjectID oidForName = (ObjectID) ctx.lookup(uniqueName);
```

Using portlet name + porlet-app id:

```
Context ctx = new InitialContext();

...

Name portletName =
     new CompositeName("portal:config/portletdefinition");
portletName.add(appID);
portletName.add(portletName);

ObjectID portletDefOID = (ObjectID) ctx.lookup(portletName);
```

c. Obtain an instance of the DynamicUICtrl interface from the factory. The factory expects the Render/ Action Request/Response followed by the configuration name (String) as input parameters. The DynamicUICtrl that is returned is parameterized with the request/response. The DynamicUICtrl must be obtained once per request and should not be stored.

```
DynamicUICtrl DynamicUICtrl =
    dynamicUIManagerFactoryService.getDynamicUICtrl(request, response, extensionNode);
```

d. Create the properties that need to be passed to the dynamic UI.

```
PropertyController property1 = propertyFactory.createProperty(config);
property1.setName(propertyKey);
property1.setClassname("java.lang.String");
property1.setDirection(Direction.OUT);

PropertyValue value =
    propertyFactory.createPropertyValue(request, property1, propertyValue);
PropertyValue[] propertyValues = new PropertyValue[1];
propertyValues[0] = value;
```

e. Launch the dynamic UI using the addPage() or addPortlet methods and passing the object ID of the page/portlet definition. Example of launching a page:

```
DynamicUICtrl.addPage(pageDefinitionID,
                new LocalizedImpl(title,description), propertyValues);
```

f. Optional: Navigate the user to the newly launched page using a redirect.

```
RedirectURLGenerator redirector =
                    redirectService.getURLGenerator(request, response);
EngineURL redirectURL = redirector.createPortletURL(launchedPortlet);

response.sendRedirect(redirectURL.toString());
```

6. Providing controls for closing dynamic UIs. In many cases you can allow the user to explicitly close a dynamic UI from a theme or skin. These icons are enabled by using the `<portal:closePage/>` and `<portal:closePortlet/>` tags. See "Tags used by the portal JSPs" on page 2790 for more information.

   As an alternative, the launching portlet can close a dynamic UI using the removePage() or removePortlet() methods of the DynamicUICtrl interface, providing the object ID of the dynamic UI as input on the call. If removing a dynamic portlet, the calling portlet must be on the same page.

7. Testing the configuration. Each dynamic UI configuration has its own requirements, design, and implementation, and therefore, a different set of test cases. However, you should always verify the following general behaviors.
   - Pages and portlets are created and removed successfully.
   - Each time a dynamic UI is launched, a new instance of the page or portlet is created or, in the case of shared dynamic UIs, the user is returned to an existing instance.
   - Properties are passed and processed by the dynamic portlets as expected.
   - As portlets are added and removed from a dynamic page, the page maintains a balanced layout.
8. Deploying the configuration When the dynamic UI configuration is ready to be promoted to a production level server, create the XMLAccess scripts that contain the necessary page and portlet definitions. You can use the Manage Pages portlet to export the page configuration to XMLAccess, including any wires or unique names used by the configuration.

Collaborative Services API and the person tag

Collaborative Services are a set of methods and JavaServer Page tags that allow developers who are writing portlets for WebSphere Portal Express or other

application servers to add Lotus collaborative functionality to their portlets. The services can be used to develop new custom portlets, or to add collaborative functionality (for example, menus or person links indicating online status) to existing portlets.

The Collaborative Services include a JavaServer Page tag language descriptor (TLD) for a **person** tag.

When added to your custom portlet, the person tag causes people's names to appear as hyperlinks, and the **Click here for Person Card** option to display when the user moves the cursor over an active (underlined) person's name. Clicking this option displays the Person card. If WebSphere Portal Express cannot identify the person name, it displays the name as plain text and the **Click here for Person Card** option is not available.

By default, the Person card includes the action **Profile**. The **Send Mail** action displays if the user has an email address. If Sametime is installed and enabled to work with the portal, the person tag adds an icon that indicates the person's online status and additional actions:

- **Chat**
- **Add as Sametime Contact**

Note: The **person** tag provides only default actions, but you can add your own custom actions to the person menu in any portlet.

You can configure the amount of time that the Person card displays by modifying the **personTagTimeout** custom property.

You can also customize the Person card so that only the business card fields display by default, letting users choose whether to expand the information shown.

The tag library for Collaborative Services that includes the **person** tag is installed on the portal server in the following locations:

Windows
PortalServer_root\people\people.impl\persontag\taglib\shared\app\WEB-INF\tld

Linux *PortalServer_root*/people/people.impl/persontag/taglib/shared/app/WEB-INF/tld

IBM i *PortalServer_root*/people/people.impl/persontag/taglib/shared/app/WEB-INF/tld

Note: You do not need to copy or move the `.tld` file anywhere within your portal project; you need only refer to its location in your portal installation. You need a reference to it in the JSP file for every portlet that you deploy that uses the person tag.

"Integrating the Business card and online status in a custom portlet" on page 3105
If IBM WebSphere Portal Express is configured to work with IBM Sametime, you can integrate the business card and online awareness in a custom portlet. Person names then appear with a dynamic status indicator. Users of the portlet can move the cursor over the name of an active person and then click **Click for Business Card**.

Integrating the Business card and online status in a custom portlet

If IBM WebSphere Portal Express is configured to work with IBM Sametime, you can integrate the business card and online awareness in a custom portlet. Person names then appear with a dynamic status indicator. Users of the portlet can move the cursor over the name of an active person and then click **Click for Business Card**.

Before you begin

The Business card includes person details in a collapsible section. If a photo of the person is available in the repository, the Business card also displays the photo. The photo enlarges when you hover over it with the mouse. The Business card also includes options for viewing the profile of a person, chatting, and more.

The Business card is provided by using the person tag of the Collaborative Services API. There are two methods to integrate the Business card, using the Person tag of the collaborative API and using the live text microformat.

Procedure

Integrating the Business card and online status in a custom portlet

1. Add the following line to your page:
   ```
   <%@taglib uri="/WEB-INF/tld/people.tld"prefix="pa"%>
   ```
2. Include a statement in your page similar to the following line:
   ```
   <pa:person value="CN=John Smith,OU=SALES,O=ACME" valueType="LDAPDN" displayName="John Smith" isActive="true/false" />
   ```
   The *displayName* and *isActive* attributes are optional. The *isActive* attribute controls the formation of the Business card for a users name, depending on the activity of the user.
   - If a user is active and selectable, then the *isActive* attribute is true.
   - If a user is inactive and non-selectable, then the *isActive* attribute is false.

The supported types for *valueType* are:

- EMAIL

  ```
  <pa:person value="wpsadmin@acme.com" valueType="EMAIL" displayName="John Smith"  isActive="true
  ```

- LDAPDN

  ```
  <pa:person value="CN=John Smith,OU=SALES,O=ACME" valueType="LDAPDN" displayName="John Smith" is
  ```

- MEMBERDN

  ```
  <pa:person value="CN=John Smith,OU=SALES,O=ACME" valueType="MEMBERDN" displayName="John Smith"
  ```

- OBJID

  ```
  <pa:person value="Z9eAe1JRU6N5FDRRANP14GRR47Q5CC38ANPLCI3" valueType="OBJID" displayName="John
  ```

- CN

  ```
  <pa:person value="wpsadmin" valueType="CN" displayName="John Smith"&nbp; isActive="true/false"
  ```

- WMMID

  ```
  <pa:person value="wpsadmin" valueType="WMMID" displayName="John Smith"  isActive="true/false" /
  ```

Where OBJID corresponds to the *objectId* of the user.

Integrating the Business card using live text microformat.

3. Add the following lines to your page:
   a. Business card with online status:

      ```
      <span class='vcard X-sametime-resolve'>
      ```

   b. Business card without online status:

      ```
      <span class='vcard'>
      ```

4. Include this line to add a user display name.

   ```
   <a class='fn' href='javascript:SemTagMenu.a11y(event)' style='color:black; text-decoration:none;'
      onclick='return false;'>{displayName}</a>
   ```

5. Any of the class `'email'`, `'uid'` and `'objectId'` are sufficient as long as they resolve to a unique user.

   ```
   <span class='email' style='display:none;'>{email id}span class='email' style='display:none;'>{email id}</span>

   <span class='uid' style='display:none;'>{LDAPDN}span class='uid' style='display:none;'>{LDAPDN}</span>

   <span class='userObjectId' style='display:none;'>{objectId}span class='userObjectId' style='display:none;'>{objectId}
   </span></span>
   ```

Example

In the following example, `<%@taglib uri="/WEB-INF/tld/people.tld" prefix="pa" %>` interacts with Collaborative Services. The first % statement is a reference to the Collaborative Services tag library. The `pa:person value="wpsadmin@acme.com" valueType="EMAIL"` statement uses the Collaborative Services person tag to display the name of a person as a live link.

```
<%@taglib uri="/WEB-INF/tld/people.tld" prefix="pa" %>
<%@taglib uri="/WEB-INF/tld/portlet.tld" prefix="portletAPI" %>
<portletAPO:init/>
Hello example
<h1>Collaborative Services Hello JSP</h1>
<br />
<h2>Hello,<pa:person value="wpsadmin@acme.com" valueType="EMAIL" /> !</h2>
```

Customizing Person card actions through the theme

You can use the theme to add items to the Person card's **More actions** menu in any portlet that uses the AJAX person tag.

Before you begin

About this task

Procedure

1. Locate the theme file which contains the <body></body> tags of the page. This is most often Default.jsp, or theme.html. For more information on locating your theme's files, see Location of theme resources.
2. Open the file in a text editor.
3. To add a menu item, add XML code to the end of the file, just before </body></html> tags. The following sample code adds a menu item called **Test Action**.

```
<div class="com.ibm.portal.action" style="display:none;">
 <span class="action-id">test.action1</span>
 <span class="action-impl">/javascript/TestAction.js</span>
 <span class="action-context">person</span>
 <span class="action-label">Test Action</span>
 <span class="action-description">This is a test for extending Person menu</span>
 <span class="action-showif">TestAction.showif</span>
 <span class="action-url">javascript:TestAction.execute(@@@ARGS@@@)</span>
 <span class="action-order">0</span>
</div>
```

4. Save the changes to the file.
5. Create a JavaScript file that executes the action you want to occur when the associated menu item is selected. The following sample code generates an alert when the menu item **Test Action** is selected.

```
var TestAction = {
  showif: function(person) {
    return true;
  },
  execute: function(person) {
    alert("TestAction executed for: " + person.fn);
  }
}
```

   Paste the JavaScript file (TestAction.js) in a directory where it can be accessed by a URL. For example you could put the TestAction.js file in either a javascript directory in the root of your web server (/javascript/TestAction.js) or a directory in your theme WAR file */yourthemecontext*/javascript/TestAction.js.
6. If the file you modified in step 1 was not Default.jsp, update the file's timestamp by making a change, removing the change, and then saving the file.
7. To verify that the new action was added, open a portlet that supports people awareness (for example, the People Finder) and then view the Person card for a selected user. Verify that the option you added (for example **Test Action**) is available from the **More actions** menu and that it works as expected.

Setting display duration for the Person card

You can configure the Person card to display longer than the default number of milliseconds by modifying the personTagTimeout custom property in the WebSphere Integrated Solutions Console.

Before you begin

About this task

Procedure

1. Select the appropriate console, depending on your environment:
   - If running stand-alone, use the local WebSphere Integrated Solutions Console.
   - If running in a cluster, use the console of the Deployment Manager.
2. Start the WebSphere Integrated Solutions Console by entering the URL in the location field of a Web browser:

   `http://example.com:admin_port/ibm/console`

   where *example.com* is the name of your server and *admin_port* is the port assigned to the WebSphere Integrated Solutions Console.
3. In the navigation, click **Resources** > **Resource Environment** > **Resource Environment Providers**.
4. Locate and click the resource **WP PeopleService**.
5. Under Additional Properties, click **Custom Properties**.
6. Locate **personTagTimeout** and then set its value in milliseconds.
7. Click **Apply** and then save the settings.
8. Restart the portal server.

What to do next

Related concepts:

"People awareness" on page 959
People awareness makes people's names appear as hyperlinks that users can click to display information about the individual and gain access to actions for contacting and working with him or her. If the administrator has configured an IBM Sametime server to work with WebSphere Portal Express, users can see each other's online presence in their person links according to the status options they have set in their Sametime client (for example, whether the person is active, away, offline, or does not want to be disturbed). The person's online status appears only if Sametime is enabled.

Customizing the look of the Person card

You can change elements of the **Click for Person Card** option and the appearance of the Person card such as text color, font, background color, and so on, by modifying Cascading Style Sheet (CSS) definitions specified in the `styles_people.jspf` file located in the theme directory.

Before you begin

About this task

Procedure

1. Locate your theme's Cascading Style Sheet (CSS) files. The location can differ between themes, but the CSS files are often in a `/css` or `/styles` folder within your theme. For more information on locating your theme's files, see Location of theme resources.
2. Locate and open the CSS file that contains the Person Card styles. The file may differ by theme, but is often either `styles_people.jpsf`, `styles_ibm.jspf`, or `portalLegacy.css`. You can locate the specific file by searching file contents of

the CSS folder for one of the CSS style definitions listed in the following table (for example, `personMenu`), or by loading the portal theme in a Web browser and using Web development tools to inspect the CSS style definitions loaded in the page.

3. Find the following style definitions in the file and modify them as needed:

Modify this style definition	To do this
`.menu_drop_icon`	Change the look and feel of the **Click for Person Card** option.
`.hyperlink`	Change the appearance of the person name hyperlink.
`.photoCard img`	Change the style of the image that displays in the business card section of the Person card.
`.businessCard .cardname`	Change the style of the name that displays in the business card section.
`.businessCard li`	Change the style of other user details that display in the business card section.
`.personMenuActions`	Change the style of the actions such as **Profile** and **Send Mail** that display on the Person card.
`.personMenu`	Change the style of the container that holds the business card and action items as a single unit.

4. Touch the timestamp on the theme's `styles.jsp` so that it will be recompiled by the JSP compiler. You can touch the timestamp by editing the file, adding a blank line, and saving the file.
5. Clear the browser's cache and cookies.
6. Call the Person card and verify your changes.

What to do next

Making business card fields expand and collapse

You can configure the Person card to display the business card fields for a selected name. Users can click a small control to expand the rest of the profile or hide it from view. You enable or disable this control by modifying the **showExpandableSection** custom property in the WebSphere Integrated Solutions Console.

Procedure

1. Select the appropriate console, depending on your environment:
   - In a stand-alone environment, use the local WebSphere Integrated Solutions Console.
   - If running in a cluster, use the console of the Deployment Manager.
2. Start the WebSphere Integrated Solutions Console by entering the URL in the location field of a web browser:

   `http://`*`example.com`*`:`*`admin_port`*`/ibm/console`

   Where *example.com* is the name of your server and *admin_port* is the port assigned to the WebSphere Integrated Solutions Console.
3. In the navigation, click **Resources** > **Resource Environment** > **Resource Environment Providers**.

4. Locate and click the resource **WP PeopleService**.
5. Under Additional Properties, click **Custom Properties**.
6. Locate the custom property **showExpandableSection** and set the value as needed:

   `true` enables the control, allowing users to click either **Show More** to expand the business card, or **Show Less** to collapse the business card.

   `false` hides the control.
7. Click **Apply** and then save the settings.
8. Restart the portal server.

Logging for Collaborative Services

The Lotus Collaborative Services APIs use the WebSphere JRas facility for logging error information to the WebSphere Integrated Solutions Console or to log files.

Before you begin

For Diagnostic Trace, specify the following value to log information that is related to the Collaborative Services:

```
com.lotus.cs.cslog=all=:com.lotus.ap.portlets.
*=all=:com.ibm.wkplc.people.portal.taglib.
*=finest
```

The trace file can be found in the following location:

- IBM i: *wp_profile_root*`/logs/WebSphere_Portal/trace.log`
- Linux: *wp_profile_root*`/logs/WebSphere_Portal/trace.log`
- Windows: *wp_profile_root*`\logs\WebSphere_Portal\trace.log`

IBM Portlet API

The IBM Portlet API is no longer supported starting with WebSphere Portal Express Version 8.5.0. You must convert portlets based on the IBM Portlet API to the Standard Portlet API. Learn how to convert IBM Portlets to Standard API portlets.

"Converting IBM portlets (IBM i Linux Windows)"
You can convert your basic IBM portlets and IBM portlets that use the Struts Portlet Framework to the standard portlet API.

Related reference:

"Standard portlet API" on page 2934
The Java Portlet Specification addresses the requirements of aggregation, personalization, presentation, and security for portlets running in a portal environment.

Converting IBM portlets (IBM i Linux Windows)

You can convert your basic IBM portlets and IBM portlets that use the Struts Portlet Framework to the standard portlet API.

- "Converting basic IBM portlets to the standard"
- "Converting IBM portlets that use the Struts Portlet Framework" on page 3117

Converting basic IBM portlets to the standard

This topic describes some of the more common changes (but not all) that are required to convert an IBM portlet to a standard portlet. Many conversion tasks

depend on the amount of complexity in the portlet code. You must become familiar with the Java Portlet Specification to determine any remaining changes that are not covered in this topic.

- Changing Java source
- Changing JSP source
- Changing the portlet deployment descriptor

Changing Java source

1. Change import statements to use the standard packages.

   Change this:

   ```
   import org.apache.jetspeed.portlet.*;
   import org.apache.jetspeed.service.*;
   ```

   to this:

   ```
   import javax.portlet.*;
   import com.ibm.portal.portlet.service.*;
   ```

2. Change class inheritance to use GenericPortlet. Notice that the ActionListener is not implemented.

   Change this:

   ```
   public class SamplePortlet extends PortletAdapter implements ActionListener{
   ...
   }
   ```

   to this:

   ```
   public class SamplePortlet extends GenericPortlet{
   ...
   }
   ```

3. Change objects that are used for all render methods. In the standard portlet API, the PortletRequest and PortletResponse define common functions for the RenderRequest and RenderResponse subclasses. These subclasses are the arguments for all implementations of the render() method, including doView(), doEdit(), and doHelp().

   Change this:

   ```
   public void doView(PortletRequest request, PortletResponse response) {
      ...
   }
   ```

   to this:

   ```
   public void doView(RenderRequest request, RenderResponse response)
        throws PortletException, IOException{
        ...
   }
   ```

4. Change the actionPerformed() method. In the standard portlet API, this method is replaced by the processAction() method, which does not require the portlet to implement a listener. The processAction() methods accepts the ActionRequest and ActionResponse as arguments, which extend the PortletRequest and PortletResponse.

   Change this:

   ```
   public void actionPerformed(ActionEvent event) throws PortletException{
   ...
   }
   ```

   to this:

   ```
   public void processAction(ActionRequest request, ActionResponse response)
        throws PortletException, IOException{
        ...
   }
   ```

5. Change how the response content type is set. In the standard portlet API, the MIME type of the output that is returned in the response must be set before including the JSP. IBM portlets declare the MIME type

using the contentType attribute of JSP's page directive. Therefore, this change makes the contentType setting in the JSP unnecessary.

Add the following code before including the JSP:

```
response.setContentType("text/html");
```

6. Change JSP includes. In the standard portlet API, JSPs are included by a request dispatcher's include() method. In the portlets' render method, set the MIME type of the output before returning it in the response.

   Change this:

   ```
   PortletContext context = getPortletConfig().getContext();
   context.include("/jsp/View.jsp", request, response);
   ```

   to this:

   ```
   response.setContentType("text/html");
   PortletContext context = getPortletConfig().getPortletContext();
   context.getRequestDispatcher("/jsp/View.jsp").include( request, response);
   ```

7. Change classes where user data is stored. In the standard portlet API, user data is stored in a PortletPreferences object, rather than the PortletData object that is available using the IBM portlet API. Notice the different getter methods that are used with the request object and setter methods that are used for the data object.

   Change this:

   ```
   PortletData portData = request.getData();
   portData.setAttribute("userName", userName);
   portData.store();
   ```

   to this:

   ```
   PortletPreferences prefs = request.getPreferences();
   prefs.setValue("userName",request.getParameter("username"));
   prefs.store();
   ```

   Some preferences are read-only and can be modified only by an administrator. See Change configuration parameters to preferences for more information.

8. Change the method that is used for namespace encoding. For example, if the portlet uses encodeNamespace() to return a unique string to be prefixed to a JavaScript variable name within the content that is generated by the portlet, the portlet can use getNamespace().

   Change this:

   ```
   PortletResponse.encodeNamespace()
   ```

   to this:

   ```
   RenderResponse.getNamespace()
   ```

9. Change how portlet URLs are generated. For example, a portlet's doEdit() method might save the URI to the edit mode to pass to the JSP. The portlet must instantiate a PortletURL object using the createRenderURL() method.

   Change this:

   ```
   // Save URI for the edit page
   PortletURI editURI = response.createURI();
   ...
   // Preserve the edit page URI in the request to make
   // it accessible by the edit JSP
   request.setAttribute("editURI", editURI.toString());
   ```

   to this:

   ```
   // Save URI for the edit page
   PortletURL editURL = response.createRenderURL();
   ...
   ```

```
// Preserve the edit page URI in the request
// to make it accessible by the edit JSP
request.setAttribute("editURL", editURL.toString());
```

The standard portlet API does not have an equivalent method for createReturnURI(). If the URL is intended to call the portlets' action method, however, the portlet should use the createActionURL() method.

Changing JSP source

1. Change the tag library to use the standard tag library.

   Change this:

   ```
   <%@ taglib uri="/WEB-INF/tld/portlet.tld" prefix="portletAPI" %>
   ```

   to this:

   ```
   <%@ taglib uri="http://java.sun.com/portlet" prefix="portlet" %>
   ```

2. Change references to API objects. In the standard portlet API, the <portlet:defineObjects /> JSP tag makes the RenderRequest, RenderResponse, and PortletConfig objects available to JSP files. After making this change, all references in the JSP to the PortletRequest and PortletResponse should be changed to the corresponding RenderRequest and RenderResponse.

   Change this:

   ```
   <portletAPI:init />
   ...
   <%
   PortletData prefs = portletRequest.getData();
   %>
   ```

   to this:

   ```
   <portlet:defineObjects />
   ...
   <%
   PortletPreferences prefs = renderRequest.getPreferences();
   %>
   ```

3. Change JSP tags that are used for namespace encoding. For example, if the portlet uses <portletAPI:encodeNamespace/> to uniquely qualify the name of a text input field, this tag must be changed as follows.

   Change this:

   ```
   <input name="<portletAPI:encodeNamespace value='name'/>"  type="text" >
   ```

   to this:

   ```
   <input name="<portlet:namespace/>name"  type="text" >
   ```

4. Change how portlet URLs are generated. If the portlet JSP creates a URL to itself, it should specify which method gets control using the <portlet:actionURL/> or <portlet:renderURL/> tags. Any parameters passed on the URL are specified using the <portlet:param/> tag.

   Change this:

   ```
   <a href="<portletAPI:createURI>
               <portlet:URIParameter name='action' value='search'/>
            </portlet:createURI>" >
   ```

   to this:

   ```
   <a href="<portlet:actionURL>
               <portlet:param name='action' value='search'/>
            </portlet:actionURL>" >
   ```

5. Change resource bundles. The <portletAPI:text/> tag of the IBM Portlet API has been deprecated and should be replaced in all portlets by the JSTL equivalent. See Using JSTL in portlet JSPs for more information.

Change this:

```
<portletAPI:text key="my.label" bundle="nls.myproperties"/>
```

to this:

```
<fmt:setBundle basename="nls.myproperties"/>
...
<fmt:message key="my.label"/>
```

6. Change how resources are invoked from the JSP. For example, if the JSP displays an image, it should use the encodeURL() method of the appropriate response object and, in addition, add the context path of the portlet from the request.

   Change this:

   ```
   <img src='<%= portletResponse.encodeURL("images/photo01.jpg") %>'
     alt="photo">
   ```

   to this:

   ```
   <img src='<%= renderResponse.encodeURL(renderRequest.getContextPath() +
               "/images/photo01.jpg") %>' alt="photo">
   ```

Changing the portlet deployment descriptor

The following steps describe some of the differences between the portlet deployment descriptors of the IBM Portlet API and the Java Portlet Specification. However, the order of the elements in the standard portlet descriptor is important and strictly enforced during deployment. You should use a tool, such as Rational Application Developer, that performs validation as you develop the portlet deployment descriptor.

1. Remove the DOCTYPE declaration. The portlet descriptor for the standard portlets uses an XML schema, which will be added in the next step.

   Remove this:

   ```
   <!DOCTYPE portlet-app-def PUBLIC "-//IBM//DTD Portlet Application 1.1//EN"
               "portlet_1.1.dtd ">
   ```

2. Remove the <portlet-app-def/> element. The first-level element in the standard portlet descriptor is <portlet-app/>.

   Remove this:

   ```
   <portlet-app-def>
   ....
   </portlet-app-def>
   ```

3. Update the <portlet-app/> element.
   - Add the schema definition and namespace declarations.
   - Remove the major-version and minor-version attributes.
   - Set the version attribute to the required version of the Java Portlet Specification. Currently, version 1.0 is the only supported specification version.
   - Change the uid attribute to id.

   Change this:

   ```
   <portlet-app uid="com.mycompany.samples.MyPortletApp.001c"
                major-version="1" minor-version="0">
   ```

   to this:

   ```
   <portlet-app
        xmlns="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd"
        version="1.0"
        id="com.mycompany.samples.MyPortletApp.001c"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   ```

```
 xsi:schemaLocation=
    "http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd
     http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd">
```

4. Remove all <concrete-portlet-app/> elements and their contents. Save any required information, such as configuration parameters and language definitions, for use in the portlet definition.
5. Update the <portlet/> element. Remove the href, minor-version, and major-version attributes.

   Change this:

   ```
   <portlet id="com.mycompany.samples.MyPortlet.110x"
           href="WEB-INF/web.xml#com.mycompany.samples.MyPortlet.href110x"
           major-version="1" minor-version="0">
   ```

   to this:

   ```
   <portlet id="com.mycompany.samples.MyPortlet.110x">
   ```

6. Move the definition of the portlet class from the `web.xml` to the `portlet.xml`.

   Remove this from the `web.xml`:

   ```
   <servlet id="com.mycompany.samples.MyPortlet.001c">
       <servlet-name>MyPortlet</servlet-name>
       <servlet-class>com.mycompany.samples.MyPortlet</servlet-class>
   </servlet>
   <servlet-mapping
            id="ServletMapping_com.mycompany.samples.MyPortlet.001c">
       <servlet-name>MyPortlet</servlet-name>
       <url-pattern>/MyPortlet/*</url-pattern>
   </servlet-mapping>
   ```

   Add this to the portlet.xml:

   ```
       <portlet-class>com.mycompany.samples.MyPortlet</portlet-class>
   ```

7. Change how caching is defined. Use the <expires/> value from the IBM portlet descriptor as the value for the <expiration-cache/> element in the standard descriptor. There is no equivalent in the standard descriptor to the <shared/> element. See Caching portlet output for more information.

   Change this:

   ```
   <cache>
      <expires>-1</expires>
      <shared>no</shared>
   </cache>
   ```

   to this:

   ```
   <expiration-cache>-1</expiration-cache>
   ```

8. Change the content of the <supports/> element.
   - Change supported markups to MIME types.
   - Use the <portlet-mode/> element.

   The standard portlet descriptor allows you to declare only MIME types. In some cases, two markup types use the same MIME type. For example, both HTML and cHTML use 'text/html' as the MIME type. For standard portlets, WebSphere Portal Express accepts the value of a `wps.markup` initialization parameter as the markup type.

   Change this:

   ```
   <supports>
      <markup name="html">
         <view />
         <edit />
      </markup>
   </supports>
   ```

to this:

```
<init-param>
   <name>wps.markup</name>
   <value>html,chtml</value>
</init-param>
...
<supports>
   <mime-type>text/html</mime-type>
   <portlet-mode>VIEW</portlet-mode>
   <portlet-mode>EDIT</portlet-mode>
</supports>
```

Be sure to place the initialization parameters before the <expiration-cache> element.

9. Remove window state elements. Normal, maximized, and minimized window states are supported by default and not declared in the standard portlet deployment descriptor.

   Remove this:

   ```
   <allows>
      <maximized/>
      <minimized/>
   </allows>
   ```

10. Change configuration parameters to preferences. In the standard portlet descriptor, preferences can be changed by users in any of the standard modes, or they can be declared as read-only and modified only by an administrator.

    Change this:

    ```
    <config-param>
        <param-name>Location</param-name>
        <param-value>Antartica</param-value>
    </config-param>
    ```

    to this:

    ```
    <portlet-preferences>
          <preference>
              <name>Location</name>
              <value>Antartica</value>
              <read-only>true</read-only>
          </preference>
    </portlet-preferences>
    ```

11. Change localized settings.

    a. Remove the <default-locale/> element. In the standard portlet descriptor, the first locale listed in the descriptor is the default. If no locale is specified, then English is used as the default.

    b. Create resource bundles for each supported language containing the title, short title, and keywords for the portlet. Use the following parameter names:

       ```
       javax.portlet.title = My Portlet Title
       javax.portlet.short-title = Title
       javax.portlet.keywords = portlets, JSR 168, portal
       ```

    c. Declare the resource bundle in the portlet descriptor as in the following example.

       ```
       <resource-bundle>nls.MyPortlet</resource-bundle>
       ```

       In this example, the default resource bundle `MyPortlet.properties` is in the `/WEB-INF/nls` subdirectory of the WAR file and all of the locale-specific resource bundles append the locale to the file name (for example, `MyPortlet_ja.properties` for Japanese).

    d. Declare each supported locale as in the following example:

```
<supported-locale>en</supported-locale>
<supported-locale>de</supported-locale>
```

e. Set the localized values for the portlet description and display name as in the following example.

```
<description xml:lang="EN">
   English description
</description>
<display-name xml:lang="EN">
   English display name
</display>-name>
<description xml:lang="DE">
   German description
</description>
<display-name xml:lang="DE">
   German display name
</display>-name>
```

Note: The display name should be set for compatibility reasons. However, it is not currently used by WebSphere Portal Express.

Converting IBM portlets that use the Struts Portlet Framework

The existing versions of the Struts Portlet Framework supported the IBM Portal container API, or the legacy container. This release uses a newer version of the Struts Portlet Framework that supports the standard portlet container. This release will continue to ship a version to support the legacy container and a new version for the Standard container. The Struts Portlet Framework is still shipped as example war files that can be used to build the Struts application. The war files for each container can be distinguished by the name. The SPFLegacy examples support the legacy container, and the SPFStandard examples support the standard container. The SPFLegacyBlank.war is the starting point for Struts applications for the Legacy container, and the SPFStandardBlank is the starting point for the Struts applications for the Standard container.

The Struts Portlet Framework for the Legacy Container

The SPFLegacyBlank.war includes the files to be included with the Struts application. The directories of interest are the `WEB-INF/lib` and the `WEB-INF/tld` directory. Here is the list of libraries to be used in the application from the `WEB-INF/lib` directory:

1. PortalStruts.jar
2. PortalStrutsCommon.jar
3. PortalStrutsTags.jar
4. StrutsUpdateForPortal.jar
5. wp.struts-commons-logging.jar
6. commons-beanutils.jar
7. commons-collections.jar
8. commons-fileupload.jar
9. commons-lang.jar
10. commons-validator.jar
11. struts-legacy.jar
12. struts.jar

The files from the `TLD` directory are

1. struts-bean.tld
2. struts-chtml.tld

3. struts-html.tld
4. struts-logic.tld
5. struts-nested.tld
6. struts-portal-html.tld
7. struts-portal-wml.tld
8. struts-template.tld
9. struts-tiles.tld
10. struts-wml.tld

Files common to both the standard and IBM portlet containers

The following files are the Jakarta Struts 1.1 binary files, and the same in both the Standard and Legacy versions of the Struts Portlet Framework:

1. commons-beanutils.jar
2. commons-collections.jar
3. commons-fileupload.jar
4. commons-lang.jar
5. commons-validator.jar
6. struts-legacy.jar
7. struts.jar

The following files from the TLD directory are same on for both containers. This can change in future releases, so it is strongly encouraged to use the files from the blank for the required container.

1. struts-bean.tld
2. struts-chtml.tld
3. struts-html.tld
4. struts-logic.tld
5. struts-nested.tld
6. struts-portal-html.tld
7. struts-portal-wml.tld
8. struts-template.tld
9. struts-tiles.tld
10. struts-wml.tld

Conversion to the Standard Version of the Struts Portlet Framework from previous versions of the Struts Portlet Framework

Converting the legacy version of the Struts Portlet Framework to the Standard versions starts with updating the jars, and TLDs cataloged with the SPFStandardBlank.war file.

Here is a list of the files that should be updated in the `WEB-INF/lib` directory of the application:

1. wp.struts.standard.framework.jar
2. PortalStrutsCommon.jar
3. PortalStrutsTags.jar
4. StrutsUpdateForPortal.jar
5. wp.struts-commons-logging.jar
6. commons-beanutils.jar
7. commons-collections.jar

8. commons-fileupload.jar
9. commons-lang.jar
10. commons-validator.jar
11. struts-legacy.jar
12. struts.jar
13. commons-digester.jar
14. commons-logging.jar
15. jakarta-oro.jar

Here is a list of the TLD files that should be updated with the TLDs from the SPFStandardBlank.war file:

1. struts-bean.tld
2. struts-chtml.tld
3. struts-html.tld
4. struts-logic.tld
5. struts-nested.tld
6. struts-portal-html.tld
7. struts-portal-wml.tld
8. struts-template.tld
9. struts-tiles.tld
10. struts-wml.tld

The following JAR file is only required on the IBM container and must be deleted:

1. PortalStruts.jar

Web Deployment Descriptor

The Standard container requires a web deployment descriptor because the application is packaged as a war file. However, most of the initialization parameters are now configured through the portlet deployment descriptor.

1. Remove the servlet class from the web deployment descriptor. The servlet-class is no longer that way to specify the portlet class for the application in the Standard container. The portlet is now specified as the portlet class in the portlet deployment descriptor.
2. Move the init parameters from the web deployment descriptor to the portlet deployment descriptor. Since the portlet class is now defined in the portlet deployment descriptor, the init parameters are also specified in the portlet deployment descriptor. Note, the init-parameter are specified as name and value in the portlet deployment descriptor, not param-name and param-value as they are named in the web deployment descriptor.
3. The taglib elements still remain in the web deployment descriptor, no changes required.
4. The welcome file elements still remain in the web deployment descriptor, no changes required.

Portlet Deployment Descriptor

The definition for the Portlet Deployment Descriptor for the Standard container is different from the legacy container. There are some changes that are required for the converted example to deploy in the Standard

container. The information center contains details for the semantics of the portlet deployment descriptor for the Standard container.

1. The Standard container introduces the portlet-class element for specifying the class of the portlet. The portlet class for the Struts Portlet Framework is `com.ibm.portal.struts.portlet.StrutsPortlet`.
2. The init parameters for the portlet are defined in the portlet deployment descriptor. The init parameters should be converted from the web deployment descriptor.
3. The Standard container does not have the abstract and concrete separation in the portlet deployment descriptor. The portlet element defines the supported modes, and portlet preferences.
4. The Struts Portlet Framework no longer uses a portlet filter. The FilterChain init parameter should not be converted.

Struts Configuration File

The Struts Portlet Framework defines the Request Processor that must be configured in the Struts configuration file. The controller attribute processClass must be converted to the following value to be deployed on the Standard container: `<controller processorClass="com.ibm.portal.struts.portlet.WpRequestProcessor">` If the Struts application is using the Struts Request processor that supports Tiles, then the Struts plug-in must be converted as well: `<plug-in`

```
className="com.ibm.portal.struts.plugins.WpTilesPlugin">
```

Struts Action

The Struts action class is passed a HttpServletRequest object, so the application may not have a dependency on the Portal container. However, many applications use the PortletApiUtils to obtain the portlet request and interface directly with the portlet API. If so, then the application must replace the org.apache.jetspeed interfaces with the equivalent javax.portlet interfaces. The new interfaces are documented in the information center.

Note: The following example illustrates the change in which the PortletApiUtils object is obtained:

- Old: `PortletApiUtils portletUtils =`

  ```
  PortletApiUtils.getInstance();
  ```
- New: `PortletApiUtils portletUtils =`

  ```
  PortletApiUtils.getUtilsInstance();
  ```

StrutsPortlet

The `com.ibm.wps.portlets.struts.WpsStrutsPortlet` class for the legacy container extended the PortletAdapter class. The Struts application using the Struts Portlet Framework may have been customized by extending the WpsStrutsPortlet class. If so, those changes should be applied for the Standard container. The `com.ibm.portal.struts.portlet.StrutsPortlet` class for the Standard container extends the standard container's GenericPortlet.

Request processor

The `com.ibm.wps.portlets.struts.WpsRequestProcessor` class for the legacy container may have been extended to customize the processing. The

Request Processor class for the standard container is `com.ibm.portal.struts.portlet.WpRequestProcessor`. If the legacy interfaces were used for the customizations, these changes should be converted to the Standard interfaces.

"Converting portlet instances and settings from the IBM API to the standard API"
The portal provides a portlet conversion task that allows you to convert the settings and instances of IBM API portlets to the corresponding standard API portlets. This is useful when you intend to replace IBM API portlets by standard API portlets.

Related reference:

"Standard portlet API" on page 2934
The Java Portlet Specification addresses the requirements of aggregation, personalization, presentation, and security for portlets running in a portal environment.

Converting portlet instances and settings from the IBM API to the standard API:

The portal provides a portlet conversion task that allows you to convert the settings and instances of IBM API portlets to the corresponding standard API portlets. This is useful when you intend to replace IBM API portlets by standard API portlets.

About this task

You can use this task as follows: The portlet conversion task converts portlet settings of the IBM API portlet to portlet preferences of the standard API portlet. It also converts instances of the IBM API portlet to instances of the standard API portlet. User customized portlet data that is associated with the portlet instance is converted into standard API portlet preferences.

To convert the instances and settings of an IBM API portlet to a standard API portlet, proceed by the following steps:

Procedure

1. Install the standard API portlet by which you want to replace the IBM API portlet.
2. Create a portlet conversion properties file that identifies both the IBM API portlet and the standard API portlet. To do this, create or update the following file:

   AppServer_root`/ConfigEngine/properties/portletconversion.properties`

   Confirm that the following parameters are set as specified or modify them if necessary:

   For the IBM API portlet:

   ibmwebapp.uid
   The uid of the Web application that contains the IBM API portlet. This property is required.

   Parameters for identifying the IBM API portlet:
   To identify the IBM API portlet, specify one of the following three parameters: the portlet name, the object ID, or the unique name of the IBM API portlet:

ibmportlet.portletname
The portlet name of the IBM API portlet.

ibmportlet.uniquename
The unique name of the IBM API portlet.

ibmportlet.objectid
The object ID of the IBM API portlet.

For the standard portlet:

jsrwebapp.uid
The uid of the web application that contains the standard API portlet. This property is required.

Parameters for identifying the standard API portlet:
To identify the standard API portlet, specify one of the following three parameters: the portlet name, the object ID, or the unique name of the standard API portlet:

jsrportlet.portletname
The portlet name of the standard API portlet.

jsrportlet.uniquename
The unique name of the standard API portlet.

jsrportlet.objectid
The object ID of the standard API portlet.

Additional parameters:

pages.uniquename
This parameter is optional. Specify a comma separated list of unique names of pages. If you specify this parameter, only portlets on these pages and their descendants are converted. If you leave this parameter empty or missing, instances of IBM API portlets on all pages are converted.

converter
The name of a converter class that is invoked by the `porltetconversion` task and that performs the conversion of portlet settings and portlet data. The converter class must implement the interface `com.ibm.portal.portletconversion.Converter`. You can specify the default converter `com.ibm.wps.pe.task.DefaultConverter` here. This converter performs basic conversion by filtering out portlet data items whose type is not `String`.

converter.classpath
Semicolon separated list of files and folders that are added to the classpath in order to load the converter class.

xmlaccess.url
The URL to the portal XML configuration interface servlet. You can use this parameter to run conversions for specific virtual portals. If this parameter is empty or missing, the default portal is used to run the conversion.

3. Change to the directory *AppServer_root*`/PortalServer/ConfigEngine/`.
4. Run the portlet conversion task `ConfigEngine convert-portlets` .
5. Verify the conversion by reviewing the console. The message `Build successful` indicates a successful conversion. If the message `Build failed` is displayed upon completion of the task, review the previous steps.

6. After successful conversion you can uninstall the IBM API portlet.

Example

Examples of `portletconversion.properties` files:

```
ibmportlet.objectid=3_O4C9FI930GPE90IGU02QAR0006
jsrportlet.objectid=3_O4C9FI930GPE90IGU02QAR00G3
ibmwebapp.uid=DCE:472fb1b0-3d22-1211-0000-005da8cf7ayz:2
jsrwebapp.uid=StdPortletDataTestPortlet.war.webmod
converter=com.ibm.wps.pe.task.DefaultConverter
```

```
ibmportlet.portletname=An PortletData test portlet
jsrportlet.portletname=StdPortletDataTestPortlet
ibmwebapp.uid=DCE:472fb1b0-3d22-1211-0000-005da8cf7ayz:2
jsrwebapp.uid=StdPortletDataTestPortlet.war.webmod
converter=com.ibm.wps.pe.task.DefaultConverter
```

WebSphere Portal Express provides an application extension registry which is equivalent to the application extension registry provided by IBM WebSphere Application Server. This registry allows any J2EE compliant application to define extension points for other applications to use, or to plug in to other extensible applications.

Markup guidelines

View the guidelines for using HTML, WML, and cHTML markup in your portlet JSPs to provide a consistent, clean, and complete user interface.

The portal server page is displayed with *skins* and *themes* that are defined by the portal designer or administrator. For portlets to integrate with an organization's portal or user's customized portal, they must generate markup that starts the generic style classes for portlets. They must not use tags or attributes to specify colors, fonts, or other visual elements.

Portlets are allowed to render only markup fragments, which are then assembled by the portlet framework for a page. Portlet output must contain complete, well-structured, and valid markup fragments. This output helps to prevent the portlet's HTML code, for example, from corrupting the portal's aggregated HTML code. Use a validation tool for your markup, such as the W3C HTML Validation Service or a tool from a markup editor.

These guidelines are based on the JSP coding guidelines for standard portlets. For more information, read the corresponding guide for the type of portlet you are developing on the WebSphere Portal Zone.

HTML

- Use standard HTML. For the official HTML specification, see W3C.
- Use only HTML fragments. Because portlets contribute to the content of a larger page, they must provide HTML fragments and must not have `<html>`, `<head>`, or `<body>` tags.
- Use only elements that can be rendered properly in an HTML table cell (`<td>...</td>`). Frames, for example, do not open when inserted in a table.
- Make sure that the fragments are well-formed to prevent unbalanced pages. Watch out for unterminated, extraneous, or improperly nested tags. The behavior of pages with improperly stopped tags is unpredictable.
- Avoid lengthy, complex HTML. Portlets share a page with others and the more content each portlet generates, the more the browser must process before it can open anything.
- Use portlet classes in the portal server's stylesheet, `Styles.css`. If you hardcode the fonts and colors, the portlet's appearance looks out of place when the user changes the page style settings. Portal administrators and users can affect the appearance of the portal by changing the portal theme and the portlet skins. Portlets can pick up on style changes by using styles that are defined in the portal theme's cascading stylesheet, `Styles.css`. For example, instead of decorating an `<input>` element with the **`style`** attribute, refer to the theme's input class definition: `<inputclass="portlet-form-button" type="submit">`

  Portlet style classes are marked with the following comment:

  ```
  /* Styles used in portlets
  ```

  When available, use the WSRP style classes, which have a `portlet-` prefix. See *CSS Style Definitions* in the WSRP 1.0 specification.

  The relevant document says, *"One of the goals of an aggregated page is a common look-and-feel across the Portlets contained on that page. This not only affects the decorations around the Portlets, but also their 25 content. Using a common CSS stylesheet for all Portlets, and defining a set of standard styles, provides this common look-and-feel without requiring the Portlets to generate Consumer-specific markup. Portlets SHOULD use the CSS style definitions from this specification in order to participate in a uniform display of their content by various Consumers. For markup types that support CSS stylesheets, Consumers MUST supply a CSS stylesheet to the End-User's agent 30 with definitions for the classes defined in section 10.6 of this specification. This section defines styles for various logical units in the markup."*

- Do not use CSS for absolute positioning. It can defeat the portal features that allow users and administrators to place content on the page.
- Limit the size of the portlet output. Portlets contribute a portion of a larger page. The size of the JSPs (in terms of horizontal and vertical span) can determine how easily the portlet can fit on a page with multiple columns and other portlets. A large portlet forces other portlets off the screen and creates large scrolling regions, resulting in usability issues. When you design a portlet's JSPs, avoid unnecessary layout elements. Focus the portlet's view on the pertinent information and consider whether the portlet is intended to be placed on pages with other portlets. In particular, take notice of image size, pre-formatted text (<pre/> tag), and absolute widths on elements, such as tables.
- Use Java style comments instead of HTML style. HTML comments remain in the rendered content, adding to the document size and the amount of data that passes to the client. If you use Java style comments within your JSPs, instead, they are removed from the rendered source, along with the rest of the Java code. You must embed these comments within scriptlets:

  ```
  <% // this is a comment %>
  ```
- Make pages fully accessible. To allow portal users with disabilities to be able to use your portlet, the JSPs must be fully enabled for keyboard-only control and other assistive technologies. Follow these general guidelines:
  - Use the **alt** attribute with images to define descriptive text of the image content.
  - Use <label> tags to associate labels with form input controls so that page readers are able to associate prompts with inputs.
  - Do not use color alone to denote state or information. For example, red text to emphasize information does not help people who are color blind. Use bold or italics instead, or use color with graphic changes.
  - Do not use voice or other sounds to convey information.

  For more information, see IBM Accessibility Center.
- URIs, HTML element name attributes, and JavaScript resources must be namespace encoded. Use <portlet:namespace/> (standard portlet API) for named elements to prevent name conflicts with other portlets on the portal page.
- Test the portlet output in different browsers. Check portlet behavior when you resize the page to ensure that your portlet works with different browser sizes. Check portlet behavior when the default browser font is changed; your portlet should handle these situations seamlessly.
- Do not draw portlet banners, such as title bars, since they are provided by the portal aggregation.
- Minimize dependencies on JavaScript. Because JavaScript implementations and behavior differ widely among browser types and versions, the more your portlet depends on JavaScript, the more browser-dependent your portlet becomes. Additionally, the more of the page that is rendered using JavaScript, the more difficult it is to maintain and to extend to markups other than HTML. Also, it is more difficult to namespace encode JavaScript resources and nearly impossible to properly encode (response.encodeUrl()) URLs built with JavaScript.
- Do not use pop-up windows. Interactions within the portal are state-based, which means that the portal tracks your trail through the pages and portlets. Using the browser's back button or creating pop-up windows in browser instances that contain portlets can cause the portal to lose track of your current state and cause problems. Other than using JavaScript prompts, there is no safe way to create pop-up windows within the portal, unless the new link takes you to an external page, outside the portal. The alternative is to link to an external

page within a new browser window (with the TARGET attribute on the anchor). The user remains within the portal in the original browser window.

- Use IFRAMEs with caution. IFRAMEs are an easy way to include external content within a portlet, but undermine the whole portlet principle because the portlet API is tunneled or side-stepped. Therefore, IFRAMEs can be used for special cases, such as surfacing existing applications. Consider the following potential issues when you use an IFRAME:
  - The IFRAME fills its content based on a URL. The URL must be addressable by the browser, therefore the server that is the target of the URL must be accessible by the browser.
  - Not all browser levels support IFRAMEs.
  - If the content is larger than the IFRAME region, then enable horizontal and vertical scrolling to allow the user scroll through the embedded content. Content that contains scrolling regions itself can make it difficult for the user to manipulate all scrolling regions to view all embedded content, causing usability problems.
- Use JSTL instead of inventing common tags. The Java Standard Tag Library (JSTL) defines many commonly needed tags for conditions, iterations, URLs, globalization, and formatting. For more information, go to Using JSTL in portlet JSPs.

WML

- Use standard WML. For information, refer to Open Mobile Alliance.
- When you design your portlet, assume that it can be opened alone or with other portlets.
- Watch out for unterminated and extraneous tags; the behavior of pages with improperly ended tags is undefined.
- Use only elements that can be included into a card (probably together with other portlets and elements) and do not create separate cards.
- Do not set the card title.
- Do not use templates.
- Avoid lengthy, complex WML since the buffer length can be restricted by the user agent, and portlets can share a page with others.
- Avoid having too many images. When you use images, define a meaningful **`alt`** name, since it is necessary for the devices that do not support images, or if the image cannot be fetched. If possible, define **`localsrc`**.
- Do not use intrinsic events since these events (such as oneventforward and oneventbackward) can be added only by the aggregation level.
- Avoid timers.
- Use user-triggered events only if necessary, and always define label and name parameters explicitly. Prefix the name with the portlet's unique identifier, otherwise conflict is possible between different portlets on one page. Use meaningful names for labels.
- Do not create fixed-width WML tables or images in portlets.
- Avoid long, unbroken lines of unwrapped text to help prevent unnecessary scrolling.

Compact HTML (cHTML)

- Use standard cHTML. For information on i-mode compatible HTML, refer to Compact HTML for Small Information Appliances.

- Assume when you design your portlet that it can be opened alone or with other portlets.
- Watch out for unterminated, extraneous, or improperly nested tags. The behavior of pages with improperly ended tags is unpredictable.
- Use only elements that can be included into a body; do not use <head> or <body> tags.
- Avoid lengthy, complex cHTML since portlets can share a page with others.
- Avoid having too many images and do not use alignment and positioning parameters with images.
- Do not exceed a length of 24 symbols for the phone numbers that are used as references in the <a> tag.
- Do not use URLs that are longer than 200 bytes.

Building .ear and .war files

You can run a **configengine** task to build an .ear file or a .war file from an expanded directory.

About this task

Run the following tasks to build .ear and .war files:

Procedure

1. Run the following task to build a .war file:
   - Linux: `./ConfigEngine.sh build-war-file -Dsource.war.directory=directory_path.war -Doutput.war=directory_path.war`
   - Windows: `ConfigEngine.bat build-war-file -Dsource.war.directory=directory_path.war -Doutput.war=directory_path.war`
   - IBM i: `ConfigEngine.sh build-war-file -Dsource.war.directory=directory_path.war -Doutput.war=directory_path.war`

   where the following parameters are defined as:
   - **source.war.directory**: The location of the expanded or customized war file.
   - **output.war**: The location of the generated war file.

   The following information is an example of the **build-war-file** task:

```
Extract the bannerad.war file to a directory
 cd /tmp/files
 jar -xvf /opt/IBM/WebSphere/PortalServer/bp/wp.bp.bannerad/installableApps/bannerad.war

Make an update to a file inside /tmp/files/WEB-INF

Build a new war from the expanded directory
 ./ConfigEngine.sh build-war-file -Dsource.war.directory=/tmp/files/ -Doutput.war=/tmp/wars/bannerad.war

You can now install the updated portlet into WebSphere_Portal
 /tmp/wars/bannerad.war
```

2. Run the following task to build an .ear file:
   - Linux: `./ConfigEngine.sh build-ear-file -Dsource.war.directory=directory_path.war -Doutput.ear=directory_path.ear -Dapp.name=app_name -Dwar.name=war_name.war -Ddisp.name="display_name"`
   - Windows: `ConfigEngine.bat build-ear-file -Dsource.war.directory=directory_path.war -Doutput.ear=directory_path.ear -Dapp.name=app_name -Dwar.name=war_name.war -Ddisp.name="display_name"`

- IBM i: `ConfigEngine.sh build-ear-file -Dsource.war.directory=`*`directory_path`*`.war -Doutput.ear=`*`directory_path`*`.ear -Dapp.name=`*`app_name`* `-Dwar.name=`*`war_name`*`.war -Ddisp.name="`*`display_name`*`"`

Where the following parameters are defined as:

- **source.war.directory**: The location of the expanded or customized war file.
- **output.ear**: The location of the generated ear file.
- **app.name**: The application name substituted in the `application.xml` template.
- **war.name**: The war name substituted in the `application.xml` and `ibm-application-runtime.props` files.
- **disp.name**: The display name substituted in the `application.xml` template.

The following information is an example of the **build-ear-file** task:

```
Make a local copy of the expanded PA_ThemesAndSkinsMgr.ear file (which contains an expanded
ThemesAndSkinsMgr.war file inside of it)
 cd /tmp/files
 cp -R /opt/IBM/WebSphere/wp_profile/installedApps/Cell_name/PA_ThemesAndSkinsMgr.ear/* /tmp/files

Validate the parameters to use by looking at the application.xml file
 /tmp/files/META-INF/application.xml

Build a new ear from the expanded directory
 ./ConfigEngine.sh build-ear-file -Dsource.war.directory="/tmp/files/ThemesAndSkinsMgr.war"
  -Doutput.ear="/tmp/ears/PA_ThemesAndSkinsMgr.ear" -Dapp.name="PA_ThemesAndSkinsMgr"
  -Dwar.name="ThemesAndSkinsManager.war" -Ddisp.name="ThemesAndSkinsMgr_war"

You can now install an enterprise application into the WebSphere Integrated Solutions Console.
 /tmp/ears/PA_ThemesAndSkinsMgr.ear
```

Accessing the portlet session on the anonymous page

View some pointers on handling portlet sessions in situations where portlets are placed on pages that do not require authentication.

Note: Authenticated and remembered users must have cookies enabled on their browser. Users can access portal sites without cookies enabled if they are anonymous users. If you turn on session tracking for anonymous users, then anonymous users also require cookies.

Administrators can place your portlet on a page that is presented to anonymous users (similar to the Welcome page provided by WebSphere Portal). By default, when a portlet is placed on a page that does not require authentication and no user is logged in, the portal server does track sessions across subsequent request to the server. Portlets should not create a session using the `request.getSession(true)` call in this case; which results in WebSphere Application Server warning messages similar to:

```
SESN0066E: Response is already commited to client. Session cookie cannot be set.
```

In this case, a temporary session is created and your session information will be lost in the next request. If you need to enable session tracking across requests for non-authenticated users, you can do so by setting the `public.session` parameter in the portal Navigator service configuration or by setting the `com.ibm.portal.public.session` container run time option in a JSR 286 portlet deployment descriptor. Note that this may result in significantly increased memory consumption. For details about the `com.ibm.portal.public.session` option and a code sample refer to the topic about Deployment descriptors, section about Container run time options. Instead of using these options, portlets that need to maintain interaction state even for non-authenticated users should use render parameters to keep this information instead of the portlet session, as recommended by the Java Portlet Specification.

The portlet may need to present the user with an appropriate message if it requires a valid portlet session to operate correctly. For example:

```
This content cannot be displayed until you log in.
Please report this problem to the site administrator.
```

In addition, the administrator will need more helpful information that the portlet can provide in the portlet log:

```
Unable to locate the portlet session.
This portlet requires a session to function.
Move the portlet to an authenticated page or
turn on session tracking for anonymous users.
```

If the portlet does not require a session for critical operation, then perhaps any subfunctions within the portlet require the session can be suppressed to anonymous users. This should be evaluated for each individual portlet.

If `request.getPortletSession()` or `request.getPortletSession(true)` are called when the user is not logged in and WebSphere Portal is not configured to use a session for anonymous users, each request from each client creates an extraneous `PortletSession` object that is lost and consumes JVM memory. This causes more frequent JVM garbage collection and hurts overall WebSphere Portal performance.

In order for a portlet to function without a portlet session, you must add this line to the beginning of all portlet JSPs.

```
<%@ page session="false" %>
```

Without this directive, the JSP page compiler generates code that accesses the session even if you don't use it in your JSP. You also cannot access any beans with scope set to session in any of your JSP pages as shown.

```
<jsp:useBean ... scope="session" />
```

This will create sessions when you do not want them. Instead, determine whether the session exists, for example:

```
<%
   com.ibm.MyClassName theBeanId = null;
   PortletSession session = request.getPortletSession(false);
   if (session != null) {
      theBeanId = (com.ibm.MyClassName)session.getAttribute("theBeanId");
   }

   // later in your code always check to see if the bean exists before using it
   if (theBeanId != null) {
      // use the bean
   }
%>
```

Deployment descriptors

The deployment descriptors define configuration information for the portlets that a portlet application contains.

Each portlet application requires two deployment descriptors:

- The *portlet deployment descriptor* provides the portal server with information about the portlet resources in the application, including configuration, support characteristics, and titles. The portal server uses this information to provide services for the portlet. For example, if a portlet registers its support for help

and edit mode in the portlet deployment descriptor, the portal server renders icons to allow the user to start the portlet's help and edit pages. This file is always named `portlet.xml`.

- The *web application descriptor* provides the application server with information about the web resources in the application. This file is always named `web.xml`. The format of this file is described in the Deployment Descriptor chapter of the *Servlet Specification*.

The following topics describe the deployment descriptors of a portlet application:

- Web application deployment descriptor
- Portlet deployment descriptor
- Reserved parameter names

Web application deployment descriptor

This section describes the required elements of the `web.xml` for standard portlets. For more information about the web application deployment descriptor, see the Java Servlet Specification Version 2.3.

Web application descriptor for standard portlets

As described in the Java Portlet Specification, a portlet application is an extended web application and therefore has a servlet context. The portlet context uses most of its function from the servlet context of the portlet application. Since the `web.xml` is a mandatory item in a Java Platform, Enterprise Edition web ARchive, you must verify that your portlet application includes a `web.xml` in its WAR file that conforms to Version 2.3 or a later version of the Java servlet Specification. This ensures that the portlet application is compatible with other portal server implementations and WebSphere Portal Express. The `web.xml` must contain, at a minimum, the `<web-app/>` and `<display-name/>` elements. You can also include context-wide parameters using the `<init-param>` element. Refer to the *Java Servlet Specification Version* for more information about the structure of the web application deployment descriptor.

IBM web application descriptor

As with other servlets that follow the Java Platform, Enterprise Edition model, portlets are packaged as WAR or EAR files with a web application deployment descriptor, `web.xml`. This descriptor defines each portlet as a servlet within the web application, including unique identifiers for each portlet, the portlet class, and initialization parameters.

The definition of the servlets in the `web.xml` must be in the same order as the definition of portlets in the `portlet.xml`. The servlet identifier must be referenced by the portlet deployment descriptor, using the **`href`** attribute of the <portlet> tag. As shown in the following table, the **`href`** attribute indicates the path of the web application descriptor in the WAR file that is appended by the servlet ID as the anchor.

Table 462. The href attribute in the portlet.xml and web.xml files

portlet.xml	web.xml
`<portlet id="Portlet_1"` `href="WEB-INF/web.xml#Servlet_1">` `<portlet-name>Mail</portlet-name>` `...` `</portlet>`	`<servlet` `id="Servlet_1">` `<servlet-name>MailPortlet</servlet-name>` `...` `</servlet>`

Table 462. The href attribute in the portlet.xml and web.xml files (continued)

portlet.xml	web.xml
<portlet id="Portlet_2" href="WEB-INF/web.xml#Servlet_2"> <portlet-name>Calendar</portlet-name> ... </portlet>	<servlet id="Servlet_2"> <servlet-name>CalendarPortlet</servlet-name> ... </servlet>

Portlet deployment descriptor

This section describes the `portlet.xml` for standard portlets.

- The elements and structure of the IBM `portlet.xml` is provided in this topic.
- For information about the portlet deployment descriptor for the standard portlet API, see the Java Portlet Specification.

Guidelines for portlet application identifiers

The identifiers of portlet applications must identify them unambiguously in the area of their usage, which can be worldwide. The same is true for concrete portlet applications for portlets. To make this possible, follow these guidelines.

- Include the portlet's namespace in the identifier, using the same format that is used for the Java packages
- Add some portlet application-specific description
- Add some arbitrary characters to ensure uniqueness within the namespace, for example:

  ```
  com.ibm.wps.samplet.mail.4969
  ```

- For IBM portlets, add suffixes for the corresponding concrete portlet applications, for example:

  ```
  com.ibm.wps.samplet.mail.4969.1
  ```

Portlet identifiers must be unique within the application.

Standard portlet deployment descriptor

In the Java Portlet Specification, the portlet descriptor is in the format of an XML schema. Since the portlet is not a servlet, the portlet descriptor does not reference a corresponding servlet ID in the `web.xml`. The first-level element is the `<portlet-app/>`, which contains one or more `<portlet/>` definitions. Portlet-specific initialization parameters are stored in the `portlet.xml` by using the `<init-param/>` element and are obtained from the `PortletConfig` object that is provided during initialization.

IBM portlet deployment descriptor

The structure of the IBM portlet deployment descriptor is defined by a DTD, which is located at *wps.war*`/dtd/portlet_1.1.dtd`.

For IBM portlets, each concrete portlet definition indicates its parent portlet using the **href** attribute of the <concrete-portlet> tag. As shown in the following table, the **href** attribute indicates the portlet ID as an anchor.

Table 463. The href attribute in the portlet tag and the concrete portlet tag

Portlet tag	Concrete portlet tag
<portlet id="Portlet_1" href="WEB-INF/web.xml#Servlet_1"> <portlet-name>Mail</portlet-name> ... </portlet>	<concrete-portlet href="#Portlet_1"> <portlet-name>Mail Box</portlet-name> ... </concrete-portlet>
<portlet id="Portlet_2" href="WEB-INF/web.xml#Servlet_2"> <portlet-name>Calendar</portlet-name> ... </portlet>	<concrete-portlet href="#Portlet_2"> <portlet-name>Group calendar</portlet-name> ... </concrete-portlet>

Reserved parameter names

This section describes parameters that can be set for portlets. There are two types of parameters:

Configuration parameters
These are parameters for a portlet that can be changed only by an administrator. They are defined in the file `portlet.xml` using either the **<config-param/>** elements (for IBM portlets) or the **<preferences/>** element marked as read-only (for standard portlets).

Initialization parameters
These parameters are set during deployment. For standard portlets, they are set by the <init-param/> element in the `portlet.xml`. For IBM portlets, they are set by the <init-param/> element in the `web.xml`.

The following parameters can be set as configuration parameters in IBM portlets or initialization parameters in standard portlets:

`redirect.action.without.session = (false)`
Set this parameter to `true` to enforce a redirect after an action on anonymous pages for this portlet.

`wps.enforce.redirect = (false)`
Set this parameter to `true` if your portlet requires a redirect for a portlet action. The advantage of sending a redirect is that the URL changes to hold the complete state in the URL such that the resulting URL is present in the browser and can be bookmarked. The downside is that the additional request generates more load on the server. The portlet does not need the redirect after action if it does not set any public or private render parameters in processAction or processEvent.

`wps.markup`
This is an initialization parameter in standard portlets to define the supported markup types for the portlet. Use it to differentiate between markup types, such as HTML and cHTML, that use the same MIME type.

`com.ibm.portal.automaximize`
Set this parameter to true to automatically maximize the portlet when the user switches from view mode to any of the other supported modes. The default is false.

`wps.multiple.action.execution`
Set this parameter to `true` to enable the user to run the same action URL several times.

The following parameter can be set as a configuration parameter in IBM portlets or read-only preferences in standard portlets:

com.ibm.portal.pagecontext.enable = (false)
When you set this parameter to `true`, you indicate that the portlet can retrieve task properties. This parameter is used by task processing portlets. The default is false.

Container run time options

The portal defines container run time options, which can be used by portlets that conform to the Java Portlet Specification 2.0 (JSR286). You set these parameters by using the `<container-runtime-option>` element in the `portlet.xml`.

com.ibm.portal.public.session
Set this parameter to `true` to allow session creation for anonymous users for this particular portlet. Example:

```
<container-runtime-option>
   <name>com.ibm.portal.public.session</name>
   <value>true</value>
</container-runtime-option>
```

The Java Portlet Specification addresses the requirements of aggregation, personalization, presentation, and security for portlets running in a portal environment.

JSP tags for standard portlets

The standard portlet API defines several tags that can be used in portlet JSPs to access the portlet request and response and to generate URLs.

To make these tags available in a JSP, the following directive is required at the beginning of the JSP:

```
<%@ taglib uri="http://java.sun.com/portlet" prefix="portlet"%>
```

For more information, see Java Portlet Specification.

WebSphere Portal Express provides an extra tag for use in standard portlets. To make these tags available in a JSP, the following directive is required:

```
<%@ taglib
    uri="http://www.ibm.com/xmlns/prod/websphere/portal/v8/portlet/ibm-portlet-ext"
    prefix="portlet-ext" %>
```

The following is a brief description of the extension to the JSR 168 portlet JSP tag library.

<portlet-ext:portalRenderURL ***attribute*****="*****value*****">**
Creates a URL to pages or portlets on pages. Attributes are as follows:

contentNode="***id*** **|** ***name*****"**
Indicates the ID or unique name of the page. The name or ID of the content node is also used to specify the page where the portlet can be found.

portletWindow="***id*** **|** ***name*****"**
Indicates the ID or unique name of the control that holds the portlet. Must be used in combination with the attribute **`contentNode`** to identify the page where the portlet is located.

portletMode="view | help | edit | configure"
For URLs to a portlet indicated by **portletWindow**, this attribute sets the portlet mode. This parameter is ignored if the attribute **portletWindow** is not set.

windowState="maximized | minimized | normal"
In a portlet, this attribute indicates the state of the portlet window when it is displayed. If the portlet state is not specified, the page is shown with the previous state of the portlet. This parameter is ignored if the attribute **portletWindow** is not set.

portalState="solo | normal"
Indicates whether the specified portlet window is rendered normally or solo, that is without a theme. This parameter is ignored if the attribute **portletWindow** is not set.

newWindow="true | false"
This attribute creates a session partition. For portlet URLs, use this attribute if you want to display the portlet either in a new window or in an iFrame. The default value is false. The portlet window state for the addressed portlet in the new window is set to maximized. The portlet mode is set to the value of the current parent window.

locale="*locale*"
Specifies the locale with which subsequent portal page requests are rendered. This attribute is optional.

var ="*name*"
Specifies the name of a scripting variable that is exposed in the body of the tag. This attribute is optional. The variable exposes an object that implements the interface `com.ibm.portal.DisposableURL` that can be used to stream the URL to the output.

<portlet-ext:urlParam name="*parameter_name*" value="*parameter_value*">
Use this tag to add custom parameters of your choice to the parent **portalRenderURL**. Parameters are added to the **portalRenderURL** as render parameters of the specified portlet window. Parameters are ignored if the enclosing **portalRenderURL** does not specify the attribute **portletWindow**. Specify attributes as follows:

name Required. Indicates the name of the parameter.

value Required. Indicates the value of the parameter.

<portlet-ext:bidi dir="rtl | ltr" />
This tag is used to support bidirectional languages. Bidirectional languages contain text that reads in both directions. For example, URLs, code samples, or directory and file names can be read in the opposite direction of the rest of the text.

dir Indicates the normal direction of text in the language.

- For **dir="rtl"**, the tag content is written only if the client's locale belongs to a bidirectional language. This is the default setting if **dir** is not specified.
- For **dir="ltr"**, the tag content is written only if the client's locale does not belong to a bidirectional language.

locale The tag content is written only if the language is not bidirectional.

<portlet-ext:setBundle basename="*value*" var="*value*" scope="*value*" bundle="*value*" provider="*value*"/>

Use this tag to compute the locale that is used for the JSTL format tags that are based on the portal specific locale computation algorithms. To make sure that the locale used by JSTL matches the locale that is used by other dynamic elements on the portal page, prefer this tag over the JSTL tag `<fmt:setBundle>`. This creates a globalization context and stores it in the scoped variable or the `javax.servlet.jsp.jstl.fmt.localizationContext` configuration variable.

basename
The resource bundle base name. This is the fully qualified resource name of the bundle. It has the same form as a fully qualified class name, that is, it uses a period full stop (.) as the package component separator. It does not have a file type suffix, such as `.class` or `.properties`.

var The name of the exported scoped variable that stores the globalization context of type `javax.servlet.jsp.jstl.fmt.LocalizationContext`.

scope The scope of `var` or the globalization context configuration variable.

bundle
The instance of the `java.util.ResourceBundle` to use.

provider
The instance of the `com.ibm.portal.model.ResourceBundleProvider` to use.

The use of `basename`, `bundle`, and `provider` are mutually exclusive.

You can also use JSTL tags as described in *Generating output*.

Handling and visibility of request parameters in portlets

Learn how the standard portlets and IBM portlets set request parameters for requests targeted to portlets. Acquire an understanding of the parameter visibility for standard portlets, IBM portlets, and the included JSPs or servlets.

Both IBM and standard portlets have different ways of setting request parameters for requests targeted to portlets. This topic is best understood if you have some familiarity with passing parameters using either of these APIs for portlet programming.

1. If the portlets generate URLs using the portlet API, they can set parameters programmatically using the PortletURL.setParameter (standard) or PortletURI.addParameter (IBM) calls.
2. When HTML forms are submitted to the portal, the form values are passed as request parameters. If you use the GET method for form submission in IBM portlets, other parameters that have been programmatically set on the form action URL may not be passed back by the client. For JSR 168 and 286 HTTP GET parameters are transmitted as render parameters.
3. Portlets can trigger operations on other portlets using the Property Broker APIs. In this case, the target portlet can receive parameters that propagate values from the source portlet.
4. Portal theme and skin JSPs can create URLs to portlets with the `<portal-navigation:urlGeneration/>` tag. These portlet URLs can also include parameters that are visible to all IBM portlets (not to standard portlets).

Multiple portlets are normally called within the processing of a single client request, and these different methods of setting parameters can interact in various ways. Therefore you need to consider which parameters are actually visible to a portlet, especially if standard and IBM portlets are placed on the same page and are invoked within a single client request.

Parameter visibility for standard portlets

Standard portlets do not use parameter namespacing. Parameter namespacing is not necessary In an environment consisting of only standard portlets because these portlets receive the parameters from the client request only if they are directly targeted by a URL, so it is implicitly clear to which portlets the parameters belong.

Standard portlets are the target of a URL if the URL has been created with the RenderResponse.createRenderURL() or RenderResponse.createActionURL() methods. In this case, the portlet will receive the parameters that have been programmatically set on the URL. In the case of an action URL, the portlet can read the query or form parameters for the request, so that it can read the form input if the URL was the action of a HTML form. As stated by the Java Portlet Specification, portlets should not use render URLs for HTML form actions because form parameters may not be visible in this case.

For portlets that are not the target of a URL, the Java Portlet Specification defines the notion of render parameters. In any render call that is not triggered by a render URL targeted to the portlet (that is, when the portlet is simply shown as part of a page where the user interacts with another portlet), the portlet sees only its active set of render parameters, independent of any parameters that are set on the client request. The portlet cannot see request parameters set by the `<portal-navigation:urlGeneration/>` tag unless the tag explicitly specifies a target portlet by using the layoutNode attribute.

New render parameters are set either by a render URL or by a portlet action and the portal will keep providing those render parameters to the portlet as long as the portlet is not the explicit target of a URL or a property broker event. That means, the render parameters can (and should) be used to store the navigational state of the portlet.

Finally, an action of a standard portlet can be invoked through the property broker if property values are propagated from another portlet. In this case, the portlet will see its current set of render parameters, so that it is able to keep (parts of) its

current state across the action call. In addition, those parameters that are defined by the property passing mechanism of property broker will be visible, and they will override render parameter values with the same name. Again, the visible parameters are independent of any parameters set on the client request.

Note that the render parameters are only passed to the portlet action, if the action is invoked by property broker. Actions that are invoked by a URL will not automatically see them. You can, however, pass all render parameters by setting them explicitly on the URL:

```
PortletURL url = renderResponse.createActionURL;
url.setParameters(renderRequest.getParameterMap());
```

Parameter visibility for IBM portlets

IBM portlets normally use parameter namespacing, which means that a parameter name clearly identifies to which portlet a parameter belongs. Namespaced parameters are visible only to the portlet to which they belong. In addition, IBM portlets may also have access to additional, non-namespaced parameters that have been set on the request.

- If you use the PortletURI.addParameter() method to set parameters, the namespacing is done automatically.
- When the portlet outputs an HTML form, the programmer should explicitly namespace the input fields, including parameter names, by using the <portletAPI:encodeNamespace/> tag. However, if IBM portlets use forms without namespacing, it is guaranteed that they will receive the form parameters.
- It is guaranteed that a portlet can read request parameters that have been set by the `<portal-navigation:urlGeneration/>` tag.

Because of these guarantees, the portal is not always able to filter out parameters that are not intended for the portlet but are nevertheless visible. Therefore, an IBM portlet must be prepared to handle the fact that a PortletRequest may contain additional (non-namespaced) parameters. In the case of parameter name conflicts, a namespaced parameter overrides a non-namespaced parameter and the non-namespaced parameter is not visible.

These same considerations apply to all IBM portlet methods that take a PortletRequest or an event from which a PortletRequest can be retrieved, whether they are triggered directly by a URL or indirectly through the property broker.

Parameter visibility in included JSPs or servlets

When portlets include servlets or JSPs, the included resource will see the same parameters as the including portlet. The servlet specification allows the portlet to add a query string to the include path, as in the following example.

```
context.getRequestDispatcher("/jsps/View.jsp?mode=detailed");
```

Parameters that are set this way will always be visible in the included servlet or JSP, for both IBM and standard portlets. The value will take precedence over an old value for the same parameter name that has been specified by another mechanism. That means, the getParameter() call will return the new value and getParameterValues() will return the new value and any old values.

If the portlet being rendered is an IBM portlet, namespaced parameters still override non-namespaced parameters.

Detailed descriptions of the Struts WML tags

Learn about the WML tags used by the portlets within the Struts Application Framework.

The following tags are used by portlets within the Struts Application Framework. For a brief description of WML support in the Struts Application Framework, see Using the WML tags.

<wml:cancel/>

Renders a WML <postfield> element with a value of `cancel`. This tag is only valid when nested inside a form tag body. Posting this element causes the `Action` servlet to bypass calling the associated form bean validate() method.

Table 464. cancel attributes

Attribute name	Description
property	The parameter name with the specified value that is set in the request object. **Note:** If the property attribute is set, then the application will have to handle cancel detection. [Runtime expression]
value	The value of the request parameter. [Runtime expression]

<wml:card/>

This tag renders a card element. This element is not rendered when the tag is executed in WebSphere Portal Express. This allows writing JSPs that can be used in both the servlet and portlet environments.

Table 465. card attributes

Attribute name	Description
id	This attribute is the card unique identifier. [Runtime expression]
newcontext	This is a flag to indicate that context should be reinitialized when loaded. [Runtime expression]
onenterbackward	Load URL when accessed through `<prev>` task. [Runtime expression]
onenterforward	Load URL when accessed through `<go>` task. [Runtime expression]
ontimer	Load URL when timer expires. [Runtime expression]
ordered	This is the flag to indicate that content is ordered. [Runtime expression]
title	This tag indicates the title of the card. [Runtime expression]

Table 465. card attributes (continued)

Attribute name	Description
titleKey	Key to look up title in resource bundle, titleKey is only used if title attribute is null. [Runtime expression]

<wml:errors/>

Retrieves the set of error messages from the request object with the default key of `Action.ERROR_KEY` or the value specified by attribute name. If `ActionErrors` are found then the errors are displayed. This tag also requires the following two message keys in the application scope MessageResources.

- `errors.header` - header that is displayed before the error messages list.
- `errors.footer` - header that is displayed after the error messages list.

Table 466. error attributes

Attribute name	Description
bundle	This is the servlet context attribute key for the MessageResources instance to use. If not specified, defaults to the application resources configured for the Strut `Action` servlet. [Runtime expression]
locale	The session attribute key for the Locale used to select messages to be displayed. If not specified, defaults to the Struts standard value. [Runtime expression]
name	Name of the request scope bean under which our error messages have been stored. If not present, the name specified by the `Action.ERROR_KEY` constant string will be used. [Runtime expression]
property	Name of the property for which error messages should be displayed. If not specified, all error messages, regardless of property, are displayed. [Runtime expression]

<wml:form/>

This tag does not render any markup, but it is used to scope beans and transactions. The tags used with the body of the form tag can use the form bean to populate the input fields.

Table 467. form attributes

Attribute name	Description
action	The action is the URL that is used for the form submission. The action will be picked up by a nested tag, and postfield tags are used to submit the data. For additional information on specifying the action, see the Struts `html:form` documentation. [Required] [Runtime expression]

Table 467. form attributes (continued)

Attribute name	Description
name	This attribute is the name of the bean. The scope attribute is used to determine where the bean can be located. The tags that are contained in the body of the form tag can use the form bean for populating the input field. For additional information on specifying the name, see the Struts `html:form` documentation. [Runtime expression]
scope	Specifies the scope of the form bean associated with this form. For additional information on the scope attribute, see the Struts `html:form` documentation. [Runtime expression]
type	The fully qualified class name of the form bean. For additional information on the type attribute, see the Struts `html:form` documentation. [Runtime expression]

<wml:go/>

This tag renders a WML <go> element. If the go tag is used in the body of a form tag, the form's action is used as a hyperlink. If the form's action attribute is set, then the `forward`, `href`, and `page` attributes are ignored.

Table 468. go attributes

Attribute name	Description
accept-charset	This attribute allows specifying the character encodings that the application can handle. [Runtime expression]
action	The action is the URL that is used for the form submission. The action will be picked up by a nested tag, and postfield tags are used to submit the data. [Runtime expression]
forward	The name of the global `ActionForward` to be used to create the URL for the go element. **Note:** This attribute is ignored if this tag is specified in the body of a form tag that specifies the action attribute. For addition information on the forward attribute, see the Struts `html:link` documentation. [Runtime expression]
href	This attribute specifies the URL for the go element. **Note:** This attribute is ignored if this tag is specified in the body of a form tag that specifies the action attribute. For addition information on the href attribute, see the Struts `html:link` documentation. [Runtime expression]

Table 468. go attributes (continued)

Attribute name	Description
method	Allows specifying the HTTP submission method, get or post [Runtime expression]
page	The context relative path to the URL that will be used as the href for the go element. **Note:** This attribute is ignored if this tag is specified in the body of a form tag that specifies the action attribute. For addition information on the page attribute, see the Struts `html:link` documentation. [Runtime expression]
sendreferer	This attribute allows specifying that the deck URL should be included the request [Runtime expression]
transaction	A postfield element will be created so that the current transaction control token can be sent if this attribute is `true`. For addition information on the transaction attribute, see the Struts `html:link` documentation. [Runtime expression]
urlType	The type of portlet URL to create. If not specified URL type is standard. Supported values: return, standard [Runtime expression]

<wml:head/>

Renders a WML <head> element with language attributes extracted from the user's current Locale object, if there is one. This element is not rendered when the tag is executed in WebSphere Portal Express. This allows writing JSPs that can be used in both the servlet and portlet environments.

<wml:link/>

Renders a WML <a> element as a hyperlink to the specified URL. URL rewriting will be applied automatically to maintain session state in the absence of cookies. The tag's body is displayed as the name of the link. The base URL for this hyperlink is calculated based on which of the following attributes you specify:

- forward
- href
- page

Note: One and only one of the `forward`, `href`, or `page` attributes can be specified.

Table 469. link attributes

Attribute name	Description
accesskey	A number 0 through 9 that is displayed that indicates to a user which keypad number is required to select this element. [Runtime expression]

Table 469. link attributes (continued)

Attribute name	Description
forward	The name of the global `ActionForward` to be used to create the URL. For addition information on the forward attribute, see the Struts `html:link` documentation. [Runtime expression]
href	This attribute specifies the hyperlink to be unchanged as the URL. For addition information on the href attribute, see the Struts `html:link` documentation. [Runtime expression]
indexed	For information on this attribute, see the Struts `html:link` documentation. [Runtime expression]
indexId	For information on this attribute, see the Struts `html:link` documentation. [Runtime expression]
name	For information on this attribute, see the Struts `html:link` documentation. [Runtime expression]
page	The context relative path to the URL that will be used as the href. For addition information on the page attribute, see the Struts `html:link` documentation. [Runtime expression]
paramId	For information on this attribute, see the Struts `html:link` documentation. [Runtime expression]
paramName	For information on this attribute, see the Struts `html:link` documentation. [Runtime expression]
paramProperty	For information on this attribute, see the Struts `html:link` documentation. [Runtime expression]
paramScope	For information on this attribute, see the Struts `html:link` documentation. [Runtime expression]
property	For information on this attribute, see the Struts `html:link` documentation. [Runtime expression]
scope	For information on this attribute, see the Struts `html:link` documentation. [Runtime expression]
rel	This attribute allows specifying the relationship [Runtime expression]

Table 469. link attributes (continued)

Attribute name	Description
sendreferer	This attribute allows specifying that the deck URL should be included in the request [Runtime expression]
transaction	A postfield element will be created so that the current transaction control token can be sent if this attribute is true. For addition information on the transaction attribute, see the Struts `html:link` documentation. [Runtime expression]
urlType	The type of portlet URL to create. If not specified URL type is standard. Supported values: return, standard [Runtime expression]

<wml:option/>

Renders a WML <option> element, representing one of the choices for an enclosing <select> element. The text displayed to the user comes from either the body of this tag, or from a message string looked up based on the bundle, locale, and key attributes. If the value of the corresponding bean property matches the specified value, this option will be marked selected. This tag is only valid when nested inside a <wml:select> tag body.

Table 470. option attributes

Attribute name	Description
bundle	This attribute allows specifying the key for the MessageResources stored in the servlet context. [Runtime expression]
key	This attribute specifies the key to the text that is contained in the bundled, determined from the bundle attribute. If this attribute is not specified, then the text from the tag's body is used. [Runtime expression]
locale	The locale to use for looking up messages in the resource bundle. [Runtime expression]
onpick	The URL to navigate when a selection is made. [Runtime expression]
title	Brief field title [Runtime expression]
titleKey	Key to look up title in resource bundle, titleKey is only used if title attribute is null. [Runtime expression]
value	If the user selects this option, then this is the value that is submitted. [Required] [Runtime expression]

<wml:options/>

Renders a set of WML <option> elements, representing possible choices for a <select> element. This tag can be used multiple times within a single <wml:select> element, either in conjunction with or instead of one or more <wml:option> elements. The use of the collection attribute is documented in the HTML version of the `options` tag.

Table 471. options attributes

Attribute name	Description
collection	Name of the bean used to build the selection options. For addition information on the collection attribute, see the Struts `html:link` documentation. [Runtime expression]
labelName	For addition information on the labelName attribute, see the Struts `html:link` documentation. [Runtime expression]
labelProperty	For addition information on the labelProperty attribute, see the Struts `html:link` documentation. [Runtime expression]
name	For addition information on the href attribute, see the Struts `html:link` documentation. [Runtime expression]
property	For addition information on the href attribute, see the Struts `html:link` documentation. [Runtime expression]

<wml:password/>

Renders a WML <input> element of type password, populated from the specified value or the specified property of the bean associated with our current form. This tag is only valid when nested inside a form tag body.

Table 472. password attributes

Attribute name	Description
accesskey	A number 0 through 9 that is displayed that indicates to a user which keypad number is required to select this element. [Runtime expression]
emptyok	Flag to indicate that this field can remain blank. [Runtime expression]
format	Format mask for the input field [Runtime expression]
maxlength	Maximum number of input characters to accept. [No limit] [Runtime expression]

Table 472. password attributes (continued)

Attribute name	Description
name	The attribute name of the bean whose properties are consulted when rendering the current value of this input field. If not specified, the bean associated with the form tag we are nested within is utilized. [Runtime expression]
property	Name of the request parameter that will be included with this submission, set to the specified value. [Required] [Runtime expression]
size	Number of character positions to allocate. [Runtime expression]
tabindex	The tab order in a card. [Runtime expression]
title	Brief field title [Runtime expression]
titleKey	Key to look up title in resource bundle, titleKey is only used if title attribute is null. [Runtime expression]
value	Value of the label to be placed on this button. This value will also be submitted as the value of the specified request parameter. [Runtime expression]

<wml:postfield/>

Renders a WML <postfield> element. This tag is only valid when nested inside a form tag body.

Table 473. postfield attributes

Attribute name	Description
name	The attribute name of the bean whose properties are consulted when rendering the current value of this input field. If not specified, the bean associated with the form tag we are nested within is utilized. [Runtime expression]
property	The corresponding bean property. [Required] [Runtime expression]
value	The value of the postfield tag. [Runtime expression]

<wml:rewrite/>

Renders a request URI based on exactly the same rules as the link tag does, but without creating the <a> hyperlink. The base URI for this hyperlink is calculated based on which of the following attributes you specify:

- forward
- href
- page

Note: One and only one of the `forward`, `href`, or `page` attributes can be specified.

Table 474. rewrite attributes

Attribute name	Description
forward	The name of the global `ActionForward` to be used to create the URL. For addition information on the forward attribute, see the Struts `html:link` documentation. [Runtime expression]
href	This attribute specifies the hyperlink to be unchanged as the URL. For addition information on the href attribute, see the Struts `html:link` documentation. [Runtime expression]
indexed	For information on this attribute, see the Struts `html:rewrite` documentation. [Runtime expression]
indexId	For information on this attribute, see the Struts `html:rewrite` documentation. [Runtime expression]
name	For information on this attribute, see the Struts `html:rewrite` documentation. [Runtime expression]
page	The context relative path to the URL that will be used as the href. For addition information on the page attribute, see the Struts `html:rewrite` documentation. [Runtime expression]
paramId	For information on this attribute, see the Struts `html:rewrite` documentation. [Runtime expression]
paramName	For information on this attribute, see the Struts `html:rewrite` documentation. [Runtime expression]
paramProperty	For information on this attribute, see the Struts `html:rewrite` documentation. [Runtime expression]
paramScope	For information on this attribute, see the Struts `html:rewrite` documentation. [Runtime expression]
property	For information on this attribute, see the Struts `html:rewrite` documentation. [Runtime expression]

Table 474. rewrite attributes (continued)

Attribute name	Description
scope	For information on this attribute, see the Struts `html:rewrite` documentation. [Runtime expression]
transaction	A postfield element will be created so that the current transaction control token can be sent if this attribute is `true`. For addition information on the transaction attribute, see the Struts `html:rewrite` documentation. [Runtime expression]

<wml:select/>

Renders a WML <select> element, associated with a bean property specified by our attributes. This tag is only valid when nested inside a form tag body. See the `html:select` for additional information on usage.

Table 475. select attributes

Attribute name	Description
iname	Index number of default option(base 1) [Runtime expression]
ivalue	Default value [Runtime expression]
multiple	Set to support multiple selections. [Runtime expression]
name	The name of the bean used to determine the pre-selected options. [Runtime expression]
property	The attribute sets the name of the request parameter used for the value submission. [Required] [Runtime expression]
tabindex	The tab order in a card. [Runtime expression]
title	Brief field title. [Runtime expression]
titleKey	Key to look up title in resource bundle. `titleKey` is only used if the title is `null`. [Runtime expression]
value	The value for determining if an option has been selected. [Runtime expression]

<wml:text/>

Renders a WML <input> element of type text, populated from the

specified value or the specified property of the bean associated with our current form. This tag is only valid when specified in the body of a form tag.

Table 476. text attributes

Attribute name	Description
accesskey	A number 0 through 9 that is displayed that indicates to a user which keypad number is required to select input. [Runtime expression]
emptyok	Flag to indicate that this field can remain blank.
format	Format mask for input field. [Runtime expression]
maxlength	Maximum number of input characters to accept. [No limit] [Runtime expression]
name	The attribute name of the bean whose properties are consulted when rendering the current value of this input field. If not specified, the bean associated with the form tag we are nested within is utilized. [Runtime expression]
property	Name of this input field, and the name of the corresponding bean property if value is not specified. The corresponding bean property (if any) must be of type String. [Required] [Runtime expression]
size	Number of character positions to allocate. [Runtime expression]
tabindex	The tab order in a card. [Runtime expression]
title	Brief field title. [Runtime expression]
titleKey	Key to look up title in resource bundle. Title must be null. [Runtime expression]
value	Value to which this field should be initialized. [Use the corresponding bean property value] [Runtime expression]

<wml:wml/>

Renders a <wml/> element. In the WebSphere Portal Express environment, the element is not rendered.

Application extension registry

WebSphere Portal Express provides an application extension registry which is equivalent to the application extension registry provided by IBM WebSphere

Application Server. This registry allows any J2EE compliant application to define extension points for other applications to use, or to plug in to other extensible applications.

The application extension registry uses the Eclipse plug-in descriptor format and APIs as the standard extensibility mechanism for WebSphere applications. For more information about the application extension registry, see *Application extension registry* in the *IBM WebSphere Application Server information center* and *Notes on the Eclipse Plug-in Architecture*.

Predefined public render parameters

WebSphere Portal defines a set of portal-specific public render parameters, which can be used to work with portal-specific state information within portlets.

Public render parameters is a concept that is defined by the Java Portlet Specification 2.0. As opposed to private render parameters, public render parameters can be shared between portlets to implement coordination use cases.

The main benefit of these predefined parameters is that the portlet developer can rely on the Portlet API to work with portal_specific state information without using any portal-specific APIs or SPIs. For example, you can easily create a portlet render URI that addresses a portal page by using the public render parameter that holds the portal page selection information.

"Pre-defined public render parameters representing portal state" on page 3150
Pre-defined public render parameters that represent portal-specific state information are available in all lifecycle methods of the portlet: processAction, processEvent, render, and serveResource. During rendering, you can create portlet URLs that address these parameters.

"To register pre-defined public render parameters in portlet.xml" on page 3152
To use these pre-defined public render parameters in your portlet, declare each of them in your portlet deployment descriptor (`portlet.xml`) as specified in the Java Portlet specification.

"To use pre-defined public render parameters in your portlet" on page 3153
Creating portlet URLs based on these pre-defined public render parameters is not different from creating any other portlet URL. The typical use case is to create a portlet render URL that addresses one or multiple pre-defined public render parameters.

Related concepts:

"Public render parameters" on page 3070
Public render parameters allow JSR 286 portlets to share navigational state information. They are specially useful for coordinating the multiple navigation or viewer portlets that display different information items that are all related to the same parameter name. The portal stores all portlet render parameters, including public render parameters, as an encoded part of the current portal URL. Therefore, public render parameters are correctly preserved by typical browser navigation actions such as the Back button and bookmarking.

Pre-defined public render parameters representing portal state

Pre-defined public render parameters that represent portal-specific state information are available in all lifecycle methods of the portlet: processAction, processEvent, render, and serveResource. During rendering, you can create portlet URLs that address these parameters.

The following table lists all predefined public render parameters and explains their semantics. All of them represent portal-specific state information and are part of the following namespace:

`http://www.ibm.com/xmlns/prod/websphere/portal/publicparams`

Table 477.

Local name	Value (String array)	Description
selection	Serialized *ObjectID/unique* name of page; for example, `[Z6_0000000AGKJ0G3RCD00]`	Parameter that provides read/write access to the portal page selection information in the navigational state. This parameter can be used to create portlet URLs to portal pages, read the page selection, or modify it during action/event processing.
URI	Serialized *URI*; for example, `[pm:oid:Z3_SASD8732DSG3RCD00]`	Parameter that allows for addressing portal resources that use POC URIs. This parameter can be used to create portlet URLs that address an arbitrary portal resource through its POC URI.
locale	Serialized *locale*; for example, `[en]`	Parameter that provides read/write access to the locale information in the navigational state. This parameter can be used to address a certain locale through a portlet URL, read the locale information from the state, or modify it during action/event processing.

Table 477. (continued)

Local name	Value (String array)	Description
themeTemplate	*Template name*; for example, [Plain]	Parameter that provides read/write access to the theme template that is used during rendering. This parameter can be used to create portlet URLs that enforce a certain theme template that is used for rendering the addressed portal page. The parameter can also be used to read the theme template information from the state or modify it during action / event processing.
editMode	Serialized *boolean value*; for example,[true]	Parameter that provides read/write access to the state of the page edit mode. A value of true means that page edit mode is active; a value of false indicates that it is inactive. This parameter can be used to create portlet URLs that address page edit mode, read the state of the page edit mode or modify it during action/event processing.
infoMode	Serialized *boolean value*; for example, [false]	Parameter that provides read/write access to the state of the page information mode. A value of true means that page information mode is active; a value of false indicates that it is inactive. This parameter can be used to create portlet URLs that address page information mode, read the state of the page edit information mode or modify it during action/event processing.

Table 477. (continued)

Local name	Value (String array)	Description
showTools	Serialized *boolean value*; for example, [true]	Parameter that provides read/write access to the state of the site toolbar; a value of true means that the toolbar is opened, a value of false indicates that it is closed. This parameter can be used to create portlet URLs to open / close the toolbar, read the toolbar state, or modify it during action/event processing.

To register pre-defined public render parameters in portlet.xml

To use these pre-defined public render parameters in your portlet, declare each of them in your portlet deployment descriptor (portlet.xml) as specified in the Java Portlet specification.

The following example shows how to register the parameters that hold the portal page selection and locale information. In this case, the prefix mapping for the portal namespace is defined on the root *portlet-app* element of the deployment descriptor.

Note: The portlet itself does not need to deal with the qualified names of the respective render parameters in its implementation. It can use local identifiers instead, which are defined as part of the respective public-render-parameter element at the end of the descriptor. In this specific case, the page selection parameter is mapped to the local identifier *pageID* whereas the locale parameter is mapped to the local identifier *locale*.

Code Sample:

```
<?xml version="1.0" encoding="UTF-8"?>
<portlet-app id="my.sample.portlet"
     xmlns="http://java.sun.com/xml/ns/portlet/portlet-app_2_0.xsd"
     xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/publicparams"
     version="2.0">
     <portlet>
          <portlet-name>My sample portlet</portlet-name>
          ...
          <supported-public-render-parameter>pageID</supported-public-render-parameter>
          <supported-public-render-parameter>locale</supported-public-render-parameter>
     </portlet>
     <public-render-parameter>
          <identifier>pageID</identifier>
          <qname>portal:selection</qname>
     </public-render-parameter>
     <public-render-parameter>
          <identifier>locale</identifier>
          <qname>portal:locale</qname>
     </public-render-parameter>
</portlet-app>
```

To use pre-defined public render parameters in your portlet

Creating portlet URLs based on these pre-defined public render parameters is not different from creating any other portlet URL. The typical use case is to create a portlet render URL that addresses one or multiple pre-defined public render parameters.

The following code snippet shows how to create a portlet render URL that takes the user to a specific portal page. And to create a portlet render URL that requests the page to be displayed in a certain locale. The URL is created within the render phase of the portlet lifecycle. The sample code assumes that the page selection and locale parameter are registered in the portlet deployment descriptor and mapped to the local identifiers *pageID* and *locale*. For more information, see the sample in *To register pre-defined public render parameters in portlet.xml*.

The logic that determines the values of the parameters is not a part of the code example as it strongly depends on the specific use case. Typically you would use the Model SPI to search for a specific page in the content model and then address the page by using its *ObjectID*. If you want to create deep links to specific pages, you can also address the page through its unique name. In this case, you can set the unique name as the value for the selection parameter.

Code Sample:

```
import com.ibm.portal.ObjectID;
import com.ibm.portal.identification.Identification;
import com.ibm.portal.serialize.SerializationException;

public class MyPortlet extends GenericPortlet {

    /** The identification service. */
    private Identification identification = null;;

    @Override
    public void init() throws PortletException {
        try {
            // default handling
            // ...
            // lookup identification service
            final Context ctx = new InitialContext();
            identification = (Identification) ctx.lookup(Identification.JNDI_NAME);
        } catch (NamingException e) {
           throw new PortletException(e);
        }
   }

   @Override
   protected void doView(final RenderRequest request, final RenderResponse response)
           throws PortletException, IOException {
       try {
           // content type handling, markup generation etc.
           // ...
           // determine the values that should be set
           final ObjectID pageID = getPageID(request);
           final Locale locale = getLocale(request);
           // create a new render URL
           final PortletURL renderURL = response.createRenderURL();
           // set the page selection parameter
           renderURL.setParameter("pageID", identification.serialize(pageID));
           // set the locale parameter
           renderURL.setParameter("locale", locale.toString());
           // write the URL to the markup
           // ...
     } catch (SerializationException e) {
```

```
            throw new PortletException(e);
        }
    }
    ....
```

The IBM Web Content Manager API

You can use the Web Content Manager API to extend functions of Web Content Manager.

Use the Web Content Manager API to:

- create items
- delete items
- move items
- copy items
- retrieve items
- approve items in a workflow
- search for items

See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *PortalServer_root*/doc/Javadoc/spi_docs/com/ibm/workplace/wcm directory.

Getting started

To use the Web Content Manager API, you have 2 options:

1. Write your code as JSPs that you deploy on your server in your Java enterprise application. These JSPs can then be used in your Web Content Manager content by using JSP components or custom JSPs in elements.
2. Write you code as a compiled java enterprise application. In this case, you need to create a project in your development environment that has the two JAR files *ilwwcm-api.jar* and *wp.base.jar* in the build path. These JAR file files can be copied from your portal server from here:
   - /opt/WebSphere/PortalServer/wcm/prereq.wcm/wcm/shared/app/ilwwcm-api.jar
   - /opt/WebSphere/PortalServer/base/wp.base/shared/app/wp.base.jar

   This code can then be used in your Web Content Manager content by using custom plug-ins. See “How to create custom plug-ins” on page 3205 for further information.

   “How to use the Web Content Manager API” on page 3155
   The workspace is the heart of the IBM Web Content Manager API. Items are created, saved, deleted and searched for in the workspace item. A workspace is basically an interface to Web Content Manager that is associated with a user. Using a workspace item, the user can perform operations as that user.

   “The Query API” on page 3156
   The query API provides querying capabilities that are much more rich than the "findBy" methods on the workspace class.

   “Web Content Manager JSP tags” on page 3157
   You use IBM Web Content Manager JSP tags with the Web Content Manager API to pull Web Content Manager content and components into external JSP applications.

"Web content library management APIs" on page 3161
You can perform various web content library functions by using the Web content API.

"Syndication APIs" on page 3163
You can run various syndication functions by using the web content API.

How to use the Web Content Manager API

The workspace is the heart of the IBM Web Content Manager API. Items are created, saved, deleted and searched for in the workspace item. A workspace is basically an interface to Web Content Manager that is associated with a user. Using a workspace item, the user can perform operations as that user.

To get a workspace item, you must first retrieve the `WebContentService`:

```
try
 {
    // Construct and initial Context
    InitialContext ctx = new InitialContext();

    // Retrieve WebContentService using JNDI name
    WebContentService webContentService = (WebContentService)
    ctx.lookup("portal:service/wcm/WebContentService");
 }
 catch (NamingException ne)
 {
    System.out.print("Naming Exception: " + ne);
 }
```

You then request one from the repository singleton with the following call:

```
webContentService.getRepository().getWorkspace("my username", "my password");
```

To get a workspace item without specifying a user name and password, use one of the following calls:

- When used in a portlet: `Workspace workspace = webContentService.getRepository().getWorkspace( (Principal) portletRequest.getUser() );`
- When not used in a portlet: `Workspace workspace = webContentService.getRepository().getWorkspace((Principal) request.getUserPrincipal() );`

If the user is not recognized as a Web Content Manager user, or for some other reason could not be authenticated, an `OperationFailedException` will be thrown.

Note: Only Web Content Manager users (including external LDAP users if enabled) are recognized. For example, A workspace cannot be retrieved using an LTPA token.

Operations available on the workspace include:

- Searching for items with the provided "findBy" methods.
- Creating new items of available editable types.
- Saving and deleting editable items.

You must call `endWorkspace()` when finished with the workspace item.

```
webContentService.getRepository().endWorkspace();
```

Note: You don't need to call `endWorkspace()` when using a JSP component as rendering and session management is handled by Web Content Manager.

Note: You use the `setCurrentDocumentLibrary` method to make calls library-specific. If not specified, the default library that has been configured in the WCM WCMConfigService service is used.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

The Query API

The query API provides querying capabilities that are much more rich than the "findBy" methods on the workspace class.

Here is an example of how to retrieve and use the QueryService to find the first content directly under the SiteArea parentSiteArea that has an element that is called "myElement":

```
Content contentWithMyElement;
QueryService queryService = workspace.getQueryService();
Query query = queryService.createQuery(Content.class);
query.addParentId(parentSiteArea.getId(), QueryDepth.CHILDREN);
try
{
   ResultIterator resultIterator = queryService.execute(query);
   if (resultIterator.hasNext())
   {
      Content childContent = (Content) resultIterator.next();
      while (childContent.hasComponent("myElement"))
      {
         contentWithMyElement = childContent;
         break;
      }
   }
}
catch (QueryServiceException e)
{
   // Handle exception
}
```

Here is an example of how to use create a query with 'AND' and 'OR' conditions by using Conjunction and Disjunction. The example processes all content whose name starts with 'news', or whose name starts with 'article' and has a keyword 'news':

```
QueryService queryService = workspace.getQueryService();
Query query = queryService.createQuery(Content.class);
Disjunction or = new Disjunction();
or.add(Selectors.nameLike("news%"));
Conjunction and = new Conjunction();
and.add(Selectors.nameLike("article%"));
and.add(ProfileSelectors.keywordsContain("news"));
or.add(and);
query.addSelector(or);
try
{
   ResultIterator resultIterator = queryService.execute(query);
   while (resultIterator.hasNext())
   {
```

```
            Content content = (Content) resultIterator.next();

            // Process Content result
        }
    }
    catch (QueryServiceException e)
    {
        // Handle exception
    }
```

Web Content Manager JSP tags

You use IBM Web Content Manager JSP tags with the Web Content Manager API to pull Web Content Manager content and components into external JSP applications.

Note: A JSP referenced within a JSP component must not include a reference, directly or indirectly, to the same JSP component. This includes references within Web Content Manager tags or the API. If it does, a loop is created and your server crashes.

Note: To use the Web Content Manager JSP tags, the following directive must be provided in the JSP:

```
<%@ taglib uri="/WEB-INF/tld/wcm.tld" prefix="wcm" %>
```

Storing JSP files: JSP files are stored within a web application that runs on the portal. To reference a JSP file in another web application, use the following path: `contextPath;jspPath`. For example: `/wps/customapplication;/jsp/jspFilename.jsp`.

A dynamic context path value can be defined by adding a token to the context path that corresponds to a key and value pair to the Web Content Manager configuration service environment provider. When this key is used as the token in the jsp value field, it is replaced dynamically at render time. For example: `my.custom.key;myfile` where *my.custom.key* is a constant within the Web Content Manager configuration service.

Writing JSP to be referenced within a JSP component:

The setExplicitContext and setContext tags are not required when you render a JSP file with a JSP Component. They are only required when directly accessing a JSP file.

Reloading JSP files:

JSP files that are referenced by Web Content Manager are reloaded once every 10 seconds. If you update a JSP file, you might need to wait for it to be reloaded before your changes are displayed.

InitWorkspace tag

This is used to set the initial workspace. This tag:

- Sets the WCM workspace as a local variable called wcmWorkspace.
- Sets the WCM workspace on the pageContext as a parameter with key com.ibm.workplace.wcm.api.Workspace.WCM_WORKSPACE_KEY.
- Sets the WCM RenderingContext on the request as a parameter with key Workspace.WCM_RENDERINGCONTEXT_KEY

```
<wcm:initworkspace username=" " password=" " user=" " >
[Error Message]
</wcm:initworkspace>
```

Table 478. Parameters

Parameter	Details
username	The user name of a valid Web Content Manager user.
user	This parameter is used to specify a java.security.Principal object instead of the user name.
password	The password for the valid Web Content Manager user name or user.

Note: User name, user, and password are optional. If not specified, the current user is used instead, including the anonymous user.

This is an example use of this tag:

```
<%@ taglib uri="/WEB-INF/tld/wcm.tld" prefix="wcm"%>
<%@ page import="com.ibm.workplace.wcm.api.*" %>

<p><wcm:initworkspace>login fail</wcm:initworkspace>
<%
  // Get the workspace for use
  Workspace workspace = (Workspace) pageContext.getAttribute(Workspace.WCM_WORKSPACE_KEY);

  // Get the WCM rendering context for use
  RenderingContext renderingContext = (RenderingContext) request.getAttribute(Workspace.WCM_RENDERIN
%>
```

Explicit context tag

This sets the path to your Web Content Manager server. This is not required in JSP that is displayed using a JSP component.

```
<wcm:setExplicitContext wcmWebAppPath=" " wcmServletPath=" " path=" "
 requestParameters=" " prefix=" " project=" " >
[Error Message]
</wcm:setExplicitContext>
```

Table 479. Parameters

Parameter	Details
wcmWebAppPath	The URL up to the web application. For example: `http://localhost:10040/wps/wcm`
wcmServletPath	The servlet path to the Web Content Manager servlet. For example: `/connect`
path	The path to the content and site areas. For example: `/Site Area A/Site Area B/Content C`
requestParameters	You specify java Map request parameters to set in the context. These parameters can be used by menu components that are rendered via the JSP that use a query string. See "Writing links to web content" on page 1836 for details of request parameters that can be used when referencing web content items.
project	The name of the project to set in the context. If the corresponding project cannot be found, it is ignored and an error is logged. An empty string is used to clear any project that is previously set in the context.

Note: The **project**, **wcmWebAppPath**, and **wcmServletPath** parameters are optional. However, if **wcmWebAppPath** is specified, **wcmServletPath** must also be specified.

Developers can add insert context tags at any place in the page and it changes the context for the rest of the page execution, but the tags cannot be nested.

Context retrieval tag

Sets the context given the location of a path string. This is not required in JSP that is displayed using a JSP component.

```
<wcm:setContext location=" "  wcmWebAppPath=" " wcmServletPath=" " param=" " project=" " defaultPa
[Error Message]
</wcm:setContext>
```

Table 480. Parameters

Parameter	Details
location	This sets the context of the location of a path string. Either: **location="query"** The context is obtained from the query parameter. **location="request"** The context is obtained from the value of the request. **location="session"** The context is obtained from the value of the current session. **location="portalContext"** This is used to define the path of a site area or content item that is used as the current context of a page. For example: `/library1/sitearea3/content4` **location="portalMapping"** This is used to define the path of a site area or content item that is used as the default site area of a page. For example: `/library1/sitearea3`
wcmWebAppPath	The URL up to the web application. For example: `http://localhost:10040/wps/wcm`
wcmServletPath	The servlet path to the Web Content Manager servlet. For example: `/connect`
param	This is the name of the parameter that the path string is in.
project	The name of the project to set in the context. If the corresponding project cannot be found, it is ignored and an error is logged. An empty string is used to clear any project that is previously set in the context.
defaultPath	If the location parameter does not resolve to a valid location, then the value of the **defaultPath** is used. For example: `/library2/sitearea1`

Note: The **project**, **wcmWebAppPath**, **wcmServletPath**, and **defaultPath** parameters are optional. However, if **wcmWebAppPath** is specified, **wcmServletPath** must also be specified.

Developers can add context tags at any place in the page and it changes the context for the rest of the page execution, but the tags cannot be nested.

Rendering tags

These are equivalent to element and component tags.

Rendering an element from the current site area, or content item

```
<wcm:contentComponent type=" " key=" " >
[Error Message]
</wcm:contentComponent>
```

Table 481. Parameters

Parameter	Details
type	This determines where the element is being referenced from. Either *content* or *sitearea*.
key	This is the name of the element that is being referenced.

```
<wcm:libraryComponent name=" " library=" " >
[Error Message]
</wcm:libraryComponent >
```

Rendering a component from the Component Library

Table 482. Parameters

Parameter	Details
name	This is the name of the component that is being referenced.
library	This is the name of the library where the component is stored.

For example:

```
<wcm:libraryComponent name="SC Menu Events" library="Showcase" />
You do not have access to this item.
</wcm:libraryComponent >
```

Rendering Content based on the current context of a page

```
<wcm:content pageDesign=" " >
[Error Message]
</wcm:content >
```

Table 483. Parameters

Parameter	Details
pageDesign	This name of the Presentation Template used to determine context. This parameter is optional.

Error handling

The following tag can be added to error messages to enable error handling:

```
<%=error%>
```

Plug-in tag

Rendering plug-ins can be referenced within JSP code by using a plug-in tag:

```
<wcm:plugin name=" " param1="value" param2="value2" >

// Your text.

</wcm:plugin>
```

See Creating a plug-in tag for further information.

Web content library management APIs

You can perform various web content library functions by using the Web content API.

- Create a library
- Delete a library
- Copy a library
- Import a library
- Export a library

Note: Drafts are not copied or exported when using the API to copy or export libraries.

See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *PortalServer_root*/doc/Javadoc/spi_docs/com/ibm/workplace/wcm directory.

Invoking web content library API methods asynchronously

Although Web content library API functions can be invoked synchronously, if you run these against web content libraries containing large amounts of data, they may take extremely long to complete execution. For example, if these methods are invoked from a JSP page, this may result in the JSP page being invalidated due to a session timeout.

WebSphere Application Server uses a mechanism known as asynchronous beans. An asynchronous bean is a Java object that can be run asynchronously. The "Work object" asynchronous bean is used to invoke web content library API methods asynchronously.

A Work object (which is represented by the interface com.ibm.websphere.asynchbeans.Work) extends java.lang.Runnable It is used to run a block of code as an independent thread. WebSphere Application Server maintains a pool of independent threads that can be assigned to run code encapsulated in Work instances. This pool of threads is managed by the WorkManager. This is used to spawn threads to run Work objects and to monitor them. WebSphere Application Server maintains default Work Managers for each of the application servers that are contained on a particular node. The sample in this topic makes use of the default Work Manager (wm/wpsWorkManager) for the WebSphere Portal application server. This maintains a pool of 300 threads. It is possible to create new Work manager instances with customized thread pools. This is done using the WebSphere Integrated Solutions Console for the WebSphere Portal server.

The example uses the DeleteWork class to implement the Work interface:

```
package deletesample;

import com.ibm.workplace.wcm.api.*;
import javax.naming.*;

public class DeleteWork implements com.ibm.websphere.asynchbeans.Work
{
   private String m_username = null;

   private String m_password = null;

   private String m_libraryToDelete = null;
```

```
   public DeleteWork(String username, String password, String library)
   {
      m_username = username;
      m_password = password;
      m_libraryToDelete = library;
   }

   public void release()
   {
   }

   public void run()
   {
       try
       {
  // Construct and inital Context
      InitialContext ctx = new InitialContext();

  // Retrieve WebContentService and WebContentLibraryService using JNDI name
  WebContentService webContentService = (WebContentService)
     ctx.lookup("portal:service/wcm/WebContentService");
  WebContentLibraryService webContentLibraryService = (WebContentLibraryService)
    ctx.lookup("portal:service/wcm/WebContentLibraryService");

  Workspace ws = webContentService.getRepository().getWorkspace(m_username, m_password);
  DocumentLibrary docLib = ws.getDocumentLibrary(m_libraryToDelete);
  LibraryTaskResult res = webContentLibraryService.deleteLibrary(ws, docLib);

  // Once you get the result object back, print status to StandardOut
  if (res.getResultType() == ResultTypes.OPERATION_SUCCESS)
  {
   System.out.println("Successfully Deleted Library " + m_libraryToDelete);
  }
  else
  {
   System.out.println("Failed To Delete Library " + m_libraryToDelete);
  }
       }
       catch (Exception e)
       {
                 e.printStackTrace();
       }
   }
}
```

The run method is what is required in order to implement this interface. This is where you wrap the library method that you want to run in a thread separate from the calling thread. In the previous example, `DeleteWork` is instantiated passing in credentials as well as the library to be deleted. In `run()`, the repository is logged into and a Workspace instance is obtained as is a `DocumentLibrary` corresponding to the library that is to be deleted. `deleteLibrary()` is then called to perform the actual deletion. Once this method is completed, the Result object can be queried to determine the status of the deletion. This can then be logged or processed as required.

The following JSP file is used to invoke the `DeleteWork` object:

```
<%@ page import="java.util.*" %>
<%@ page import="java.io.*" %>
<%@ page import="java.lang.*" %>
<%@ page import="com.ibm.workplace.wcm.api.*" %>
<%@ page import="com.aptrix.identity.*" %>
<%@ page import="com.ibm.workplace.wcm.services.library.*" %>
<%@ page import="com.ibm.workplace.wcm.services.*" %>
```

```
<%@ page import="com.ibm.workplace.wcm.services.repository.*" %>
<%@ page import="com.ibm.websphere.asynchbeans.*" %>
<%@ page import="javax.naming.*" %>
<%@ page import="deletesample.DeleteWork" %>

<%
/*
 *  JSP Sample to demonstrate how to delete a WCM Library
 *  making use of the WebSphere Application Server
 *  Work asynchronous bean.
 */

try
{
   //obtain a work manager instance - the work manager manages a pool of threads
   //which can be used to invoke the functionality encapsulated
   // within a work instance
   InitialContext ctx  = new InitialContext();
   com.ibm.websphere.asynchbeans.WorkManager wm  =
   (com.ibm.websphere.asynchbeans.WorkManager)
        ctx.lookup("wm/wpsWorkManager");

   //create a new work instance
   DeleteWork workItem = new DeleteWork(request.getParameter("username"),
request.getParameter("password"),
   request.getParameter("library"));
   //spawn a thread to run the create work instance
   wm.startWork(workItem);

}
catch (Exception e)
{
%>  <%= e.toString() %><%
}%>
```

In order to run a Work object, it is necessary to do a JNDI lookup to obtain the default WebSphere Portal Server Work Manager instance. Once this is done, the `DeleteWork` class can be instantiated. To run `DeleteWork` on a separate thread, call `startWork()` on the `WorkManager` passing in the `DeleteWork` instance. For example, `wm.startWork(workItem);` The `System.out` log can be checked to see when `DeleteWork` finishes.

Syndication APIs

You can run various syndication functions by using the web content API.

- Retrieve, enable, or disable syndicators and subscribers.
- Start full and partial syndication updates.
- Dynamically review syndication progress.
- View syndicator and subscriber details such as the name of the libraries that are being syndicated.
- Query syndication details such as which items were updated, saved, modified, or removed.

See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *PortalServer_root*`/doc/Javadoc/spi_docs/com/ibm/workplace/wcm` directory.

Search REST API specification

The following document describes the API call to search IBM WebSphere Portal Express. You can search WebSphere Portal Express to find content that contains a specific text string in its title or content, or is tagged with a specific tag.

Context Paths

There are a number of different context paths available for this API to allow for different authentication mechanisms:

Context Path	Authentication
`/PORTAL_CONTEXT/contenthandler/searchfeed/search`	None
`/PORTAL_CONTEXT/mycontenthandler/searchfeed/search`	Basic

Parameters

The order of the parameters in the requests does not matter. The parameter names are case-sensitive; they must be entered in the format documented. Any unknown or unsupported parameters that are submitted as part of a request is ignored.

The request must be a standard **`HTTP GET`** or **`POST`** command.

- When the request is **`GET`**, the URL is formed by combining the search server's host name, port, and path; and a collection of name-value pairs (input parameters) separated by *&* characters. Any parameter value must be URL-escaped if in **`GET`** request.
- When the request is **`POST`**, the URL is formed by combining the search server's host name, port, and path; and a collection of name-value pairs (input parameters) is passed on the request as parameters.

Name	Description	Comments
`locale`	• Locale of request client • Any message that is returned is in the client locale • Available scopes and collections; titles and description are in the client locale • Sorting method might be effected by the locale • Any additional information in the search results that are locale aware, like description	Specifies the language to use to parse the search request. See *ISO-639* and *ISO-3166* for valid values, for example. *en_US*. This parameter is optional. When specified, the appropriate dictionary for the specified language is used. **Note:** The dictionary for the language that is specified must be enabled for this parameter to work.

Name	Description	Comments
query		• Text to search; returns a list of results with the specified text in the title, description, or content. • Encode the strings. • By default, spaces are treated as an **OR** operator. The following operators are supported: **AND or &&** Searches for items that contain both words. For example: **query=red%20AND%20test** returns items that contain both the word *red* and *test*. **AND** is the default operator. **NOT or !** Excludes the word that follows the operator from the search. For example: **query=test%20NOT%20red** returns items that contain the word *test*, but not the word *red*. **OR** Searches for items that contain either of the words. For example: **query=test%20OR%20red**. To search for a phrase, enclose the phrase in quotation marks (" "). **+** The plus sign indicates that the word must be present in the result. For example: **query=+test%20red** returns only items that contain the word *test* and many that also contain *red*, but none that contain only the word *red*. **?** Use a question mark to match individual characters. For example: **query=te%3Ft** returns items that contain the words *test*, *text*, *tent*, and

Name	Description	Comments
queryLang	Language of the query string	Specifies the language to use to parse the query parameter. See *ISO-639* and*ISO-3166* for valid values, for example, *en_US*. This parameter is optional. When specified, the appropriate dictionary for the specified language is used. **Note:** The dictionary for the language that is specified must be enabled for this parameter to work.
start	Offset to first result to return in results	Defines an offset from the first result in the set. This parameter is ignored if a page parameter is provided. The value starts from *0*. The default is *0*. If specified value is negative, the value is defaulted to *0*; if the specified value is greater than the number of results, no results are returned.
page	Page number	Specifies the page to be returned. The default value is *1*, which returns the first page.
pageSize	Number of results that are wanted for a single request	Specifies the number of entries to return per page. The minimum value is *0* (negative values default to *0*). The default value is *10*. The maximum value that you can specify is *150*.
scope	Identifier of which scope to search; the list of valid scopes is available in the *Scopes API*.	Default is to search all scopes.
sortKey	The key, which controls the sorting order of the search results.	The following values are supported: *date* and *relevance*. A valid value for this parameter is one of these values, or the name of any other sortable field.
sortOrder	Determines the order by which the results are sorted: ascending or descending.	The only valid values are *asc* or *desc*.
constraint	Allows constraining the search results according to the provided criteria.	The provided criteria. For more information, see *Constraints API*.
facet	Specifies which facets are returned for the query, in addition to search results.	Addition to search results. For more information, see *Facets API*.

Name	Description	Comments
index	Specifies which index (collection) to use for the search	For more information, see *Indexes API*.

Examples

/searchfeed/search?**queryLang**=en&locale=en&resultLang=en&query=development &**scope**=1345374377545&start=0&results=10 Search query with query text = *development*.

Response Format

The response is Atom-compliant. The following table describes the significance of the elements that are returned in the response:

Section	Remarks
/feed	The container element for metadata and data that is associated with the search results feed.
/feed/title	Descriptive title of the feed.
/feed/link[@href]	Reference from the feed to a web resource. For more information, see *Feed Paging and Archiving*.
/feed/link[@rel= "next"|"previous"|"first"|"last"]	*first*, *last*, *next*, and *previous* links are included, for supporting.
/feed/author/name	Description of the feed generator.
/feed/id	Permanent, universally unique identifier for the feed.
/feed/updated	Date and time the query was issued. The value conforms to the date-time production in RFC3339.
/feed/openSearch:totalResults	Total number of results for submitted query.
/feed/openSearch:Query	Contains information about the query that was submitted by the user.
/feed/openSearch:Query[@role]	The role attribute value is *request*.
/feed/openSearch:Query[@searchTerms]	Represents the user submitted query terms.
/feed/openSearch:startIndex	Initial result number for the search results returned in this feed.
/feed/openSearch:itemsPerPage	Number of search results that are returned in this feed.
/feed/entry	Encompasses the information for a single search result.
/feed/entry/category	Conveys information about a category (often corresponding to a facet) associated with an entry.
/feed/entry/category@term	A string that identifies the category to which the entry belongs.
/feed/entry/category@scheme	An IRI that identifies a categorization scheme.

Section	Remarks
/feed/entry/title	Text construct that conveys a human-readable title for an entry.
/feed/entry/title[@type]	Indicates whether the text construct is *text*, *html*, or *xhtml*. Text construct is *text* if not otherwise specified.
/feed/entry/link	Defines a reference to the search result resource.
/feed/entry/link[@rel]	Indicates the link relation type. If not present, the link relation type is `alternate`.
/feed/entry/link[@href]	URI link to document.
/feed/entry/link[@type]	Content type of the URI document link is an advisory media type.
/feed/entry/relevance:score	Indicates a relative assessment of relevance for a particular search result with regards to the search query.
/feed/entry/updated	Last modified date for the document. The value conforms to the date-time production in RFC3339.
/feed/entry/id	Unique identifier of the document.
/feed/entry/summary	Text construct that conveys a short summary, abstract, or excerpt of an entry.
/feed/entry/summary[@type]	Indicates whether the text construct is *text*, *html*, or *xhtml*. Text construct is *text* if not otherwise specified.
/feed/entry/author	A person construct that indicates the author of the entry or feed.
/feed/entry/author/name	Human-readable name for the person.
/feed/entry/author/uri	Identifier that is associated with the person.
/feed/entry/author/email	The person email address. Depending on the IBM Connections configuration settings, this value might not be returned as part of the feed.
/feed/entry/wplc:field	This element is used to represent the name and value of a field of a document. The **id** attribute represents the name of the field. The body of the element represents the value of the field. More fields are included in the search result response if specified through the **includeField** parameter.
/feed/ibmsc:facets	For more information, see *Facets*.

- The *namespace* in the table is `http://www.w3.org/2005/Atom` unless otherwise specified.
- The *openSearch* identifier is used to refer to the namespace `http://a9.com/-/spec/opensearch/1.1`.
- The *relevance* identifier is used to refer to the namespace `http://a9.com/-/opensearch/extensions/relevance/1.0/`.
- The *ibmsc* identifier is used to refer to the namespace `http://www.ibm.com/search/content/2010`.

- The *spelling* identifier is used to refer to the namespace `http://a9.com/-/opensearch/extensions/spelling/1.0/`.

Example

To search for all content across IBM WebSphere Portal Express that contains the text *Development*, send the following HTTP request:

```
> GET /searchfeed/search?query=development&scope=com.ibm.lotus.search.ALL_SOURCES HTTP/1.1
```

The following content is returned by the server:

```
<?xml version="1.0" encoding="UTF-8"?>
   <atom:feed xmlns:opensearch="http://a9.com/-/spec/opensearch/1.1/"
       xmlns:xhtml="http://www.w3.org/1999/xhtml"
       xmlns:wplc="http://www.ibm.com/wplc/atom/1.0"
       xmlns:atom="http://www.w3.org/2005/Atom">
       <atom:title>Search results for query "development" on scope "com.ibm.lotus.search.ALL_S

```

Search constraints REST API specification

Constraints are part of the Search API. They provide a structured method for advanced search over document metadata. They limit search results to the ones that match specific metadata values. It is an alternative for client-side applications, which include filters and advanced search options.

Instead of concatenating values into the query parameter with specific query syntax, an application can pass the values as separate parameters, regardless of

query syntax. The constraint parameter can be passed multiple times in a Search API request to indicate multiple constraints. The constraint parameter is optional in the Search API. Constraints are mandatory that is each search result must match all the constraints that are provided on the request. If a query parameter is provided, all search results must match the query and the constraints. Constraints are differentiated between three basic types: **field**, **category**, and **range** constraints. Each constraint can apply to single or multiple values. The value of the constraint parameter is a JSON string. The following section outlines the details of the syntax for the various types of constraints.

Field Constraint

A field constraint allows only results that match specific field values.

Syntax: constraint=**type**: *field*, **id**: *field_id*, **values**: *[fieldValue1,fieldValue2]*

Parameters:

Context Path	Authentication
type	Always equals *field* for this type of constraint.
id	The identifier of the indexed field.
values	An array of field values. Each search result must match at least one of the values.

Example: constraint=**type**:*field*, **id**:*title*, **values**:*[test]*

Category Constraint

A category constraint refers to a constraint on a specific category in a *Facet*. A category constraint is similar to a field constraint in its syntax. However, since categories are indexed differently than regular fields, it is declared as a special type of constraint to allow better handling of the request. Category constraints are always an exact match.

Syntax: constraint=**type**: *category*, **values**: [*root/a/x*, *root/a/y]*

Parameters:

Context Path	Authentication
type	Always equals *category* for this type of constraint
values	An array of category IDs. Each search result must match at least one of the categories.

Examples:

- Constraint=**type**: *category*, **values**:*[Tag/tag1]*
- Constraint=**type**: *category*, **values**:*[Tag/tag1,Tag/tag2]*
- Constraint=**type**: *category*, **values**:*[Source/forums,Source/profiles,Source/wikis,Source/status_updates]*
- Constraint=**type**: *category*, **values**:*[Tag/tag1]}*
- Constraint=**type**: *category*, **values**:*[Tag/tag2]*

Range Constraint

A range constraint allows only results in a specific range of field values. Values can be strings or numbers.

Numeric Syntax: constraint=**type**: *range*, **id**: *field_id*, **values**: *[{ge: 0.1, le: 0.5}, {g: 3.6}, {l: -5}]*

String Syntax: constraint=**type**: *range*, **id**: *field_id*, **values**: *[{ge: cat, le: dog}, {g: horse}, {l: animal}]*

Parameters:

Context Path	Authentication
type	Always equals *range* for this type of constraint.
id	The identifier of the indexed field.
values	An array of range values. Each value consists of lower and upper boundaries. Each boundary can be inclusive or exclusive. One or more boundaries can be specified for each value. The allowed attributes are • *ge* for lower inclusive boundary. • *g* for lower exclusive boundary. • *le* for upper inclusive boundary. • *l* for upper exclusive boundary.

"Search facets REST API specification"
The following document describes the **facet** parameter of the Search API and the corresponding response elements. The **facet** parameter allows obtaining the facets, which are relevant for the search query. The facets that are supported in Portal Search include **Tag**, **Person**, **Date**, **Source**, and for status updates only **Trend**.

Search facets REST API specification

The following document describes the **facet** parameter of the Search API and the corresponding response elements. The **facet** parameter allows obtaining the facets, which are relevant for the search query. The facets that are supported in Portal Search include **Tag**, **Person**, **Date**, **Source**, and for status updates only **Trend**.

Request Format

The **facet** parameter of the Search API is optional. When absent, facets are not returned with the search results. The **facet** parameter can repeat multiple times. Each instance of the parameter defines a category for which facets must be computed. For example: **Person**, **Date**, **Tag**, and so on. The value of the **facet** parameter is a JSON string. A number of attributes for the JSON string are

supported. All of the attributes, which have a default value are optional. Any unknown attributes are ignored. The following are the attributes that are supported for the JSON string:

Name	Description	Default Value	Comments
id	Defines the ID of the category from which facets must be computed. This attribute is mandatory.		This value can be obtained from a response of a previous search request.
depth	Defines how to collect facet values in the category. If the depth is *0*, only the category is returned. If the depth is *1*, its immediate children are also returned. If the depth is the constant value *ALL*, then there's no limitation on how deep to collect facet values.	*1*	Negative values are not allowed.
count	Defines the maximal number of values to return for this category. If the count is the constant value *ALL*, then all the category's descendants in the provided depth are returned, up to the maximum.	*10*	Negative values are not allowed. The maximum is *1000*.
sortOrder	Defines how results must be sorted, either in ascending or descending order. Facets results are sorted by weight.	*DESC*	This attribute has only 2 allowed values: *ASC*, *DESC*.

The full structure of the parameter in JSON format is

```
facet={"id": "<facet_id>", "depth": <depth>, "count": <count>, "sortOrder": "<order>"}
```

Examples

Some examples:

```
facet={"id": "Tag", "count": 50}
facet={"id": "Person", "count": 250}
facet={"id": "Date", "count": 250, "depth": 2}
facet={"id": "Source", "count": 50}
facet={"id": "Trend", "count": 50}
```

Response Format

The response format is designed to allow a faceted search client, which is as generic as possible. The format is XML-based, and augments the existing Atom search feed with elements. All additional elements have the *ibmsc* namespace, where *ibmsc* is short for `http://www.ibm.com/search/content/2010`. The root *atom:feed* element is augmented with *ibmsc:facet* elements, as defined in the following schema:

```
atomFeed = element atom:feed {
 ibmscFacets ~//in addition to existing elements
 }

  ibmscFacets = element ibmsc:facets {
 attribute taxonomyId { text},
 ibmscFacet*
 }

  ibmscFacet = element ibmsc:facet {
 attribute id { text},
 attribute type { text },
 ibmscFacetValue*
 }

 ibmscFacetValue = element ibmsc:facetValue{
 attribute id { text},
 attribute label { text },
 attribute weight { float },
 ibmscFacetValue*
 }
```

Description of response elements:

Element	Description
ibmsc:facets	Root element for all facets information.
ibmsc:facets/@taxonomyId	Identifies the facets taxonomy to be used in a category Constraint.
ibmsc:facet	Defines the category for which facets were computed.
ibmsc:facet/@id	The identifier of the category.
ibmsc:facet/@type	Defines the type of facet. Can be used as a hint to the client side on how to render the facet. For example, if **type** is *Person*, it can be rendered as a *live* person link. If **type** is *Tag*, it can be rendered as cloud. These values are predefined: *Date*, *Tag*, *Person*, *String*, *Number*, *Integer*.
ibmsc:facetValue	Defines a category for which search results were found. A **facetValue** might contain sub elements, in a tree-like structure.
ibmsc:facet:facetValue/@id	The identifier of the category for which search results were found.
ibmsc:facetValue/@label	A human-readable label for this facet value.
ibmsc:facetValue/@weight	A number that indicates the relative weight of this facet value within the search results. This number might correlate to the actual number of search results that match this query, but that is not mandatory.

Note: When a facet value is selected by the user, the API provides the following ways to reflect that selection in the faceted search request:

1. To limit search results to the ones that match this facet value, use the **constraint** parameter. Combine the *id* of the **facetValue** element with the **taxonomyId** attribute of the facets element on the response to build the new service URL. This option can also be used to select two-facet values or more simultaneously. The category value must match the *Id* of the selected facet value.
2. To explore facets in a subcategory of the selected facet value if it exists, use the *id* of the **facetValue** element as the *id* attribute of the facet request parameter.

Example

```
<ibmsc:facets taxonomyId="facets">
<ibmsc:facet id="Date" type="Date">
<ibmsc:facetValue id="Date/2012" label="2012" weight="1">
<ibmsc:facetValue id="Date/2012/07" label="07" weight="1"/>
</ibmsc:facetValue>
</ibmsc:facet>
</ibmsc:facets>
```

Introducing JSON

Extending tagging and rating by using service APIs

Developers can enhance and extend the tagging and rating features of the portal. For this purpose the portal tagging and rating feature provides service APIs that you can use to enhance tagging and rating by your requirements.

The portal provides a Java Model API and a RESTful API that relates to tagging and rating. You can also extend the included Dojo widget user interface. For example, you can enhance portal tagging and rating in the following ways:

- You can create additional queries about different aspects of the tagging and rating behavior of your portal users.
- You can build additional user interfaces to show the statistics about the tagging and rating behavior of your portal users.
- You can implement additional functionality by exploiting the tags via the access to shared render parameters. Thereby portlets on a page can react to what is currently happening in the tag widget.

"The Java API"
The Java API that the portal provides for tagging and rating follows the pattern of the portal controller SPI. For more details refer to the section about the portal controller API.

"The REST API" on page 3177
The REST API provides various possibilities to work with tagging and rating.

The Java API

The Java API that the portal provides for tagging and rating follows the pattern of the portal controller SPI. For more details refer to the section about the portal controller API.

The following controllers are available for working with resources, tags and ratings:

RatingModelController
Use this controller to control ratings, that is to create or delete ratings.

TagModelController
Use this controller to control tags, that is to create or delete tags.

ResourceModelController
Use this controller to control resources that are tagged or rated or both. For example, specify a category to which a resource belongs.

Related concepts:

"Controller SPI " on page 2883
You can use the Controller SPI for portal administration. It allows you to modify portal resources. It enhances the read-only portal Model SPI by adding writable aspects.

"Model SPI overview" on page 2858
Models provide information that is needed by WebSphere Portal Express to perform tasks such as content aggregation or building navigation to browse the aggregated content. The information that is aggregated is represented through models that can be accessed programmatically by using the Model SPI (read-only). The information of a model is usually persistent (stored in a database) but can also be transient (computed and stored only in memory). Models can be represented by using a tree structure (nodes have a parent-child relationship), a list structure, or a selection structure (a selected element in a tree structure).

Related reference:

"The tagging and rating user interface" on page 1309
Learn about the user interface that IBM WebSphere Portal Express provides for users to work with tags and rating.

The REST API

The REST API provides various possibilities to work with tagging and rating.

"Basic addressing"
Portal users can address resources that have been registered with the tagging and rating engine.

"Adding query parameters" on page 3181
You can add query parameters as required by using the following instructions.

"Querying models in correlation to each other" on page 3185
You can query one model in correlation to another model.

"Other queries" on page 3187
You can add other query parameters, for example for related tags.

"Using the Rest API to add, update, and delete tags and ratings" on page 3190
You can create, update, and delete tags and ratings by using the REST API.

Related reference:

"The tagging and rating user interface" on page 1309
Learn about the user interface that IBM WebSphere Portal Express provides for users to work with tags and rating.

Basic addressing

Portal users can address resources that have been registered with the tagging and rating engine.

Users can address resources, tags, tag spaces, ratings, and rating spaces. They can either address all entities part of these five models or start with an empty set of these models and add single entities by adding additional query parameters. For details refer to the topic about Adding query parameters.

The URL that is to be used for addressing resources is as follows:
`http://host:port/wps/mycontenthandler?uri=uri`

Valid URIs are given in the following sections.

Addressing resources

To address resources, use the following URIs:

rm:all This returns a feed that contains all resources that are registered with the tagging and rating engine. A resource is registered with the tagging and rating engine when a user tags or rates it at least once. Note that using this operation can be rather expensive, depending on the amount of registered resources. Sample feed:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:thr="http://purl.org/syndication/thread/1.0"
   xmlns:xhtml="http://www.w3.org/1999/xhtml"

             7_2QC68B1A086070IK5UQSRK20O4?mode=view"
             type="application/atom+xml"/>
</atom:entry>
```

rm:empty
This returns a feed that represents the empty set of resources. You can add individual resources to this feed by adding additional query parameters.

rm:*type_schema*:*ssp*
This returns a feed that represents a single unique resource. Samples:

- For a portal resource: `rm:nm:oid:oid_of_a_page` . This URI addresses a portal content node.
- For a custom resource: `rm:dvd:rambo` . This addresses a custom resource of some kind.

Addressing tags

To address tags, use the following URIs:

tm:all This returns a feed that contains all available tags. Note that using this operation can be rather expensive depending on the amount of registered tags. Sample feed:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:thr="http://purl.org/syndication/thread/1.0"
   xmlns:xhtml="http://www.w3.org/1999/xhtml"
   xmlns:atom="http://www.w3.org/2005/Atom"
   xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
   xmlns:cp="http://www.ibm.com/xmlns/prod/websphere/portal/v7.0/portal-contextual-portal"
   xmlns:opensearch="http://a9.com/-/spec/opensearch/1.1/"
   xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base">
```

```

</atom:entry>
```

tm:empty
: This returns a feed that represents the empty set of tags. You can add individual tags to this feed by adding additional query parameters.

tm:name:*tag_name*
: This returns a feed that contains all tags that match the name *tagname*.

tm:oid:*oid_of_a_tag*
: This returns a feed that represents a single unique tag with the ID `oid_of_a_tag`.

Addressing tag spaces

Unlike the tag model, the tag space model does not contain information about which user has assigned a certain tag or to which concrete resource a tag has been assigned. A tag space represents only the association between a tag name and its count. Therefore tag spaces are useful to aggregate tag clouds. Use the following URIs:

tm:ts:all
: This returns a feed that contains all available tag spaces, that is all available tags and their names and counts. Sample feed:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:thr="http://purl.org/syndication/thread/1.0"
  xmlns:xhtml="http://www.w3.org/1999/xhtml"
  xmlns:atom="http://www.w3.org/2005/Atom"
  xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
  xmlns:cp="http://www.ibm.com/xmlns/prod/websphere/portal/v7.0/portal-contextual-portal"
  xmlns:opensearch="http://a9.com/-/spec/opensearch/1.1/"
  xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base">

        type="application/atom+xml"/>
</atom:entry>
```

tm:ts:empty
This returns a feed that represents the empty set of tag spaces. You can add individual tag spaces to this feed by adding additional query parameters.

Addressing ratings

To address ratings, use the following URIs:

rtm:all This returns a feed that contains all available ratings. Note that using this operation can be rather expensive depending on the amount of registered ratings. Sample feed:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:thr="http://purl.org/syndication/thread/1.0"
  xmlns:xhtml="http://www.w3.org/1999/xhtml"
  xmlns:atom="http://www.w3.org/2005/Atom"
  xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
  xmlns:cp="http://www.ibm.com/xmlns/prod/websphere/portal/v7.0/portal-contextual-portal"
  xmlns:opensearch="http://a9.com/-/spec/opensearch/1.1/"
  xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base">
    <atom:author>
      <atom:name>IBM WebSphere Portal/8.0</atom:name>
    </atom:author>
    <atom:id>rtm:all</atom:id>
    <atom:link href="/wps/mypoc/!ut/p/digest!vLQAhj2WCgHcg0_gV7N7XQ/rtm/all?mode=download"
      rel="self" type="application/atom+xml"/>

</atom:entry>
```

rtm:empty
This returns a feed that represents the empty set of ratings. You can add individual ratings to this feed by adding additional query parameters.

rtm:oid:*oid_of_a_rating*
This returns a feed that represents a single unique rating with the ID `oid_of_a_rating`.

Addressing rating spaces

Unlike the rating model, the rating space model does not contain information about which user has assigned a certain rating or to which concrete resource a rating has been assigned. A rating space represents only the association between a rating value and its count. Use the following URIs:

rtm:rs:all
This returns a feed that contains all available rating spaces, that is all available ratings and their values and counts. Sample feed:

```
<?xml version="1.0" encoding="UTF-8"?>
<atom:feed xmlns:thr="http://purl.org/syndication/thread/1.0"
   xmlns:xhtml="http://www.w3.org/1999/xhtml"
```

```
    xmlns:atom="http://www.w3.org/2005/Atom"
    xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
    xmlns:cp="http://www.ibm.com/xmlns/prod/websphere/portal/v7.0/portal-contextual-portal"
    xmlns:opensearch="http://a9.com/-/spec/opensearch/1.1/"
    xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base">
       <atom:author>
          <atom:name>IBM WebSphere Portal/8.0</atom:name>
       </atom:author>
       <atom:id>rtm:rs:all</atom:id>
       <atom:link href="/wps/mypoc/!ut/p/digest!vLQAhj2WCgHcg0_gV7N7XQ/rtm/rs:all?mode=download"

</atom:entry>
```

rtm:rs:empty

This returns a feed that represents the empty set of rating spaces. You can add individual rating spaces to this feed by adding additional query parameters.

Related reference:

"Adding query parameters"
You can add query parameters as required by using the following instructions.

"Querying models in correlation to each other" on page 3185
You can query one model in correlation to another model.

"Other queries" on page 3187
You can add other query parameters, for example for related tags.

Adding query parameters

You can add query parameters as required by using the following instructions.

Sorting the results

Use the query parameters `orderMetric` and `order` to sort entries of a result set.

orderMetric

Use this parameter to specify by what metric you want to sort the result list. Valid values depend on the model that you are using:

For the resource model:

- RESOURCE_ID
- RESOURCE_CREATION_DATE
- RESOURCE_LAST_MODIFIED_DATE
- RESOURCE_TYPE_SCHEMA
- RESOURCE_SCHEME_SPECIFIC_PART
- RESOURCE_URI
- RESOURCE_TITLE

For the tag model:

- TAG_ID
- TAG_CREATION_DATE

- TAG_LAST_MODIFIED_DATE
- TAG_LOCALE
- TAG_NAME
- TAG_RESOURCE_ID
- TAG_OWNER_ID
- TAG_SCOPE

For the tag space model:

- TAG_SPACE_COUNT_REVERSE_NAME. This is the default.
- TAG_SPACE_NAME
- TAG_SPACE_COUNT
- TAG_SPACE_CREATION_DATE
- TAG_SPACE_LAST_MODIFIED_DATE
- TAG_SPACE_COUNT_NAME

For the rating model:

- RATING_ID
- RATING_CREATION_DATE
- RATING_LAST_MODIFIED_DATE
- RATING_VALUE
- RATING_RESOURCE_ID
- RATING_OWNER_ID
- RATING_SCOPE

For the rating space model:

- RATING_SPACE_VALUE
- RATING_SPACE_COUNT
- RATING_SPACE_CREATION_DATE
- RATING_SPACE_LAST_MODIFIED_DATE

order=ASC|DESC
Use this parameter to specify whether you want to sort in ascending or descending order. Valid values are `ASC` and `DESC`.

Example:

```
tm:ts:all&orderMetric=TAG_SPACE_COUNT_NAME&order=ASC
```

This returns a feed that contains all available tag spaces, that is all available tags and their names and counts. The results are sorted in ascending order, first by tag count, and, if counts are equal, by tags name.

Limiting the results

You can use the query parameters `start-index` and `max-results` to limit the query results in the feed to a subset.

start-index
Use this parameter to specify the first item from the overall result set that you want to have returned.

max-results
Use this parameter to specify how many additional items after the start item you want to have returned.

Examples:

1. `uri=tos:typeahead&term=A&max-results=10`

   This example returns a feed that contains at the most the first 10 elements of the result.
2. `uri=tos:typeahead&term=A&start-index=20&max-results=10`

   This example returns a feed that contains at the most 10 elements, starting with the 20th element from the result.
3. `tm:name:`*`tag_name`*`&start-index=5&max-results=5`

   This example returns a feed that contains 5 tag entries of the overall result set that match the name `tag_name`, leaving out the first four results, and returning the following 5 tag entries.

Using scopes

Users can apply both tags and ratings as community tags or personal tags, either public or private. For details refer to the topic about how tagging and rating works in the portal. To control whether you query only community or personal tags or ratings, or both types of tags or ratings, use the parameter `scope`. Valid values are as follows:

For tagging:

COMMUNITY
Use this value to return only community tags.

PERSONAL_PRIVATE
Use this value to return only personal private tags.

PERSONAL_PUBLIC
Use this value to return only personal public tags.

PERSONAL
Use this value to return all personal tags, both public and private. This has the same effect as using the scope parameter with both values `PERSONAL_PRIVATE` and `PERSONAL_PUBLIC` .

ALL Use this value to return all tags, community tags, and personal public and private tags. This has the same effect as using the scope parameter with multiple values `PERSONAL_PRIVATE` , `PERSONAL_PUBLIC`, and `COMMUNITY` .

Valid combinations of values are as follows:

- `COMMUNITY` and `PERSONAL`
- `COMMUNITY` and `PERSONAL_PRIVATE`
- `COMMUNITY` and `PERSONAL_PUBLIC`
- `COMMUNITY` and `PERSONAL_PUBLIC` and `PERSONAL_PRIVATE`
- `PERSONAL_PUBLIC` and `PERSONAL_PRIVATE`

For rating:

COMMUNITY
Use this value to return only community ratings.

PERSONAL_PRIVATE
Use this value to return only personal private ratings.

PERSONAL_PUBLIC
Use this value to return only personal public ratings.

PERSONAL
Use this value to return all personal ratings, both public and private. This has the same effect as using the scope parameter with both values `PERSONAL_PRIVATE` and `PERSONAL_PUBLIC` .

ALL Use this value to return all ratings, community ratings, and personal public and private ratings. This has the same effect as using the scope parameter with multiple values `PERSONAL_PRIVATE` , `PERSONAL_PUBLIC`, and `COMMUNITY` .

Valid combinations of values are as follows:

- `COMMUNITY` and `PERSONAL`
- `COMMUNITY` and `PERSONAL_PRIVATE`
- `COMMUNITY` and `PERSONAL_PUBLIC`
- `COMMUNITY` and `PERSONAL_PUBLIC` and `PERSONAL_PRIVATE`
- `PERSONAL_PUBLIC` and `PERSONAL_PRIVATE`

Example:

```
tm:ts:all&scope=COMMUNITY&scope=PERSONAL_PUBLIC
```

This returns a feed that contains all available tag spaces with community tags and the public tags of the current user.

Locale sensitive queries

You can specify that you want to search only a specific locale or set of locales. This can be useful when you work with URIs that address tags by their name locales. To do this, use the parameter `locale`. Examples:

```
tm:name:tag_name&locale=de
```

This returns a feed that contains all tags that match the name *`tag_name`* in the locale `de`.

```
tm:name:tag_name&locale=de&locale=en
```

This returns a feed that contains all tags that match the name *`tag_name`* in the locale `de` or `en`.

Related concepts:

"Introduction to tagging and rating" on page 1299
Tagging and rating are features that support collaboration and interaction between users when using Web content.

Related reference:

"Normalizing tags" on page 1305
The portal provides several options for normalizing tags. Normalization is a process of transforming a text fragment, such as a tag, into another, more generic representation. This bundles different spellings or grammatical versions of the same lexical word that users might use as tags, for example `color`, `Color`, `COLOR`, `colour`, `colors`, `colored`.

"How tagging and rating works in the portal" on page 1303
Use these topics for general administrative information about tagging and rating in the portal.

"Grouping tags and ratings via resource categorization" on page 1304
Users apply tags and ratings to resources. Users can tag and rate all resources that can be uniquely identified.

"How public and private tags and ratings work in the portal" on page 1303
Users can choose between applying a tag or rating as a private or public tag or rating.

Querying models in correlation to each other

You can query one model in correlation to another model.

To do this, you start with an empty set of one of the available models, and add single entries by using additional query parameters. For details about empty sets and additional query parameters refer to the topic about Adding query parameters.

Examples:

- To correlate resources with tags, you start with the feed that represents an empty set of resources and add single resources based on how these have been tagged.
- To correlate resources with ratings, you start with the feed that represents an empty set of resources and add single resources based on how these have been rated.
- To correlate tags with resources you start with the feed that represents an empty set of tags and add single tags based on the resources to which these tags have been assigned.
- To correlate ratings with resources, you start with the feed that represents an empty set of ratings and add single ratings based on the resources to which these ratings have been assigned.

Note: You cannot correlate a model with itself. For example, the tag model query parameter `tm_param` is not supported for the tag model; equally, the rating model query parameter `rtm_param` is not supported the rating model, and so on. The only exception from this rule is to use the URI `tm:name:related`, which is listed under the topic about *Other queries*.

Correlating the resource model with other models

To correlate the resource model with other models, use the following parameters:

rm:empty&tmparam=tm:name:*tag_name*
: This returns a feed that contains all resources that have been tagged with the tag `tagname`.

rm:empty&tmparam=tm:name:*tag_name*&rmparam=rm:type:*type*
: This returns a feed that contains all resources that are registered with type schema `type` and that have been tagged with the tag `tagname`.

rm:empty&tmparam=tm:name:*tag_name*&rmparam=rm:category:*category_name*
: This returns a feed that contains all resources that are registered under the category `category_name` and that have been tagged with the tag `tag_name`.

Correlating the tag model with other models

To correlate the tag model with other models, use the following parameters:

tm:empty&rmparam=rm:*resource_uri*
: This returns a feed that contains all tags for a resource with the URI `resource_uri`.

tm:empty&rmparam=rm:*resource_uri_1*&rmparam=rm:*resource_uri_2*
This returns a feed that contains all tags for resources with the URIs `resource_uri_1` or `resource_uri_2` .

Correlating the tag space model with other models

To correlate the tag space model with other models, use the following parameters:

tm:ts:empty&rmparam=rm:*resource_uri*
This returns a feed that contains all tag spaces for a resource with the URI `resource_uri`.

tm:ts:empty&rmparam=rm:*resource_uri_1*&rmparam=rm:*resource_uri_2*
This returns a feed that contains all tag spaces for resources with the URIs `resource_uri_1` or `resource_uri_2` .

tm:ts:empty&rmparam=rm:type:*type*
This returns a feed that contains all tag spaces for resources registered with the type schema `type`.

tm:ts:empty&rmparam=rm:category:*category*
This returns a feed that contains all tag spaces for resources registered in category `category`.

tm:ts:empty&rmparam=rm:type:*type_1*&rmparam=rm:type:*type_2*
This returns a feed that contains all tag spaces for resources registered with the type schema `type_1` or `type_2` .

tm:ts:empty&rmparam=rm:category:*category_1*&rmparam=rm:category:*category_2*
This returns a feed that contains all tag spaces for resources registered in category `category_1` or `category_2` .

Correlating the rating model with other models

rtm:empty&rmparam=rm:*resource_uri*
This returns a feed that contains all ratings for a given resource with the URI `resource_uri` .

rtm:empty&rmparam=rm:*resource_uri1*&rmparam=rm:resource_uri2
This returns a feed that contains all ratings for a given resource with the URIs `resource_uri_1` or `resource_uri_2` .

Correlating the rating space model with other models

rtm:rs:empty&rmparam=rm:*resource_uri*
This returns a feed that contains all rating spaces for a given resource with the URI `resource_uri` .

rtm:rs:empty&rmparam=rm:*resource_uri1*&rmparam=rm:resource_uri2
This returns a feed that contains all ratings for a given resource with the URIs `resource_uri_1` or `resource_uri_2` .

rtm:rs:empty&rmparam=rm:type:*type*
This returns a feed that contains all rating spaces for resources registered with the type schema `type` .

rtm:rs:empty&rmparam=rm:category:*category*
This returns a feed that contains all rating spaces for resources registered in the category `category` .

rtm:rs:empty&rmparam=rm:type:*type_1*&rmparam=rm:type:*type2*
This returns a feed that contains all rating spaces for resources registered with type schema `type_1` or `type_2` .

rtm:rs:empty&rmparam=rm:category: *category_1*
&rmparam=rm:category:*category_2*
This returns a feed that contains all rating spaces for resources registered in category `category_1` or `category_2` .

"Adding query parameters" on page 3181
You can add query parameters as required by using the following instructions.

Other queries

You can add other query parameters, for example for related tags.

The query for related tags can be useful to search for related content, that is for resources that are or can be similar to a given resource. Resources are considered to be similar if they share at least one tag with a given resource.

Example: To search for resources `r2 . . . rn` that are related to a resource `r1`, you determine the tags of resource `r1` and hand them over to the following query:
`tm:ts:related&tmparam=tm:name:`*`tagname`*

This query returns a feed that contains all tags related to the tag names or set of tags that you specified. The query results in a list of all tags assigned to all resources that have been assigned at least one of the tags that resource `r1` has also been assigned. In other words, This query lists all tags of all similar or related resources `r2 . . . rn`. You can now use this list to query for all these listed resources `r2...rn`.

"Type-ahead with the deprecated tag widget"
The tag widget from earlier IBM WebSphere Portal Express versions provided a query for the type-ahead feature. With portal V 8.5, that tag widget is deprecated. The type-ahead feature makes it easier for users to find suitable tags. Type-ahead supports users when they work with tags. For example, when users apply tags using the tag widget, or when they search for tags, for example by using the open search functionality, type-ahead provides users suggestions for tags that other users have applied already before. Type-ahead can also help reduce the number of variants of tags.

"Search suggestions for tag names" on page 3189
To make search for tag names by users easier, search suggestions provide suggestions for tag names as they appear in the tag cloud and in the tag result portlet.

"Querying for the OpenSearch description document" on page 3190
You can query for the OpenSearch description document.

Type-ahead with the deprecated tag widget:

The tag widget from earlier IBM WebSphere Portal Express versions provided a query for the type-ahead feature. With portal V 8.5, that tag widget is deprecated. The type-ahead feature makes it easier for users to find suitable tags. Type-ahead supports users when they work with tags. For example, when users apply tags using the tag widget, or when they search for tags, for example by using the open search functionality, type-ahead provides users suggestions for tags that other users have applied already before. Type-ahead can also help reduce the number of variants of tags.

Note: The type-ahead feature works only with the dialog tag widget of the default tagging user interface of portal versions earlier than V 8.5. With WebSphere Portal Express V 8.5, the tag and rating widgets of earlier portal versions are deprecated. To query for the type-ahead feature, use the following query:
