Last Successful Probe	A specified amount of time has passed since a probe or performance monitor was able to collect data about a storage system. You can use this alert to be notified when up-to-date configuration, status, or performance data is not being collected about a storage system and its existing data might be stale. This situation might occur if the resource, network, or IBM Spectrum Control server is unavailable.
Last Successful Monitor	
Performance Monitor Status*	<p>One of the following statuses is detected for a performance monitor:</p> <p>Not Normal An error or warning occurred during data collection. This status indicates that a performance monitor did not collect any data, or only collected a partial set of data about a resource.</p> <p>Warning A performance monitor completed, but did not collect a complete set of performance data. This status might occur if the resource was rebooted during data collection, no valid performance data was provided by the resource, or a communication error occurred with the resource or its associated agent.</p> <p>Error A performance did not complete when it attempted to collect performance data about the resource. This status might occur if the resource cannot be reached during data collection, or if no configuration data is available for the resource.</p> <p>For details about why a specific status occurred, check the log for the performance monitor. To check the log, go to the details page for a resource, click Data Collection, and select Actions > Open Logs in the Performance Monitor section on the Data Collection page.</p>
Probe Status*	<p>One of the following statuses is detected for a probe:</p> <p>Not Successful An error or warning occurred during data collection. This status indicates that a probe did not collect any data, or only collected a partial set of data about a resource.</p> <p>Warning A probe completed, but might not have collected a complete set of data. This status might occur if data cannot be collected about one or more of the internal resources of a resource.</p> <p>Error (default) A probe did not complete when it attempted to collect asset data about the resource. This status might occur if the resource cannot be reached during data collection.</p> <p>For details about why a specific status occurred, check the log for the probe. To check the log, go to the details page for a resource, click Data Collection, and select Actions > Open Logs in the Probe section on the Data Collection page.</p>
Status	<p>One of the following statuses is detected for a storage system:</p> <p>Not Normal An error or warning status was detected for a storage system.</p> <p>Warning A warning status was detected for a storage system. This status might occur if a storage system comes online or if its version changes.</p> <p>Error An error status was detected for a storage system. This status might occur if the cooling fans in a storage system are stopped and the internal temperature is too high or if a storage system goes offline.</p>

- [Triggering conditions for storage system internal resource alerts](#)

You can set up IBM Spectrum Control so that it examines the attributes, capacity, and performance of the internal resources of storage systems and notifies you when changes or violations are detected.

Triggering conditions for storage system internal resource alerts

You can set up IBM Spectrum® Control so that it examines the attributes, capacity, and performance of the internal resources of storage systems and notifies you when changes or violations are detected.

Alerts can notify you of general changes and performance issues on the following internal resources of storage systems:

- [Internal resources \(common conditions\)](#)
- [Clusters](#)
- [Drives](#)
- [Disk Groups](#)
- [FC Ports](#)
- [Filesets](#)
- [File Systems](#)
- [File System Pools](#)
- [Host Connections](#)
- [I/O Groups](#)
- [IP Ports](#)
- [Managed Disks](#)
- [Modules](#)
- [Network Shared Disks](#)
- [Nodes](#)
- [Pools](#)
- [Quotas](#)
- [RAID Arrays](#)
- [Shares](#)
- [Volumes](#)

Important: Not all the attributes upon which you can alert are listed here. To view a complete list of attributes upon which you can alert, go to Settings > Alert Policies. Double-click a default policy for a storage system. Click Edit Alert Definitions on the Alert Definitions tab. View the attributes that are available in the general, capacity, and performance categories. Note that the attributes that are automatically configured for alerts in the default alert policies, or default alerts, have a status of Active. In the tables, default alerts are marked with an asterisk (*).

Tips:

- The type of storage system determines which attributes and performance conditions are available for alerts. For example, triggering conditions for shares are available only for storage systems that are configured for file storage, such as Storwize® V7000 Unified.
- For capacity attributes, you can generate alerts when the amount of storage is greater than, less than, or equal to a specified value. You can also determine the unit of measurement for the attribute, such as KiB, MiB, GiB, or TiB.

Internal resources (common conditions)

There are a number of alert conditions that are common to many of the internal resources in a storage system. These common conditions represent key changes in your storage infrastructure. For example, you can specify conditions that generate alerts when specific internal resources are added to or deleted from a storage system, or when current data isn't being collected about resources.

By default, asset, capacity, and configuration metadata for storage systems is aggregated and collected daily. Define alerts to track daily changes to the attributes and conditions of the internal resources in your storage systems.

Table 1. Triggering attributes and conditions that are common to internal resources

General Attributes	Triggering Conditions for Attributes
New resource	A resource is detected for the first time. Use this alert to be notified when new physical and logical resources are added to a storage system.
Removed physical resource	A previously monitored resource can no longer be found. Historical data about the resource is retained, but no current data is being collected. Use these alerts to be notified if a physical or logical resource is removed, deleted, or becomes unavailable.
Deleted logical resource	Physical resources include disks, RAID arrays, I/O groups, ports, nodes, host connections, clusters, and file systems. Logical resources include volumes, pools, filesets, and shares.

Clusters

Table 2. Triggering attributes and conditions for general changes on clusters

General Attributes	Triggering Conditions for Attributes
New Cluster	A cluster is detected for the first time.
Removed NAS Cluster	A previously monitored NAS cluster can no longer be found. Historical data about the cluster is retained, but no current data is being collected. Use this alert to be notified if a cluster is removed or becomes unavailable.

Drives

Table 3. Triggering attributes and conditions for general changes on storage system drives

General Attributes	Triggering Conditions for Attributes
New drive	A drive is detected for the first time.
Removed drive	A previously monitored drive can no longer be found. Historical data about the drive is retained, but no current data is being collected. Use this alert to be notified if a drive is removed or becomes unavailable.

Table 4. Triggering attributes and conditions for capacity changes on drives

Capacity Attributes	Triggering Conditions for Attributes
Available Drive Capacity (Previously known as Available Disk Space)	The capacity that is available (not allocated) on the drive.
Capacity (Previously known as Disk Capacity)	The total amount of storage capacity that is on the drive.

Disk Groups

Table 5. Triggering attributes and conditions for general changes on storage system disk groups

General Attributes	Triggering Conditions for Attributes
New Disk Group	A disk group is detected for the first time.
Removed Disk Group	A previously monitored disk group can no longer be found. Historical data about the disk group is retained, but no current data is being collected. Use this alert to be notified if a disk group is removed or becomes unavailable.
Status	<p>One of the following statuses is detected for a disk group:</p> <p>Not Normal An error or warning condition is detected on a disk group.</p> <p>Warning A warning condition is detected on a disk group. This condition might occur if any of the disks in the disk group goes offline.</p> <p>Error An error condition is detected on a disk group. This condition might occur under the following conditions:</p> <ul style="list-style-type: none"> The percentage of remaining, unused volume capacity in a disk group that is not available to be used is too high. The available capacity in a disk group that is not reserved for volumes is too low. The disk group provisioned capacity exceeds the warning or critical threshold boundary value.

FC Ports

Table 6. Triggering attributes and conditions for general changes on Fibre Channel ports

General Attributes	Triggering Conditions for Attributes
New FC Port	A new FC port was detected for the first time.
Removed FC Port	A previously monitored FC port can no longer be found. Historical data about the port is retained, but no current data is being collected. Use this alert to be notified if a port is deleted or becomes unavailable.
Status	<p>One of the following statuses is detected for an FC port:</p> <p>Not Normal An error or warning condition is detected on a port.</p> <p>Warning A warning condition is detected on a port.</p> <p>Error An error condition is detected on a port.</p>

Filesets

Table 7. Triggering attributes and conditions for general changes on filesets

General Attributes	Triggering Conditions for Attributes
Deleted NAS Fileset	A previously monitored NAS fileset can no longer be found. Historical data about the fileset is retained, but no current data is being collected. Use this alert to be notified if a fileset is deleted or becomes unavailable.
New Fileset	A fileset is detected for the first time.
State	A fileset is linked to a file system, unlinked from a file system, or deleting.

File Systems

Table 8. Triggering attributes and conditions for general changes on file systems

General Attributes	Triggering Conditions for Attributes
New File System	A file system is detected for the first time.
Removed NAS File System	A previously monitored NAS file system can no longer be found. Historical data about the file system is retained, but no current data is being collected. Use this alert to be notified if a file system is deleted or becomes unavailable.

File System Pools

Table 9. Triggering attributes and conditions for general changes on file system pools

General Attributes	Triggering Conditions for Attributes
Deleted Pool	A previously monitored NAS pool can no longer be found. Historical data about the pool is retained, but no current data is being collected. Use this alert to be notified if a pool is deleted or becomes unavailable.
New Pool	A NAS pool is detected for the first time.

Host Connections

Table 10. Triggering attributes and conditions for general changes on host connections

General Attributes	Triggering Conditions for Attributes
New Host Connection	A host connection is detected for the first time.
Removed Host Connection	A previously monitored host connection can no longer be found. Historical data about the host connection is retained, but no current data is being collected. Use this alert to be notified if a host connection is removed or becomes unavailable.

Table 11. Triggering attributes and conditions for changes to performance metrics for unmap operations on host connections

Performance Attribute	Triggering Conditions for Attributes
Data Rate (Unmap)	Define an alert to monitor the average number of MiBs per second that were unmapped. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.1 or later.
Overall I/O Rate (Unmap)	Define an alert to monitor the average number of unmap operations per second. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.1 or later.
Peak Response Time (Unmap)	Define an alert to monitor the worst response time measured for an unmap operation in the sample interval. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.1 or later.
Response Time (Unmap)	Define an alert to monitor the average number of milliseconds required to complete an unmap operation. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.1 or later.
Unaligned Unmap I/O Rate	Define an alert to monitor the average number of volumes unmap operations per second that are not aligned on an 8K boundary. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.1 or later.

I/O Groups

Table 12. Triggering attributes and conditions for general changes on I/O groups

General Attributes	Triggering Conditions for Attributes
New I/O Group	A new I/O group was detected for the first time.
Removed I/O Group	A previously monitored I/O group can no longer be found. Historical data about the I/O group is retained, but no current data is being collected. Use this alert to be notified if an I/O group is removed or becomes unavailable.

IP Ports

Triggering attributes and conditions are available for Internet Protocol ports on the nodes on block storage systems that run IBM Spectrum Virtualize, such as SAN Volume Controller, the IBM® Storwize family, and some models of the IBM FlashSystem® family.

Table 13. Triggering attributes and conditions for general changes on IP ports

General Attributes	Triggering Conditions for Attributes
Status	One of the following statuses was detected for an IP port: <ul style="list-style-type: none"> Configured Unconfigured
Removed Port	A previously monitored IP port can no longer be found. Historical data about the port is retained, but no current data is being collected. Use this alert to be notified if a port is deleted or becomes unavailable.
New Port	A new IP port was detected for the first time.
Host Attach	An IP port was attached to, or detached from, a host.
Storage Attach	An IP port was attached to, or detached from, a storage system.
Management	One of the following management statuses was detected for an IP port: <ul style="list-style-type: none"> Configured Unconfigured
Remote Copy Relationship	The remote copy relationship changed, or one of the following remote copy statuses was detected for an IP port: <ul style="list-style-type: none"> Active Unconfigured Standby

Managed Disks

Table 14. Triggering attributes and conditions for general changes on managed disks

General Attributes	Triggering Conditions for Attributes
Managed Disk Status	One of the following statuses is detected for a managed disk: Not Normal An error or warning status was detected on a managed disk. Warning A warning status was detected on a managed disk. Error An error status was detected on a managed disk.
New Managed Disk	A new managed disk was detected for the first time.
Removed Managed Disk	A previously monitored managed disk can no longer be found. Historical data about the managed disk is retained, but no current data is being collected. Use this alert to be notified if a managed disk is removed or becomes unavailable.

Table 15. Triggering attributes and conditions for capacity changes on managed disks

Capacity Attributes	Triggering Conditions for Attributes
Available Capacity	The unused storage capacity on the managed disk.
Capacity (Previously known as Total Space)	The total capacity on the managed disk on the storage system. This attribute is only available for Storwize V7000 storage systems that are configured as back-end storage.

Modules

Table 16. Triggering attributes and conditions for general changes on modules

General Attributes	Triggering Conditions for Attributes
Deleted Module	A previously monitored module can no longer be found. Use this alert to be notified if a module is removed or becomes unavailable.

Network Shared Disks

Table 17. Triggering attributes and conditions for general changes on NSDs

General Attributes	Triggering Conditions for Attributes
New NSD	A new NSD was detected for the first time.
Removed NSD	A previously monitored NSD can no longer be found. Historical data about the NSD is retained, but no current data is being collected. Use this alert to be notified if an NSD is removed or becomes unavailable.
Status	One of the following statuses is detected for an NSD: Not Normal An error or warning status was detected on an NSD. Warning A warning status was detected on an NSD. This status might occur if a storage system comes online or if its version changes. Error An error status was detected on an NSD.

Nodes

Table 18. Triggering attributes and conditions for general changes on nodes

General Attributes	Triggering Conditions for Attributes
New Node	A new node was detected for the first time.
Removed Node (Block storage)	A previously monitored node can no longer be found. Historical data about the node is retained, but no current data is being collected. Use this alert to be notified if a node is removed or becomes unavailable.
Removed NAS Node (File storage)	A previously monitored NAS node can no longer be found. Historical data about the node is retained, but no current data is being collected. Use this alert to be notified if a node is removed or becomes unavailable.
Cloud Gateway Status (File storage)	One of the following statuses is detected for a node. This attribute is available only for IBM Spectrum Scale. Not Running The gateway service is not running because, for example, the service is stopped, no cloud account is configured, or the connection to the cloud provider failed. Not Installed The node is not a cloud gateway. No File System The node is a cloud gateway and the gateway service is running, but the node is not yet assigned to a file system. Stopped The node is a cloud gateway for a file system, but the gateway service is stopped. No Cloud Account The node is a cloud gateway for a file system and the gateway service is running, but no cloud account is configured. Disconnected The node is a cloud gateway, the gateway service is running, and a cloud account is configured, but the connection to the cloud provider failed.

Table 19. Triggering attributes and conditions for changes to performance metrics for cache fullness on nodes

Performance Attributes	Triggering Conditions for Attributes
Max Read Cache Fullness	Define an alert to monitor the maximum amount of the lower cache which the cache partitions of the pools that are managed by the node use for read operations. If the maximum value for the cache reaches 100%, the read cache partition for one or more of the pools is full. The read operations that pass through the node to the affected pools will be queued and the I/O response times will increase for the volumes in the affected pools. This metric applies to systems that are running IBM Spectrum Virtualize V7.3 or later.
Max Write Cache Fullness	Define an alert to monitor the maximum amount of the lower cache which the cache partitions of the pools that are managed by the node use for write operations. If the maximum value for the cache reaches 100%, the write cache partition for one or more of the pools is full. The write operations that pass through the node to the affected pools will be queued and the I/O response times will increase for the volumes in the affected pools. This metric applies to systems that are running IBM Spectrum Virtualize V7.3 or later.
Read Cache Fullness	Define an alert to monitor the average amount of the lower cache which the cache partitions of the pools that are managed by the node use for read operations. Use this alert to monitor the average cache fullness for read operations to identify the nodes that experience heavy cache usage. This metric applies to systems that are running IBM Spectrum Virtualize V7.3 or later.
Write Cache Fullness	Define an alert to monitor the average amount of the lower cache which the cache partitions of the pools that are managed by the node are using for write operations. Use this alert to monitor the average cache fullness for write operations to identify the nodes that experience heavy cache usage. This metric applies to systems that are running IBM Spectrum Virtualize V7.3 or later.

Table 20. Triggering attributes and conditions for changes to performance metrics for recovering data in data reduction pools on nodes

Performance Attributes	Triggering Conditions for Attributes
Data Rewrite Rate	Define an alert to monitor the rate at which data is rewritten when a host overwrites data in data reduction pools on the node. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.2 or later.
Extent Collection Rate	Define an alert to monitor the number of volume extents that were processed for garbage collection. The reclaimable capacity in the volume extents is collected so that it can be reused in the data reduction pools on the node. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.2 or later.
Data Movement Rate	Define an alert to monitor the rate at which valid data in a reclaimed volume extent is moved to a new extent in the data reduction pool on the node. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.2 or later.
New Address Write Rate	Define an alert to monitor the rate at which capacity is used to write the host's data to unallocated addresses in the data reduction pool on the node. Use this alert to determine which hosts are increasing the amount of capacity that is being written to data reduction pools on a node. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.2 or later.
Reclaimable Capacity	Define an alert to monitor the amount of capacity that can be reclaimed in the data reduction pools on the node. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.2 or later.
Recovered Capacity Rate	Define an alert to monitor the rate at which capacity is recovered by garbage collection for reuse in the data reduction pools on the node. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.2 or later.

Pools

Table 21. Triggering attributes and conditions for general changes on pools

General Attributes	Triggering Conditions for Attributes
Deleted Pool	A previously monitored pool can no longer be found. Historical data about the pool is retained, but no current data is being collected. Use this alert to be notified if a pool is deleted or becomes unavailable.
New Storage Pool	A new pool was detected for the first time.
Status	One of the following statuses is detected for a pool: Not Normal An error or warning condition is detected on a pool. Warning A warning condition is detected on a pool. This condition might occur if a pool goes offline. Error An error condition is detected on a pool. This condition might occur under the following conditions: <ul style="list-style-type: none"> The percentage of remaining, unused volume capacity in a pool that is not available to be used is too high. The available capacity in a pool that is not reserved for volumes is too low. The pool total provisioned capacity exceeds the warning or critical threshold boundary value.

Table 22. Triggering attributes and conditions for capacity changes on pools

Capacity Attributes	Triggering Conditions for Attributes
Adjusted Used Capacity	The amount of capacity that can be used without exceeding the capacity limit. For example, you set a capacity limit of 80% for your pools. You want to get an informational alert when the adjusted used capacity exceeds 60% and a critical alert when the adjusted used capacity exceeds 80%. So, you define an informational alert with these parameters: Adjusted Used Capacity ≥ 60% And, you define a critical alert with these parameters: Adjusted Used Capacity ≥ 80%

Capacity Attributes	Triggering Conditions for Attributes
Available Repository Capacity	The amount of available, unallocated storage space on all extents in the repository of a pool for Track Space-Efficient (TSE) thin-provisioning. This attribute applies only to the DS8000® storage systems. You can use this alert to be notified about space-efficient volumes.
Available Virtual Capacity	The amount of provisioned capacity in a thin-provisioned pool that is not used by volumes.
Available Written Capacity (Previously known as Effective Available Capacity)	The total amount of the provisioned capacity in the pools that is not allocated to the volumes in the pools.
Capacity-to-Limit	The amount of capacity that is available for storing data before the capacity limit is reached. For example, if you set a capacity limit, you can define a warning alert when the available capacity relative to the capacity limit, falls below the value that you specify, such as: Capacity-to-Limit ≤ 500 GiB
Compression Savings	The estimated percentage of capacity that is saved by using data compression. The percentage is calculated across all compressed volumes in the pool and does not include the capacity of non-compressed volumes. Inline compression is a software feature that is supported by FlashSystem A9000 and FlashSystem A9000R, IBM Spectrum Accelerate, XIV® storage systems with firmware version 11.6 or later, and resources that run IBM Spectrum Virtualize.
Deduplication Savings	The estimated percentage of capacity that is saved by using data deduplication. The percentage is calculated across all deduplicated volumes in the pool and does not include the capacity of volumes that are not deduplicated. Available for resources that run IBM Spectrum Virtualize 8.1.3 or later.
Mapped Capacity (Previously known as Assigned Volume Space)	The amount of space on all the volumes in a pool that are mapped or assigned to host systems. For a thin-provisioning pool, this value includes the provisioned capacity of thin-provisioned volumes, which might exceed the total capacity in the pool. For Hitachi VSP non-thin provisioning pool capacity, this value is the sum of assigned regular host-accessible volumes. Volumes that are used for thin-provisioning (pool volumes) are not included.
Enterprise HDD Capacity	The total capacity on Enterprise hard disk drives in the pool. Easy Tier® can use the capacity on these drives to retire the volume extents in the pool.
Enterprise HDD Available Capacity	The available capacity on Enterprise hard disk drives in the pool. Easy Tier can use the available capacity to retire the volume extents in the pool.
Enterprise HDD Available Capacity (%)	The percentage of capacity on Enterprise hard disk drives in the pool that is available. Easy Tier can use the available capacity to retire the volume extents in the pool.
Nearline HDD Capacity	The total capacity on Nearline hard disk drives in the pool. Easy Tier can use the capacity on these drives to retire the volume extents in the pool.
Nearline HDD Available Capacity	The available capacity on Nearline hard disk drives in the pool. Easy Tier can use the available capacity to retire the volume extents in the pool.
Nearline HDD Available Capacity (%)	The percentage of capacity on Nearline hard disk drives in the pool that is available. Easy Tier can use the available capacity to retire the volume extents in the pool.
Provisioned Capacity (Previously known as Virtual Allocation)	The percentage of physical space in a pool that is committed to the provisioned capacity of the volumes in the pool. You can use this alert to be notified about space-efficient volumes.
Repository Space	The amount of space on all extents in the repository of a pool. This attribute applies only to the DS8000 storage systems.
Reserved Capacity (Previously known as Reserved Pool Space)	The amount of unused capacity in a pool that is reserved for provisioning and optimization tasks. Pool capacity is reserved when a provisioning or optimization task is created, and used when the task is run.
Reserved Volume Capacity (Previously known as Unused Space)	The amount of pool capacity that is reserved but has not been used yet to store data on the thin-provisioned volume.
Safeguarded Capacity	The total amount of capacity that is used to store volume backups that are created by the Safeguarded Copy feature in DS8000.
Shortfall	The difference between the amount of provisioned capacity that is committed to the volumes in the pools and the actual physical capacity that is available in the pools. As the provisioned capacity is allocated to the thin-provisioned and compressed volumes, the shortfall increases and becomes more critical. This value is determined by the formula, <i>Overprovisioned Capacity ÷ Committed but Unused Capacity</i> For example, the physical capacity of the pools is 70 GiB, but 150 GiB of provisioned capacity was committed to the thin-provisioned volumes. If the volumes are using 50 GiB, then there is still 100 GiB committed to those volumes (150 GiB – 50 GiB) with only 20 GiB of available pool capacity (70 GiB – 50 GiB). Because only 20 GiB of the pool capacity is available, 80 GiB of the committed capacity cannot be allocated (100 GiB – 20 GiB).
SCM Capacity	The total capacity on Storage Class Memory (SCM) drives in the pool. Easy Tier can use the capacity on SCM drives to retire the volume extents in the pool. Available for IBM Spectrum Virtualize systems, such as IBM FlashSystem 9100, IBM FlashSystem 7200, and the IBM Storwize family.
SCM Available Capacity	The available capacity on Storage Class Memory (SCM) drives in the pool. Easy Tier can use the available capacity to retire the volume extents in the pool. Available for IBM Spectrum Virtualize systems, such as IBM FlashSystem 9100, IBM FlashSystem 7200, and the IBM Storwize family.
SCM Available Capacity (%)	The percentage of capacity on Storage Class Memory (SCM) drives in the pool that is available. Easy Tier can use the available capacity to retire the volume extents in the pool. Available for IBM Spectrum Virtualize systems, such as IBM FlashSystem 9100, IBM FlashSystem 7200, and the IBM Storwize family.
Tier 0 Flash Capacity	The total capacity on Tier 0 flash solid-state drives in the pool. Easy Tier can use the capacity on these drives to retire the volume extents in the pool.
Tier 0 Flash Available Capacity	The available capacity on Tier 0 flash solid-state drives in the pool. Easy Tier can use the available capacity to retire the volume extents in the pool.
Tier 0 Flash Available Capacity (%)	The percentage of capacity on Tier 0 flash solid-state drives in the pool that is available. Easy Tier can use the available capacity to retire the volume extents in the pool.

Capacity Attributes	Triggering Conditions for Attributes
Tier 1 Flash Capacity	The total capacity on Tier 1 flash solid-state drives in the pool. Easy Tier can use the capacity on these drives to retier the volume extents in the pool.
Tier 1 Flash Available Capacity	The available capacity on Tier 1 flash solid-state drives in the pool. Easy Tier can use the available capacity to retier the volume extents in the pool.
Tier 1 Flash Available Capacity (%)	The percentage of capacity on Tier 1 flash solid-state drives in the pool that is available. Easy Tier can use the available capacity to retier the volume extents in the pool.
Tier 2 Flash Capacity	The total capacity on Tier 2 flash, high-capacity drives in the pool. Easy Tier can use the capacity on these drives to retier the volume extents in the pool. Available for DS8000 storage systems.
Tier 2 Flash Available Capacity	The available capacity on Tier 2 flash, high-capacity drives in the pool. Easy Tier can use the available capacity to retier the volume extents in the pool. Available for DS8000 storage systems.
Tier 2 Flash Available Capacity (%)	The percentage of capacity on Tier 2 flash, high-capacity drives in the pool that is available. Easy Tier can use the available capacity to retier the volume extents in the pool. Available for DS8000 storage systems.
Total Capacity Savings (Previously known as Total Data Reduction Savings)	The estimated percentage of capacity that is saved by using data deduplication, data compression, and thin provisioning. Available for FlashSystem A9000 and FlashSystem A9000R, IBM Spectrum Accelerate, XIV storage systems with firmware version 11.6 or later, and resources that run IBM Spectrum Virtualize.
Total Reserved Capacity	The total amount of space on the pool that is reserved for provisioning and optimization tasks. Pool space is reserved when a provisioning or optimization task is created, and allocated when the task is run.
Used Capacity (Previously known as Allocated Space)	The amount of space that is reserved for all the volumes in a pool.
Used Capacity (%) (Previously known as Physical Allocation)	The percentage of physical capacity in the pool that is used by the standard-provisioned volumes, the thin-provisioned volumes, and the volumes in child pools. This value is always less than or equal to 100% because you cannot allocate more physical space than is available in a pool. This value is determined by the formula, $Used\ Capacity \div Capacity \times 100$. For example, if the space that is reserved for volumes is 50 GiB for a volume size of 200 GiB, used capacity is 25%.
Used Repository Space	The amount of used capacity on all extents in the repository of a pool. This attribute applies only to the DS8000 storage systems. You can use this alert to be notified about space-efficient volumes.
Used Volume Space	The amount of space on the storage system that is used by volumes.
Used Written Capacity (%) (Previously known as Effective Used Capacity)	The percentage of capacity that is provisioned to the standard-provisioned volumes and the thin-provisioned volumes, given the drive compression savings.
Used Written Capacity (Previously known as Effective Used Capacity)	The total amount of provisioned capacity that is used by all the volumes given the drive compression savings.
User Reserved Capacity	The amount of space in the pools on the storage system that is reserved for user-defined purposes.
Virtual Capacity Limit	The maximum amount of virtual storage space available to allocate to volumes in the storage pools that are associated with the storage system. You can use this alert to be notified about space-efficient volumes.
Virtual Volume Space	The total amount of physical space in a pool that is committed to the total virtual capacity of the volumes in the pool. You can use this alert to be notified about space-efficient volumes.
Written Capacity Limit (Previously known as Effective Capacity)	The amount of provisioned capacity that can be created, given the drive compression savings.

Table 23. Triggering attributes and conditions for changes to performance metrics for cache fullness on pools

Performance Attributes	Triggering Conditions for Attributes
Read and Write Cache Fullness	Define an alert to monitor the average amount of the lower cache which the pools' cache partitions on the nodes use for read and write operations. Use this alert to monitor the average cache fullness for read and write operations to identify the pools that experience heavy cache usage. This metric applies to systems that are running IBM Spectrum Virtualize V7.3 or later.
Max Read and Write Cache Fullness	Define an alert to monitor the maximum amount of the lower cache, which the cache partitions on the nodes that manage the pool use for read and write operations. If the maximum value for the cache reaches 100%, one or more cache partitions on one or more pools is full. The operations that pass through the pools with full cache partitions will be queued and I/O response times will increase for the volumes in the affected pools. This metric applies to systems that are running IBM Spectrum Virtualize V7.3 or later.

Quotas

Table 24. Triggering attributes and conditions for general changes on quotas

General Attributes	Triggering Conditions for Attributes
Deleted Quota	A previously monitored quota can no longer be found. Historical data about the quota is retained, but no current data is being collected. Use this alert to be notified if a quota is deleted or becomes unavailable.
New Quota	A new quota was detected for the first time.

RAID Arrays

Table 25. Triggering attributes and conditions for general changes on RAID arrays

General Attributes	Triggering Conditions for Attributes
New RAID Array	A new RAID array was detected for the first time.
Removed RAID Array	A previously monitored RAID array can no longer be found. Historical data about the RAID array is retained, but no current data is being collected. Use this alert to be notified if a RAID array is removed or becomes unavailable.
Status	One of the following statuses is detected for a RAID array: Not Normal An error or warning condition is detected on a RAID array. Warning A warning condition is detected on a RAID array. Error An error condition is detected on a RAID array.

Table 26. Triggering attributes and conditions for capacity changes on RAID arrays

Capacity Attributes	Triggering Conditions for Attributes
Available Physical Capacity, Available Physical Capacity (%)	The amount and percentage of storage space that is unused on all the disk drive modules (DDMs) in the RAID array. Available for RAID arrays with disk drive modules that use inline data compression, such as RAID arrays on FlashSystem 9100 and FlashSystem 900.
Compression Savings, Compression Savings (%)	For compressed RAID arrays, the amount and percentage of capacity that is saved by using drive compression.
Capacity (Previously known as Total Space)	For uncompressed RAID arrays, the total capacity is the same as the physical capacity and represents the total storage capacity of all the DDMs in the array. For compressed RAID arrays, the total capacity is the estimated amount of data that can be written to the array. This value is larger than the physical capacity as the drive compression is used to reduce the size of the data.

Table 27. Triggering attributes and conditions for changes to performance metrics for RAID arrays

Performance Attribute	Triggering Conditions for Attributes
Data Rate	The average rate at which data is transferred in MiB per second.
I/O Rate	The average number of operations per second.
Response Time	The average number of milliseconds required to complete an operation.
Transfer size	The average number of KiB that are transferred per I/O operation.
Disk Utilization Percentage	The average percentage of time the disks that are associated with an array are busy.
Sequential I/O Percentage	The percentage of operations among all I/O operations that were sequential I/O operations.

Shares

Table 28. Triggering attributes and conditions for general changes on shares

General Attributes	Triggering Conditions for Attributes
New Share	A new share was detected for the first time.
Deleted Share	A previously monitored share can no longer be found. Historical data about the share is retained, but no current data is being collected. Use this alert to be notified if a share is deleted or becomes unavailable.

Volumes

Table 29. Triggering attributes and conditions for general changes on volumes

General Attributes	Triggering Conditions for Attributes
Deleted Volume	A previously monitored volume can no longer be found. Historical data about the volume is retained, but no current data is being collected. Use this alert to be notified if a volume is deleted or becomes unavailable. If you are doing tasks where many volumes are being deleted, you might want to temporarily disable alerts that use the Deleted Volume attribute. For example, you might want to disable Deleted Volume alerts temporarily if you are doing maintenance tasks or decommissioning storage.
New Volume	A new volume was detected for the first time.
Status	One of the following statuses is detected for a volume: Not Normal An error or warning condition is detected on a RAID array. Warning A warning condition is detected on a RAID array. Error An error condition is detected on a RAID array.

Table 30. Triggering attributes and conditions for capacity changes on volumes

Capacity Attributes	Triggering Conditions for Attributes
Compression Savings	The estimated percentage of capacity that is saved by using data compression. Inline compression is a software feature that is supported by FlashSystem A9000 and FlashSystem A9000R, IBM Spectrum Accelerate, XIV storage systems with firmware version 11.6 or later, and resources that run IBM Spectrum Virtualize.

Capacity Attributes	Triggering Conditions for Attributes
Provisioned Capacity (Previously known as Unallocatable Space)	The amount of space by which the capacity of a volume exceeds the physical capacity of the associated pool. In thin-provisioned environments, it is possible to over commit (over provision) storage in a pool by creating volumes with more virtual capacity than can be physically allocated in the pool. This value represents the amount of volume space that cannot be allocated based on the current capacity of the pool.
Real Capacity	The total amount of storage space that is physically allocated to a volume. For thin-provisioned volumes, this value is less than the provisioned capacity of the volume. In an XIV and IBM Spectrum Accelerate, this value represents the physical ("hard") capacity of the volume, not the provisioned ("soft") capacity.
Remaining Managed Space	The amount of storage space that is available on a managed disk. This value is only available for Storwize V7000 storage systems that are configured as back-end storage.
Reserved Volume Capacity (Previously known as Unused Space)	The amount of pool capacity that is reserved but has not been used yet to store data on the thin-provisioned volume. The value for Reserved Volume Capacity is available only for SAN Volume Controller and Storwize family storage systems that are configured with block storage.
Safeguarded Capacity	The amount of capacity that is used to store volume backups that are created by the Safeguarded Copy feature in DS8000.
Space	The amount of space in a pool that is allocated to a volume.
Unused Capacity (Previously known as Unallocated Space)	The capacity in a pool that is not reserved for a volume. This value is determined by the formula: <i>Capacity – Used Capacity</i> The value for Unused Capacity is available only for thin provisioned volumes.
Uncompressed Used Capacity	The amount of storage space that is used if the compressed volume space is uncompressed. For example, if 100 GiB of uncompressed data is compressed, and the size of the compressed data is 20 GiB, the value is 100.
Used Capacity (Previously known as Allocated Space)	The capacity on a pool that is physically allocated to a volume.
Written Capacity (Previously known as Written Space)	The amount of data that is written from the assigned hosts to the volume before compression or data deduplication are used to reduce the size of the data.

Table 31. Triggering attributes and conditions for changes to performance metrics for unmap operations on volumes

Performance Attribute	Triggering Conditions for Attributes
Data Rate (Unmap)	Define an alert to monitor the average number of MiBs per second that were unmapped. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.1 or later.
Overall I/O Rate (Unmap)	Define an alert to monitor the average number of unmap operations per second. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.1 or later.
Peak Response Time (Unmap)	Define an alert to monitor the worst response time measured for an unmap operation in the sample interval. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.1 or later.
Response Time (Unmap)	Define an alert to monitor the average number of milliseconds required to complete an unmap operation. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.1 or later.
Unaligned Unmap I/O Rate	Define an alert to monitor the average number of volumes unmap operations per second that are not aligned on an 8K boundary. This metric applies to systems that are running IBM Spectrum Virtualize V8.1.1 or later.

Triggering conditions for hypervisor alerts

You can set up IBM Spectrum® Control so that it examines the attributes and capacity of a hypervisor and notifies you when changes are detected.

Alerts can notify you of general changes and capacity changes on the following resources:

- [Hypervisors](#)
- [Controllers](#)
- [Data Stores](#)
- [Disks](#)
- [Paths](#)
- [Virtual Machines](#)
- [VMDKs](#)

Important: Not all the attributes upon which you can alert are listed here. A number of other attributes are available for alerts and are based on the key properties of a hypervisor. To view a complete list of hypervisor attributes upon which you can alert, go to [Settings > Alert Policies](#). Double-click a default policy for a hypervisor. Click Edit Alert Definitions on the Alert Definitions tab. View the attributes that are available in the general and capacity categories. Note that the attributes that are automatically configured for alerts in the default alert policies, or default alerts, have a status of Active.

In the tables, default alerts are marked with an asterisk (*).

Tip: For capacity attributes, you can generate alerts when the amount of storage is greater than, less than, or equal to a specified value. You can also determine the unit of measurement for the attribute, such as KiB, MiB, GiB, or TiB.

Hypervisors

Table 1. Triggering attributes and conditions for general hypervisor changes

General Attributes	Descriptions of Triggering Conditions
Last Successful Probe	A specified amount of time has passed since a probe was able to collect data about a hypervisor. You can use this alert to be notified when up-to-date configuration and status data is not being collected about a hypervisor and its existing data might be stale. Data collection might be interrupted or not occur if the resource, network, or IBM Spectrum Control server is unavailable.

General Attributes	Descriptions of Triggering Conditions
Probe Status*	<p>One of the following statuses is detected for a probe:</p> <p>Not Successful</p> <p>An error or warning occurred during data collection. This status indicates that a probe did not collect any data, or only collected a partial set of data about a resource.</p> <p>Warning</p> <p>A probe completed, but might not have collected a complete set of data. This status might occur if data cannot be collected about one or more of the internal resources of a resource.</p> <p>Error (default)</p> <p>A probe did not complete when it attempted to collect asset data about the resource. This status might occur if the resource cannot be reached during data collection.</p> <p>For details about why a specific status occurred, check the log for the probe. To check the log, go to the details page for a resource, click Data Collection, and select Actions > Open Logs in the Probe section on the Data Collection page.</p>
Status	<p>One of the following statuses is detected on a hypervisor:</p> <p>Not Normal</p> <p>An error or warning status was detected on the hypervisor or its internal resources.</p> <p>Warning</p> <p>A warning status was detected on the hypervisor or its internal resources.</p> <p>Error (default)</p> <p>An error status was detected on the hypervisor or its internal resources. For example, an error status might occur when a hypervisor goes offline, or a server disk is disconnected or partially disconnected if it has multiple paths and one of the paths is disconnected.</p> <p>Unreachable</p> <p>One or more of the monitored resources for a hypervisor are not responding. This status might be caused by a problem in the network.</p>

Controllers

Table 2. Triggering attributes and conditions for general changes on controllers

Controller Attributes	Descriptions of Triggering Conditions
New Disk Controller	A disk controller is detected for the first time. Use this alert to be notified of hardware additions on servers.
Removed Disk Controller	A previously monitored disk controller can no longer be found. Historical data about the controller is retained, but no current data is being collected. Use this alert to be notified if a controller is removed or becomes unavailable.

Data Stores

Table 3. Triggering attributes and conditions for general changes on data stores

Data Store Attributes	Descriptions of Triggering Conditions
Deleted Logical Volume	A previously monitored logical volume on a data store can no longer be found. Historical data about the volume is retained, but no current data is being collected. Use this alert to be notified if a volume is deleted or becomes unavailable.
New Logical Volume	A logical volume on the data store is detected for the first time.
VMDKs	You can use a number of operators to determine when you are notified of the number of virtual machine disk files (VMDKs) on the data store. For example, you can select to be notified when the number of VMDKs changes, or when the number is or is not a specific number, or when the number lies outside a specific range.

Table 4. Triggering attributes and conditions for capacity changes on data stores

Capacity Attributes	Descriptions of Triggering Conditions
Available Data Store Space	The amount of unused storage capacity on the hypervisor data store.
Available File System Capacity	The total amount of unused storage capacity on a file system.
Data Store Capacity	The total amount of storage capacity that is assigned to a data store.
File System Capacity (Previously known as Total File System Capacity)	The capacity of a file system.
Used File System Capacity	The used capacity on the hypervisor file system.
Used Capacity	The percentage of storage capacity that is used on the hypervisor data store.

Disks

Table 5. Triggering attributes and conditions for general changes on disks

General Attributes	Descriptions of Triggering Conditions
Firmware	The version of the Licensed Internal Code on the disk changes. You can use a number of operators to determine when you are notified of a firmware change, such as when the firmware is, or is not, a specific version, or when the version number contains a specific value.
Multipathing Policy	The multipathing policy that is in effect for a disk. For example, you can be notified when the policy changes, or when the policy is Round Robin, Load Balancing, Failover Only, or other another policy.
New Disk	A disk is detected for the first time. Use this alert to be notified of hardware changes on servers or hypervisors.
Paths	The number of access paths that are associated with the disk falls outside a specified range, or is equal to or not equal to a specified value.

General Attributes	Descriptions of Triggering Conditions
Removed Disk	A previously monitored disk can no longer be found. Historical data about the disk is retained, but no current data is being collected. Use this alert to be notified if a disk is removed or becomes unavailable.
Status*	One of the following statuses is detected on a disk: Not Normal An error or warning status was detected on the disk. Warning A warning status was detected on the disk. Error (default) An error status was detected on the disk.

Table 6. Triggering attributes and conditions for capacity changes on disks

Capacity Attributes	Descriptions of Triggering Conditions
Available Drive Capacity (Previously known as Available Disk Space)	The unused capacity on a hypervisor disk.
Capacity	The total amount of storage capacity assigned to a hypervisor disk.
Used Capacity	The amount of used storage capacity on a hypervisor disk .

Paths

Table 7. Triggering attributes and conditions for general changes on paths

Path Attributes	Descriptions of Triggering Conditions
Deleted Path	A previously monitored access path for a server disk can no longer be found. This change might or might not affect the availability of the disk because there might be more than one path available.
New Path	An access path for a disk is detected for the first time.
Status*	One of the following statuses is detected on a path: Not Normal An error or warning status was detected on the path. Warning A warning status was detected on the path. Error (default) An error status was detected on the path.

Virtual Machines

Table 8. Triggering attributes and conditions for general changes on virtual machines

Virtual Machine Attributes	Descriptions of Triggering Conditions
Deleted Virtual Machine	A previously monitored access path for a virtual machine can no longer be found. Historical data about the virtual machine is retained, but no current data is being collected. Use this alert to be notified if a virtual machine is deleted or becomes unavailable.
New Virtual Machine	A virtual machine is detected for the first time.
Status	One of the following statuses is detected on a virtual machine: Not Normal An error or warning status was detected on the virtual machine. Warning A warning status was detected on the virtual machine. Error (default) An error status was detected on the virtual machine.
VMDKs	You can use a number of operators to determine when you are notified of the number of VMDKs on the virtual machine. For example, you can select to be notified when the number of VMDKs changes, or when the number is or is not a specific number, or when the number lies outside a specific range.

Table 9. Triggering attributes and conditions for capacity changes on virtual machines

Capacity Attributes	Descriptions of Triggering Conditions
Capacity	The total amount of storage capacity assigned to a virtual machine hosted by the hypervisor.

VMDKs

Table 10. Triggering attributes and conditions for general changes on virtual machine disks (VMDKs)

VMDK Attributes	Descriptions of Triggering Conditions
Deleted Virtual Disk	A previously monitored virtual disk can no longer be found. Historical data about the virtual disk is retained, but no current data is being collected. Use this alert to be notified if a virtual disk is deleted or becomes unavailable.
New Virtual Disk	A virtual disk is detected for the first time.

Table 11. Triggering attributes and conditions for capacity changes on VMDKs

Capacity Attributes	Descriptions of Triggering Conditions
Size	The size of the VMDK on the hypervisor data store.

Capacity Attributes	Descriptions of Triggering Conditions
Used Capacity	The percentage of storage capacity that is used on the VMDK on the hypervisor data store. The used capacity is available if a Storage Resource agent is deployed.

Triggering conditions for switch alerts

You can set up IBM Spectrum® Control so that it examines the attributes and performance of a switch and notifies you when changes or violations are detected.

Alerts can notify you of general changes and performance issues on the following resources:

- [Switches \(performance\)](#)
- [Switches \(general changes\)](#)
- [Ports \(general changes\)](#)
- [Ports \(performance\)](#)
- [Trunks \(performance\)](#)

Important: Not all the attributes upon which you can alert are listed here. To view a complete list of attributes upon which you can alert, you can either edit alert definitions for a switch with no alert policy assigned, or you can create a new custom alert policy and define new alerts in the policy. To create a custom alert policy go to Configuration > Alert Policies and click Create Policy.

Not all the attributes upon which you can alert are listed here. A number of other attributes are available for alerts and are based on the key properties of a switch. To view a complete list of attributes upon which you can alert, go to Settings > Alert Policies. Double-click a default policy for a switch. Click Edit Alert Definitions on the Alert Definitions tab. View the attributes that are available in the general, capacity, and performance categories. Note that the attributes that are automatically configured for alerts in the default alert policies, or default alerts, have a status of Active.

In the tables, default alerts are marked with an asterisk (*).

Switches (general changes)

Table 1. Pre-defined alerts for Switches

General Attributes	Defining Conditions for Attributes
Last Successful Probe	A specified amount of time has passed since a probe or performance monitor was able to collect data about a switch. You can use this alert to be notified when up-to-date configuration, status, or performance data is not being collected about a switch and its existing data might be stale. This situation might occur if the resource, network, or IBM Spectrum Control server is unavailable.
Last Successful Monitor	
Probe Status*	<p>One of the following statuses is detected for a probe:</p> <p>Not Successful An error or warning occurred during data collection. This status indicates that a probe did not collect any data, or only collected a partial set of data about a resource.</p> <p>Warning A probe completed, but might not have collected a complete set of data. This status might occur if data cannot be collected about one or more of the internal resources of a resource.</p> <p>Error (default) A probe did not complete when it attempted to collect asset data about the resource. This status might occur if the resource cannot be reached during data collection.</p> <p>For details about why a specific status occurred, check the log for the probe. To check the log, go to the details page for a resource, click Data Collection, and select Actions > Open Logs in the Probe section on the Data Collection page.</p>
Performance Monitor Status*	<p>One of the following statuses is detected for a performance monitor:</p> <p>Not Normal An error or warning occurred during data collection. This status indicates that a performance monitor did not collect any data, or only collected a partial set of data about a resource.</p> <p>Warning A performance monitor completed, but did not collect a complete set of performance data. This status might occur if the resource was rebooted during data collection, no valid performance data was provided by the resource, or a communication error occurred with the resource or its associated agent.</p> <p>Error A performance did not complete when it attempted to collect performance data about the resource. This status might occur if the resource cannot be reached during data collection, or if no configuration data is available for the resource.</p> <p>For details about why a specific status occurred, check the log for the performance monitor. To check the log, go to the details page for a resource, click Data Collection, and select Actions > Open Logs in the Performance Monitor section on the Data Collection page.</p>
Status*	<p>One of the following conditions is detected on a switch:</p> <p>Not Normal An error or warning status was detected on the switch or its internal resources.</p> <p>Warning A warning status was detected on the switch or its internal resources.</p> <p>Error (default) An error status was detected on the switch or its internal resources. For example, an error status might occur when a switch goes offline.</p> <p>Unreachable One or more of the monitored resources for a switch are not responding. This status might be caused by a problem in the network.</p>

Switches (performance)

Define alerts that notify you when the performance of a switch falls outside a specified threshold. In alerts, you can specify conditions based on metrics that measure the performance of switch ports, including I/O, data, and error rates, and frame transfer sizes. By creating alerts with performance conditions, you can be informed about potential bottlenecks in your network infrastructure.

For example, you can define an alert to be notified when the port congestion index for a port is greater than or equal to a specified threshold. Port congestion represents the estimated degree to which frame transmission was delayed due to a lack of buffer credits. Use this alert to help identify port conditions that might slow the performance of the resources to which those ports are connected.

You can also be notified when a metric is less than a specified threshold, such as when you want to identify ports that might be under used.

For a complete list of switch metrics that can be alerted upon, see [Performance metrics for switches](#).

Tips for performance conditions:

- A performance monitor must collect data about a resource before IBM Spectrum Control can determine whether a threshold is violated and an alert is generated for a performance condition.
- When you define a performance alert for the inter-switch connections category of a switch, the performance of ISL trunk connections is measured and alerted on. To alert on the performance of standard ISL connections, define performance alerts for the ports category of a switch.

Best practice: When you set thresholds for performance conditions, try to determine the best value so you can derive the maximum benefit without generating too many false alerts. Because suitable thresholds are highly dependent on the type of workload that is being run, hardware configuration, the number of physical disks, exact model numbers, and other factors, there are no easy or standard default rules.

A recommended approach is to monitor the performance of resources for a number of weeks and by using this historical data, determine reasonable threshold values for each performance condition. After that is done, you can fine-tune the condition settings to minimize the number of false alerts.

Click Edit alert Definitions, and for each performance alert definition click View History to see the history of switch, port or trunk performance and set the threshold you want relative to that data.

Trunks (performance)

Define alerts that notify you when the performance of a trunk falls outside a specified threshold. In alerts, you can specify conditions based on metrics that measure the performance of the trunk, including I/O, data, and error rates, and frame transfer sizes. By creating alerts with performance conditions, you can be informed about potential bottlenecks in your network infrastructure.

For example, you can define an alert to be notified when the aggregate port congestion index of the ports in the trunk is greater than or equal to a specified threshold. Port congestion represents the estimated degree to which frame transmission was delayed due to a lack of buffer credits. Use this alert to help identify port conditions that might slow the performance of the resources to which those ports are connected.

You can also be notified when a metric is less than a specified threshold, such as when you want to identify trunks that might be under used.

For a complete list of trunk metrics that can be alerted upon, see [Performance metrics for switches](#)

Ports (general changes)

Table 2. Pre-defined alerts for ports

General Attributes	Defining Conditions for Attributes
Removed Port	A previously monitored port can no longer be found. Historical data about the port is retained, but no current data is being collected. Use this alert to be notified if a port is removed or becomes unavailable.
State	A port is online, enabled but offline, or disabled.
Status*	One of the following statuses is detected for a port: Not Normal An error or warning status is detected on a port. Warning A warning status is detected on a port. This status might occur if the switch is stopped, starting, or in service (being maintained, cleaned, or administered). Error An error status is detected on a port.

Ports (performance)

Define alerts that notify you when the performance of a port falls outside a specified threshold. In alerts, you can specify conditions based on metrics that measure the performance of switch ports, including I/O, data, and error rates, and frame transfer sizes. By creating alerts with performance conditions, you can be informed about potential bottlenecks in your network infrastructure.

For example, you can define an alert to be notified when the port congestion index for a port is greater than or equal to a specified threshold. Port congestion represents the estimated degree to which frame transmission was delayed due to a lack of buffer credits. Use this alert to help identify port conditions that might slow the performance of the resources to which those ports are connected.

You can also be notified when a metric is less than a specified threshold, such as when you want to identify ports that might be under used.

For a complete list of port metrics that can be alerted upon, see [Performance metrics for switches](#)

Triggering conditions for fabric alerts

You can set up IBM Spectrum® Control so that it examines the attributes of a fabric and notifies you when changes are detected.

Alerts can notify you of general changes on fabric resources.

Important: Fabrics do not have a default alert policy assigned. If you wish to define alerts for a fabric you can either edit the alert definitions for a single fabric, or create an alert policy and assign it to one or more fabrics. To define alerts for a fabric, go to [Resources > Fabrics](#), right-click a fabric, and select [View Alert Definitions](#). Then, click [Edit Alert Definitions](#) to start defining alerts. To create an alert policy that can be applied to multiple fabrics, go to [Configuration > Alert Policies >](#) and click [Create Policy](#). Then, name the policy, click [Policy Type](#), select [Fabrics](#), and select the fabrics that you want to include.

Not all the attributes upon which you can alert are listed here. A number of other attributes are available for alerts and are based on the key properties of fabrics or switches. To view a complete list of attributes upon which you can alert, go to [Settings > Alert Policies](#). Double-click a default policy for a fabric or switch. Click [Edit Alert Definitions](#) on the [Alert Definitions](#) tab. View the attributes that are available in the general and capacity categories, and in the performance category for switches. Note that the attributes that are automatically configured for alerts in the default alert policies, or default alerts, have a status of Active.

Not all attributes are available for all types of fabrics. For example, you can't probe fabrics that contain Cisco switches or Brocade switches that run Fabric OS 8.2.1 or later. Therefore the [Last Successful Probe](#) and [Probe Status](#) attributes are not available for those types of fabric.

In the table, default alerts are marked with an asterisk (*).

Fabrics

Table 1. Alerts for fabrics

Fabric Attributes	Defining Conditions for Attributes
Probe Status*	<p>One of the following statuses is detected for a probe:</p> <p>Not Successful An error or warning occurred during data collection. This status indicates that a probe did not collect any data, or only collected a partial set of data about a resource.</p> <p>Warning A probe completed, but might not have collected a complete set of data. This status might occur if data cannot be collected about one or more of the internal resources of a resource.</p> <p>Error (default) A probe did not complete when it attempted to collect asset data about the resource. This status might occur if the resource cannot be reached during data collection.</p> <p>For details about why a specific status occurred, check the log for the probe. To check the log, go to the details page for a resource, click Data Collection, and select Actions > Open Logs in the Probe section on the Data Collection page.</p>
Status	<p>One of the following statuses is detected on a fabric:</p> <p>Not Normal An error or warning status was detected on the fabric or its internal resources.</p> <p>Warning A warning status was detected on the fabric or its internal resources.</p> <p>Error (default) An error status was detected on the fabric or its internal resources.</p> <p>Unreachable One or more of the monitored resources for a fabric are not responding.</p>
Custom alerts	You may choose from a small number of custom alerts to add to a fabric or policy. Conditions include number of Switches, number of Ports, etc.

Triggering conditions for server alerts

You can set up IBM Spectrum® Control so that it examines the attributes and capacity of a server and notifies you when changes are detected.

Alerts can notify you of general changes and capacity changes on the following resources:

- [Servers](#)
- [Controllers](#)
- [Disks](#)
- [Disk Groups](#)
- [File Systems and Logical Volumes](#)
- [Paths](#)
- [Shares](#)
- [Triggering conditions for the IBM Spectrum Control server](#)

Important: A number of other attributes are available for alerts and are based on the key properties of a server. To view a complete list of server attributes upon which you can alert, go to [Settings > Alert Policies](#). Double-click a default policy for a server. Click [Edit Alert Definitions](#) on the [Alert Definitions](#) tab. View the attributes that are available in the general and capacity categories. Note that the attributes that are automatically configured for alerts in the default alert policies, or default alerts, have a status of Active.

In the tables, default alerts are marked with an asterisk (*).

Tip: For capacity attributes, you can generate alerts when the amount of storage is greater than, less than, or equal to a specified value. You can also determine the unit of measurement for the attribute, such as KiB, MiB, GiB, or TiB.

Servers

Table 1. Triggering attributes and conditions for general changes on servers

General Attributes	Descriptions of Triggering Conditions
Agent State*	<p>A Storage Resource agent is in one of the following states:</p> <p>Not Normal An error or warning state was detected on a Storage Resource agent.</p> <p>Warning A warning state was detected on a Storage Resource agent. For example, a warning state might occur when an agent must be upgraded to the same version level as the IBM Spectrum Control server to which it is communicating.</p> <p>Error (default) An error state was detected on a Storage Resource agent. For example, an error state might occur when an agent was not able to be upgraded.</p>
Last Successful Probe	A specified amount of time has passed since a probe was able to collect data about a server. You can use this alert to be notified when up-to-date configuration and status data is not being collected about a server and its existing data might be stale. Data collection might be interrupted or not occur if the resource, network, or IBM Spectrum Control server are unavailable.
Probe Status*	<p>One of the following statuses is detected for a probe:</p> <p>Not Successful An error or warning occurred during data collection. This status indicates that a probe did not collect any data, or only collected a partial set of data about a resource.</p> <p>Warning A probe completed, but might not have collected a complete set of data. This status might occur if data cannot be collected about one or more of the internal resources of a resource.</p> <p>Error (default) A probe did not complete when it attempted to collect asset data about the resource. This status might occur if the resource cannot be reached during data collection.</p> <p>For details about why a specific status occurred, check the log for the probe. To check the log, go to the details page for a resource, click Data Collection, and select Actions > Open Logs in the Probe section on the Data Collection page.</p>
Status*	<p>One of the following statuses is detected on a server:</p> <p>Not Normal An error or warning status was detected on the server or its internal resources.</p> <p>Warning A warning status was detected on the server or its internal resources. For example, a warning status might occur when an HBA or HBA to a server node is newly discovered, is missing, or is rediscovered.</p> <p>Error (default) An error status was detected on the server or its internal resources. For example, an error status might occur when a server goes offline, or a server disk is disconnected or partially disconnected if it has multiple paths and one of the paths is disconnected.</p> <p>Unreachable One or more of the monitored resources for a server are not responding. This status might be caused by a problem in the network or by a Storage Resource agent that is no longer running and did not communicate that it was shutting down.</p>

Table 2. Triggering attributes and conditions for capacity changes on servers

Capacity Attributes	Descriptions of Triggering Conditions
Available Drive Capacity (Previously known as Available Disk Space)	The unused disk capacity on the local and SAN-attached storage for the server. SAN-attached storage is assigned to the server from storage systems.
Available File System Capacity	<p>The amount of unused capacity in the file systems on the server.</p> <p>Available file system capacity does not include capacity that is reserved for the operating system. For example, the available capacity for <code>tmpfs</code> on UNIX operating systems is not included in this value.</p>
Drive Capacity (Previously known as Total Disk Space)	The total disk capacity for all the local and SAN-attached storage on the server. SAN-attached storage is assigned to the server from storage systems.
File System Capacity	The amount of file system capacity on the server.
File System Capacity from Storage Systems	<p>The amount of file system capacity that is assigned to the server from storage systems.</p> <p>The file system capacity from storage systems is only available when SAN-attached storage is assigned to the server.</p>
Mapped SAN Capacity (Previously known as Assigned SAN Space)	<p>The amount of disk capacity that is assigned to the server from storage systems.</p> <p>The disk capacity from storage systems is only available when SAN-attached storage is assigned to the server.</p>
Used Capacity	The amount of used disk capacity on the local and SAN-attached storage for the server. SAN-attached storage is assigned to the server from storage systems.

Controllers

Table 3. Triggering attributes and conditions for changes on disk controllers

Controller Attributes	Descriptions of Triggering Conditions
<ul style="list-style-type: none"> Driver Version Firmware ROM Version 	<p>The version of the driver, firmware, or read-only memory (ROM) on a disk controller changes. You can use a number of operators to determine when you are notified of a version change, such as when the driver, firmware, or ROM is, or is not, a specific version, or when the version number contains a specific value.</p> <p>Use this alert for HBAs only.</p>
Last Data Collection	A specified amount of time since data was collected about a controller. Use this alert to be notified if data is not being collected about a controller or if the existing data is becoming too stale.
New Disk Controller	A disk controller is detected for the first time. Use this alert to be notified of hardware additions on servers.

Controller Attributes	Descriptions of Triggering Conditions
Removed Disk Controller	A previously monitored disk controller can no longer be found. Historical data about the controller is retained, but no current data is being collected. Use this alert to be notified if a controller is removed or becomes unavailable.
Status*	One of the following statuses is detected on a disk controller: Not Normal An error or warning status was detected on the controller. Warning A warning status was detected on the controller. Error (default) An error status was detected on the controller.

Disks

Table 4. Triggering attributes and conditions for general changes on disks

General Attributes	Descriptions of Triggering Conditions
Firmware	The version of the Licensed Internal Code on the disk changes. You can use a number of operators to determine when you are notified of a firmware change, such as when the firmware is, or is not, a specific version, or when the version number contains a specific value.
Multipathing Policy	The multipathing policy that is in effect for a disk. For example, you can be notified when the policy changes, or when the policy is Round Robin, Load Balancing, Failover Only, or other another policy.
New Disk	A disk is detected for the first time. Use this alert to be notified of hardware changes on servers or hypervisors.
Paths	The number of access paths that are associated with the disk falls outside a specified range, or is equal to or not equal to a specified value.
Removed Disk	A previously monitored disk can no longer be found. Historical data about the disk is retained, but no current data is being collected. Use this alert to be notified if a disk is removed or becomes unavailable.
Status*	One of the following statuses is detected on a disk: Not Normal An error or warning status was detected on the disk. Warning A warning status was detected on the disk. Error (default) An error status was detected on the disk.

Table 5. Triggering attributes and conditions for capacity changes on disks

Capacity Attributes	Descriptions of Triggering Conditions
Available Drive Capacity (Previously known as Available Disk Space)	The unused capacity on a disk that is attached to the server.
Capacity	The total amount of storage capacity on a disk that is attached to the server.
Used Capacity	The amount of used storage capacity on a disk that is attached to the server.

Disk Groups

Table 6. Triggering attributes and conditions for general changes on disk groups (volume groups)

General Attributes	Descriptions of Triggering Conditions
Deleted Volume Group	A previously monitored volume group can no longer be found. Historical data about the volume group is retained, but no current data is being collected. Use this alert to be notified if a volume group is deleted or becomes unavailable.
New Volume Group	A volume group is detected for the first time.
Status*	One of the following statuses is detected on a disk group: Not Normal An error or warning status was detected on the disk group. Warning A warning status was detected on the disk group. Error (default) An error status was detected on the disk group.

Table 7. Triggering attributes and conditions for capacity changes on disk groups (volume groups)

Capacity Attributes	Descriptions of Triggering Conditions
Available Capacity	The unused storage capacity on a server disk group.
Used Capacity	The amount of used storage capacity on a server disk group.
Volume Group Capacity	The total amount of storage capacity on a server volume group. This value is inclusive of all storage capacity and applies to all capacity values related to volume groups.

File Systems and Logical Volumes

Table 8. Triggering attributes and conditions for general changes on file systems and logical volumes

General Attributes	Descriptions of Triggering Conditions
--------------------	---------------------------------------

General Attributes	Descriptions of Triggering Conditions
Available Inodes	The number of unused inodes on file systems on the operating system changes, falls outside a specified range, or is equal to or not equal to a specified value.
Deleted File System	A previously monitored file system is deleted or unmounted from a server. Historical data about the file system is retained, but no current data is being collected. This attribute applies to file systems on the following resources: <ul style="list-style-type: none"> Storage systems that are configured for file storage, including Storwize® V7000 Unified Servers that are managed by Storage Resource agents
Deleted Logical Volume	A previously monitored logical volume can no longer be found. Historical data about the logical volume is retained, but no current data is being collected. Use this alert to be notified if a logical volume is removed or becomes unavailable.
New File System	A file system was detected for the first time. This alert applies to file systems on the following resources: <ul style="list-style-type: none"> Storage systems that are configured for file storage, including Storwize V7000 Unified Servers that are managed by Storage Resource agents
New Logical Volume	A logical volume is detected for the first time.
Used Inodes	The number of used inodes on file systems on the operating system changes. You can use a number of operators to determine when you are notified, such when the number of used inodes falls outside a specified range, or is equal to or not equal to a specified value.

Table 9. Triggering attributes and conditions for capacity changes on file systems and logical volumes

Capacity Attributes	Descriptions of Triggering Conditions
Available File System Capacity	The amount of unused storage capacity on a file system on the server disk.
File System Capacity	The total amount of storage capacity on a file system on the server disk.
Logical Volume Capacity	The total amount of storage capacity on a logical volume on the server disk.
Used File System Capacity	The capacity on a file system on the server disk.
Used Capacity	The percentage of used storage capacity on a file system or logical volume on the server disk.

Paths

Table 10. Triggering attributes and conditions for general changes on paths

Path Attributes	Descriptions of Triggering Conditions
Deleted Path	A previously monitored access path for a server disk can no longer be found. This change might or might not affect the availability of the disk because there might be more than one path available.
New Path	An access path for a disk is detected for the first time.
Status*	One of the following statuses is detected on a path: <ul style="list-style-type: none"> Not Normal <ul style="list-style-type: none"> An error or warning status was detected on the path. Warning <ul style="list-style-type: none"> A warning status was detected on the path. Error (default) <ul style="list-style-type: none"> An error status was detected on the path.

Shares

Table 11. Triggering attributes and conditions for general changes on shares

Share Attributes	Descriptions of Triggering Conditions
Deleted Share	A previously monitored share can no longer be found. Historical data about the share is retained, but no current data is being collected. Use this alert to be notified if a share is removed or becomes unavailable.
New Share	A new share was detected for the first time.

Triggering conditions for the IBM Spectrum Control server

The server on which IBM Spectrum Control is installed is automatically monitored for conditions that might cause an interruption in product functions. When these conditions are detected, alerts are triggered and shown on the Home > Alerts page. You do not need to manually define alerts for these product-related conditions; they are automatically enabled.

Table 12. Triggering conditions for the IBM Spectrum Control server

Triggering Condition	Explanation	Related Error Message
Database unavailable	The product database is not available. This database is the repository for information that is collected about the monitored resources in your environment.	ALR4112E, ALR4113E
High memory usage*	A high amount of memory is being used by a server process and might cause stability problems.	ALR4103W
Database alarm*	The system database or the database manager that hosts the product's database repository is reporting an alarm.	ALR4104W
High workload	The workload queue for the Device server is high and might cause performance issues.	ALR4105W
High number of external events	The server is receiving a high number of external events, such as CIM indications or SNMP traps. The high number of events might cause performance issues.	ALR4106W

Alert notifications and actions

Specify how you are notified when alert conditions are detected on resources, and define actions to take as a result of those alerts. These settings are defined globally for all resources, and can be overridden for a specific alert definition, for all alert definitions that apply to a specific resource, or for an alert policy.

Notifications and override behavior

You can specify notification settings at the following levels:

- Globally, for all alerts.
- In alert policies, for groups of resources of the same type.
- In individual alert definitions, which can be part of an alert policy, or can be specific to a resource.

Notification settings at the lower levels override the settings at the higher levels. For example, if you want to use email for alert notifications, you can specify email notification settings like this:

1. If you want all email notifications to go to a specific set of email addresses, specify email addresses for global alert notifications.
2. If you're using alert policies, you can also specify a list of email addresses to notify that are applicable to that policy. These addresses override the global setting.
3. For an alert definition, you can specify a set of email addresses to notify. This email addresses override the alert policy and global settings.

Scenarios for the different levels of alert notification

A small organization might specify only global email addresses if they want to send all alert notifications to one team.

A larger organization can have multiple storage environments that are managed by different teams. They can create alert policies for each environment and specify different email addresses for each alert policy. For example, they might create alert policies for their mainframe, VMware, and AIX® environments, and specify different email addresses for each of those policies. These email addresses override any global email addresses.

If you want to notify a specific person when a specific condition occurs, you set an email address in an individual alert definition. This email address overrides any alert policy or global email addresses. For example, an operations team might review all of the alerts, but might want to notify their storage architect if capacity in a pool exceeds 80%.

Specifying the frequency of alert notifications

You can use the Notification Frequency settings to avoid triggering too many alerts for some conditions. You can select one of the following options:

Option	Description
Send every time condition is violated	Receive alert notifications whenever an alert condition is violated.
Send once until problem clears	Receive one notification for a violation, even if the condition is violated multiple times.
Send every <i>time_period</i>	Receive one notification when an alert condition is initially violated. The alert is suppressed and no notifications are sent until both the specified time has passed and the alert is triggered again.

You can also select to only send notifications if the violation is not cleared for longer than a time period that you specify. Select Send after condition is violated for *time_period*, then specify the time period.

For example, you might want to be notified about an alert only after the condition has been violated for 20 minutes, and you only want to be notified about the alert once until the problem clears. In this case, you can set up an alert with the following notification frequency settings:

Notification Frequency

Send once until problem clears

▼

☒ Send after condition is violated for

20

↑
↓

minute(s)

▼

Restrictions:

- For some attributes, not all the notification frequency options are available. Specifically, you cannot change the notification frequency for the following attributes: New *resource*, Removed or Deleted *resource*, Last Successful Probe, and Last Successful Monitor.
- For attributes that use the changes operator (for example, the Firmware attribute), only the Send every time condition is violated and Send every *time_period* notification frequency options are available.

Specifying alert actions and notification settings in the GUI

Table 1. Locations where you can specify alert actions and notification settings

Task	Location in GUI
Specify the global notification settings for all alerts	Global Alert Notifications To specify the global notification settings, go to Configuration > Notification Settings, and specify the details for email, SNMP, and Tivoli® Netcool®/OMNIBus. These notification settings are applied globally to all alert definitions, unless overridden. Important: You must specify the global alert notifications settings for each type of alert notification that you want to enable.

Task	Location in GUI
Specify the notification settings for an alert policy	Alert policies page To specify the notification settings for an alert policy, go to Settings > Alert Policies. Double-click the policy whose notification settings you want to specify. Click Edit Policy Notifications. Specify the details for email, SNMP, and Tivoli Netcool/OMNIBus. These notification settings are applied to all of the alert definitions for all resources in the policy, unless overridden.
Specify the notification settings for all the alert definitions that apply to a resource that is not managed by an alert policy	Resource details page For example, to specify the notification settings for a block storage system, go to Storage > Block Storage Systems. Double-click the resource for which you want to define alerts. In the General section of the resource details page, click Alerts. Then click Edit Notifications. These notification settings are applied to all the alert definitions that are specified for the selected storage system. You can override the global settings by specifying different settings for each alert definition.
Specify alert actions and notification settings for a specific alert definition	Alert definitions page, Resource details page For example, to specify the notification settings for an alert definition in an alert policy, go to Settings > Alert Policies. Double-click the policy whose notification settings you want to specify. Click Edit Alert Definitions. Alternatively, to specify the notification settings for an alert definition for a resource that is not managed by an alert policy, go to Storage > Block Storage Systems. Double-click the resource for which you want to define alerts. In the General section of the resource details page, click Alerts. Then click Edit Alert Definitions. Click on the alert definition to show advanced options. Specify the details for email, SNMP, and Tivoli Netcool/OMNIBus. The notification settings that you define override any global notification settings, any policy settings, and any settings for the resource.

Alert actions

You can specify that the following actions are taken when alert conditions are detected on monitored resources:

Run script

Run a script when an alert is triggered for the condition. Use a script to call external programs or run commands that take action as the result of an alert. By using a script, you can automatically address potential storage issues when they are detected to avoid unplanned downtime or performance bottlenecks. [Learn more.](#)

Email

Send emails to specific email addresses when an alert is detected on a monitored resource.

Netcool or OMNIBus EIF Probe Server

Send alert notifications to a Netcool server or OMNIBus EIF probe server within your environment that was configured to receive IBM Spectrum Control alerts.

SNMP trap

Generate SNMP trap messages to any network management station (NMS), console, or terminal when an alert condition is detected. System administrators must set up their SNMP trap ringer with the provided management information base (MIB) files to receive SNMP traps from the product.

Windows event log or UNIX syslog

Write alert messages to the OS log. If you already have an administrator monitoring OS logs, this method is a way to centralize your priority messages for quick notification and viewing.

- [How scripts are run](#)

After an alert is triggered, scripts can be run from the server where IBM Spectrum Control is installed or from any server where a Storage Resource agent is deployed. For some alert conditions, scripts can be specified to run on the server where the change was detected.

Related tasks

- [Defining alerts](#)

How scripts are run

After an alert is triggered, scripts can be run from the server where IBM Spectrum® Control is installed or from any server where a Storage Resource agent is deployed. For some alert conditions, scripts can be specified to run on the server where the change was detected.

You must include the script files that you want to run in the /scripts directory on the server where IBM Spectrum Control is installed. The default path of /scripts is determined by the operating system of the server:

- Windows: C:\Program Files\IBM\TPC\Data\scripts
- UNIX or Linux®: /opt/IBM/TPC/Data/scripts or /usr/IBM/TPC/Data/scripts

Tip: When you run a script against a NAS filer, the script is run from the Storage Resource agent that is assigned to the file system where the condition was detected.

Script parameters

You can run scripts in response to alerts. Parameters for the conditions and attributes in an alert definition are included in the script. Each parameter is associated with a number, such as \$1, \$2, \$3, and so on. These parameters are used when the alert is triggered.

The following examples show the parameters that are included in a script for different alerting scenarios.

Alerting example: Storage System Pool Used Capacity >= 10

```
$1 = Pool
$2 = tpcvm4-3
$3 = "Storage System"
$4 = SVC-storage1
```

```
$5 = "Storage System Pool Used Capacity Percent >= 10 %"
$6 = "75.97 %"
```

Alerting example: Storage System Write Data Rate <= 1,100 MiB/s

```
$1 = ""
$2 = ""
$3 = "Storage System"
$4 = SVC-storage1
$5 = "Write Data Rate <= 1,100 MiB/s"
$6 = "0 MiB/s"
```

Alerting example: Pool Total I/O Rate <= 445 ops/s

```
$1 = Pool
$2 = scv5k2c0_pool
$3 = "Storage System"
$4 = SVC-storage1
$5 = "Total I/O Rate - overall <= 445 ops/s"
```

Alerting example: Custom alert with the multiple conditions

Conditions:

- Storage System Volume Capacity >= 1,000,000 KiB
- Storage System Volume Compressed is yes
- Storage Volume Compression Savings Percent >= 13

Parameters:

```
$1 = Volume
$2 = vol1
$3 = "Storage System"
$4 = SVC-storage1
$5 = "Storage System Volume Capacity >= 1,000,000 KiB"
$6 = "2,097,152 KiB"
$7 = Volume
$8 = vol1
$9 = "Storage System"
$10 = SVC-storage1
$11 = "Storage System Volume Compressed is yes"
$12 = yes
$13 = Volume
$14 = vol1
$15 = "Storage System"
$16 = SVC-storage1
$17 = "Storage Volume Compression Savings Percent >= 13 %"
$18 = "17.25 %"
```

Restriction: For some alerts, such as custom alerts with multiple conditions and attributes, the number of parameters in the associated script might exceed nine. In Windows, only the first nine parameters in a script can be referenced by number (parameter %1 to parameter %9). Additional parameters are ignored.

How script names are resolved

When you run scripts in response to alerts, the names of those scripts are resolved by using the following criteria:

- The operating system of the server where the product is installed.
- The script name that you specify on the Script name field when you define or edit an alert definition.

The operating system of the server or Storage Resource agent where you choose to run a script determines how that script that is run:

UNIX, Linux operating systems

A Storage Resource agent that is deployed on a UNIX or Linux operating system does not run scripts that have an extension. If the specified script name contains an extension, the agent ignores the extension and searches for a file of the same name (without an extension). For example, if you enter **backup.vbs** in the Script name field, a UNIX or Linux agent searches for a file with the name **backup**. If the script exists, the first line of the script is read and the appropriate interpreter is used to run the script. If a file cannot be found, no action is taken.

Windows operating systems

A Storage Resource agent that is deployed on a Windows operating system runs scripts that have an extension. The extension of a script file determines which interpreter is used to run the script. If you specify a script name that does not contain an extension, the agent searches for the file name in the following order (based on its extension): **.com**, **.exe**, **.bat**, **.cmd**, **.vbs**, **.vbe**, **.js**, **.jse**. If a file cannot be found, no action is taken.

Tip: You can run scripts with the same name across multiple operating systems. To run a script on both a UNIX or Linux and Windows operating systems, you must have two versions of that file in the /scripts directory. For example, if you want to run a provisioning script against Storage Resource agents on UNIX or Linux and Windows servers, you must have two versions of that file (**provision.bat** and **provision**) in /scripts.

Viewing information about resources

You can view detailed information about the resources that are monitored by IBM Spectrum® Control. Resources include storage systems, volumes, pools, servers, hypervisors, fabrics, and switches. You can also view information about internal and related resources.

Remember: Data collection jobs retrieve information about monitored resources. To ensure that the most up-to-date information about resources is available in the GUI, run data collection jobs regularly. To learn about how to collect data, see [Collecting data](#).

- [How information is organized](#)

Information about monitored resources is organized into different pages in the GUI. You can use the pages to view summary information about all types of

monitored resources, such as storage systems, fabrics, and switches. You can see what resources are consuming storage and the alerts that are being detected on those resources. You can also view a chart of the most active storage systems in your environment.

- [Dashboard view](#)

Use the dashboard to monitor the overall condition of monitored resources and identify potential problem areas in a storage environment. The dashboard also displays alerts, as well as a chart showing the most active storage systems.

- [Viewing information about top-level resources](#)

Use a resource list page as a central location for viewing information about all the monitored resources of a specific type. Resources that have a list page include storage systems, volumes, pools, shares, servers, hypervisors, switches, and fabrics.

- [Viewing information about internal, object, and related resources](#)

Use resource details pages to view information about a specific top-level resource and its internal, object, and related resources.

- [Overview charts](#)

Monitor the activity and storage usage of your storage systems. Use the charts and key metrics to gauge the workload activity of your storage resources and to check whether you have sufficient capacity.

- [Viewing information about enclosures](#)

View information about enclosures. Enclosures are the metal structures in which various storage components are mounted, including control units, nodes, disks and drives, and power supplies.

How information is organized

Information about monitored resources is organized into different pages in the GUI. You can use the pages to view summary information about all types of monitored resources, such as storage systems, fabrics, and switches. You can see what resources are consuming storage and the alerts that are being detected on those resources. You can also view a chart of the most active storage systems in your environment.

Dashboard view

The dashboard is view displayed when you start a new session of IBM Spectrum® Control or when you go to Home > Dashboard in the menu bar. Use the dashboard to view the following summary information about a storage environment

- Condition of storage: block, file, and object storage systems
- Condition of storage consumers: hypervisors and servers
- Condition of network resources: fabrics and switches
- Number error, warning, and information alerts that are generated on resources
- Most active storage systems in your environment.

You can click on resource icons in the dashboard to add more resources for monitoring and to see detailed information about resources that IBM Spectrum Control is currently monitoring. Position the mouse pointer over the lines in the Most Active Storage Systems chart to see performance information about specific resources. For more information about the dashboard, see [Dashboard view](#).

Resource list pages

Use a resource list page as a central location for viewing information about the top-level resources of a specific type. For example, use the File Storage Systems page to view a list of the file storage systems that are monitored by IBM Spectrum Control. Each resource list page corresponds to a specific type of resource, which includes block storage systems, file storage systems, object storage systems, volumes, pools, servers, hypervisors, switches, and fabrics. You can view the following information on resource list pages:

- Overall condition of the resources
- Key information about the resources
- Alerts that were generated for the resources
- Jobs that were run for the resources

To learn about how to access the list pages for resources, see [Viewing information about top-level resources](#).

Note: Volumes and pools are internal resources of storage systems, but have their own resource list pages so that you can view them all in a central location.

Resource detail pages

Use resource details pages to view information about resources that are internal or related to a top-level resource. For example, use the File Storage System details page to view detailed information about a specific file storage system. You can view the following information on resource details pages:

- The overall capacity and storage usage for a resource
- The status of resources
- Key information about a resource
- Alerts that were generated for a resource
- Data collection that was run for a resource
- Information about components that exist in top-level resources
- Information about the resources that are related to another resource

To learn about how to access detail pages for resources, see [Viewing information about internal, object, and related resources](#).

Alerts page

Use the Alerts page to view and manage the alert conditions that were detected on monitored resources. Specifically, you can complete the following actions:

- View the overall number of alerts that were detected on monitored resources. This information is presented in a bar chart for the following types of alerts:
 - Database
 - Fabric
 - Hypervisor

- Other
- Performance
- Server
- Storage system
- IBM Spectrum Control
- View information about specific alerts, including severity, last occurrence, and the resources where they were detected.
- Acknowledge alerts that were reviewed but are not yet resolved.
- Unacknowledge alerts.
- Remove alerts from the page.

To access the Alerts page, go to Home > Alerts in the menu bar.

Performance Monitors page

IBM Spectrum Control can collect information about the performance of monitored storage systems and switches. This information includes key performance metrics. On the Performance Monitors page, you can view detailed information about performance monitors that are collecting data. Use this information to identify performance monitors that are encountering problems when they run. You can also view the metrics that are collected by a performance monitor for a resource.

To access the Performance Monitors page, select Home > Performance Monitors.

Tasks page

Use the Tasks page to view and manage the tasks that IBM Spectrum Control uses to optimize resources and provision storage. Tasks are created when you complete any of the following actions:

- Analyzing tiering by moving volumes to higher or lower tiers.
- Transforming storage by moving or converting volumes.
- Balancing pools by distributing the workload of volumes across pools on the same tier.

To access the Tasks page, go to Home > Tasks .

System Management page

Use the System Management page to view information about the overall condition of IBM Spectrum Control. You can view information about the servers on which IBM Spectrum Control is installed. This information includes component server and database status, certain server alerts and database connection alerts, server file-system capacity information, and remote volume-performance information.

To access the System Management page, go to Home > System Management in the menu bar.

Reporting

Use the optional Cognos® Analytics reporting tool in the GUI to view detailed reports about resources. The following reports are available:

Predefined reports

These reports are included with IBM Spectrum Control. The following types of predefined reports are available:

- Capacity and relationships of resources
- Performance
- Historical space
- Storage tiering

Custom reports

Unlike predefined reports, you can select the information that you want to include in custom reports. Custom reports can contain detailed information about the relationships between monitored resources, the properties of monitored resources, and detailed information about the performance of monitored resources.

To learn about how to use the Cognos Analytics reporting tool, see [Reporting with Cognos Analytics](#).

Dashboard view

Use the dashboard to monitor the overall condition of monitored resources and identify potential problem areas in a storage environment. The dashboard also displays alerts, as well as a chart showing the most active storage systems.

Viewing the status of monitored resources

The dashboard provides status information for the resources that IBM Spectrum® Control is monitoring.

The overall status for each resource type

A status symbol and number are shown below each resource icon on the dashboard. This symbol represents the most critical status that was detected on the internal resources for a resource type. For example, if 20 storage systems are monitored, and an error was detected on a volume for one of those storage systems, a

1 status is shown below the storage systems icon or label in the dashboard. If no errors, warnings, or unreachable statuses were detected on the monitored resources, then a green symbol is shown without a number.

Use the status to quickly determine the condition of your monitored resources and if any actions must be taken. On the dashboard, the following statuses might be shown for a resource type:

Error (red)

An error status was detected on one or more of the monitored resources for a resource type. Error statuses represent serious problems on a resource. Resolve these problems as soon as possible. View the details of a resource to learn more about the status of its internal resources.

Unreachable (orange)

One or more of the monitored resources for a resource type are not responding. This status might be caused by a problem in the network or by a Storage Resource agent that is no longer running and did not communicate that it was shutting down.

Warning (yellow)

A warning status was detected on one or more of the monitored resources for a resource type. Warning conditions are not critical, but represent potential problems. View the details of a resource to learn more about the status of its internal resources.

Normal (green)

No warnings or errors were detected on the monitored resources for a resource type.

Unknown status (gray)

One or more of the monitored resources for a resource type have an unknown status. This status might occur if no data was collected about a resource. To change an unknown status, use a data collection job to collect status information about the resource.

For information about how status is determined, see [How the condition of a resource is determined](#).

The number of statuses that were detected and acknowledged for each resource type

To view the total number of statuses for a resource type, move the mouse pointer over the related status symbol. Hover help shows the total number of occurrences for each status, and the number of statuses that were acknowledged by a IBM Spectrum Control user. An acknowledged status indicates that a status was reviewed and is either resolved or can be ignored.

Viewing the status of monitored storage systems

Storage systems can be configured for block storage, file storage, object storage, a combination of block and file storage, or a combination of file and object storage. The top left section of the dashboard shows the type, number, and status of the storage systems that IBM Spectrum Control is monitoring. The number in the circle next to the storage system type shows how many storage systems of that type are being monitored. The status icon below each storage system type shows the status of the monitored systems. Click the storage system type, for example Block Storage Systems, to see more detailed status and information about those storage systems. Use the information in the horizontal bar charts to view details about the used and free space of the monitored storage systems in your environment:

Storage systems that are configured for block data

The following information is shown for monitored storage systems that are configured for block data:

Used Block Storage Space

Amount of space that is being used for block data on all the storage systems that are configured for block data.

Available Block Storage Space

Amount of unused space on all the storage systems that are configured for block data.

Storage systems that are configured for file data

The following information is shown for monitored storage systems that are configured for file data:

Used File System Capacity

Amount of file system capacity that is being used by files and directories on the storage systems and filers that are configured for file data.

Available File System Capacity

Amount of unused storage space on the storage systems and filers that are configured for file data.

Storage systems that are configured for object data

The following information is shown for monitored storage systems that are configured for object data:

Used Object Storage Space

Amount of storage space that is used on all the object storage systems.

Available Object Storage Space

Amount of storage space that is available on all the object storage systems.

Viewing the status of monitored resources that are consuming storage

The diagram in the top middle section of the dashboard provides a visual representation of the monitored resources that are consuming storage. You can click the icons in this section to add resources of that type or to see detailed information about the resources you have already added. The number next to each icon shows the number of those resources that are being monitored by IBM Spectrum Control. If IBM Spectrum Control is monitoring resources of a particular type, such as servers, you will see a status icon that shows the overall status of those types of resources.

The types of resources that are consuming storage

Each type of resource in the diagram is represented by an icon. To learn more detailed information about the individual resources that are monitored, click the icon in the diagram. For example, if you click the departments icon, a new page shows detailed information about the individual departments that are being monitored.

The number of resources that are monitored for each resource type

A number in a circle is shown next to each resource icon. This number represents the number of monitored resources for each resource type. For example, if 4 file storage systems are monitored, the value ④ is shown. This number excludes resources that are not monitored by IBM Spectrum Control.

Tip: If no resources are being monitored for a resource type, click its icon on the dashboard to add a resource of that type. For example, if the dashboard shows a 0 next to the departments icon, you can click the icon or the circle for departments to add a department. The GUI guides you through the process for adding the resource for monitoring. For more information about adding resources, see [Adding resources](#).

Viewing the status of monitored network fabrics and switches

The top right section of the dashboard shows the number and status of the fabrics and switches that IBM Spectrum Control is monitoring. The number in the circle next to the fabric or switch icon shows how many fabrics and switches are being monitored. The status icon below the fabric or switch shows the status of those entities. Click the icon to see more detailed status and information about those fabrics and switches. The dashboard shows the following information for the monitored fabrics and switches in your environment:

Fabrics

- The number of fabrics that are being monitored.
- The most critical status of the monitored fabrics. If more than one fabric is monitored, the dashboard shows the most critical status level of those fabrics.

Switches

- The number of switches that are being monitored.
- The most critical status of the monitored switches. If more than one fabric is monitored, the dashboard shows the most critical status level of those switches.

Viewing the status of alerts that were detected on monitored resources

Alerts are generated when IBM Spectrum Control detects certain conditions or events on monitored resources. The Alerts section of the dashboard shows a status summary of the alerts that were detected in your environment during a specified time period. This summary includes the number of alerts that have the following statuses: Critical, Warning, and Informational.

Use the following actions to manage the display of statuses for alerts:

- To select the time period in which you want to view alert statuses, click the down arrow and select a time period. You can view the status of all alerts that were detected in the last hour, last day, or last week.
- To view more detailed information about alerts, click View all alerts to access the Alerts page.

Viewing the most active storage systems in your environment

The Performance chart provides information about the most active storage systems in your storage environment. Position your cursor over a data point in the chart to see the total I/O rate for a particular storage system. The I/O rate is displayed in operations per second (ops/s) on the left vertical axis, and in milliseconds per operation (ms/ops) on the right vertical axis. The horizontal axis shows the time of the performance data in hourly increments.

Viewing information about top-level resources

Use a resource list page as a central location for viewing information about all the monitored resources of a specific type. Resources that have a list page include storage systems, volumes, pools, shares, servers, hypervisors, switches, and fabrics.

About this task

Procedure

1. In the menu bar, hover the mouse pointer over the menu item for the type of resource that you want to view.
You can access the following types of resources:
 - Storage Block storage systems, file storage systems, Object Storage systems, volumes, pools, shares
 - Servers Servers, hypervisors
 - Network Switches, fabrics
2. Select the type of resource that you want to view.
For example, if you want to view information about servers, go to Servers > Servers.
A list of monitored servers is displayed on Servers page.
3. Locate the resource that you want to view in the list.
Each column in the list shows information about the resource.
4. Optional: To view key attributes of a specific top-level resource without leaving the page, right-click the resource and select View Properties.
A properties notebook is displayed. Information in a properties notebook can include storage statistics, hardware attributes, volume assignments, disk assignment, and performance metrics.
5. Optional: To view more detailed information about a specific top-level resource, including its internal and related resources, right-click the resource and select View Details.
A resource details page is displayed. The page includes information about storage statistics, alerts, jobs, internal resources, and related resources.

Results

A resource list page shows information about the monitored resources for the selected type. You can view the following information on the page:

- The overall status of the resources for a specific type.
- Key information about the resources.
- Alerts that were generated for the resources.
- Jobs that were run for the resources.

Tip: To view descriptions of the information that is available on a resource list page, click the Help icon  in the upper right of the page.

To view information about rollup resources, you must be in rollup mode. To enter rollup mode, move the mouse pointer over the rollup icon  in the menu bar and select Enter rollup mode.

- [Resources that you can monitor](#)

Viewing information about internal, object, and related resources

Use resource details pages to view information about a specific top-level resource and its internal, object, and related resources.

About this task

Procedure

1. In the menu bar, hover the mouse pointer over the menu item for the type of resource that you want to view.
You can access the following types of resources:
 - Storage: block storage systems, file storage systems, object storage systems, volumes, pools, shares
 - Servers: servers, hypervisors
 - Network: switches, fabrics
2. Select the type of the resource that you want to view.
A resource list page shows the monitored resources for the selected type. For example, if you want to view a block storage system, go to [Storage > Block Storage Systems](#). A list of monitored block storage systems is displayed.
3. In the list of resources, right-click the resource that you want to view and select View Details.
A resource details page is displayed. This page includes information about storage statistics, alerts, jobs, internal resources, object resources, and related resources.
4. To view information about the internal resources of the top-level resource, click the name of the internal resource in the Internal Resources section.
A list of the internal resources is displayed. Each column in the list shows information about the resources. For example, on the details page for a server, click Controllers to view a list of the controllers that are associated with the server.
5. Optional: To view key attributes of a specific internal resource without leaving the page, right-click the resource and select View Properties.
6. To view information about the object resources in an object storage system, click the name of the object resource in the Object Resources section.
Object resources are associated only with object storage systems, such as IBM Spectrum Scale that is configured for object storage.
7. To view information about resources that are related to the top-level resource, click the name of the related resource in the Related Resources section.
A list of the related resources is displayed. For example, on the server details page, click Block Storage Systems to view a list of the block storage systems that have at least one disk (volume) assigned to the server.
8. Optional: To view key attributes of a specific related resource without leaving the page, right-click the resource and select View Properties.
9. Optional: To view the resource details page for a related resource, right-click the resource and select View Details.

Results

A resource details page shows information about a top-level resource. The information is available in the following links and sections on the page:

- Overview: The overall capacity and storage usage for a resource.
- Properties: Key information about a resource.
- Alerts: Alerts that were generated for a resource.
- Tasks: Jobs that were run for a resource.
- Internal Resources: Information about the components that exist in a higher-level resource.
- Object Resources: Information about the resources in a IBM Spectrum Scale cluster, such as accounts and containers, that enable the IBM Spectrum Scale cluster to be used as an object storage system.
- Related Resources: Information about the resources that are related to another resource. A related resource is external to a higher-level resource, but is related to it through assigned storage, a network connection, or virtual hosting.

Tip: To view descriptions of the information that is available on a resource details page, click the Help icon  in the upper-right corner of the page.

Overview charts

Monitor the activity and storage usage of your storage systems. Use the charts and key metrics to gauge the workload activity of your storage resources and to check whether you have sufficient capacity.

Review the charts and key information about the activity and availability of capacity:

- [For block storage systems](#)
- [For file storage systems](#)
- [For object storage systems](#)

Block storage systems

On the Overview page for a storage system, monitor storage usage, detect capacity shortages, and plan your capacity needs. The type of block storage system determine the information that is displayed.

Metrics for storage systems that have both block and file storage

The following information is shown for storage systems that have both block and file storage, such as Dell EMC Unity and NetApp ONTAP 9:

- The Capacity section shows how much capacity is used and how much capacity is available for storing data.
- The Provisioned Capacity section shows the written capacity values in relation to the total provisioned capacity values before data reduction techniques are applied:
 - % Written: The capacity of the data that is written to the volumes as a percentage of the total provisioned capacity of the volumes.
 - GiB Available: The amount of capacity that is still available for writing data to the thin-provisioned volumes. It is the difference between the provisioned capacity and the written capacity, which is the thin-provisioning savings.

- The Capacity Savings section shows the amount of capacity that is saved by using deduplication, thin provisioning, and the data compression capabilities of the storage system.

Get more views of Capacity, Provisioned Capacity, and Capacity Savings:

- To get a breakdown of the capacity usage by pool or volume, click the links in each section. For example, on the Block Storage Systems page, double-click a storage system, and then click View capacity by pool. You get a capacity breakdown of the storage system by pool, and you see the fill and growth rate for each pool.
- To view the capacity savings of a storage system with data reduction metrics and savings summary that includes duplication, thin provisioning, drive compression, and pool compression, click View capacity savings. If a capacity limit was set, you can hover over the capacity chart and check how much available capacity you have left before you reach the capacity limit.

Figure 1. Capacity and activity charts

Three types of charts are provided:

- Capacity overview charts
- Capacity by storage resource charts
- Workload activity charts

The Capacity chart at the top of the Overview page shows how much capacity is used and how much capacity is available for storing data.

The Provisioned Capacity chart shows the written capacity values in relation to the total provisioned capacity values before data reduction techniques are applied. The following values are shown:

- The capacity of the data that is written to the volumes as a percentage of the total provisioned capacity of the volumes.
- The amount of capacity that is still available for writing data to the thin-provisioned volumes in relation to the total provisioned capacity of the volumes. Available capacity is the difference between the provisioned capacity and the written capacity, which is the thin-provisioning savings.

A breakdown of the total capacity savings that are achieved when the written capacity is stored on the thin-provisioned volumes is also provided.

In the capacity overview chart, a horizontal bar is shown when a capacity limit is set for the storage system. Just hover over the chart to find out what the capacity limit is and how much capacity is left before the capacity limit is reached.

To get a breakdown of the capacity usage by pool or volume, click the links.

Try it: Click View capacity by pool. You get a capacity breakdown of the storage system by pool, and you can see the recent fill and growth rates for each pool in the storage system.

Depending on the type of storage system, the following activity and capacity by storage resource charts are shown:

Table 1. Capacity by storage resource

Chart Name	Purpose
Capacity	Use this chart to monitor the available, used, and provisioned capacity in your storage system over the last 30 days.
Capacity by Host	Use this chart to monitor the current capacity of the storage system that is mapped to hosts.
Capacity by Pool	Use this chart to monitor the current available and used capacity of your largest pools.
Capacity by Volume	Use this chart to monitor the current used and unused provisioned capacity of your largest volumes.
Capacity by Tier	Use this chart to monitor the current used and available capacity of the pools that are assigned to tiers.

Exclusive to IBM Storage Insights Pro: In IBM® Storage Insights Pro, users with Administrator privileges, can set capacity limits for storage systems and pools. When you hover over the capacity overview chart, you can see the value for the Capacity Limit and the Capacity-to-Limit. The Capacity-to-Limit is the amount of capacity that is left before the capacity limit is reached.

Table 2. Activity charts

Chart Name	Purpose
Overall system activity	Use this chart to monitor the overall activity of your storage system, which is broke down into total I/O rate, read I/O rate, and write I/O rate in operations per second over the last 24 hours.
Most Active Nodes	Use this chart to monitor the nodes with the heaviest workloads, which is calculated in operations per second, over the last 24 hours.
Most Active Pools	Use this chart to monitor the pools with the heaviest workloads, which is calculated in operations per second, over the last 24 hours.
Most Active Volumes	Use this chart to monitor the volumes with the highest response times over the last 24 hours.
MDisk Activity	Use this chart to monitor managed disks (M Disks) with the heaviest workloads, which is calculated in operations per second, over the last 24 hours.

File storage systems

The following capacity charts and Inode usage charts are shown for file storage systems:

Table 3. Capacity and Inode charts

Chart Name	Purpose
Total File System Space	Use this chart to monitor the capacity, the used capacity, and the available capacity of your file systems over the last 30 days.
Capacity by File System	Use this chart to monitor the current capacity and the used and available capacity of your fullest file systems .
Inodes by File System	Use this chart to monitor the availability of Inodes.

Object storage systems

The following capacity charts are shown for object storage systems:

Table 4. Charts for object storage systems

Chart Name	Purpose
Capacity	Use this chart to monitor the total capacity, used and available capacity of your object storage system.
Sites	Use this chart to monitor the distribution of Accesser® and SliceStor® nodes across sites.
Capacity by IDA	Use this chart to monitor the used capacity of the vaults that are configured with IDA (Information Dispersal Algorithm).
Failure Tolerance	Monitor the availability and fault tolerance of vaults and SliceStors.

- [Capacity by pool](#)
Monitor the capacity, fill rate %, and growth rate for your pools. You can also check how much capacity is left before the pools reach their capacity limit.
- [Capacity by volume](#)
Monitor the total provisioned capacity of your volumes to identify the volumes that have sufficient capacity to meet your storage needs.

Capacity by pool

Monitor the capacity, fill rate %, and growth rate for your pools. You can also check how much capacity is left before the pools reach their capacity limit.

To help you make decisions about the capacity that you need to store data, monitor the growth in used capacity and the following key capacity metrics:

Adjusted Used Capacity (%)

The amount of capacity that can be used without exceeding the capacity limit.

Example: Adjusted Used Capacity

Before Capacity Limit Was Set

100 GiB Capacity

■ Used Capacity = 40 GiB

■ Available Capacity = 60 GiB

After Capacity Limit Was Set

100 GiB Capacity

■ Capacity Limit = 80 GiB or 80 GiB

■ Adjusted Used Capacity = 50 GiB or 40 GiB

■ Capacity-to-Limit = 30 GiB or 40 GiB

The formula for calculating Adjusted Used Capacity (%) is $(\text{Used Capacity in GiB} / \text{Capacity Limit in GiB}) * 100$. For example, if the capacity is 100 GiB, the used capacity is 40 GiB, and the capacity limit is 80 GiB, then the value for Adjusted Used Capacity (%) is $(40 \text{ GiB} / 80 \text{ GiB}) * 100$ or 50%. So, in this example, you can use 30% or 40 GiB of the usable capacity of the resource before you reach the capacity limit.

If the used capacity exceeds the capacity limit, the value for Adjusted Used Capacity (%) is over 100%.

To add the Adjusted Used Capacity (%) column, right-click any column heading on the Pools page.

See these related values for more information Capacity Limit (%) and Capacity-to-Limit (GiB).

Availability: This metric is not available for all storage systems, such as Dell EMC VMAX.

Available Capacity (GiB)

The amount of usable capacity that is not yet used in the pool.

Capacity (GiB)

The amount of capacity that is available for storing data in the pool after formatting and RAID techniques are applied.

Capacity Limit (%) and Capacity Limit (GiB)

The limit that was set on the capacity that is used by your pools. For example, the policy of your company is to keep 20% of the usable capacity of your pools in reserve. So, you log into the GUI as Administrator and set the capacity limit of your pools to 80%.

Example: Administrator Sets Capacity Limit to 80%

100 GiB Capacity

■ Used Capacity = 40 GiB

■ Available Capacity = 60 GiB

100 GiB Capacity

■ Capacity Limit = 80 GiB or 80 GiB

Click the illustration above to find out how to set capacity limits.

The GiB value for the capacity limit for the pool is calculated when you set the value for the Capacity Limit (%).

To add the Capacity Limit (%) and the Capacity Limit (GiB) columns, right-click any column heading on the Pools page.

See these related values for more information Adjusted Used Capacity (%) and Capacity-to-Limit (GiB).

Zero capacity: When you set the capacity limit for pools, the values shown for Zero Capacity are readjusted to take into account the capacity limit of the pool. The date will represent when the capacity limit of the pool is reached. If the pool has already reached the capacity limit, Depleted is shown. None is shown when a trend in storage consumption can't be detected because the pool's storage isn't being consumed or because not enough data was collected to predict storage consumption.

Availability: This metric is not available for all storage systems, such as Dell EMC VMAX.

Capacity-to-Limit (GiB)

The amount of capacity that is available before the capacity limit is reached.

Example: Capacity-to-Limit

The formula for calculating Capacity-to-Limit (GiB) is (Capacity Limit in GiB - Used Capacity in GiB). For example, if the capacity limit is 80% or 80 GiB and the used capacity is 40 GiB, then the value for Capacity-to-Limit (GiB) is (80 GiB - 40 GiB or 80% - 50%) which is 30% or 40 GiB.

See these related values for more information Capacity Limit (%) and Adjusted Used Capacity (%).

This metric is not available for all storage systems, such as FlashSystem A9000, FlashSystem A9000R, and Dell EMC VMAX.

Used Capacity (GiB) and Used Capacity (%)

The amount of usable capacity that is taken up by the data in the pool after data reduction techniques have been applied.

Availability: All storage systems, except FlashSystem A9000 and FlashSystem A9000R.

Recent Fill Rate (%)

The rate at which the capacity of the pool is being consumed over the last 30 days. Use this value to see how quickly your pools are filling up.

The Recent Fill Rate (%) tells you how quickly your pools are filling up

The Recent Fill Rate (%) of the pool is the difference between the fill rate % of the pool 30 days ago and today's fill rate % of the pool.

The fill rate % of the pool is calculated by dividing the capacity of the pool by its used capacity and multiplying it by 100.

Example

The fill rate % of the pool 30 days ago was $(40/100) \times 100$, which is 40%.

The fill rate % of the pool today is $(60/100) \times 100$, which is 60%.

So, in this example, the Recent Fill Rate (%) for the pool is $(60\% - 40\%)$, which is 20%.

If insufficient historical data is available to calculate the Recent Fill Rate (%), it is the difference between today's fill rate % and the oldest value for the fill rate % that can be calculated in the last 30 days.

Availability: This metric is not available for all storage systems, such as FlashSystem A9000, FlashSystem A9000R, and Dell EMC VMAX.

Recent Growth (GiB)

The growth in used capacity over the last 30 days. Use this value to identify the pools with the highest growth in storage consumption.

Recent growth is the difference between the current used capacity for the pool and the used capacity for the pool that was reported 30 days ago. If insufficient historical data is available, it is the difference between the current used capacity for the pool and the oldest value for the used capacity of the pool that was reported in the last 30 days.

Availability: This metric is not available for all storage systems, such as FlashSystem A9000, FlashSystem A9000R, and Dell EMC VMAX.

Tier Distribution (%)

For storage systems that support Easy Tier®, the distribution of the capacity of the volume extents across each drive class or tier.

Tip: To check the fill rate of all the pools in your storage systems, click [Storage > Block Storage Systems](#). To check the growth in used capacity, right-click any column heading on the Block Storage Systems page and click Recent Growth (GiB).

Monitor the total provisioned capacity of your volumes to identify the volumes that have sufficient capacity to meet your storage needs.

The following key capacity metrics provide information about storage usage and the availability of capacity for storing data:

Capacity (GiB)

The provisioned capacity of the volume.

Used Capacity (GiB) and Used Capacity (%)

The amount of provisioned capacity that is taken up by written data in a thin-provisioned volume after data reduction techniques are applied.

Unlike thin-provisioned volumes, which use capacity when it is needed, the capacity that is provisioned to standard-provisioned volumes is fully allocated and is no longer available to the pool. That is, the Used Capacity (%) of standard-provisioned volumes is reported as `Fully Allocated` and the Used Capacity (GiB) is the same value as the provisioned capacity.

Available for: All storage systems, except FlashSystem A9000 and FlashSystem A9000R.

Available Capacity (GiB)

The difference between the provisioned capacity of the thin-provisioned volume and the used capacity of the thin-provisioned volume.

Because the pool's capacity is dedicated to the standard-provisioned volume, the Available Capacity (GiB) is reported as `0.00`.

Tier Distribution (%)

For storage systems that support Easy Tier®, the distribution of capacity for the volume extents across each drive class or tier.

Viewing information about enclosures

View information about enclosures. Enclosures are the metal structures in which various storage components are mounted, including control units, nodes, disks and drives, and power supplies.

Information about enclosures is available for storage systems, including systems that run IBM Spectrum Virtualize.

To view information about enclosures and their related resources, complete any of the following tasks:

Table 1. Viewing information about enclosures

Actions	Navigation
<p>View information about the enclosures that are associated with a storage system.</p> <p>Depending on the type of storage system, the following information about an enclosure is shown:</p> <ul style="list-style-type: none">• Status• Type of enclosure: Control, Expansion, or Storage• Machine Type model (MTM)• Physical location• I/O Group• The number of disks, drives, and slots that it contains• The number of nodes that it contains• The number of power supplies and canisters that it contains• The status of its power supplies (PSUs) and canisters	<ol style="list-style-type: none">1. In the menu bar, go to Storage >> Block Storage Systems.2. Right-click a storage system and select View Details.3. Under Internal Resources, click Enclosures.
<p>View the disks in an enclosure.</p>	<ol style="list-style-type: none">1. In the menu bar, go to Storage >> Block Storage Systems.2. Right-click a storage system and select View Details.3. Under Internal Resources, click Enclosures.4. In the Disks column, click the number to view more information about each of the disks.
<p>View the enclosure that a disk or drive is in.</p>	<ol style="list-style-type: none">1. In the menu bar, go to Storage >> Block Storage Systems.2. Right-click a storage system and select View Details.3. Under Internal Resources, click Disks or Drives.4. In the Enclosure column, view the name of the enclosure.5. (Optional) To view information about the enclosure, click its name.
<p>View the nodes in an enclosure.</p>	<ol style="list-style-type: none">1. In the menu bar, go to Storage >> Block Storage Systems.2. Right-click a storage system and select View Details.3. Under Internal Resources, click Enclosures.4. In the Nodes column, click the number to view more information about each of the nodes.
<p>View the enclosure that a node is in.</p>	<ol style="list-style-type: none">1. In the menu bar, go to Storage >> Block Storage Systems.2. Right-click a storage system and select View Details.3. Under Internal Resources, click Nodes.4. In the Enclosure column, view the name of the enclosure.5. (Optional) To view information about the enclosure, click its name.

Actions	Navigation
View the statuses of power supplies (PSUs) in an enclosure.	<ol style="list-style-type: none"> 1. In the menu bar, go to Storage > Block Storage Systems. 2. Right-click a storage system and select View Details. 3. Under Internal Resources, click Enclosures. 4. Right-click an enclosure and select View Properties. 5. View the Power Supply Status field.
View the statuses of canisters in an enclosure.	<ol style="list-style-type: none"> 1. In the menu bar, go to Storage > Block Storage Systems. 2. Right-click a storage system and select View Details. 3. Under Internal Resources, click Enclosures. 4. Right-click an enclosure and select View Properties. 5. View the Canister Status field.
<p>Add enclosures to general groups.</p> <p>Adding storage systems and their associated enclosures to general groups can be helpful when you want to receive alert notifications about changes to a group of logically related storage systems.</p>	<ol style="list-style-type: none"> 1. In the menu bar, go to Storage > Block Storage Systems. 2. Right-click a storage system and select View Details. 3. Under Internal Resources, click Enclosures. 4. Right-click an enclosure and select Add to General Group. 5. Add the enclosure to an existing group or create a new group and click Save.

Monitoring the status and condition of resources

Monitor the operational condition of storage systems, servers, hypervisors, fabrics, and switches and the status of their internal resources. Use this information to identify potential problem areas in a storage environment.

Table 1. Monitoring the status and condition of resources

	Explanation	Steps to view status or condition
Status	<p>The status of a resource that is reported by its own hardware to IBM Spectrum® Control. Statuses include Normal, Online, Offline, Degraded Ports, Operational, Error, Stopped, Starting, Completed, Unknown, and other statuses. Use the status to determine the condition, and if any actions must be taken to correct the problem. For example:</p> <ul style="list-style-type: none"> • If the cooling fans in a storage system are stopped and the internal temperature is too high, an error status  is reported by that storage system. • If a disk on a storage system is starting, a warning status  is reported for that disk by the storage system. <p>Tip: The status of internal resources is used to determine the operational condition of the associated top-level resources.</p>	<ol style="list-style-type: none"> 1. In the menu bar, go to the resource type that you want to view. For example, if you want to view the status of switches, go to Network > Switches. 2. Right-click a resource and select View Details. A status icon is shown next to the image of its related resource and its internal resources.
Condition	<p>The overall operational condition of a storage system, server, hypervisor, fabric, or switch. This condition represents the most critical status that was detected on the resource itself and on its internal resources.</p> <p>For example, if an error status was detected on a storage system pool, an error icon  is shown for the overall condition of the storage system. If no errors, warnings, or unreachable statuses were detected on a resource or on its internal resources, then a green symbol is shown for the condition of the storage system.</p> <p>Tip: Call Home events do not affect the condition of a top-level resource.</p>	<p>Dashboard view</p> <p>In the menu bar, go to Home > Dashboard. The icons that show overall condition are shown next to the image of a resource type.</p> <p>Resource list pages</p> <p>In the menu bar, go to the resource type that you want to view. For example, if you want to view the condition of switches, go to Network > Switches. The overall condition of a resource is displayed in the Condition column, and aggregated in the condition icons at the top left corner of its details page.</p>

IBM Spectrum Control IBM® Storage Insights provides a number of different icons to help you quickly determine the health of resources.

Table 2. Possible statuses and conditions of resources

Icon	Health	Explanation
	Error	A serious problem was detected on a resource or on its internal resources. Resolve these problems as soon as possible.
	Error - Acknowledged	<p>An Error status was detected and acknowledged. An Error - Acknowledged status indicates that a status was reviewed and is either resolved or can be ignored.</p> <p>An acknowledged status is not used when determining the condition of related, higher-level resources. For example, if the status of a volume is Error, the condition of the associated storage system is also Error. If the Error status of the volume is acknowledged, its status is not used to determine the overall condition of the storage system.</p>

Icon	Health	Explanation
	Unreachable	A resource is not responding to requests from the IBM Spectrum Control server. This status might be caused by a problem in the network or by a Storage Resource agent that is no longer running and did not communicate that it was shutting down.
	Unreachable - Acknowledged	<p>An Unreachable status was detected and acknowledged. An Unreachable - Acknowledged status indicates that a status was reviewed and is either resolved or can be ignored.</p> <p>An acknowledged status is not used when determining the condition of related, higher-level resources. For example, if the status of a controller is Unreachable, the condition of the associated server is also unreachable. If the Unreachable status of the controller is acknowledged, its status is not used to determine the overall condition of the server.</p>
	Warning	A Warning status represents potential problems on a resource or on its internal resources. This status is not critical.
	Warning - Acknowledged	<p>A Warning status was detected and acknowledged. A Warning - Acknowledged status indicates that a status was reviewed and is either resolved or can be ignored.</p> <p>A Warning - Acknowledged status is not used when determining the condition of related, higher-level resources. For example, if the status of a controller is Warning, the condition of the associated server is also Warning. If the Warning status of the controller is acknowledged, its status is not used to determine the overall condition of the server.</p>
	Normal	No warnings or errors were detected on a monitored resource.
	Not Monitored	For hosts, this status is displayed when IBM Spectrum Control monitors the storage system that the host is connected to, but the host itself was not added for monitoring. Unmonitored hosts are automatically created based on the host connections of monitored storage systems. Each host connection is represented as an unmonitored host.
	Unknown	A resource is known to IBM Spectrum Control but is not monitored. To change an Unknown status, run a probe to collect status information about the resource.

- [How the condition of a resource is determined](#)
The operational condition of a resource represents the most critical status that was detected on the resource itself and on its internal resources.
- [Viewing the overall condition of resources](#)
On the dashboard, you get an overview of the health of your storage resources such as fabrics, hypervisors, servers, storage systems, and switches and of storage consumers such as departments and applications.
- [Viewing the condition of specific types of resources](#)
Use resource list pages as a central location for viewing the condition of storage systems, servers, hypervisors, switches, and fabrics.
- [Viewing the status of resources](#)
Use detail pages to view the status of storage systems, servers, hypervisors, switches, and fabrics and the status of their internal resources. The status of a resource is reported to IBM Spectrum Control by its hardware.
- [Acknowledging the condition and status of resources](#)
Sometimes the status of resources might represent problems that commonly occur but can be ignored. In such cases, you can acknowledge those statuses so that they are not used when determining the overall condition of storage systems, servers, hypervisors, fabrics, and switches.
- [Monitoring vaults in IBM Cloud Object Storage](#)
Monitor access risk and storage risk for vaults in IBM Cloud Object Storage.

How the condition of a resource is determined

The operational condition of a resource represents the most critical status that was detected on the resource itself and on its internal resources.

To determine the condition of top-level resources (storage systems, servers, hypervisors, fabrics, and switches), IBM Spectrum® Control uses the status of those resources and the status of their internal resources.

The statuses of the following internal resources are used to calculate the overall condition of a top-level resource.

Table 1. Internal resources that are used to determine the condition of top-level resources

Top-level resource	Internal resources that are used to determine the condition of a top-level resource
 Fabric	 Ports  Switches
 Switch	 Blades  Inter-switch connections  Logical switches  Ports
	 Switches  Trunks  Blades  Ports
 Hypervisor	 Disks  Virtual machines  VMDKs

Top-level resource	Internal resources that are used to determine the condition of a top-level resource
 Server	 Controllers  Disks
 Block storage system	 Disks  Drives  External disks  FC ports  I/O groups  IP ports  Managed disks  Modules  Nodes  Pools  RAID arrays  Volumes
 File storage system	 Network shared disks  Nodes
 Object storage system	 Network shared disks  Nodes

The following statuses of internal resources are used to help calculate the condition of top-level resources:

- Normal
- Warning
- Error

Exceptions:

- Statuses that are acknowledged are not used to calculate the overall condition of a top-level resource.
- Events that are detected through Call Home do not affect the overall condition of a top-level resource. For example, a critical event is detected by Call Home, but the status of the storage system and its internal resources are normal based on metadata collection. In this case, the condition of the top-level resource remains as normal.

Internal resources for a top-level resource might have different statuses. IBM Spectrum Control[®] Storage Insights uses the most critical status of an internal resource to help determine the overall condition of a top-level resource. For example, in a storage system, a port might have an Error status, a pool might have a Warning status, and multiple controllers might have an Unknown status. In this case, if the storage system itself has a normal status, its overall condition is Error because it is the most critical status that was detected on internal resources.

The following table shows some of the possible combinations of statuses and the resulting, overall condition for a top-level resource.

Table 2. Propagation of the statuses for resources

Error 	Unreachable ¹ 	Warning 	Normal 	Unknown ² 	Resulting condition for a top-level resource
				X	 Unknown
			X		 Normal
			X	X	 Normal
		X			 Warning
		X		X	 Warning
		X	X	X	 Warning
	X				 Unreachable
	X			X	 Unreachable
	X		X	X	 Unreachable

Error 	Unreachable ¹ 	Warning 	Normal 	Unknown ² 	Resulting condition for a top-level resource
	X	X	X	X	 Unreachable
X					 Error
X				X	 Error
X			X	X	 Error
X		X	X	X	 Error
X	X	X	X	X	 Error

Note:

- The Unreachable status applies only to top-level resources.
- The Unknown status of an internal resource is not used to determine the condition of a top-level resource.

Viewing the overall condition of resources

On the dashboard, you get an overview of the health of your storage resources such as fabrics, hypervisors, servers, storage systems, and switches and of storage consumers such as departments and applications.

About this task

The condition of a resource represents the most critical status that was detected on that resource or on its internal resources.

Procedure

- From the Home menu, click Dashboard.
- Review the health of your storage environment.
The following conditions icons are shown for block storage systems:

-  Error
-  Unreachable
-  Warning
-  Normal

Viewing the condition of specific types of resources

Use resource list pages as a central location for viewing the condition of storage systems, servers, hypervisors, switches, and fabrics.

Procedure

- In the menu bar, go to the type of top-level resource that you want to view.
For example, if you want to view the condition of switches, go to Network > Switches.
- To view the total number of different conditions that were detected for the type of resource, check the condition icons on the resource list page.
The number next to the icon represents how many occurrences of each condition were detected.
For example, if 15 switches are monitored, but five switches have internal resources with a warning status, two switches have internal resources with an unreachable status, and three switches have internal resources with an error status, the following condition information is displayed:

-  5 Normal
-  5 Warning
-  2 Unreachable
-  3 Error

- To view the condition for specific resources, check the Condition column in the list of resources.
- Optional: Click the Search icon  to filter the list so that only resources with a specified condition are shown.
You can use filtering to identify the resources with the most serious conditions in your environment.
- Optional: Select Condition.
- Optional: In the Choose Value list, select the condition on which you want to filter.

The list of resources is automatically refreshed and only resources with the filtered status are shown. For example, select Warning  to view only the resources with a Warning condition.

Viewing the status of resources

Use detail pages to view the status of storage systems, servers, hypervisors, switches, and fabrics and the status of their internal resources. The status of a resource is reported to IBM Spectrum® Control by its hardware.

About this task

The status of a resource is different from the operational condition that is calculated by IBM Spectrum Control for top-level resources:

- *Condition* is determined by propagating the statuses of resources and is only shown for top-level resources.
- *Status* represents the status of a resource as reported by its hardware and is shown for top-level resources and internal resources. The following examples illustrate statuses that might be reported by a resource:
 - If the cooling fans in a storage system are stopped and the internal temperature is too high, an error status  is reported by that storage system.
 - If a disk on a storage system is starting, a warning status  is reported for that disk by the storage system.

Tip: View condition to identify which top-level resources might be encountering problems. View status to identify the specific resources that are causing the problems in a top-level resource.

Procedure

1. In the menu bar, go to the resource type that you want to view.
For example, if you want to view the status of block storage systems and their internal resources, go to Storage > Block Storage Systems.
2. Right-click a resource and select View Details.
3. To view the status of the top-level resource, view the status icon that is displayed next to its image on the page.
4. To view the aggregated status of an internal resource, view the status icon that is displayed next to its image in the Internal Resources section.
If a resource has a status other than normal, an icon is displayed for the most critical status.
For example, if a server has three controllers with an error status and two controllers with a warning status, the error status icon is shown for controllers in the Internal Resources section:

5. To view the status of a specific internal resource, click the name of that internal resource in the Internal Resources section.
A list of the monitored internal resources is displayed. For example, on the details page for a server, click Controllers (5) to view a list of the five controllers that are associated with the server.
6. Check the Status column to view the status for each internal resource.
Tip: When you view information about some internal resources, the Status column might show values that are more specific than Error, Unreachable, Warning, Unreachable, Unknown, and Normal. Use this additional status to determine the cause of the problem for an internal resource.
For example, in the Internal Resources section on the details page for a storage system, an error status might be shown for managed disks:

When you view the list of managed disks, the Status column might show an Offline status for a specific managed disk. When a managed disk is reported as offline, an error status icon  indicates that status.

Acknowledging the condition and status of resources

Sometimes the status of resources might represent problems that commonly occur but can be ignored. In such cases, you can acknowledge those statuses so that they are not used when determining the overall condition of storage systems, servers, hypervisors, fabrics, and switches.

- [Acknowledging the condition of top-level resources](#)
A summary of the conditions for storage systems, servers, hypervisors, fabrics, and switches is available in the Dashboard view and on resource list pages. You can acknowledge the condition of a top-level resource so that its condition is not shown as Error, Unreachable, or Warning on those pages.
- [Acknowledging the status of internal resources](#)
The statuses of internal resources are used to determine the condition of the associated storage systems, servers, hypervisors, fabrics, and switches. Sometimes these statuses might represent problems that commonly occur or are known, but can be ignored. In such cases, you can acknowledge the status of an internal resource so that it is not used to determine the condition of a top-level resource.

Acknowledging the condition of top-level resources

A summary of the conditions for storage systems, servers, hypervisors, fabrics, and switches is available in the Dashboard view and on resource list pages. You can acknowledge the condition of a top-level resource so that its condition is not shown as Error, Unreachable, or Warning on those pages.

Procedure

1. In the menu bar, go to the type of resource that has a condition you want to acknowledge.
For example, if you want to acknowledge the condition of a switch, go to Network > Switches.
2. In the list of resources, locate the resource with the Error, Unreachable, or Warning condition that you want to acknowledge.
3. Right-click the resource and select Mark Condition as Acknowledged.

A window shows that the condition for the specified resource was acknowledged.

- Optional: To acknowledge the condition of multiple resources at the same time, press Ctrl and click each resource. To select a series of resources, select the first resource, and then press Shift and click the last resource. When the resources are selected, right-click a row in the list and select Mark Condition as Acknowledged.
- Click Close.

Results

When you acknowledge the condition of a top-level resource, the following actions are taken:

Dashboard view

- The condition of the acknowledged resource is not used to determine the condition icon that is displayed for that resource type on the Dashboard view. For example, if you acknowledge the unreachable condition for a switch, the condition of that switch is not used to determine the number of unreachable conditions that is shown for switches on the Dashboard view.
- The acknowledged condition is shown as Acknowledged for a resource on the Dashboard view. For example, if 10 switches have Unreachable conditions and you acknowledge the condition for one of them, the following information is shown for switches:

 9 Unreachable (1 Acknowledged)

Resource details page

- The condition icons at the top of the page are updated. For example, if 10 switches have Unreachable conditions, and you acknowledge one of them, the total number Unreachable conditions decreases by one and the number of Unreachable - Acknowledged conditions increases by one. The following information is updated at the top of the Switches page:

 9 Unreachable  1 Unreachable - Acknowledged

- The value in the Condition column for the resource is updated to show an acknowledged condition. For example, if you acknowledge the Unreachable condition for a switch, the following value is shown in the Condition column:

 Unreachable

- [How the condition of a resource is determined](#)

Acknowledging the status of internal resources

The statuses of internal resources are used to determine the condition of the associated storage systems, servers, hypervisors, fabrics, and switches. Sometimes these statuses might represent problems that commonly occur or are known, but can be ignored. In such cases, you can acknowledge the status of an internal resource so that it is not used to determine the condition of a top-level resource.

About this task

For example, if the status of a volume is Error, the condition of the associated storage system is also Error. If the Error status of the volume is acknowledged, its status is not used to determine the overall condition of its storage system. In this case, if the other internal resources of the storage system are Normal, then the condition of the storage system is also Normal.

Procedure

- In the menu bar, go to the type of resource in which the internal resource is located.
For example, if you want to acknowledge the status of internal resources for a switch, go to Network > Switches.
- Right-click a resource and select View Details.
For example, if you want to acknowledge the status of a port on a switch, right-click that switch and select View Details.
- In the Internal Resources section of the resource details page, click the name of the internal resource.
For example, if you want to acknowledge the status of a port on a switch, click Ports.
- Right-click the resource and select Mark Condition as Acknowledged.
A window shows that the status for the specified resource was acknowledged. For example, if you want to acknowledge the status of a port, right-click the port and select Mark Condition as Acknowledged.
- Optional: To acknowledge multiple resources at the same time, press Ctrl and click each resource. To select a series of resources, select the first resource, and then press Shift and click the last resource. When the resources are selected, right-click a row in the list and select Mark Condition as Acknowledged.
- Click Close.
The status of the related, top-level resource might take several minutes to update.

Results

When you acknowledge the status of an internal resource, the following actions occur:

- The status of the internal resource is no longer used to determine the condition of the associated top-level resource.
- The status icons at the top of the page for the internal resource are updated.
For example, if you acknowledge the Error status for a controller on a server, the total number of Error statuses decreases by one and the number of Error - Acknowledged statuses increases by one on the Controllers page. If originally there were five controllers with Error statuses, the following updated status information is shown:

Monitoring vaults in IBM Cloud Object Storage

Monitor access risk and storage risk for vaults in IBM® Cloud Object Storage.

You can use this information to complete the following tasks:

- Identify the vaults that cannot be accessed and the vaults that are at risk of access failure.
- Identify the vaults that are not available for write operations and the vaults that are at risk of storage failure.
- [Monitoring access to vaults in IBM Cloud Object Storage](#)
In these scenarios, you use IBM Spectrum® Control to identify the vaults that cannot be accessed and the vaults that are at risk of access failure. Then, you identify the access pools and the COS Accesser® nodes that the vaults depend on.
- [Calculating the failure tolerance for vaults](#)
The failure tolerance value for vaults represents the tolerance of a vault to drive failures across all of the COS Slicestor® nodes in its storage pool. The lower the value for drive failure tolerance, the greater the risk that write operations can no longer be completed for the vault.

Monitoring access to vaults in IBM Cloud Object Storage

In these scenarios, you use IBM Spectrum® Control to identify the vaults that cannot be accessed and the vaults that are at risk of access failure. Then, you identify the access pools and the COS Accesser® nodes that the vaults depend on.

How the accessibility value for a vault is determined

The accessibility value that is calculated for each vault comprises the number of COS Accesser nodes that are available to access the vault. For example, if five COS Accesser nodes are configured for a vault and four of the nodes are in a failed state, then the accessibility value is one.

On the details page for IBM® Cloud Object Storage, the Vaults by Accessers chart shows the vaults that are inaccessible and the accessibility values for the remaining vaults in the storage system.

- [Investigating vaults that cannot be accessed](#)
In this scenario, you use IBM Spectrum Control to identify the vaults that cannot be accessed because of COS Accesser node failures.
- [Monitoring vaults that are at risk of access failure](#)
In this scenario, you use IBM Spectrum Control to check which vaults are at risk because of COS Accesser node failures.

Investigating vaults that cannot be accessed

In this scenario, you use IBM Spectrum® Control to identify the vaults that cannot be accessed because of COS Accesser® node failures.

About this task

You have a backup application that uses IBM® Cloud Object Storage vaults. Because the application is critical to your business, you want to quickly identify vaults that cannot be accessed because of COS Accesser node failures. You also want to know the access pools that the vaults depend on and the COS Accesser nodes that failed in those pools.

Procedure

1. To determine whether any of your vaults cannot be accessed, click Storage > Object Storage Systems.
2. Right-click the storage system that is used by your backup application and click View Details.
3. In the navigation pane, click Overview.
The first line of the Vaults by Accessers chart shows the number of vaults that cannot be accessed, for example, Inaccessible 4.
4. To identify the vaults that are inaccessible, click Vaults in the navigation pane. To sort the data, click the Accessibility column.

A value of 0 in the Accessibility column indicates that the vault is inaccessible. The error status  indicates that the vault is inaccessible because none of the COS Accesser nodes that are configured for the vault are available. In this scenario, all the inaccessible vaults are configured to use just one access pool. The name of that access pool is shown in Access Pools.

Vaults

✓ 104 Normal
⚠ 2 Warning
✗ 5 Error

Actions		
Name	Access Pools	Accessibility
accessertest1	AccessPool2	✗ 0
demovault7	AccessPool2	✗ 0
myvault	AccessPool2	✗ 0
vault2	AccessPool2	✗ 0

5. To identify the COS Accesser nodes that failed in the access pool, click the access pool name. Then, click the Accesser Nodes tab.

What to do next

To restore access to the vaults, fix the COS Accesser nodes that failed or add COS Accesser nodes to the access pool.

Monitoring vaults that are at risk of access failure

In this scenario, you use IBM Spectrum® Control to check which vaults are at risk because of COS Accesser® node failures.

About this task

You have a backup application that uses IBM® Cloud Object Storage vaults. Because the application is critical to your business, you want to monitor the tolerance of the vaults to COS Accesser node failures and identify the vaults that are at risk of access failure.

For the vaults with a high risk of failure, you want to identify the access pools that the vaults depend on and the status of the COS Accesser nodes in the access pools.

Procedure

1. Click **Storage > Object Storage Systems**.
2. Right-click the storage system that is used by your backup application and click **View Details**.
3. In the navigation pane, click **Overview**.

The **Vaults by Accessers** chart shows the tolerance of the vaults to COS Accesser node failures. For example, a line on the chart that shows a value of 1 **Node Failure 57 Vaults at Risk** indicates that 57 vaults rely on a single COS Accesser node for access. If the node fails, the vault cannot be accessed.

4. To identify the vaults with an accessibility value of 1, click **Vaults** in the navigation pane. To sort the data, click the **Accessibility** column.

Vaults

✓ 104 Normal
⚠ 2 Warning
✗ 5 Error

Actions		
Name	Access Pools	Accessibility
failovertest	2	⚠ 1
test2	2	⚠ 1
DemoVault	AccessPool1	1
arun878172498111...	AccessPool1	1
arunagiri123	AccessPool1	1
arunagiri123.meta	AccessPool1	1
containermodetest	AccessPool1	1

In this scenario, there are some vaults that depend on only one access pool. The name of that access pool is shown in Access Pools. For other vaults that depend on multiple pools, a number is shown in Access Pools instead.

Tip: To reduce the risk of access failure for the vaults that depend on only one access pool, add COS Accesser nodes to the access pool or deploy the vaults to other access pools.

For the vaults that depend on multiple access pools, the warning status  indicates that some of the COS Accesser nodes in the pools are not available.

5. To investigate the cause of the access warning, click the number in the Access Pools column.

You see that one of the access pools is shown with an error status , which indicates that the COS Accesser nodes in the pool are not available.

6. To identify the COS Accesser nodes that failed in the access pool, click Accesser Nodes in the navigation pane. To sort the data, click the Access Pool column.

What to do next

Fix the COS Accesser nodes that failed or add COS Accesser nodes to the access pool.

Calculating the failure tolerance for vaults

The failure tolerance value for vaults represents the tolerance of a vault to drive failures across all of the COS Slicestor® nodes in its storage pool. The lower the value for drive failure tolerance, the greater the risk that write operations can no longer be completed for the vault.

The calculation of drive failure tolerance is based on the following values:

- The write threshold value in the IDA that is configured for the vault. The write threshold is the minimum number of COS Slicestor nodes that must be available to complete write operations for the vault.
- The number of available COS Slicestor nodes in the storage pool that the vault belongs to.
- The value for drive failure tolerance for each of the available COS Slicestor nodes in the storage pool. This value represents the tolerance of the node to drive failures and is based on the number of failed drives in the node and the drive error threshold. A value of 2 means that the node will be unavailable to store vault data if 2 drives fail in the node.

For example, a vault in your IBM® Cloud Object Storage environment is configured with an IDA of 8-4-6. The IDA determines that the vault data is stored across 8 COS Slicestor nodes and a minimum of 6 nodes must be available to complete write operations for the vault.

The nodes have the following values for drive failure tolerance:

Node	Drive Failure Tolerance
node_1	3
node_2	4
node_3	0*
node_4	2
node_5	4
node_6	1
node_7	3
node_8	3

*A failure tolerance value of 0 means that node_3 is not available to store vault data.

7 COS Slicestor nodes are available in the storage pool and a minimum of 6 nodes must be available to complete write operations. Therefore, if 2 more nodes fail, the write threshold value is exceeded and write operations can no longer be completed for the vault.

Use the following steps to calculate the value for drive failure tolerance for a vault:

1. Use the IDA column on the Vaults page to identify the write threshold value for the vault. In the example, the write threshold value is 6.
2. Use the Slicestor Nodes page to determine the number of available COS Slicestor nodes in the storage pool that the vault belongs to. A value > 0 in the Drive Failure Tolerance column means that the node is available. In the example, 7 nodes are available.
3. Calculate how many nodes must fail for the number of available nodes to fall below the write threshold value. In the example, $(7 - 6) + 1 = 2$. When 2 nodes fail, the vault is not available for write operations.
4. Use the Drive Failure Tolerance column on the Slicestor Nodes page to identify the 2 available nodes in the storage pool that have the lowest tolerance to drive failures.

In the example, the 2 nodes are as follows:

Node	Drive Failure Tolerance
node_4	2
node_6	1

5. To calculate the overall failure tolerance for the vault, sum the failure tolerance values for the 2 nodes. $2 + 1 = 3$.
The drive failure tolerance for the vault is 3. If 3 drives fail, write operations can no longer be completed for the vault.

Monitoring the performance of resources

IBM Spectrum® Control can collect information about the performance of storage systems and switches. This information includes key performance metrics that can help you measure, identify, and troubleshoot performance issues and bottlenecks in your storage.

You can use the performance monitoring to complete the following tasks:

- Measure, compare, and troubleshoot the performance of switches, storage systems, and their internal resources.
- Review the alerts that were triggered when the performance of a resource fell outside of a specific range.
- Customize views of performance so that you can analyze specific resources and metrics during time ranges that you specify.

- View performance information in a chart or table format to help you quickly identify where and when performance issues are occurring. The chart is a visual representation of how the performance of resources trend over time.
- Drill down into resources to view detailed information about the performance of internal and related resources. For example, if a SAN Volume Controller is shown in the chart, you can quickly view and compare the performance of its internal and related resources, such as disks, volumes, ports, managed disks, and back-end storage.
- Implement server-centric monitoring of SAN resources without requiring a Storage Resource agent. When you add an agentless server, IBM Spectrum Control correlates the server with the known host connections on monitored storage systems. If matches are found, you can view the amount of storage that is assigned to the server, and trace that storage back to the storage system. You can then view details about the internal resources of the related storage system, including performance information.
- Export performance information to a CSV file. A CSV file is a file that contains comma-delimited values and can be viewed with a text editor or imported into a spreadsheet application.

Before you begin

Before you can view performance information for resources, you must complete the following tasks:

Task	 Learn more
Add storage systems and switches for monitoring by IBM Spectrum Control.	For information about how to add these resources, see the following topics: <ul style="list-style-type: none"> • Adding storage systems • Adding fabrics and switches
Ensure that performance data is being collected for a resource. Typically, data collection is scheduled when resources are added for monitoring.	For information about verifying data collection and scheduling performance monitors, see the following topics: <ul style="list-style-type: none"> • Verifying that a performance monitor is running for a resource • Creating performance monitors in IBM Spectrum Control
Define performance alerts to be notified if the performance of a resource falls outside a specified range and might represent a potential problem. When you define a performance alert for a resource, select a specific metric that you want to measure. For example, you can define a threshold that notifies you when the total I/O port rate for a storage system falls outside a specified range.	For information about how to define performance alerts, see Defining alert definitions for performance changes .

- [Viewing performance information](#)
View the performance of storage systems, switches, and their internal resources. You can also view the performance of resources that violated a performance threshold and generated an alert.
- [IBM Spectrum Virtualize guideline values for key performance indicators](#)
To improve the performance and resiliency of your storage environment, compare the guideline values for key performance indicators with the values reported for your storage systems and devices.
- [Viewing performance alerts](#)
View the alerts that were generated when the measured value of a performance metric falls outside of the specified threshold for a resource.
- [Exporting performance data for storage systems and fabrics](#)
To help resolve performance issues with storage systems and fabrics, you can export performance data for the resources to a compressed file. If you contact IBM® Support to help you analyze the problem, you might be asked to send this file.
- [Performance metrics](#)
IBM Spectrum Control can collect information about the performance of storage systems and switches. This information includes metrics that measure the performance of volumes, ports, and disks. You can view performance information or specify alerts for when the performance of a resource falls outside a specified range.

Related reference

- [Performance information is not displayed for a resource](#)

Viewing performance information

View the performance of storage systems, switches, and their internal resources. You can also view the performance of resources that violated a performance threshold and generated an alert.

Before you begin

Before you view the performance of resources, ensure that performance data was collected for those resources during the time ranges that you want to analyze. IBM Spectrum® Control uses performance monitors to collect metrics for measuring the performance of storage systems and switches. For information about how to verify that performance monitors were run, see [Verifying that a performance monitor is running for a resource](#).

About this task

You can access the performance view for a resource from different locations in IBM Spectrum Control:

Task	Accessing the performance view in the GUI
View the performance of specific storage systems, switches, and their internal resources.	<ol style="list-style-type: none"> 1. In the menu bar, go to the type of resource that you want to view. For storage systems, depending on the type of storage system that you want to view, go to Storage > Block Storage Systems, Storage > File Storage Systems, or Storage > Object Storage Systems. For switches, go to Network > Switches. 2. Right-click a resource and select View Performance. By default, the following information is displayed in a chart for each type of resource: <ul style="list-style-type: none"> • For storage systems, the top 5 storage systems with the highest total I/O rate are shown. • For switches, the top 5 switches with the highest total port data rate are shown. 3. To view the performance of an internal resource, right-click the top-level resource in the chart legend and select the option for the internal resource that you want to view. For example, for a SAN Volume Controller, right-click its name in the chart legend and select MDisk Performance to view the performance of its managed disks. For managed disks, the top 5 contributors to the storage system workload are shown on the chart. The default metrics are total back-end I/O rate and total back-end response time. <p>Tips:</p> <ul style="list-style-type: none"> • To add or change the metrics that are displayed for a resource, click the select metrics icon  and select the metrics to display. • You can also view the performance of internal resources on the details page for the related, top-level resource. For more information, see Table 1. • To view the performance of multiple resources at the same time, press Shift or Ctrl and click the resources that you want to view. Press Shift and click to select consecutive rows in the list of resources; press Ctrl and click to select non-consecutive rows. Then, right-click any of the selected resources and select View Performance. Each resource is represented by a separate line in the performance chart and separate rows in the table view.
View the overall performance of resources of the same type.	<ol style="list-style-type: none"> 1. In the menu bar, go to the type of resource that you want to view. For storage systems, depending on the type of storage system that you want to view, go to Storage > Block Storage Systems, Storage > File Storage Systems, or Storage > Object Storage Systems. For switches, go to Network > Switches. 2. Click the Performance tab. By default, the following information is displayed in a chart: <ul style="list-style-type: none"> • For storage systems, the top 5 storage systems with the highest total I/O rate are shown. • For switches, the top 5 switches with the highest total port data rate are shown. <p>Tip: To add or change the metrics that are displayed for a resource, click the select metrics icon  and select the metrics to display.</p>
View the alerts that were generated by threshold violations and the performance of the resources where the violation occurred.	For information about how to view performance alerts, see Viewing performance alerts .
View the performance of a resource that is included in a specific performance monitor.	<ol style="list-style-type: none"> 1. In the menu bar in the web-based GUI, go to Home > Performance Monitors. 2. In the Name column, locate the name of the resource that you want to view. 3. Right-click the performance monitor and select View Performance.
View predefined reports and create custom reports that show the performance of resources. In the optional Cognos® Analytics reporting tool, you can view reports about storage systems, components of storage systems, switches, and switch ports.	<ol style="list-style-type: none"> 1. Go to the URL for your Cognos Analytics server. The URL is similar to this URL: http://myhostname:9300/bi 2. Click Team Content in the Welcome portal. 3. To view a predefined performance report, complete the following steps: <ol style="list-style-type: none"> a. Click IBM Spectrum Control Predefined Reports. b. Navigate to the performance report that you want to view and click the name of the report. 4. To create custom performance reports, complete the following steps: <ol style="list-style-type: none"> a. Click IBM Spectrum Control Packages. b. Right-click Performance, then click Create report. c. Click a template for the report.

You can also view the performance of internal resources on the details pages for the related, top-level resources. For example, you can view the performance of the controllers for a storage system on the details page for that storage system. To access the performance view for an internal resource on a details page, select the type of internal resource and click the Performance tab.

The following information summarizes the internal resources and locations where you can access a performance view.

Table 1. Internal resources and locations where you access the performance view

Internal resource	Locations in the GUI where you can access the performance view
Pools	<ul style="list-style-type: none"> • Storage > Pools • Click Storage, and then click Block Storage Systems, File Storage Systems, or Object Storage Systems, depending on the storage system that you require. Right-click the storage system, click View Details, and click Pools <p>Available only for pools that are associated with the following storage systems and virtualizers: DS8000®, SAN Volume Controller, the IBM® Storwize® family, IBM Spectrum Accelerate, and XIV® systems.</p>
Volumes	<ul style="list-style-type: none"> • Storage > Volumes • Click Storage, and then click Block Storage Systems, File Storage Systems, or Object Storage Systems, depending on the storage system that you require. Right-click the storage system, click View Details, and click Volumes
Controllers	Click Storage, and then click Block Storage Systems, File Storage Systems, or Object Storage Systems, depending on the storage system that you require. Right-click the storage system, click View Details, and click Controllers
Disks	<p>Click Storage, and then click Block Storage Systems, File Storage Systems, or Object Storage Systems, depending on the storage system that you require. Right-click the storage system, click View Details, and click Disks</p> <p>Available only for disks that are associated with storage virtualizers such as SAN Volume Controller and the IBM Storwize family.</p>

Internal resource	Locations in the GUI where you can access the performance view
Host Connections	Click Storage, and then click Block Storage Systems, File Storage Systems, or Object Storage Systems, depending on the storage system that you require. Right-click the storage system, click View Details, and click Host Connections Available only for host connections that are associated with the following storage systems and virtualizers: DS8000, SAN Volume Controller, the IBM Storwize family, and XIV systems.
I/O Group	Click Storage, and then click Block Storage Systems, File Storage Systems, or Object Storage Systems, depending on the storage system that you require. Right-click the storage system, click View Details, and click I/O Groups
Modules	Click Storage, and then click Block Storage Systems, File Storage Systems, or Object Storage Systems, depending on the storage system that you require. Right-click the storage system, click View Details, and click Modules
Nodes	Click Storage, and then click Block Storage Systems, File Storage Systems, or Object Storage Systems, depending on the storage system that you require. Right-click the storage system, click View Details, and click Nodes
Managed Disks	Click Storage, and then click Block Storage Systems, File Storage Systems, or Object Storage Systems, depending on the storage system that you require. How performance information is displayed

The performance view is displayed when you view the performance of resources, which includes resources in alerts and performance monitors. Information in the performance view is organized into two main sections: a chart or table and a legend.

Performance chart

The top section of the performance view shows information about the selected resources. You can view this information in the following formats:

Chart

The chart shows a visual representation of how the performance of a resource trends over time. Each line on the chart represents a metric and a resource. For example, if you select two metrics and three resources, six lines are shown on the chart. The y-axis shows the unit of measurement for a metric. If more metrics were selected with a different unit of measurement, an extra y-axis is shown on the right side of the chart window.

Table

The table shows performance and asset information that is formatted into rows and columns. Each row represents a resource and a time stamp from the chart; each column represents a metric from the chart. For example, if two metrics and three resources are displayed on a chart, and each of the lines on the chart have 10 data points, 30 rows and 2 columns are shown in the table.
To view other metrics and asset information for a resource, right-click anywhere in the header row of the table and select extra columns. The type of resource determines the metrics and information that is available.

Performance chart legend

The bottom section of the performance view shows more information about the resources in the chart. The information is formatted into rows and columns. Each row represents a resource that was selected for the view. Each column provides asset and performance information about a resource.

Each metric on the chart is represented by two columns in the legend. The first column includes the weighted average of the metric for each resource in the selected time range. The second column represents the peak data point of the metric for each resource in the selected time range. For example, if a metric in the chart is Total I/O Rate, the following columns are displayed in the legend: Avg Total I/O Rate, Worst Total I/O Rate. The worst value can be the minimum or the maximum number, depending on the metric. For example, the worst value for an I/O rate metric is a maximum number, while the worst value for the Cache Hit Percentage metric is a minimum number.

You can also view information about the resources that are related to the resources in the legend. For example, if a SAN Volume Controller is listed in the legend, right-click it to view the performance of its internal and related resources, such as disks, volumes, ports, managed disks, and back-end storage. For more information about the resources that you can view in the chart legend, see [Resources in the chart legend](#).

Tip:

- If you hide a resource in the performance chart, the row for that resource remains visible in the chart legend.
- In the chart legend, information about a resource represents the state of that resource during the selected time range. Specifically, this information does not represent the current state of a resource, but instead shows the final state of the resource during the selected time range.

For example, if the current date is January 1, and you view a volume with the time range set to December 1 to December 7, the legend shows the capacity of that volume on December 7. If the capacity of the volume was changed between December 7 and January 1, this historical capacity is different from the current capacity of the volume on January 1.

- **Controls**
Each performance view includes controls for customizing how information is displayed. The type of view and the resources that you are viewing determine which controls are available.
- **Resources in the chart legend**
In the performance view, performance metrics and related information for resources are shown in a chart and in the chart legend. For resources in the chart legend, you can open separate performance views for their internal or related resources. The separate performance views use the same time range as the performance view in the main window of the GUI.

Controls

Each performance view includes controls for customizing how information is displayed. The type of view and the resources that you are viewing determine which controls are available.

View chart

View performance information in a chart format. The chart shows a visual representation of how resource performance trends over time. Each line on the chart represents a metric and a resource. The y-axis shows the unit of measurement for a metric. If more metrics were selected with a different unit of measurement, an extra y-axis is shown on the right side of the chart window.

Hover the mouse pointer over points on a line to view a snapshot of performance information at a specific time.

View table

View performance information in a table format. Each row represents a resource and a time stamp. Each column represents a metric. You can view other metrics and information for a resource by right-clicking anywhere in the header row for the table and selecting more columns. The type of resource determines the metrics and information that is available.

For information how to filter, sort, and customize the columns in a table, see [Customizing lists](#).

Metrics

Add metrics to the performance chart. On the Select Chart Metrics dialog, metrics are organized into Volume, Disk, Pool, Port, and Node categories. The metrics and categories that are available depend on the type of resource that is being shown in the chart. The number next to the name of the category represents the number of metrics that are currently selected from that category.

You can select multiple metrics at the same time and from different categories, but you cannot include more than two unit types in the same view. For example, if you select metrics that use % and ops/s as units of measurement, you cannot select more metrics that use different units of measurement such as KiB/op or MiB/s.

For a list of metrics that you can view for resources, see [Performance metrics](#).

Hide and show resources

When the chart includes multiple resources, you can click the icon next to a resource to show only the line for that resource. Each icon is shown in a different color to match the color of line for the resource.

You can also show and hide resources in the chart by selecting resources in the chart legend. To select multiple resources at the same time, press Shift or Ctrl and click those resources. Press Shift and click to select consecutive rows in the legend; press Ctrl and click to select non-consecutive rows.

You can show up to 10 resources in a chart at the same time.

Specify granularity

Determine the granularity of the data that is shown in a performance view. Granularity determines the points that are shown on the y-axis of a chart, the points on the lines in a chart, and the rows in a table. When you first view performance information, the default time range is the last 12 hours and the granularity matches the frequency of data collection by the performance monitor (sample).

To change the granularity of chart or table, select one of the following options from the granularity menu:

(daily)

Set the granularity to show 1-day increments for performance information that is shown on the chart and table.

This granularity is only available if the time range of the chart is more than 1 day.

(hourly)

Set the granularity to show one-hour increments for performance information that is shown on the chart and table.

This granularity is only available if the time range of the chart is more than 1 hour.

(Sample)

Set the granularity to match the frequency of data collection by a performance monitor. For example, if a performance monitor is scheduled to collect sample data every 15 minutes, each point on the chart is shown in 15-minute increments.

This granularity is only available if the time range of the chart is less than 2 weeks.

If the performance monitor collects sample data at 1-minute intervals, data is displayed as 1-minute intervals in the chart only when data is available for all of the selected time range. If data is not available at 1-minute intervals for any portion of the selected time range, the data is displayed in 5-minute intervals. For example, the performance monitor for a resource collects sample data every 5 minutes. Six hours ago, the performance monitor was changed to start collecting data every minute. You want to view sample data for the resource for the last 12 hours. However, the performance monitor did not collect sample data every minute for 6 of the last 12 hours. Therefore, the data is displayed in 5-minute intervals rather than 1-minute intervals.

Restriction: Each granularity has a maximum time range for displaying data. This time range is dynamically calculated based on the resources and metrics that are shown on the chart, and the data points per line. When the maximum range is exceeded, the granularity icon is disabled and a message indicates that there are too many lines on the chart. To avoid this problem, reduce the time range or the number of resources or metrics that are selected.

Specify a time range

The time range of the performance information is shown below the chart. You can change this range to display information for different times when data was collected. When you first access the performance view, the default time range is the last 12 hours.

Ensure that performance data was collected during the time range that you select. If data was not collected during the time range, the chart and table are blank. If data collection was interrupted during the time range, the chart and table show gaps for the time increments when data was not collected.

For example, if you select a time range for the last 7 days, but data was not collected on days 4 and 5, the lines in the chart do not show data for days 4 and 5.

Hide and show chart controls

The performance view lists the names of resources that are being shown in the chart and the controls for customizing that chart. Click the left arrow icon to hide the controls and display the chart in the entire window. Click the right arrow icon again to show the controls.

Export information about the chart to a file

Export information on a performance view to a CSV file.

Open the performance view in a separate web browser window

Open a duplicate of the current performance view in a separate web browser window. You can change the information that is displayed in this separate window while retaining the original performance view for comparison.

Synchronize the time range across all the open performance views

Synchronize the time range across all the performance views that are displayed in separate browser windows. Use this action when you change the time range in a performance view and want to apply the same time range to the other performance views.

Restriction: This action affects only the performance views that are displayed in separate browser windows. The time range of the performance view that is shown as part of the main window for the GUI is not affected.

For example, you can view the storage system volumes that are assigned to a server. You can then open separate browser windows for the host connections, pools, and managed disks that are related to one of the volumes. If you change the time range in the performance view for host connections, click the synchronize button to apply the same time range to the views for pools and managed disks. The performance view of the original volume is not changed.

Actions for managing the resources in the chart legend

The chart legend in bottom section of the view shows more information about the selected resources. This information is organized into rows and columns, where each row represents a resource.

When you select one or more resources in the legend, the following actions are available in the Actions menu:

View Properties

View key details about a resource, including asset, status, configuration, capacity, and performance information.

View *resource* Performance

View the performance of resources that are internal or related to a resource in the chart legend. For example, when you view the performance of a SAN Volume Controller, you can right-click it and view the performance of its internal resources, such as disks, volumes, ports, managed disks, and back-end storage.

Information about an internal or related resource is shown in a separate web browser window. This window uses the same time range as the performance view in the main window of the GUI.

Restriction: If performance data was not collected for an internal or related resource, that resource is not shown in the view. For example, if you right-click a storage system and select Volume performance, only the volumes for which performance data was collected are shown.

For more information about the resources that you can view in the chart legend, see [Resources in the chart legend](#).

Key Metrics View

View a set of predefined metrics for resources in the chart legend.

Custom View

Customize the set of metrics that are shown for resources in the chart legend.

Resources in the chart legend

In the performance view, performance metrics and related information for resources are shown in a chart and in the chart legend. For resources in the chart legend, you can open separate performance views for their internal or related resources. The separate performance views use the same time range as the performance view in the main window of the GUI.

For example, when you view the performance of a SAN Volume Controller, you can right-click it in the chart legend to open a performance view for its internal and related resources, such as disks, volumes, ports, managed disks, and back-end storage.

The type of resource determines the internal and related resources that you can view. The following tables show the internal and related resources that are available when you right-click a resource in the chart legend.

Table 1. Resources that you can view for DS8000 storage systems in the chart legend

Resource in the chart legend	Right-click the resource in the chart legend to view the performance of the following resources	Right-click the resource in the chart legend to view the performance of the following related resources
Storage system	Volume, RAID array, pool, controller, host connection, port	Storage virtualizer, switch
Volume	Storage system, RAID array, pool, controller, host connection	Managed disk
RAID array	Storage system, volume, pool, controller, host connection	None
Pool	Storage system, volume, RAID array, controller, host connection	None
Controller	Storage system, volume, RAID array, pool, host connection	None
Host connection	Storage system, volume, RAID array, pool, controller	None
Storage system port	Storage system	Switch port

Table 2. Resources that you can view for SAN Volume Controller, Storwize V3500, Storwize V3700, Storwize V7000, and Storwize V7000 Unified storage systems in the chart legend

Resource in the chart legend	Right-click the resource in the chart legend to view the performance of the following resources	Right-click the resource in the chart legend to view the performance of the following related resources
Storage system	Volume, pool, node, I/O group, disk, managed disk, host connection, port	Back-end storage system, storage virtualizer, switch

Resource in the chart legend	Right-click the resource in the chart legend to view the performance of the following resources	Right-click the resource in the chart legend to view the performance of the following related resources
Server	None	Storage system, volume, pool, controller, module, node, I/O group, disk, managed disk, host connection, switch, storage system port, switch port

Saving URLs for performance views

You can create a bookmark or a favorite for a performance view.

About this task

The link in the bookmark or favorite stores details of the performance view, such as the resources, metrics, interval, and other details. The link also stores the time period that is specified in the time selector at the top of the chart.

You can also copy the URL from the address bar if you want to share the URL with colleagues.

Procedure

Do one of the following steps:

- In Firefox, right-click in the performance view and click Bookmark This Page.
- In Internet Explorer, right-click in the performance view and click Add to favorites.

Identifying performance issues for IBM Spectrum Virtualize storage systems

You can identify key metrics that are outside of a standard range for resources that run IBM Spectrum Virtualize by using the key performance indicators charts.

Before you begin

Before you view the performance of your resources that run IBM Spectrum Virtualize, ensure that performance data was collected for those systems during the time ranges that you want to analyze. IBM Spectrum® Control uses performance monitors to collect data so that you can measure the performance of storage systems and switches. To verify that performance monitors were run, follow the instructions in [Verifying that a performance monitor is running for a resource](#).

About this task

In this documentation, IBM Spectrum Virtualize is used to refer collectively to IBM® SAN Volume Controller, IBM Spectrum Virtualize for Public Cloud, IBM Spectrum Virtualize as Software Only, and IBM Storwize® storage systems, and to IBM FlashSystem® devices that run IBM Spectrum Virtualize.

Restriction: Key performance indicators are provided only for IBM FlashSystem 9100 from the IBM FlashSystem family. Key performance indicators are not provided for file storage in Storwize V7000 Unified storage systems.

Procedure

1. To select a storage system, choose one of the following options from the menu bar:

Resource	Menu bar
Block storage systems	Storage > Block Storage Systems
File storage systems	Storage > File Storage Systems

2. From the list of storage systems that are displayed, right-click the resource that you want to view and click View Details.
For example, select a SAN Volume Controller or a Storwize storage system on the Block Storage Systems page, or select a Storwize V7000 Unified storage system on the File Storage Systems page.
3. In the General section of the resource details page, click Performance.
The key performance indicators charts are displayed with data that was collected from monitored resources over the last 24 hours. The performance of each monitored resource is charted against the best practice guidelines for IBM Spectrum Virtualize storage systems.
4. Optional: If you want to view the performance charts for a period other than the default 24-hour period, change the date for all of the charts. Click Last 24 hours and use the calendar to specify a date.
5. Optional: Drill down to view detailed information about a specific I/O group, port, or node. Click a resource from the chart's list.
For example, select the name of an I/O group in the Read Response Time by I/O Group chart to view the average number of milliseconds taken by the I/O group to complete a read operation.

By default, metrics are shown on the charts for the following time periods:

- The last 24 hours
- The same 24-hour period for yesterday
- The same 24-hour period for the day seven days before today

If you selected a date from the calendar, the metrics are shown on the charts for the following time periods:

- The selected date
- The day before the selected date
- The day seven days before the selected date

IBM Spectrum Virtualize guideline values for key performance indicators

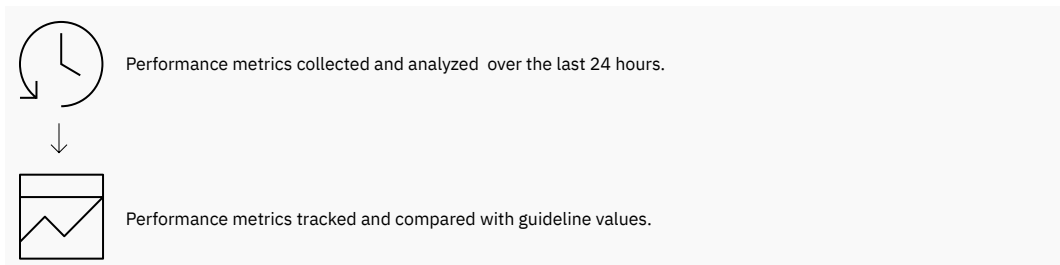

To improve the performance and resiliency of your storage environment, compare the guideline values for key performance indicators with the values reported for your storage systems and devices.

Guideline values for performance were established by monitoring, measuring, analyzing, and stress testing the performance of IBM Spectrum Virtualize storage systems.

The name IBM Spectrum Virtualize is used to refer to the following types of storage systems:

- IBM® SAN Volume Controller
- IBM Spectrum Virtualize for Public Cloud
- IBM Spectrum Virtualize as Software Only
- IBM Storwize® block storage systems
- IBM FlashSystem® devices that run IBM Spectrum Virtualize

Try it out! From the Storage menu, click Block Storage Systems. Double-click a storage system that runs IBM Spectrum Virtualize, and then click Performance in the General section of the navigation pane.

By default, the charts compare the performance metrics that were collected each hour over the last 24 hours with the guideline values. You can use the calendar, which is next to the title of the page, to change the date and compare current values with historical values.

In most of the charts, a horizontal line is used to indicate the guideline value for the metric. If your devices report prolonged periods of slow response times, you can check whether the performance values for your devices are over the guideline values.

For example, you experience slow send response times for a node in a cluster. You check the chart that tracks the send response times for the nodes and see that one of the node's response times is higher than the guideline value. You can then take remedial action such as balancing the workload of the nodes across the cluster. Alternatively, you can move some of the workloads to other storage systems.

The following key performance indicators are analyzed:

Max Cache Fullness by Pool

The maximum amount of the lower cache that the write cache partitions on the nodes that manage the pool are using for write operations. If the value is 100%, one or more cache partitions on one or more pools is full. The operations that pass through the pools with full cache partitions are queued and I/O response times will increase for the volumes in the affected pools. Available in IBM Spectrum Virtualize 7.3 or later.

The guideline value is 80%.

A critical alert for max write cache fullness is automatically generated when the value is equal to or more than 99%.

Overall Port Bandwidth Percentage by Port

The percentage of the port bandwidth that is used for receive and send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

The guideline value is 50%.

Compare the guideline value for this metric with the values measured for the switch ports. Because a cluster can have many ports, the chart shows only the eight ports with the highest average bandwidth.

A warning alert is automatically generated when the value for port receive bandwidth or port send bandwidth is equal to or more than 75%. A critical alert is generated when the value for port receive bandwidth or port send bandwidth is equal to or more than 85%.

Port-to-Local Node Send Response Time by Node

The average number of milliseconds to complete a send operation to another node that is in the local cluster. This value represents the external response time of the transfers.

The guideline value is 0.6 ms/op.

Port-to-Remote Node Send Response Time by Node

The average number of milliseconds it takes to complete a send operation to a node in the remote cluster. And, the average number of milliseconds it takes to complete a receive operation from a node in the remote cluster. This value represents the external response time of the transfers.

A guideline value isn't available for this metric because response times for copy-service operations can vary widely.

You can compare the response times to identify discrepancies between the response times for the different nodes.

Read Response Time by I/O Group

The average number of milliseconds to complete a read operation.

The guideline value is 15 ms/op.

Write Response Time by I/O Group

The average number of milliseconds to complete a write operation.

The guideline value is 5 ms/op.

Node Utilization Percentage by Node

The average bandwidth percentages for the ports in the node that are actively used for host and MDisk receive and send operations. The average is weighted based on the port speed and the technology limitations of the node hardware.

The guideline value is 60%.

Port Send Delay Time

The average number of milliseconds of delay that occurs on the port for each send operation. The reason for these delays might be a lack of buffer credits.

A guideline value isn't available for this metric because delay times can vary significantly depending on configuration and usage.

Compare the delay times to identify discrepancies between the ports' delay times and any spikes that might correlate with the time of any reported performance problems.

The Port Send Delay Time is shown instead of the Zero Buffer Credit Percentage by Node chart for some IBM FlashSystem storage systems, such as FlashSystem 9110.

Zero Buffer Credit Percentage by Node

The amount of time, as a percentage, that the port wasn't able to send frames between ports because of insufficient buffer-to-buffer credit. The amount of time value is measured from the last time that the node was reset. In Fibre Channel (FC) technology, buffer-to-buffer credit is used to control the flow of frames between ports.

Information about zero buffer credit is only collected and analyzed for 8 Gbps FC ports.

The guideline value is 20%.

Tip: When you add a storage system, a default alert policy is assigned to the storage system. For example, when you add IBM SAN Volume Controller, the default policy for IBM SAN Volume Controller is automatically assigned to the storage system. To find out which alerts are in the default policy, click the Settings menu and click Alert Policies. To see the alerts that are defined for the policy, double-click the default policy.

More actions

Review the following resources to find out:

- [How to investigate the causes of slow drain.](#)
- [Defining alerts.](#)
- [How to define warning and critical thresholds for alerts.](#)

Restrictions

The following charts aren't available for storage systems that run IBM Spectrum Virtualize and use the iSCSI protocol to connect to storage systems:

- Overall Port Bandwidth Percentage by Port
- Node Utilization Percentage by Node
- Port Send Delay Time

Viewing performance alerts

View the alerts that were generated when the measured value of a performance metric falls outside of the specified threshold for a resource.

Before you begin

To generate performance alerts, you must collect performance data and define performance alerts for that resource, or for the alert policy that manages the resource. For information about how to collect performance data, see [Creating performance monitors in IBM Spectrum Control](#). For information about how to define performance alerts, see [Defining alert definitions for performance changes](#).

Procedure

1. Complete one of the following tasks to view performance alerts:

Task	Steps
View the performance alerts for a specific storage system	<ol style="list-style-type: none">a. In the menu bar, choose one of the following options:<ul style="list-style-type: none">• Storage > Block Storage Systems• Storage > File Storage Systemsb. Double-click a storage system.c. Click Alerts in the General section.
View all the performance alerts that were generated for switches	<ol style="list-style-type: none">a. In the menu bar, select Network > Switches.b. Click the Alerts tab.
View the performance alerts for a specific switch	<ol style="list-style-type: none">a. In the menu bar, select Network > Switches.b. Double-click a switch.c. Click Alerts in the General section.

2. Right-click the performance alert that you want to view and select View Alert.

In this view, a chart shows the performance of the resource that violated the threshold and generated the alert. The time range of the chart is 2 hours before and 2 hours after the violation occurred. The lines on the chart represent the following values:

- The blue line represents the performance of the resource for the selected metric.
- The red line represents the threshold that was violated.
- The dotted line represents the time when the violation occurred.

For certain storage systems, a ranked list of the 25 volumes that were the top contributors to the workload on the resource where the threshold violation occurred might be displayed below the chart. This list is shown under the following conditions:

- The performance threshold was violated on an internal resource other than a port.
- The performance threshold was violated on any of the following storage systems:
 - DS8000®
 - XIV®
 - IBM Spectrum Accelerate
 - SAN Volume Controller
 - Storwize® V3500
 - Storwize V3700
 - Storwize V7000
 - Storwize V7000 Unified

You can also view the servers or hosts to which those volumes are assigned.

3. Optional: To access the full performance view of a resource that violated the threshold, click the open performance view icon  on the chart.

Exporting performance data for storage systems and fabrics

To help resolve performance issues with storage systems and fabrics, you can export performance data for the resources to a compressed file. If you contact IBM® Support to help you analyze the problem, you might be asked to send this file.

You can export performance data for the following types of resource: storage systems, nodes, modules, I/O groups, host connections, pools, RAID arrays, managed disks, disks, volumes, file systems, switches, ports, and inter-switch connections.

The summarization type for the exported data can be sample, hourly, or daily.

The performance data is created as CSV files, one file for each resource type. By default, the files are compressed as .zip files.

- [Exporting performance data by using the GUI](#)

You can export performance data for a managed resource. If you contact IBM Support to help you analyze a performance problem with storage systems or fabrics, you might be asked to send this data.

- [Exporting performance data by using a script](#)

Use the exportPerformanceData script to export performance data for managed resources. If you contact IBM Support to help you analyze a performance problem with storage systems or fabrics, you might be asked to send this data.

Exporting performance data by using the GUI

You can export performance data for a managed resource. If you contact IBM® Support to help you analyze a performance problem with storage systems or fabrics, you might be asked to send this data.

Before you begin

The performance data might be large, especially if the data is for storage systems that have many volumes, or the performance monitors are running with a 1-minute sampling frequency. If the time range for the data is greater than 12 hours, volume data and 1-minute sample data is automatically excluded from the performance data even if it is available. To include volume data and 1-minute sample data, select the Advanced package option when you export performance data.

About this task

When you export performance data, you can specify a time range to export performance data for. The time range cannot exceed the history retention limit for sample performance data. By default, this history retention limit is two weeks.

To export hourly or daily performance data, use the exportPerformanceData script. However, the time range still cannot exceed the history retention limits for the type of performance data.

Procedure

1. In the menu bar, select the type of storage system.
For example, to create a compressed file for a block storage system, go to Storage > Block Storage Systems.
To create a compressed file for a fabric, go to Network > Fabrics.
2. Right-click the storage resource, and then click Export Performance data.

Related tasks

- [Configuring history and data retention](#)

Exporting performance data by using a script

Use the exportPerformanceData script to export performance data for managed resources. If you contact IBM® Support to help you analyze a performance problem with storage systems or fabrics, you might be asked to send this data.

Running the exportPerformanceData script

You can run the exportPerformanceData script on the server where IBM Spectrum® Control is installed. The script is run from the *installation_directory/scripts* directory on the server. You can export the performance data for one or more managed resources.

The exportPerformanceData script can be run on Windows and AIX®/Linux® servers:

- Windows default location: `C:\Program Files\IBM\TPC\scripts\exportPerformanceData.bat`
- AIX/Linux default location: `/opt/IBM/TPC/scripts/exportPerformanceData.sh` or `/usr/IBM/TPC/scripts/exportPerformanceData.sh`

The following arguments are required when you run the **exportPerformanceData** script:

```
-user user_name
    Specifies an IBM Spectrum Control user ID.
-pwd password
    Specifies the password for the IBM Spectrum Control user ID.
-resNames resource_name1 resource_name2 resource_name3...
    Specifies the names of storage system, switch, or fabric names as displayed in the UI, separated by spaces. If the resources have spaces in the names, then you must enclose the resource names in double quotation marks ("").
```

To view the optional parameters that the script uses, run the script with the -help option.

Examples

To collect and export performance data to a compressed file for a storage system:

```
>cd c:\Program Files\IBM\TPC\scripts\
>exportPerformanceData -user scUser1 -pwd scPwd1
    -out "c:\web_data\performance_reports\Array1.20160402"
    -resTypes storageSystem,Nodes,Pools,Ports
    -start "2016-02-04 00:00:00" -end "2016-02-04 23:59:59"
```

```
-summType hourly -advPkg yes -zip no  
-resNames "Production Array 1"
```

This command creates a directory Array1.20160402 in c:\web data\performance reports\ if the directory does not exist already. The command writes to that directory the CSV files that contain the hourly performance data for the whole storage system, nodes, pools, and ports. The data is for the storage system named Production Array 1. The time range of the data is from Apr 2, 2016 0:00 AM to Apr 2, 2016 11:59 PM. One minute sample and volume data are included where they are available in the specified time range.

Performance metrics

IBM Spectrum® Control can collect information about the performance of storage systems and switches. This information includes metrics that measure the performance of volumes, ports, and disks. You can view performance information or specify alerts for when the performance of a resource falls outside a specified range.

You can view performance metrics at the following locations:

Resource pages

To access a view of performance metrics for a resource, go to the following pages:

- Storage systems page, Storage system details page
- Volumes page
- Pools page
- Switches page, Switch details page
- Server details page > Related Resources
- Hypervisor details page > Related Resources

Cognos® Analytics reports

To view detailed performance reports for multiple resources in the Cognos Analytics reporting tool, go to the following URL:

http://hostname:port/bi

The *hostname* is the server that Cognos Analytics is running on. The default value for *port* is 9300.

For example, to view performance reports, go to the following URL:

http://myhostname:9300/bi

- [Performance metrics for DS8000](#)
Monitor the performance metrics that are collected for DS8000® storage systems.
- [Performance metrics for resources that run IBM Spectrum Virtualize](#)
Monitor the performance metrics that are collected for IBM Spectrum Virtualize storage systems.
- [Performance metrics for XIV, IBM Spectrum Accelerate, IBM FlashSystem A9000, and IBM FlashSystem A9000R](#)
Monitor the performance metrics that are collected for XIV® systems, IBM Spectrum Accelerate, IBM FlashSystem® A9000, and IBM FlashSystem A9000R.
- [Performance metrics for IBM Spectrum Scale](#)
Monitor the performance metrics that are collected for IBM Spectrum Scale storage systems.
- [Performance metrics for IBM FlashSystem 900](#)
To review trends in performance for IBM FlashSystem 900 storage systems, you add performance metrics to performance charts. Use the charts to monitor the performance of the storage systems.

Performance metrics for DS8000

Monitor the performance metrics that are collected for DS8000® storage systems.

Overview

Performance metrics are available for the following resources:

- [Volume metrics](#)
- [Disk metrics](#)

- [Port metrics](#)

A performance metric might apply to one or more storage resources. To check which resources the performance metric applies to, see the tips and the table footnotes.

Volume metrics

Volume performance metrics are divided into the following categories:

- [Key volume metrics](#)
- [I/O rate metrics](#)
- [Cache hit percentage metrics](#)
- [Average transfer size and HPF I/O metrics](#)

Tip: Unless otherwise noted, you can view the volume metrics in [Table 1](#), [Table 2](#), [Table 3](#), and [Table 4](#) for the following resources:

- Host connections
- Nodes
- Pools
- Storage systems
- Volumes

Table 1. Key volume metrics

Metric	Description
Cache Holding Time ¹	The average number of seconds that I/O data for a storage system node is held in the cache. A short cache-holding time indicates adverse performance.
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Pool Activity Score ²	The activity level of pools, which is set to the following value: $[\text{Read I/O Rate} \times (1 - \text{Read I/O Cache Hit \%})] \div \text{Total Pool Capacity}$
Response Time (Read)	The average number of milliseconds to complete a read operation.
Response Time (Write)	The average number of milliseconds to complete a write operation.
Response Time (Overall)	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.
Volume Utilization ³	The average percentage of time that the volume is busy.
Write-Cache Delay Percentage	The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.
Notes:	
1. This metric is only available when you view the performance of nodes or storage systems.	
2. This metric is only available when you view the performance of pools.	
3. This metric is only available when you view the performance of volumes.	

Table 2. I/O Rates

Metric	Description
Average Transfer Rate (Cache-to-Disk) ¹	The average number of sectors or tracks per second that are transferred from the cache to the disks.
Average Transfer Rate (Disk-to-Cache) ¹	The percentage of cache hits for record-mode read operations. For record-mode read operations, only the requested data, rather than a full track of data, is managed in the cache.
High Performance FICON® (Read)	The average number of read operations per second that are issued by the High Performance FICON feature of the storage system.
High Performance FICON (Write)	The average number of write operations per second that are issued by the High Performance FICON feature of the storage system.
High Performance FICON (Total)	The average number of I/O operations per second that are issued by the High Performance FICON feature of the storage system. This value includes both read and write operations.
Normal I/O Rate (Read)	The average number of nonsequential read operations per second.
Normal I/O Rate (Write)	The average number of nonsequential write operations per second.
Normal I/O Rate (Total)	The average number of nonsequential I/O operations per second. This value includes both read and write operations.
PPRC Transfer Rate	The average number of tracks per second that are transferred to the secondary device of a Peer-to-Peer Remote Copy (PPRC) pair. This value shows the activity for the source of the PPRC relationship, but shows no activity for the target.
Record Mode Read I/O Rate ¹	The average number of I/O operations per second for record-mode read operations. For record-mode read operations, only the requested data is managed in the cache rather than a full track of data.
Sequential I/O Rate (Read)	The average number of sequential read operations per second.
Sequential I/O Rate (Write)	The average number of sequential write operations per second.
Sequential I/O Rate (Total)	The average number of sequential I/O operations per second. This value includes both read and write operations.
Write-Cache Delay I/O Rate	The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.

Metric	Description
Notes:	
1. This metric is only available when you view the performance of volumes, pools, nodes, and host connections.	

Table 3. Cache hit percentages

Metric	Description
Normal I/O Cache Hits (Read)	The percentage of nonsequential read operations that find data in the cache. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
Normal I/O Cache Hits (Write)	The percentage of nonsequential write operations that are handled in the cache.
Normal I/O Cache Hits (Total)	The percentage of nonsequential I/O operations that are handled in the cache. This value includes both read and write operations. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
Overall I/O Cache Hits (Read)	The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.
Overall I/O Cache Hits (Write)	The average percentage of all write operations that are handled in the cache, across all volumes on the server. This value includes both sequential and nonsequential write operations.
Overall I/O Cache Hits (Total)	The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
Record Mode Read Cache Hit Percentage ¹	The percentage of cache hits for record-mode read operations. For record-mode read operations, only the requested data, rather than a full track of data, is managed in the cache.
Sequential I/O Cache Hits (Read)	The percentage of sequential read operations that find data in the cache. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
Sequential I/O Cache Hits (Write)	The percentage of sequential write operations that are handled in the cache.
Sequential I/O Cache Hits (Total)	The percentage of sequential I/O operations that are handled in the cache. This value includes both read and write operations. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
Note:	
1. This metric is only available when you view the performance of volumes, pools, nodes, and host connections.	

Table 4. Average transfer size, HPF I/O, and miscellaneous metrics

Metric	Description
Average Transfer Size (Read)	The average number of KiB that are transferred per read operation.
Average Transfer Size (Write)	The average number of KiB that are transferred per write operation.
Average Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.
HPF I/O Percentage	The percentage of all I/O operations that are issued by the High Performance FICON feature of the storage system.

Disk metrics

Disk performance metrics are divided into the following categories:

- [Key disk metrics](#)
- [Transfer size metrics](#)

Tip: Unless otherwise noted, you can view the disk metrics in [Table 5](#) and [Table 6](#) for the following resources:

- Nodes
- Pools
- RAID arrays
- Ranks
- Storage systems

Table 5. Key disk metrics

Metric	Description
Data Rate (Read)	The average number of MiB per second that are read from the back-end storage resources.
Data Rate (Write)	The average number of MiB per second that are written to the back-end storage resources.
Data Rate (Total)	The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Metric	Description
Disk Utilization Percentage ¹	<p>The average percentage of time that the disks that are associated with an array are busy. No value is calculated for this property if there are multiple ranks in the extent pool where the thin-provisioned volumes are allocated. In this case, the value N/A is displayed. This limitation applies only to DS8000 storage systems. If there is only a single rank in the extent pool, the value for this property is calculated regardless of the thin-provisioned volumes.</p> <p>Tip: Some highly sequential workloads such as batch or backup processing might continually exceed the threshold because they drive the arrays to high utilization percentages. For these types of workloads, a high utilization indicates that the work is being performed very efficiently and is not a cause for concern.</p> <p>For DS8000, this metric is available only for 8.5.0 or later. For earlier versions, the value N/A is shown in the performance table view and the metric is not shown on the performance chart.</p>
I/O Rate (Read)	The average number of read operations per second that are issued to the back-end storage resources.
I/O Rate (Write)	The average number of write operations per second that are issued to the back-end storage resources.
I/O Rate (Total)	The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.
Response Time (Read)	The average number of milliseconds for the back-end storage resources to respond to a read operation.
Response Time (Write)	The average number of milliseconds for the back-end storage resources to respond to a write operation.
Response Time (Overall)	The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.
<p>Note:</p> <p>1. This metric is only available when you view the performance of RAID arrays.</p>	

Table 6. Transfer size metrics

Metric	Description
Average Transfer Size (Read)	The average number of KiB that are transferred per read operation from the back-end storage resources.
Average Transfer Size (Write)	The average number of KiB that are transferred per write operation to the back-end storage resources.
Average Transfer Size (Overall)	The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Port metrics

Port performance metrics are divided into the following categories:

- [Key port metrics](#)
- [Port I/O rate metrics](#)
- [Port data rate metrics](#)
- [Port response time metrics](#)
- [Error rate metrics](#)
- [Remote mirror metrics](#)
- [Transfer size metrics](#)

Tip: Unless otherwise noted, you can view the port metrics in [Table 7](#), [Table 11](#), [Table 12](#), and [Table 13](#) for ports and storage systems. The port metrics in [Table 8](#), [Table 9](#), [Table 10](#) are only available for ports.

Table 7. Key port metrics

Metric	Description
Data Rate (Receive)	The average rate at which data is received by the port. The rate is measured in MiB per second.
Data Rate (Send)	The average rate at which data is sent from the port. The rate is measured in MiB per second.
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.
I/O Rate (Receive)	The average number of I/O operations per second for operations in which the port receives data.
I/O Rate (Send)	The average number of I/O operations per second for operations in which data is sent from a port.
I/O Rate (Total)	The average number of send operations and receive operations per second.
Response Time (Receive)	The average number of milliseconds to complete a receive operation.
Response Time (Send)	The average number of milliseconds to complete a send operation.
Response Time (Overall)	The average number of milliseconds to complete a send or receive operation.
Port Utilization (Receive) ¹	The average percentage of time that the port is busy receiving data.
Port Utilization (Send) ¹	The average percentage of time that the port is busy sending data.
Port Utilization (Overall) ¹	The average percentage of time that the port is busy sending or receiving data.
Bandwidth (Receive) ¹	The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Bandwidth (Send) ¹	The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Bandwidth (Overall) ¹	The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Metric	Description
Note:	
1. This metric is only available when you view the performance of ports.	

Table 8. Port I/O rate metrics

Metric	Description
FICON I/O Rate (Send)	The average number of send operations per second for Fibre Channel connection (FICON) usage.
FICON I/O Rate (Receive)	The average number of receive operations per second for FICON usage.
FICON I/O Rate (Total)	The average number of send and receive operations per second for FICON usage.
FCP I/O Rate (Send)	The average number of send operations per second for Fibre Channel Protocol (FCP) usage.
FCP I/O Rate (Receive)	The average number of receive operations per second for FCP usage.
FCP I/O Rate (Total)	The average number of send operations and receive operations per second for FCP usage.

Table 9. Port data rates

Metric	Description
FICON Data Rate (Send)	The average number of MiB per second that is sent for FICON usage.
FICON Data Rate (Receive)	The average number of MiB per second that is received for FICON usage.
FICON Data Rate (Total)	The average number of MiB per second that is transferred for FICON usage. This value includes both send and receive FICON operations.
FCP Data Rate (Send)	The average number of MiB per second that are sent for FCP usage.
FCP Data Rate (Receive)	The average number of MiB per second that are received for FCP usage.
FCP Data Rate (Total)	The average number of MiB per second that are transferred for FCP usage. This value includes both send and receive FCP operations.

Table 10. Port response times

Metric	Description
FICON Response Time (Send)	The average number of milliseconds to complete a send operation for FICON usage.
FICON Response Time (Receive)	The average number of milliseconds to complete a receive operation for FICON usage.
FICON Response Time (Overall)	The average number of milliseconds to complete a send or receive operation for FICON usage. This value includes both send and receive FICON operations.
FCP Response Time (Send)	The average number of milliseconds to complete a send operation for FCP usage.
FCP Response Time (Receive)	The average number of milliseconds to complete a receive operation for FCP usage.
FCP Response Time (Overall)	The average number of milliseconds to complete a send or receive operation for FCP usage.

Table 11. Error rate metrics.

Tip: You can view the following metrics for ports and storage systems.

Metric	Description
Frame Errors (CRC Errors)	The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.
Frame Errors (Error Frame)	The average number of error frames per second that are received. An error frame is a frame that violates the Fibre Channel Protocol.
Frame Errors (Invalid Relative Offset Rate)	The average number of times per second that frames are received with an invalid relative offset in the frame header.
Link Errors (Invalid Link Transmission)	The average number of times per second that an invalid transmission word was detected by the port while the link did not experience any signal or synchronization loss.
Link Errors (Invalid Transmission Words)	The average number of bit errors per second that are detected.
Link Errors (Link Failures)	The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.
Link Errors (Primitive Sequence Protocol Error Rate)	The average number of primitive sequence protocol errors per second that are detected. This error occurs when there is a link failure for a port.
Link Errors (Sequence Timeouts)	The average number of times per second that the port detects a timeout condition after the port receives a sequence initiative for a Fibre Channel exchange.
Link Errors (Signal Loss)	The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.
Link Errors (Sync Loss)	The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled.
Port Protocol Errors (Credit Recovery Link Resets)	The estimated average number of link resets per second that a switch or port completed to recover buffer credits. This estimate attempts to disregard link resets that were caused by link initialization. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

Metric	Description
Port Protocol Errors (Duplicate Frames)	The average number of duplicate frames per second that are received. A duplicate frame is a frame that the system previously processed for the port.
Port Protocol Errors (Link Reset Received)	The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR2) state.
Port Protocol Errors (Link Reset Transmitted)	The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR1) state.
Port Protocol Errors (Out of Order ACK)	The average number of times per second that an out-of-order acknowledge (ACK) frame is detected. An ACK frame is used for end-to-end flow control and is sent to verify receipt of a frame.
Port Protocol Errors (Out of Order Data)	The average number of times per second that an out-of-order frame is detected.
Note:	
1. This metric is only available when you view the performance of ports.	

Table 12. Remote mirror metrics

Metric	Description
PPRC Data Rate (Receive)	The average number of MiB per second that are received by using the Peer-to-Peer Remote Copy (PPRC) protocol.
PPRC Data Rate (Send)	The average number of MiB per second that are sent by using the PPRC protocol.
PPRC Data Rate (Total)	The average number of MiB per second that are transferred by using the PPRC protocol. This value includes both send and receive PPRC operations.
PPRC I/O Rate (Receive)	The average number of operations per second that are received by using the PPRC protocol.
PPRC I/O Rate (Send)	The average number of operations per second that are sent by using the PPRC protocol.
PPRC I/O Rate (Total)	The average number of send operations and receive operations per second using the PPRC protocol.
PPRC Response Time (Receive)	The average number of milliseconds to complete a receive operation by using the PPRC protocol.
PPRC Response Time (Send)	The average number of milliseconds to complete a send operation by using the PPRC protocol.
PPRC Response Time (Overall)	The average number of milliseconds to complete a send or receive operation by using the PPRC protocol.

Table 13. Transfer size metrics

Metric	Description
Average Transfer Size (Receive)	The average number of KiB that are transferred per receive operation.
Average Transfer Size (Send)	The average number of KiB that are transferred per send operation.
Average Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

Performance metrics for resources that run IBM Spectrum Virtualize

Monitor the performance metrics that are collected for IBM Spectrum Virtualize storage systems.

Overview

In this documentation, IBM Spectrum Virtualize is used to refer collectively to IBM® SAN Volume Controller, IBM Spectrum Virtualize for Public Cloud, IBM Spectrum Virtualize as Software Only, and IBM Storwize® storage systems, and to IBM FlashSystem® devices that run IBM Spectrum Virtualize.

Definitions are provided for the performance metrics that are collected for the following storage systems:

- FlashSystem 5000
- FlashSystem 5100
- FlashSystem 7200
- FlashSystem 7300
- FlashSystem V9000
- FlashSystem 9100
- FlashSystem 9200
- FlashSystem 9500
- SAN Volume Controller
- IBM Spectrum Virtualize for Public Cloud
- Storwize V3500
- Storwize V3700
- Storwize V5000
- Storwize V7000
- Storwize V7000 Unified (block storage only)

The following terms are used in the performance metrics for these storage systems:

Stage

To write data from a disk to the cache. The data is not prefetched data.

Destage

To write data from the cache to a disk.

Prestage

To write prefetched data from a disk to the cache.

The performance metrics are divided into the following categories:

- [Volume performance metrics](#)
- [Disk performance metrics](#)
- [Pool performance metrics](#)
- [FC Port performance metrics](#)
- [IP Workload performance metrics](#)
- [Node performance metrics](#)

Volume performance metrics

Volume performance metrics are divided into the following categories:

- [Key metrics for volumes](#)
- [I/O rate metrics for volumes](#)
- [Cache hit percentage metrics for volumes](#)
- [Response time metrics for volumes](#)
- [Remote mirror metrics for volumes](#)
- [Volume cache \(VC\) metrics for volumes](#)
- [Volume copy cache \(VCC\) metrics for volumes](#)
- [Compression metrics for volumes](#)
- [Miscellaneous metrics for volumes](#)
- [Legacy cache metrics for volumes](#)

Tip:

Unless otherwise noted, you can view the volume metrics in [Table 1](#), [Table 2](#), [Table 3](#), [Table 4](#), [Table 5](#), [Table 6](#), [Table 7](#), [Table 9](#), and [Table 10](#) for the following resources:

- Host connections
- I/O groups
- Nodes
- Pools
- Storage systems
- Volumes

Table 1. Key metrics for volumes

Metric	Definition
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Unmap) ¹	The average number of MiBs per second that were unmapped. This metric corresponds to the collected ub statistic.
Data Rate (Total)	The average number of MiB per second that are transferred for read, write, and unmap operations. ¹
Overall Host Attributed Response Time Percentage	The percentage of the average response time that can be attributed to delays from host systems. This value includes both read response times and write response times, and can help you diagnose slow hosts and fabrics that are not working efficiently. For read response time, the value is based on the time that it takes for hosts to respond to transfer-ready notifications from the nodes. For write response time, the value is based on the time that it takes for hosts to send the write data after the node responds to a transfer-ready notification.
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Unmap) ¹	The average number of unmap operations per second. This metric corresponds to the collected uo statistic.
Overall I/O Rate (Total)	The average number of nonsequential I/O operations per second. This value includes read, write, and unmap operations. ¹
Pool Activity Score ²	The activity level of pools, which is set to the following value: $[\text{Read I/O Rate} \times (1 - \text{Read I/O Cache Hit \%})] \div \text{Total Pool Capacity}$
Response Time (Read)	The average number of milliseconds to complete a read operation.
Response Time (Write)	The average number of milliseconds to complete a write operation.
Response Time (Unmap) ¹	The average number of milliseconds required to complete an unmap operation. This metric corresponds to the collected ul statistic.
Response Time (Overall)	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.
Transfer Size (Read)	The average number of KiB that are transferred per read operation.
Transfer Size (Write)	The average number of KiB that are transferred per write operation.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Metric	Definition
Notes:	
<ol style="list-style-type: none"> 1. This metric applies only to storage systems that are running IBM Spectrum Virtualize 8.1.1 or later. To view details about collected statistics, see Starting statistics collection. 2. This metric is also available when you view the performance of pools. 3. This metric is only available when you view the performance of volumes. 	

Table 2. I/O rate metrics for volumes

Metric	Definition
Transfer Rate (Cache-to-Disk)*	The average number of sectors or tracks per second that are transferred from the cache to the disks.
Transfer Rate (Disk-to-Cache)*	The average number of sectors or tracks per second that are transferred per second from the disks to the cache.
Unaligned Unmap I/O Rate	The average number of volume unmap operations per second that are not aligned on an 8K boundary. This metric corresponds to the collected uou statistic. This metric applies only to storage systems that are running IBM Spectrum Virtualize 8.1.1 or later. To view details about collected statistics, see Starting statistics collection .
Note: *This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.	

Table 3. Cache hit percentages metrics for volumes

Metric	Definition
Overall I/O Cache Hits (Read)	The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.
Overall I/O Cache Hits (Write)	The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Table 4. Response time metrics for volumes

Metric	Definition
Peak Response Time (Read)	The worst response time measured for a read operation in the sample interval.
Peak Response Time (Write)	The worst response time measured for a write operation in the sample interval.
Peak Response Time (Unmap)	The worst response time measured for an unmap operation in the sample interval. This metric corresponds to the collected ulw statistic. This metric applies only to storage systems that are running IBM Spectrum Virtualize 8.1.1 or later. To view details about collected statistics, see Starting statistics collection .

Table 5. Remote mirror metrics for volumes

Metric	Definition
Global Mirror (Overlapping Write I/O Rate)	The average number of overlapping write operations per second that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.
Global Mirror (Overlapping Write Percentage)	The percentage of overlapping write operations that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.
Global Mirror (Secondary Write Lag)	The average number of additional milliseconds that it takes to service each secondary write operation for Global Mirror. This value does not include the time to service the primary write operations. You monitor the value of Global Mirror Secondary Write Lag to identify delays that occurred during the process of writing data to the secondary site.
Global Mirror (Write I/O Rate)	The average number of write operations per second that are issued to the Global Mirror secondary site.

Volume cache (VC) metrics are only available for SAN Volume Controller, Storwize, and FlashSystem block storage systems whose firmware version is 7.3 or later.

Tip:

The volume cache is sometimes referred to as *upper cache*.

Table 6. Volume cache (VC) metrics for volumes

Metric	Definition
Cache Hits (Dirty Writes)	The percentage of all cache write hits that occur on data that is marked as modified in the volume cache. This value represents how effectively write operations are coalesced before the data is written to disk.
Cache Hits (Read)	The percentage of read operations that find data in the volume cache.
Cache Hits (Write)	The percentage of cache hits for write operations that are handled in the volume cache.
Fast-Write Write Data Rate	The average number of MiB per second that were written to disk in fast-write made in the upper cache. Use this information to help identify the source of back-end overloading, measure the workloads that exit the upper caches, and detect IO amplification in general.
I/O Rate (Destage)	The average number of cache-to-disk transfer operations per second that are processed in the volume cache.
I/O Rate (Read)	The average number of read operations per second that are processed in the volume cache. This value includes operations that are started by hosts or by remote replication sources.
I/O Rate (Write)	The average number of write operations per second that are processed by the volume cache. This value includes operations that are started by hosts or by remote replication sources.
Response Time (Destage)	The average number of milliseconds that it took to complete each destage operation in the volume cache. That is, the time that it took to do write operations from the volume cache to the disk.
Response Time (Stage)	The average number of milliseconds that it took to complete each stage operation in the volume cache. That is, the time that it took to do read operations from the disk to the volume cache.

Metric	Definition
Write Delay Percentage (Flush-through)	The percentage of write operations that are written to disk in flush-through mode in the volume cache.
Write Delay Percentage (Total Delay)	The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions in the volume cache. The value is a percentage of all operations.
Write Delay Percentage (Write-through)	The percentage of write operations that are written to disk in write-through mode in the volume cache.
Write Delay Rate (Flush-through)	The average number of tracks per second that are written to disk in flush-through mode in the volume cache.
Write Delay Rate (Total Delay)	The average number of I/O operations per second that are delayed. The delay might occur because of space constraints in the write cache, or because of other conditions in the volume cache. The value is an average of all operations.
Write Delay Rate (Write-through)	The average number of sectors per second that are written to disk in write-through mode in the volume cache.

Volume copy cache (VCC) metrics are only available for SAN Volume Controller, Storwize, and FlashSystem block storage systems whose firmware version is 7.3 or later.
Tip: The volume copy cache is sometimes referred to as *lower cache*.

Table 7. Volume copy cache (VCC) metrics for volumes

Metric	Definition
Cache Hits (Dirty Writes)	The percentage of all cache write hits that occur on data that is marked as modified in the volume copy cache. This value represents how effectively write operations are coalesced before the data is written to disk.
Cache Hits (Read-ahead)*	The percentage of all read cache hits that occur on pre-staged data.
Cache Hits (Read)	The percentage of read operations that find data in the volume copy cache.
Cache Hits (Write)	The percentage of cache hits for write operations that are handled in the volume copy cache.
Fast Write Data Rate	The average number of MiB per second that were written to disk in fast-write mode in the lower cache. Use this information to help identify the source of back-end overloading, measure the workloads that exit the lower copy caches, and detect IO amplification in general.
I/O Rate (Destage)	The average number of cache-to-disk transfer operations per second that are processed in the volume copy cache.
I/O Rate (Prestage)	The average number of prefetch disk-to-cache transfer operations per second that are processed in the volume copy cache.
I/O Rate (Read)	The average number of read operations per second that are processed in the volume copy cache. This value includes read operations that are associated with FlashCopy® services, volume mirroring, and other internal processes. This value might also include some operations that are passed from the volume cache.
I/O Rate (Write)	The average number of write operations per second that are processed by the volume copy cache. This value includes read operations that are associated with FlashCopy services, volume mirroring, and other internal processes. This value might also include some operations that are passed from the volume cache.
Response Time (Destage)	The average number of milliseconds that it took to complete each destage operation in the volume copy cache. That is, the time that it took to do write operations from the volume copy cache to the disk.
Response Time (Prestage)	The average number of milliseconds that it took to complete each prestage operation in the volume copy cache. That is, the time that it took to prefetch data from the disk into the volume copy cache.
Response Time (Stage)	The average number of milliseconds that it took to complete each stage operation in the volume copy cache. That is, the time that it took to do read operations from the disk to the volume copy cache.
Transfer Rates (Cache-to-Disk)	The average number of sectors that are transferred per second from the volume copy cache to the disks.
Transfer Rates (Disk-to-Cache)	The average number of sectors that are transferred per second from the disks to the volume copy cache.
Write Delay Percentage (Flush-through)	The percentage of write operations that are written to disk in flush-through mode in the volume copy cache.
Write Delay Percentage (Total Delay)	The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions in the volume copy cache. The value is a percentage of all operations.
Write Delay Percentage (Write-through)	The percentage of write operations that are written to disk in write-through mode in the volume copy cache.
Write Delay Rate (Flush-through)	The average number of sectors per second that are written to disk in flush-through mode in the volume copy cache.
Write Delay Rate (Total Delay)	The average number of I/O operations per second that are delayed. The delay might occur because of space constraints in the write cache, or because of other conditions in the volume copy cache. The value is an average of all operations.
Write Delay Rate (Write-through)	The average number of sectors per second that are written to disk in write-through mode in the volume copy cache.
Note: *This metric is only available for SAN Volume Controller, Storwize, and FlashSystem block storage systems whose firmware version is 7.4 or later.	

Note:

Unless otherwise noted, you can view the volume metrics in [Table 8](#) for the following resources:

- Nodes
- I/O groups
- Storage systems

Table 8. Compression metrics for volumes

Metric	Definition
--------	------------

Metric	Definition
Compressed Volumes I/O Rate	The average number of all read and write operations per second for compressed volumes.
Compressed Volumes Data Rate	The average number of MiB per second that were read from or written to compressed volumes.
Compressed Volumes Response Time	The average number of milliseconds to complete an I/O operation for compressed volumes. This value includes both read and write operations.
Uncompressed Volumes I/O Rate	The average number of all read and write operations per second for uncompressed volumes.
Uncompressed Volumes Data Rate	The average number of MiB per second that were read from or written to uncompressed volumes.
Uncompressed Volumes Response Time	The average number of milliseconds to complete an I/O operation for uncompressed volumes. This value includes both read and write operations.

Tip:

Unless otherwise noted, you can view the volume metrics in [Table 9](#) for the following resources:

- Nodes
- I/O groups
- Host connections
- Storage systems

Table 9. Miscellaneous metrics for volumes

Metric	Definition
Cache to Host Transfer Response Time ¹	The average number of milliseconds that is taken to transfer a track from the cache to the host, including any queuing time that occurs because of throttling.
Non-Preferred Node Usage Percentage ²	The overall percentage of I/O operations that are not directed against the preferred node for each volume in an I/O Group. There is a small performance penalty when I/O does not go to the preferred node for each volume.

Notes:

1. The metric is only available for SAN Volume Controller, Storwize, and FlashSystem block storage systems whose firmware version is 7.3 or later.
2. This metric is only available when you view the performance of volumes, I/O groups, and host connections.

Legacy cache metrics are only available for SAN Volume Controller and Storwize block storage systems whose firmware version is earlier than 7.3.

Table 10. Legacy cache metrics for volumes

Metric	Definition
Dirty Write Percentage of Cache Hits	The percentage of all cache write hits that occur on data in the cache that is marked as modified. This value represents how effectively write operations are coalesced before the data is written to disk. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Disk performance metrics

Disk performance metrics are divided into the following categories:

- [Key metrics for disks](#)
- [Response time metrics for disks](#)
- [Miscellaneous metrics for disks](#)

Unless otherwise noted, you can view disk metrics for the following resources:

- Managed disks
- Pools
- Nodes
- I/O Groups
- Storage systems

Restriction: Performance metadata for managed disks in IBM Spectrum Virtualize for Public Cloud is not yet available.

Table 11. Key metrics for disks

Metric	Definition
Data Rate (Read)	The average number of MiB per second that are read from the back-end storage resources.
Data Rate (Write)	The average number of MiB per second that are written to the back-end storage resources.
Data Rate (Total)	The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.
I/O Rate (Read) ¹	The average number of read operations per second that are issued to the back-end storage resources.
I/O Rate (Write) ²	The average number of write operations per second that are issued to the back-end storage resources.
I/O Rate (Total) ³	The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.
Response Time (Read)	The average number of milliseconds for the back-end storage resources to respond to a read operation.
Response Time (Write)	The average number of milliseconds for the back-end storage resources to respond to a write operation.
Response Time (Overall)	The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Notes:

1. The performance metrics for I/O Rate (Read) are available for pools, nodes, I/O groups, and storage systems.
2. The performance metrics for I/O Rate (Write) are available for pools, nodes, I/O groups, and storage systems.
3. The performance metrics for I/O Rate (Total) are available for pools, nodes, I/O groups, and storage systems.

Table 12. Response time metrics for disks

Metric	Definition
Queue Time (Read)	The average number of milliseconds that a read operation spends in the queue before the operation is sent to the back-end storage resources.
Queue Time (Write)	The average number of milliseconds that a write operation spends in the queue before the operation is sent to the back-end storage resources.
Queue Time (Overall)	The average number of milliseconds that a read or a write operation spends in the queue before the operation is sent to the back-end storage resources.
Peak Back-end Queue Time (Read)	The longest time that a read operation spends in the queue before the operation is sent to the back-end storage resources.
Peak Back-end Queue Time (Write)	The longest time that a write operation spends in the queue before the operation is sent to the back-end storage resources.
Peak Back-end Response Time (Read)	The longest time for a back-end storage resource to respond to a read operation.
Peak Back-end Response Time (Write)	The longest time for a back-end storage resource to respond to a write operation by a node.

Table 13. Miscellaneous metrics for disks

Metric	Definition
Transfer Size (Read)	The average number of KiB that are transferred per read operation from the back-end storage resources.
Transfer Size (Write)	The average number of KiB that are transferred per write operation to the back-end storage resources.
Transfer Size (Overall)	The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.
Cache Destage (In-Flight I/O)*	The actual number of concurrent operations that are issued from the cache to the managed disk. The number of in-flight operations cannot exceed the target, but also varies over time, depending on the type of I/O operations and on the performance of the managed disk.
Cache Destage (Target I/O)*	The maximum number of concurrent operations that can be issued from the cache to the managed disk. This target changes over time, depending on changes in cache utilization and on changes in the performance of the managed disk.
Note: *This metric is only available when you view the performance of managed disks. The metric is only available for SAN Volume Controller, Storwize, and FlashSystem block storage systems whose firmware version is 7.3 or later.	

Pool performance metrics

Key performance metrics are available for pools.

Unless otherwise noted, you can view pool metrics for the following resources:

- Pools

Table 14. Key metrics for pools

Metric	Definition
Max Write Cache Fullness*	The maximum amount of the lower cache that the write cache partitions on the nodes that manage the pool are using for write operations. If the value is 100%, one or more cache partitions on one or more pools is full. The operations that pass through the pools with full cache partitions will be queued and I/O response times will increase for the volumes in the affected pools.
Write Cache Fullness*	The average amount of the lower cache that the pools' write cache partitions on the nodes are using for write operations. Monitor average cache fullness to identify the pools that are experiencing heavy cache usage.
Note: *This cache fullness metric applies to systems that are running IBM Spectrum Virtualize 7.3 or later.	

FC Port performance metrics

FC Port performance metrics are divided into the following categories:

- [Key metrics for FC ports](#)
- [I/O rate metrics for FC ports](#)
- [Data rate metrics for FC ports](#)
- [Response time metrics for FC ports](#)
- [Error rate metrics for ports](#)
- [Miscellaneous metrics for FC ports](#)

Unless otherwise noted, you can view port metrics for the following resources:

- Ports
- Nodes
- I/O Groups
- Storage systems

Table 15. Key metrics for FC Ports

Metric	Definition
I/O Rate (Receive)	The average number of I/O operations per second for operations in which the port receives data.
I/O Rate (Send)	The average number of I/O operations per second for operations in which data is sent from a port.
Data Rate (Receive)	The average rate at which data is received by the port. The rate is measured in MiB per second.
Data Rate (Send)	The average rate at which data is sent from the port. The rate is measured in MiB per second.

Metric	Definition
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.
Bandwidth (Receive)	The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Bandwidth (Send)	The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Bandwidth (Overall)	The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Table 16. I/O rate metrics for FC Ports

Metric	Definition
Port-to-Disk I/O Rate (Receive)	The average number of exchanges per second that are received from back-end storage resources.
Port-to-Disk I/O Rate (Send)	The average number of IOs per second that are sent from the storage system to the back-end storage it is virtualizing. Use this metric to help measure the rate of data that is sent to back-end storage.
Port-to-Disk I/O Rate (Total)	The average number of IOs per second that are transmitted between the storage system and the back-end storage it is virtualizing. Use this metric to help measure the rate of data that is sent to back-end storage.
Port-to-Host I/O Rate (Receive)	The average number of IOs per second that are received by the storage system from the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.
Port-to-Host I/O Rate (Send)	The average number of IOs per second that are sent by the storage system to the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.
Port-to-Host I/O Rate (Total)	The average number of IOs per second that are transmitted between the storage system and the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.
Port-to-Local Node I/O Rate (Receive)	The average number of IOs per second that are received from other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.
Port-to-Local Node I/O Rate (Send)	The average number of IOs per second that are sent to other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.
Port-to-Local Node I/O Rate (Total)	The average number of IOs per second that are transmitted between the resource and other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.
Port-to-Remote Node I/O Rate (Receive)	The average number of IOs per second that are received from nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.
Port-to-Remote Node I/O Rate (Send)	The average number of IOs per second that are sent to nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.
Port-to-Remote Node I/O Rate (Total)	The average number of IOs per second that are transmitted between the resource and nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Table 17. Data rate metrics for FC Ports

Metric	Definition
Port-to-Disk Data Rate (Receive)	The average rate at which data is received from back-end storage resources. The rate is measured in MiB per second.
Port-to-Disk Data Rate (Send)	The average rate at which data is sent to back-end storage resources. The rate is measured in MiB per second.
Port-to-Disk Data Rate (Total)	The average rate at which data is transmitted between back-end storage resources and the component. The rate is measured in MiB per second and includes both send and receive operations.
Port-to-Host Data Rate (Receive)	The average rate at which data is received from host computers. The rate is measured in MiB per second.
Port-to-Host Data Rate (Send)	The average rate at which data is sent to host computers. The rate is measured in MiB per second.
Port-to-Host Data Rate (Total)	The average rate at which data is transmitted between host computers and the component. The rate is measured in MiB per second and includes both send and receive operations.
Port-to-Local Node Data Rate (Receive)	The average rate at which data is received from other nodes that are in the local cluster. The rate is measured in MiB per second.
Port-to-Local Node Data Rate (Send)	The average rate at which data is sent to other nodes that are in the local cluster. The rate is measured in MiB per second.
Port-to-Local Node Data Rate (Total)	The average rate at which data is transmitted between the component and other nodes that are in the local cluster. The rate is measured in MiB per second.
Port-to-Remote Node Data Rate (Receive)	The average rate at which data is received from nodes that are in the remote cluster. The rate is measured in MiB per second.
Port-to-Remote Node Data Rate (Send)	The average rate at which data is sent to nodes that are in the remote cluster. The rate is measured in MiB per second.
Port-to-Remote Node Data Rate (Total)	The average rate at which data is transmitted between the component and nodes that are in the remote cluster. The rate is measured in MiB per second.

Table 18. Response time metrics for FC Ports

Metric	Definition
Port-to-Local Node Response Time (Receive)	The average number of milliseconds to complete a receive operation from another node that is in the local cluster. This value represents the external response time of the transfers.
Port-to-Local Node Response Time (Send)	The average number of milliseconds to complete a send operation to another node that is in the local cluster. This value represents the external response time of the transfers.
Port-to-Local Node Response Time (Overall)	The average number of milliseconds to complete a send or receive operation with another node that is in the local cluster. This value represents the external response time of the transfers.
Port-to-Remote Node Response Time (Receive)	The average number of milliseconds to complete a receive operation from a node that is in the remote cluster. This value represents the external response time of the transfers.

Metric	Definition
Port-to-Remote Node Response Time (Send)	The average number of milliseconds to complete a send operation to a node that is in the remote cluster. This value represents the external response time of the transfers.
Port-to-Remote Node Response Time (Overall)	The average number of milliseconds to complete a send operation to, or a receive operation from a node in the remote cluster. This value represents the external response time of the transfers.

Metrics availability restrictions: The response time metrics are available for nodes, I/O groups, and storage systems.

Table 19. Error rate metrics for FC Ports

Metric	Definition
CRC Error Rate	The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.
Link Errors (Invalid Link Transmission Rate)	The average number of bit errors per second that are detected.
Link Errors (Invalid Transmission Word Rate)	The average number of bit errors per second that are detected.
Link Errors (Link Failures)	The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.
Link Errors (Primitive Sequence Protocol Error Rate)	The average number of primitive sequence protocol errors per second that are detected. This error occurs when there is a link failure for a port.
Link Errors (Signal Loss)	The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.
Link Errors (Sync Loss)	The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled.
Port Congestion Index*	The estimated degree to which frame transmission was delayed due to a lack of buffer credits. This value is generally 0 - 100. The value 0 means there was no congestion. The value can exceed 100 if the buffer credit exhaustion persisted for an extended amount of time. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.
Port Protocol Errors (Port Send Delay Time)	The average number of milliseconds of delay that occur on the port for each send operation. The reason for these delays might be a lack of buffer credits. You cannot view zero buffer credit performance metrics for 16 Gbps Fibre Channel ports on resources that run IBM Spectrum Virtualize. Use the Port Send Delay Time metric if the Zero Buffer Credit Timer metric is not available.
Port Protocol Errors (Port Send Delay I/O Percentage)	The percentage of send operations where a delay occurred, relative to the total number of send operations that were measured for the port. Use this metric with the Port Send Delay Time metric to distinguish a few long delays from many short delays.
Port Protocol Errors (Zero Buffer Credit Percentage)	The amount of time, as a percentage, that the port was not able to send frames between ports because of insufficient buffer-to-buffer credit. The amount of time value is measured from the last time that metadata was collected. In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports.
Port Protocol Errors (Zero Buffer Credit Timer)	The number of microseconds that the port is not able to send frames between ports because there is insufficient buffer-to-buffer credit. In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports. Buffer-to-buffer credit is measured from the last time that metadata was collected. If this metric is not available, use the Port Send Delay Time metric instead.
»Total Physical Port Error Rate (cnt/s)«	<p>»The sum of all the physical error rates such as Error Frames, CRC Errors, Short Frames, and Link Failures that are detected on the storage system port.</p> <p>Total Physical Port Error Rate is the sum of the following physical error rates:</p> <ul style="list-style-type: none"> • Error Frame Rate • CRC Error Rate • Short Frame Rate • Long Frame Rate • Bad EOF CRC Error Rate • Link Failure Rate • Loss of Sync Rate • Loss of Signal Rate • Primitive Sequence Protocol Error Rate • Invalid Word Transmission Rate <p>«</p>

Metric	Definition
»Total Logical Port Error Rate (cnt/s)« «	»The sum of all the logical error rates such as F-BSY Frames, F-RJT Frames, Discarded Frames, and Encoding Disparity that are detected on the storage system port. Total Logical Port Error Rate is the sum of the following logical error rates: <ul style="list-style-type: none"> • F-BSY Frame Rate • F-RJT Frame Rate • Discarded Class 3 Frame Rate • Discarded Frame Rate • Link Reset Transmitted Rate • Link Reset Received Rate • Class 3 Send Timeout Frame Rate • Class 3 Receive Timeout Frame Rate • Encoding Disparity «
Note: *The performance metric for Port Congestion Index is only available for ports.	

Table 20. Miscellaneous metrics for FC Ports

Metric	Definition
Port-to-Local Node Queue Time (Receive)	The average time in milliseconds that a receive operation spends in the queue before the operation is processed. This value represents the queue time for receive operations that are issued from other nodes that are in the local cluster.
Port-to-Local Node Queue Time (Send)	The average time in milliseconds that a send operation spends in the queue before the operation is processed. This value represents the queue time for send operations that are issued to other nodes that are in the local cluster.
Port-to-Local Node Queue Time (Overall)	The average number of milliseconds that a send or receive operation spends in the queue before the operation is processed. This value is for send and receive operations that are issued between the component and other nodes that are in the local cluster.
Port-to-Remote Node Queue Time (Receive)	The average time in milliseconds that a receive operation spends in the queue before the operation is processed. This value represents the queue time for receive operations that are issued from a node that is in the remote cluster.
Port-to-Remote Node Queue Time (Send)	The average time in milliseconds that a send operation spends in the queue before the operation is processed. This value represents the queue time for send operations that are issued to a node that is in the remote cluster.
Port-to-Remote Node Queue Time (Overall)	The average number of milliseconds that a send or receive operation spends in the queue before the operation is processed. This value is for send and receive operations that are issued between the component and a node that is in the remote cluster.

IP Workload performance metrics

You can view the following metrics for IP Workload.

Table 21. IP Workload metrics for ports

Metric	Definition
IP Replication Compressed Data Rate (Send)	Average number of mebibytes per second that are transmitted after any compression (if active).
IP Replication Compressed Data Rate (Receive)	Average number of mebibytes per second that are received before any decompression.
IP Replication-to-Remote Node Data Rate (Send)	Average number of mebibytes per second that are transferred to other nodes in other clusters by the IP partnership driver. The rate is measured in MiB/second. Use this metric to measure the transferred data rate between the IP Replication to Remote Node.
IP Replication-to-Remote Node Data Rate (Receive)	Average number of mebibytes per second that are received from other nodes in other clusters by the IP partnership driver. The rate is measured in MiB/second. Use this metric to measure the Received data rate between the IP Replication to Remote Node.
IP Replication-to-Remote Node Data Rate (Total)	Average number of mebibytes per second that are re-transferred to other nodes in other clusters by the IP partnership driver. The rate is measured in MiB/second. Use this metric to measure the total data rate between the IP Replication to Remote Node.
IP Replication Latency	Average round-trip time for the IP partnership link since the last statistics collection period. The rate is measured in milliseconds.
IP Replication Transfer Size (Send)	Average number of mebibytes that are transferred by the IP partnership driver since the last statistics collection period. The rate is measured in MiB. Use this metric to measure the data size that is transferred by IP partnership driver.
IP Replication Transfer Size (Receive)	Average number of mebibytes that are received by the IP partnership driver since the last statistics collection period. The rate is measured in MiB. Use this metric to measure the data size that is received by IP partnership driver.
IP Replication Transfer Size (Total)	Total number of mebibytes that are transferred by the IP partnership driver since the last statistics collection period. The rate is measured in MiB. Use this metric to measure the total data size that is transferred by IP partnership driver.

Node performance metrics

Unless otherwise noted, you can view node metrics for the following resources:

- Nodes
- I/O Groups
- Storage systems

Table 22. Metrics for nodes

Metric	Definition
Compression CPU Utilization (Core 1 to Core 28)	The approximate percentage of time that a processor core was busy with data compression tasks. The performance of each core is shown with a separate metric. Note that the value for this metric will be zero or close to zero if compression accelerator hardware is installed in the nodes.
CPU Utilization (Compression CPU)	The average percentage of time that the processors used for data compression I/O tasks are busy.
CPU Utilization (System CPU)	The average percentage of time that the processors on nodes are busy doing system I/O tasks.

Metric	Definition
Data Movement Rate (MiBs) ¹	The capacity, in MiBs per second, of the valid data in a reclaimed volume extent that garbage collection has moved to a new extent in the data reduction pool on the node. The valid data must be moved so that the whole extent can be freed up or reused to write new data. This metric corresponds to the collected mm statistic.
Data Rewrite Rate (MiBs) ¹	The rate, in MiBs per second, at which data is rewritten when a host overwrites data in data reduction pools on the node. The new version of the host data is written to a different location so that the capacity that was used by the previous version of the host data can be freed up and reclaimed. This metric corresponds to the collected cm statistic. You can view this metric for nodes only.
Extent Collection Rate (cnt/s) ¹	The number of volume extents per second that were processed for garbage collection. The reclaimable capacity in the volume extents is collected so that it can be reused in the data reduction pools on the node. This metric corresponds to the collected ext col statistic. You can view this metric for nodes only.
Logical Data Rate (Sent)	The average number of logical mebibytes per second (both local node and remote node) that are sent to other nodes.
Logical Data Rate (Receive)	The average number of logical mebibytes per second (both local node and remote node) that are received from other nodes.
Logical Data Rate (Total)	The average number of logical mebibytes per second (both local node and remote node) that are transmitted between nodes.
Max Read Cache Fullness (%) ²	The maximum amount of the lower cache which the cache partitions of the pools that are managed by the node are using for read operations. If the maximum value for the cache is 100%, the read cache partition for one or more of the pools is full. The read operations that pass through the node to the affected pools will be queued and the I/O response times will increase for the volumes in the affected pools. This metric corresponds to the collected lower cache rfm statistic.
Max Write Cache Fullness (%) ²	The maximum amount of the lower cache which the cache partitions of the pools that are managed by the node are using for write operations. If the maximum value for the cache is 100%, the write cache partition for one or more of the pools is full. The write operations that pass through the node to the affected pools will be queued and the I/O response times will increase for the volumes in the affected pools. This metric corresponds to the collected lower cache wfm statistic.
New Address Write Rate (MiBs) ¹	The capacity in MiBs per second that was used to write the host's data to unallocated addresses in the data reduction pool on the node. Review this metric to determine which hosts are increasing the amount of capacity that is being written to data reduction pools on a node. This metric corresponds to the collected nm statistic. You can view this metric for nodes only.
Node Utilization by Node	The average of the bandwidth percentages of those ports in the node that are actively used for host and MDisk send and receive operations. The average is weighted by port speed and adjusted according to the technology limitations of the node hardware.
Node-to-Local Node Physical Data Rate (Send)	The average number of mebibytes per second that are sent to other nodes in the local cluster.
Node-to-Local Node Physical Data Rate (Receive)	The average number of mebibytes per second that are received from other nodes in the local cluster.
Node-to-Local Node Physical Data Rate (Total)	The average number of mebibytes per second that are transmitted between nodes in the local cluster.
Node-to-Local Node Logical Data Rate (Send)	The average number of logical mebibytes per second that are sent to the other nodes in the local cluster.
Node-to-Local Node Logical Data Rate (Receive)	The average number of logical mebibytes per second that are received from the other nodes in the local cluster.
Node-to-Local Node Logical Data Rate (Total)	The average number of logical mebibytes per second that are transmitted between nodes in the local cluster.
Node-to-Remote Node Logical Data Rate (Send)	The average number of logical mebibytes per second that are sent to nodes in the remote cluster.
Node-to-Remote Node Logical Data Rate (Receive)	The average number of logical mebibytes per second that are received from nodes in the remote cluster.
Node-to-Remote Node Logical Data Rate (Total)	The average number of logical mebibytes per second that are transmitted between nodes in the remote cluster.
Node-to-Remote Node Physical Data Rate (Send)	The average number of mebibytes per second that are sent to nodes in the remote cluster.
Node-to-Remote Node Physical Data Rate (Receive)	The average number of mebibytes per second that are received from nodes in the remote cluster.

Metric	Definition
Node-to-Remote Node Physical Data Rate (Total)	The average number of mebibytes per second that are transmitted between nodes in the remote cluster.
Physical Data Rate (Send)	The average number of physical mebibytes per second that are sent to other nodes.
Physical Data Rate (Receive)	The average number of physical mebibytes per second that are received from other nodes.
Physical Data Rate (Total)	The average number of Physical mebibytes that are transferred per second.
Read Cache Fullness (%) ²	The average amount of the lower cache which the cache partitions of the pools that are managed by the node are using for read operations. Monitor the average cache fullness for read operations to identify the nodes that are experiencing heavy cache usage. This metric corresponds to the collected lower cache rfav statistic.
Reclaimable Capacity (MiB) ¹	The capacity that can be reclaimed in the data reduction pools on the node. This metric corresponds to the collected rec statistic. You can view this metric for nodes only.
Recovered Capacity Rate (MiBs) ¹	The capacity in number of MiBs per second that was recovered by garbage collection for reuse in the data reduction pools on the node. This metric corresponds to the collected rm statistic. You can view this metric for nodes only.
System CPU Utilization » (Core 1 to Core 48)«	The approximate percentage of time that a processor core was busy with system I/O tasks. The performance of each core is shown with a separate metric.
Write Cache Fullness (%) ²	The average amount of the lower cache which the cache partitions of the pools that are managed by the node are using for write operations. Monitor the average cache fullness for write operations to identify the nodes that are experiencing heavy cache usage. This metric corresponds to the collected lower cache wfav statistic.
Notes: <ol style="list-style-type: none"> 1. This garbage collection metric applies to systems that are running IBM Spectrum Virtualize 8.1.2 or later. To view details about collected statistics, see Starting statistics collection. 2. This cache fullness metric applies to systems that are running IBM Spectrum Virtualize 7.3 or later. To view details about collected statistics, see Starting statistics collection. 	

Performance metrics for XIV, IBM Spectrum Accelerate, IBM® FlashSystem A9000, and IBM FlashSystem A9000R

Monitor the performance metrics that are collected for XIV® systems, IBM Spectrum Accelerate, IBM FlashSystem® A9000, and IBM FlashSystem A9000R.

For XIV systems, IBM FlashSystem A9000, and IBM FlashSystem A9000R, performance metrics are available for the following resources:

- [Volume metrics](#)
- [Port metrics](#)

For IBM Spectrum Accelerate, performance metrics are available for the following resource:

- [Volume metrics](#)

Restriction: XIV systems, IBM Spectrum Accelerate, IBM FlashSystem A9000, and IBM FlashSystem A9000R do not track performance statistics for volumes that were never used. Because there are no performance statistics, performance metrics are not shown for these volumes and their related components.

Volume metrics

Volume performance metrics are organized into the following categories:

- [Key storage metrics](#)
- [Cache hit percentage metrics](#)
- [Response time metrics](#)
- [Miscellaneous metrics](#)

Unless otherwise noted, you can view volume metrics for the following resources:

- Volumes
- Pools
- Modules
- Host connections
- Storage systems

Table 1. Key volume metrics

Metric	Description
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Metric	Description
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Response Time (Read)	The average number of milliseconds to complete a read operation.
Response Time (Write)	The average number of milliseconds to complete a write operation.
Response Time (Overall)	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.
Important: For XIV systems, all the key storage metrics are available for 10.2.2 or later.	

Table 2. Cache hit percentage metrics

Metric	Description
Data Cache Hits (Read) ²	The percentage of all read data that is read from the cache.
Data Cache Hits (Write) ²	The percentage of all write data that is written to cache slots that are marked as modified.
Data Cache Hits (Overall) ²	The percentage of all data that is handled in the cache. This value includes read data that is read from the cache and write data that is written to cache slots that are marked as modified.
Overall I/O Cache Hits (Read) ¹	The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.
Overall I/O Cache Hits (Write) ¹	The average percentage of all write operations that are handled in the cache, across all volumes on the server. This value includes both sequential and nonsequential write operations.
Overall I/O Cache Hits (Total) ¹	The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
SSD Read Cache Hits (I/O) ²	The percentage of read operations that find data in the cache on a solid-state drive (SSD). The value for this metric is also included in the value for the Overall Read Cache Hit Percentage metric. This metric is only available for XIV systems that use solid-state drives as drives for caching.
SSD Read Cache Hits (Data) ²	The percentage of all read data that was read from cache memory on a solid-state drive. This metric is only available for XIV systems that use solid-state drives as drives for caching.
Notes:	
1. For XIV systems, this metric is available in 10.2.2 or later.	
2. For XIV systems, this metric is available in 10.2.4 or later.	

Table 3. Response time metrics

Metric	Description
Cache Hit Response Time (Read)	The average number of milliseconds to complete a read-cache hit operation.
Cache Hit Response Time (Write)	The average number of milliseconds to complete a write-cache hit operation.
Cache Hit Response Time (Overall)	The average number of milliseconds to complete a cache hit operation. This value includes the times for both read-cache hit and write-cache hit operations.
Cache Miss Response Time (Read)	The average number of milliseconds to complete a read-cache miss operation.
Cache Miss Response Time (Write)	The average number of milliseconds to complete a write-cache miss operation.
Cache Miss Response Time (Overall)	The average number of milliseconds to complete a cache miss operation. This value includes the times for both read-cache miss and write-cache miss operations.
Response Time by Transfer Size (Small)	The average number of milliseconds to complete an I/O operation that has a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.
Response Time by Transfer Size (Medium)	The average number of milliseconds to complete an I/O operation that has a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.
Response Time by Transfer Size (Large)	The average number of milliseconds to complete an I/O operation that has a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.
Response Time by Transfer Size (Very Large)	The average number of milliseconds to complete an I/O operation with a data transfer size that is greater than 512 KiB.
SSD Read Cache Hit Response Time	The average number of milliseconds that it takes to complete a hit operation on the read cache on a solid-state drive. The value for this metric is also included in the value for the Read Cache Hit Response Time metric. This metric is only available for XIV systems that use solid-state drives as drives for caching.
Note: For XIV systems, all the response time metrics are available for 10.2.2 or later.	

Table 4. Miscellaneous metrics

Metric	Description
Average Transfer Size (Read) ¹	The average number of KiB that are transferred per read operation.
Average Transfer Size (Write) ¹	The average number of KiB that are transferred per write operation.

Metric	Description
Average Transfer Size (Overall) ¹	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.
I/O Transfer Size (Small) ²	The percentage of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.
I/O Transfer Size (Medium) ²	The percentage of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.
I/O Transfer Size (Large) ²	The percentage of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.
I/O Transfer Size (Very Large) ²	The percentage of I/O operations with a data transfer size that is greater than 512 KiB.
Data Transfer Size (Small) ²	The percentage of data that is transferred as a result of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.
Data Transfer Size (Medium) ²	The percentage of data that is transferred as a result of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.
Data Transfer Size (Large) ²	The percentage of data that is transferred as a result of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.
Data Transfer Size (Very Large) ²	The percentage of data that is transferred as a result of I/O operations with a data transfer size that is greater than 512 KiB.
Volume Utilization ^{1, 3}	The average percentage of time that the volume is busy.
Pool Activity Score ^{1, 3}	The activity level of pools, which is set to the following value: $[\text{Read I/O Rate} \times (1 - \text{Read I/O Cache Hit \%})] \div \text{Total Pool Capacity}$ The value of this metric is the same for all pools in the storage system.
Notes:	
1. For XIV systems, this metric is available in 10.2.2 or later. 2. For XIV systems, this metric is available in 10.2.4 or later. 3. This metric is only available when you view the performance of pools.	

Port metrics

The following performance metrics for ports are available for XIV systems that are 10.2.4 or later:

- [I/O rate metrics](#)
- [Data rate metrics](#)
- [Response time metrics](#)
- [Miscellaneous port metrics](#)

Restriction: Port metrics are not available for IBM Spectrum Accelerate.

Table 5. I/O rate metrics

Metric	Description
I/O Rate (Send)	The average number of I/O operations per second for operations in which data is sent from a port.
I/O Rate (Receive)	The average number of I/O operations per second for operations in which the port receives data.
I/O Rate (Total)	The average number of send operations and receive operations per second.

Table 6. Data rate metrics

Metric	Description
Data Rate (Send)	The average rate at which data is sent from the port. The rate is measured in MiB per second.
Data Rate (Receive)	The average rate at which data is received by the port. The rate is measured in MiB per second.
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Table 7. Response time metrics

Metric	Description
Response Time (Send)	The average number of milliseconds to complete a send operation.
Response Time (Receive)	The average number of milliseconds to complete a receive operation.
Response Time (Overall)	The average number of milliseconds to complete a send or receive operation.

Table 8. Miscellaneous port metrics

Metric	Description
Bandwidth (Send)	The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Bandwidth (Receive)	The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Bandwidth (Overall)	The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Performance metrics for IBM Spectrum Scale

Monitor the performance metrics that are collected for IBM Spectrum Scale storage systems.

Overview

The performance metrics are divided into the following categories:

- [Node performance metrics](#)
- [File system performance metrics](#)

Node performance metrics

You can view the following metrics for each IBM Spectrum Scale cluster node.

Table 1. Metrics for nodes

Metric	Definition
CPU Utilization (User)	The average percentage of time that the processors on a node are busy doing user tasks.
CPU Utilization (System)	The average percentage of time that the processors on a node are busy doing system tasks.
CPU Utilization (Total)	The average percentage of time that the processors on a node are busy doing user tasks and system tasks.
Memory Used (Cache and Buffer)	The average percentage of memory on a node that is used for cache and buffer memory.
Memory Used	The average percentage of memory that is used on a node. This value does not include the memory that is used for cache and buffer memory.
Memory Used (Total)	The average percentage of memory that is used on a node. This value includes the memory that is used for cache and buffer memory.
I/O Rate (Read)	The average number of read operations per second.
I/O Rate (Write)	The average number of write operations per second.
I/O Rate (Total)	The average number of read operations and write operations per second.

File system performance metrics

You can view file system metrics for the following resources:

- File systems
 - IBM Spectrum Scale storage systems
- Tip: For a storage system, the metrics contain summary values for all the file systems on the storage system.

Table 2. Metrics for file systems

Metric	Definition
Data Rate (Read)	The average number of MiB per second that are transferred for read operations.
Data Rate (Write)	The average number of MiB per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Maximum Data Rate (Read)	The maximum number of MiB per second that are transferred for read operations.
Maximum Data Rate (Write)	The maximum number of MiB per second that are transferred for write operations.
Maximum Data Rate (Total)	The maximum number of MiB per second that are transferred for read operations and write operations.
I/O Rate (Read)	The average number of read operations per second.
I/O Rate (Write)	The average number of write operations per second.
I/O Rate (Total)	The average number of read operations and write operations per second.
Maximum I/O Rate (Read)	The maximum number of read operations per second.
Maximum I/O Rate (Write)	The maximum number of write operations per second.
Maximum I/O Rate (Total)	The maximum number of read operations and write operations per second.
Response Time (Read)	The average number of milliseconds for the back-end storage resources to respond to a read operation from the file system.
Response Time (Write)	The average number of milliseconds for the back-end storage resources to respond to a write operation from the file system.
Response Time (Overall)	The average number of milliseconds for the back-end storage resources to respond to a read operation or a write operation from the file system.

Performance metrics for IBM FlashSystem 900

To review trends in performance for IBM FlashSystem® 900 storage systems, you add performance metrics to performance charts. Use the charts to monitor the performance of the storage systems.

Overview

The performance metrics are described in the following sections:

- [Volume metrics](#)
- [Disk metrics](#)
- [Port metrics](#)

Restrictions:

- IBM FlashSystem 900 storage systems do not track performance for individual volumes. The volume metrics that are available are provided to allow comparisons across different storage systems, but represent performance that is measured for ports rather than for volumes.
- IBM Spectrum® Control supports only Fibre Channel adapters and ports that are installed on storage systems. For IBM FlashSystem 900 storage systems that have other types of ports, performance data is only available for the drives.
- Response time metrics are not available for all IBM FlashSystem 900 storage systems, depending on the firmware release of the storage system. To collect and view response time metrics, ensure that you have firmware level 1.4.5 or later. For details of the firmware that is supported by IBM Spectrum Control, check the storage information in the [IBM Spectrum Control interoperability matrix](#).

Volume metrics

IBM FlashSystem 900 storage systems do not track the performance of individual volumes. Therefore, the performance metrics that you can view represent the sum of the measured performance of all the ports in the storage system.

Table 1. Metrics for volumes

Metric	Description
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Response Time (Read)	The average number of milliseconds to complete a read operation.
Response Time (Write)	The average number of milliseconds to complete a write operation.
Response Time (Total)	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Disk metrics

You can view the following performance metrics for drives or flash modules on IBM FlashSystem 900 storage systems.

Table 2. Metrics for disks

Metric	Description
Data Rate (Read)	The average number of MiB per second that are read from the back-end storage resources.
Data Rate (Write)	The average number of MiB per second that are written to the back-end storage resources.
Data Rate (Total)	The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.
Flash Health Percentage	The overall flash module health. The health percentage is calculated based on the number of unusable blocks on the flash module.

Port metrics

You can view the following port performance metrics for Fibre Channel ports on IBM FlashSystem 900 storage systems. No performance data is available for InfiniBand or FCoE ports.

Table 3. Metrics for ports

Metric	Description
Bandwidth (Send)	The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Bandwidth (Receive)	The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Bandwidth (Total)	The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Data Rate (Send)	The average rate at which data is sent from the port. The rate is measured in MiB per second.
Data Rate (Receive)	The average rate at which data is received by the port. The rate is measured in MiB per second.
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.
I/O Rate (Send)	The average number of I/O operations per second for operations in which data is sent from a port.
I/O Rate (Receive)	The average number of I/O operations per second for operations in which the port receives data.
I/O Rate (Total)	The average number of send operations and receive operations per second.
Response Time (Send)	The average number of milliseconds to complete a send operation.
Response Time (Receive)	The average number of milliseconds to complete a receive operation.
Response Time (Overall)	The average number of milliseconds to complete a send or receive operation.
Transfer Size (Send)	The average number of KiB that are transferred per send operation.
Transfer Size (Receive)	The average number of KiB that are transferred per receive operation.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

Performance metrics for Dell EMC storage systems

Monitor the performance metrics that are collected for Unity, VMAX, and VNX storage systems.

Overview

The performance metrics are described in the following sections:

- [Unity storage systems](#)
- [VMAX storage systems](#)
- [VNX storage systems](#)

Restriction: For Dell EMC, performance metrics are only available for block storage systems.

Unity storage systems

The following performance metrics are available for Unity resources:

- [Volume metrics for Unity](#)
- [Disk metrics for Unity](#)
- [Port metrics for Unity](#)
- [Node metrics for Unity](#)
- [File system metrics for Unity](#)

A performance metric might apply to one or more storage resources. To check which resources the performance metric applies to, see the tips and the table footnotes.

Volume metrics for Unity

Volume performance metrics are divided into the following categories:

- [Key volume metrics](#)
- [Cache hit metrics](#)

Tip: You can view the volume metrics in [Key volume metrics](#) for the following resources:

- Volumes
- Pools
- Nodes
- Storage systems

Table 1. Key volume metrics

Metric	Description
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Response Time (Overall)	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.
Transfer Size (Read)	The average number of KiB that are transferred per read operation.
Transfer Size (Write)	The average number of KiB that are transferred per write operation.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Tip: You can view the volume metrics in [Cache hit metrics](#) for the following resources:

- Nodes
- Storage systems

Table 2. Cache hit metrics

Metric	Description
Overall I/O Cache Hits (Read) %	The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.
Overall I/O Cache Hits (Write) %	The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.
Overall I/O Cache Hits (Total) %	The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Disk metrics for Unity

You can view the metrics in [Key disk metrics](#) for the following resources:

- Pools
- Disks
- Nodes
- Storage systems

Table 3. Key disk metrics

Metric	Definition
I/O Rate (Read)	The average number of read operations per second that are issued to the back-end storage resources.
I/O Rate (Write)	The average number of write operations per second that are issued to the back-end storage resources.
I/O Rate (Total)	The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.
Data Rate (Read)	The average number of MiB per second that are read from the back-end storage resources.
Data Rate (Write)	The average number of MiB per second that are written to the back-end storage resources.
Data Rate (Total)	The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.
Response Time (Overall)	The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.
Transfer Size (Read)	The average number of KiB that are transferred per read operation from the back-end storage resources.
Transfer Size (Write)	The average number of KiB that are transferred per write operation to the back-end storage resources.
Transfer Size (Overall)	The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Port metrics for Unity

You can view the metrics in [Key port metrics](#) for ports, nodes, and storage systems.

Table 4. Key port metrics

Metric	Description
I/O Rate (Send)	The average number of I/O operations per second for operations in which data is sent from a port.
I/O Rate (Receive)	The average number of I/O operations per second for operations in which the port receives data.
I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Data Rate (Send)	The average rate at which data is sent from the port. The rate is measured in MiB per second.
Data Rate (Receive)	The average rate at which data is received by the port. The rate is measured in MiB per second.
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.
Transfer Size (Send)	The average number of KiB that are transferred per send operation.
Transfer Size (Receive)	The average number of KiB that are transferred per receive operation.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

Node metrics for Unity

You can view the metrics in [Key node metrics](#) for nodes and storage systems.

Table 5. Key node metrics

Metric	Description
System CPU	The average percentage of time that the processors on nodes are busy doing system I/O tasks.

File system metrics for Unity

Unless otherwise noted, you can view the performance metrics in [Key file system metrics](#) for the following resources:

- Pools
- Nodes
- File systems
- Storage systems

Tip: For a storage system, the metrics contain summary values for all of the file systems on the storage system.

Table 6. Key file systems metrics

Metric	Definition
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Transfer Size (Read)	The average number of KiB that are transferred per read operation.
Transfer Size (Write)	The average number of KiB that are transferred per write operation.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

VMAX storage systems

The following performance metrics are available for VMAX resources:

- [Volume metrics for VMAX](#)
- [Disk metrics for VMAX](#)
- [Port metrics for VMAX](#)

A performance metric might apply to one or more storage resources. To check which resources the performance metric applies to, see the tips and the table footnotes.

Volume metrics for VMAX

Volume performance metrics are divided into the following categories:

- [Key volume metrics](#)
- [Cache hit metrics](#)
- [Transfer size metrics](#)

Tip: Unless otherwise noted, you can view the volume metrics in [Key volume metrics](#), [Cache hit metrics](#), and [Transfer size metrics](#) for the following resources:

- Volumes
- Directors
- Storage systems

Table 7. Key volume metrics

Metric	Description
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Response Time (Read) ¹	The average number of milliseconds to complete a read operation.
Response Time (Write) ¹	The average number of milliseconds to complete a write operation.
Response Time (Overall) ¹	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.
Volume Utilization ²	The average percentage of time that the volume is busy.
Normal I/O Rate (Read)	The average number of nonsequential read operations per second.
Normal I/O Rate (Write)	The average number of nonsequential write operations per second.
Normal I/O Rate (Total)	The average number of nonsequential I/O operations per second. This value includes both read and write operations.
Sequential I/O Rate (Read)	The average number of sequential read operations per second.
Sequential I/O Rate (Write)	The average number of sequential write operations per second.
Sequential I/O Rate (Total)	The average number of sequential I/O operations per second. This value includes both read and write operations.
Note:	
1. This metric is only available when you view the performance of volumes or storage systems.	
2. This metric is only available when you view the performance of volumes.	

Table 8. Cache hit metrics

Metric	Description
Normal I/O Cache Hits (Read)	The percentage of nonsequential read operations that find data in the cache. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
Normal I/O Cache Hits (Write)	The percentage of nonsequential write operations that are handled in the cache.
Normal I/O Cache Hits (Total)	The percentage of nonsequential I/O operations that are handled in the cache. This value includes both read and write operations. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
Sequential I/O Cache Hits (Read)	The percentage of sequential read operations that find data in the cache. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
Sequential I/O Cache Hits (Write)	The percentage of sequential write operations that are handled in the cache.
Sequential I/O Cache Hits (Total)	The percentage of sequential I/O operations that are handled in the cache. This value includes both read and write operations. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
Overall I/O Cache Hits (Read)	The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.
Overall I/O Cache Hits (Write)	The average percentage of all write operations that are handled in the cache, across all volumes on the server. This value includes both sequential and nonsequential write operations.

Metric	Description
Overall I/O Cache Hits (Total)	The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Table 9. Transfer size metrics

Metric	Description
Average Transfer Size (Read)	The average number of KiB that are transferred per read operation.
Average Transfer Size (Write)	The average number of KiB that are transferred per write operation.
Average Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Disk metrics for VMAX

Disk performance metrics for VMAX block storage systems are divided into the following categories:

- [Key disk metrics](#)
- [Transfer size metrics](#)

Table 10. Key disk metrics

Metric	Definition
I/O Rate (Read)	The average number of read operations per second that are issued to the back-end storage resources.
I/O Rate (Write)	The average number of write operations per second that are issued to the back-end storage resources.
I/O Rate (Total)	The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.
Data Rate (Read)	The average number of MiB per second that are read from the back-end storage resources.
Data Rate (Write)	The average number of MiB per second that are written to the back-end storage resources.
Data Rate (Total)	The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.
Response Time (Overall)	The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.
Disk Utilization Percentage	The approximate utilization percentage of a particular array over a particular time interval, that is, the average percent of time that the disk associated with the array was busy.

Table 11. Transfer size metrics

Metric	Description
Transfer Size (Read)	The average number of KiB that are transferred per read operation from the back-end storage resources.
Transfer Size (Write)	The average number of KiB that are transferred per write operation to the back-end storage resources.
Transfer Size (Overall)	The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Port metrics for VMAX

You can view the metrics below for ports and storage systems.

Table 12. Port metrics

Metric	Description
I/O Rate (Total)	The average number of send operations and receive operations per second.
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.
Response Time (Overall)	The average number of milliseconds to complete a send or receive operation.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

VNX storage systems

The following performance metrics are available for VNX resources:

- [Volume metrics for VNX](#)
- [Disk metrics for VNX](#)
- [Port metrics for VNX](#)

Volume metrics for VNX

Volume performance metrics are divided into the following categories:

- [Key volume metrics](#)
- [Transfer size metrics](#)

Tip: Unless otherwise noted, you can view the volume metrics in [Key volume metrics](#) and [Transfer size metrics](#) for the following resources:

- Volumes
- Nodes
- Storage systems

Table 13. Key volume metrics

Metric	Description
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.

Table 14. Transfer size metrics

Metric	Description
Average Transfer Size (Read)	The average number of KiB that are transferred per read operation.
Average Transfer Size (Write)	The average number of KiB that are transferred per write operation.
Average Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Disk metrics for VNX

Disk performance metrics for VNX storage systems are divided into the following categories:

- [Key disk metrics](#)
- [Transfer size metrics](#)

Table 15. Key disk metrics

Metric	Definition
I/O Rate (Read)	The average number of read operations per second that are issued to the back-end storage resources.
I/O Rate (Write)	The average number of write operations per second that are issued to the back-end storage resources.
I/O Rate (Total)	The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.
Data Rate (Read)	The average number of MiB per second that are read from the back-end storage resources.
Data Rate (Write)	The average number of MiB per second that are written to the back-end storage resources.
Data Rate (Total)	The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Table 16. Transfer size metrics

Metric	Description
Transfer Size (Read)	The average number of KiB that are transferred per read operation from the back-end storage resources.
Transfer Size (Write)	The average number of KiB that are transferred per write operation to the back-end storage resources.
Transfer Size (Overall)	The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Port metrics for VNX

You can view the metrics below for ports and storage systems.

Table 17. Port metrics

Metric	Description
I/O Rate (Total)	The average number of send operations and receive operations per second.
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

Performance metrics for Hitachi VSP storage systems

Monitor the performance metrics that are collected for storage systems.

The following performance metrics are available for Hitachi VSP storage systems.

- [Volume metrics](#)
- [Port metrics](#)
- [Node metrics](#)

A performance metric might apply to one or more storage resources. To check which resources the performance metric applies to, see the tips.

Volume metrics

Volume performance metrics are divided into the following categories:

- [Key volume metrics](#)
- [Cache hit metrics](#)

Tip: You can view the volume metrics in [Key volume metrics](#) for the following resources:

- Volumes
- Pools
- Storage systems

Table 1. Key volume metrics

Metric	Description
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Response Time (Read)	The average number of milliseconds to complete a read operation.
Response Time (Write)	The average number of milliseconds to complete a write operation.
Response Time (Overall)	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.
Transfer Size (Read)	The average number of KiB that are transferred per read operation.
Transfer Size (Write)	The average number of KiB that are transferred per write operation.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Tip: You can view the volume metrics in [Cache hit metrics](#) for the following resources:

- Volumes
- Pools
- Storage systems

Table 2. Cache hit metrics

Metric	Description
Overall I/O Cache Hits (Read) %	The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.
Overall I/O Cache Hits (Write) %	The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Port metrics

You can view the metrics in [Key port metrics](#) for ports and storage systems.

Table 3. Key port metrics

Metric	Description
I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.
Response Time (Overall)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

Node metrics

You can view the metrics in [Key node metrics](#) for storage systems.

Table 4. Key node metrics

Metric	Description
System CPU	The average percentage of time that the processors on nodes are busy doing system I/O tasks.

Performance metrics for NetApp storage systems

Monitor the performance metrics that are collected for NetApp storage systems that are running ONTAP 9.

The following performance metrics are available for storage systems that are running ONTAP 9:

- [Volume metrics](#)
- [Disk metrics](#)
- [Port metrics](#)
- [Node metrics](#)
- [File system metrics](#)

A performance metric might apply to one or more storage resources. To check which resources the performance metric applies to, see the tips.

Volume metrics

Volume performance metrics are divided into the following categories:

- [Key volume metrics](#)

- [Cache hit metrics](#)

Tip: You can view the volume metrics in [Key volume metrics](#) for the following resources:

- Volumes
- Pools
- Nodes
- Storage systems

Table 1. Key volume metrics

Metric	Description
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Response Time (Read)	The average number of milliseconds to complete a read operation.
Response Time (Write)	The average number of milliseconds to complete a write operation.
Response Time (Overall)	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.
Transfer Size (Read)	The average number of KiB that are transferred per read operation.
Transfer Size (Write)	The average number of KiB that are transferred per write operation.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Volume cache hit metrics are only available when you view the performance of nodes or storage systems. To check which resources a volume cache hit metric applies to, see the table footnotes.

Table 2. Cache hit metrics

Metric	Description
Overall I/O Cache Hits (Read) % ¹	The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.
Notes:	
1. This metric is only available when you view the performance of storage systems.	

Disk metrics

Disk performance metrics for NetApp storage systems that are running ONTAP 9 are described in [Key disk metrics](#).

Tip: You can view the disk metrics in [Key disk metrics](#) for the following resources:

- Pools
- Disks
- Nodes
- Storage systems

Table 3. Key disk metrics

Metric	Definition
I/O Rate (Read)	The average number of read operations per second that are issued to the back-end storage resources.
I/O Rate (Write)	The average number of write operations per second that are issued to the back-end storage resources.
I/O Rate (Total)	The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.
Data Rate (Read)	The average number of MiB per second that are read from the back-end storage resources.
Data Rate (Write)	The average number of MiB per second that are written to the back-end storage resources.
Data Rate (Total)	The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.
Response Time (Read)	The average number of milliseconds for the back-end storage resources to respond to a read operation.
Response Time (Write)	The average number of milliseconds for the back-end storage resources to respond to a write operation.
Response Time (Overall)	The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.
Transfer Size (Read)	The average number of KiB that are transferred per read operation from the back-end storage resources.
Transfer Size (Write)	The average number of KiB that are transferred per write operation to the back-end storage resources.
Transfer Size (Overall)	The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Port metrics

Port performance metrics are described in [Key port metrics](#).

Tip: You can view the port metrics in [Key port metrics](#) for the following resources:

- Ports
- Nodes
- Storage systems

Table 4. Key port metrics

Metric	Description
I/O Rate (Send)	The average number of I/O operations per second for operations in which data is sent from a port.
I/O Rate (Receive)	The average number of I/O operations per second for operations in which the port receives data.
I/O Rate (Total)	The average number of send operations and receive operations per second.
Response Time (Send)	The average number of milliseconds to complete a send operation.
Response Time (Receive)	The average number of milliseconds to complete a receive operation.
Response Time (Overall)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.
Data Rate (Send)	The average rate at which data is sent from the port. The rate is measured in MiB per second.
Data Rate (Receive)	The average rate at which data is received by the port. The rate is measured in MiB per second.
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.
Transfer Size (Send)	The average number of KiB that are transferred per send operation.
Transfer Size (Receive)	The average number of KiB that are transferred per receive operation.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

Node metrics

You can view the metrics in [Key node metrics](#) for storage systems.

Table 5. Key node metrics

Metric	Description
System CPU	The average percentage of time that the processors on nodes are busy doing system I/O tasks.

File system metrics

Unless otherwise noted, you can view the performance metrics in [Key file system metrics](#) for the following resources:

- Pools
- Nodes
- File systems
- Storage systems

Tip: For a storage system, the metrics contain summary values for all of the file systems on the storage system.

Table 6. Key file systems metrics

Metric	Definition
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Response Time (Read)	The average number of milliseconds to complete a read operation.
Response Time (Write)	The average number of milliseconds to complete a write operation.
Response Time (Overall)	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Transfer Size (Read)	The average number of KiB that are transferred per read operation.
Transfer Size (Write)	The average number of KiB that are transferred per write operation.
Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Performance metrics for Pure storage systems

Monitor the performance metrics that are collected for your Pure FlashArray//M and FlashArray//X storage systems.

A performance metric might apply to one or more storage resources. To check which resources the performance metric applies to, see the tips.

Volume metrics

Volume performance metrics are described in the [Key volume metrics](#) table.

Tip: You can view the volume metrics in [Key volume metrics](#) for the following resources:

- Volumes
- Storage systems

Table 1. Key volume metrics

Metric	Description
--------	-------------

Metric	Description
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Response Time (Read)	The average number of milliseconds to complete a read operation.
Response Time (Write)	The average number of milliseconds to complete a write operation.
Response Time (Overall)	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Performance metrics for other storage systems

Monitor the performance of storage systems that are managed by SMI-S providers. You collect performance metadata from storage systems that are compliant with SMI-S 1.5 or later. The SMI-S providers can be referred to by various names, such as CIM agent, CIMOM (CIM Object Manager) agent, or SMI-S agent.

Overview

Performance metrics are available for the following resources:

- [Volume metrics](#)
- [Port metrics](#)

A performance metric might apply to one or more storage resources. To check which resources the performance metric applies to, see the tips and the table footnotes.

Restriction: For NetApp storage systems managed by SMI-S providers, performance monitoring is supported only for volumes and front-end ports. It is not supported at the storage system level.

Volume metrics

Volume performance metrics are divided into the following categories:

- [Key volume metrics](#)
- [Cache hit percentage metrics](#)
- [Average transfer size metrics](#)

Tip: Unless otherwise noted, you can view the volume metrics in [Key volume metrics](#), [Cache hit metrics](#), and [Average transfer size metrics](#) for the following resources:

- Volumes
- Nodes
- Storage systems

Table 1. Key volume metrics

Metric	Description
Overall I/O Rate (Read)	The average number of read operations per second. This value includes both sequential and nonsequential read operations.
Overall I/O Rate (Write)	The average number of write operations per second. This value includes both sequential and nonsequential write operations.
Overall I/O Rate (Total)	The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
Data Rate (Read)	The average number of MiBs per second that are transferred for read operations.
Data Rate (Write)	The average number of MiBs per second that are transferred for write operations.
Data Rate (Total)	The average number of MiB per second that are transferred for read operations and write operations.
Response Time (Read)	The average number of milliseconds to complete a read operation.
Response Time (Write)	The average number of milliseconds to complete a write operation.
Response Time (Overall)	The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.
Volume Utilization ¹	The average percentage of time that the volume is busy.
Note:	
1. This metric is only available when you view the performance of volumes.	

Table 2. Cache hit percentages

Metric	Description
Overall I/O Cache Hits (Read)	The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.
Overall I/O Cache Hits (Write)	The average percentage of all write operations that are handled in the cache, across all volumes on the server. This value includes both sequential and nonsequential write operations.
Overall I/O Cache Hits (Total)	The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Table 3. Average transfer size metrics

Metric	Description
--------	-------------

Metric	Description
Average Transfer Size (Read)	The average number of KiB that are transferred per read operation.
Average Transfer Size (Write)	The average number of KiB that are transferred per write operation.
Average Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Port metrics

Port performance metrics are divided into the following categories:

- [Key port metrics](#)
- [Transfer size metrics](#)

Tip: You can view the port metrics in [Key port metrics](#) and [Transfer size metrics](#) for ports and storage systems.

Table 4. Key port metrics

Metric	Description
I/O Rate (Receive)	The average number of I/O operations per second for operations in which the port receives data.
I/O Rate (Send)	The average number of I/O operations per second for operations in which data is sent from a port.
I/O Rate (Total)	The average number of send operations and receive operations per second.
Data Rate (Receive)	The average rate at which data is received by the port. The rate is measured in MiB per second.
Data Rate (Send)	The average rate at which data is sent from the port. The rate is measured in MiB per second.
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Table 5. Transfer size metrics

Metric	Description
Average Transfer Size (Receive)	The average number of KiB that are transferred per receive operation.
Average Transfer Size (Send)	The average number of KiB that are transferred per send operation.
Average Transfer Size (Overall)	The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

Performance metrics for switches

Monitor the performance metrics that are collected for physical switches, switch ports, and inter-switch connections.

Performance metrics for switches are divided into the following categories:

- [Key port metrics](#)
- [I/O rate metrics](#)
- [Peak data rate metrics](#)
- [Frame error rate metrics](#)
- [Port protocol error rate metrics](#)
- [Link error rate metrics](#)
- [Miscellaneous metrics](#)

Attention: To enhance troubleshooting experience for switches, two new switch port metrics namely Total Physical Port Error Rate and Total Logical Port Error Rate are available from 2Q22 update of IBM® Storage Insights. With these newly added metrics, you can quickly identify specific switch port that has high rate of physical and/or logical error rates. The two new metrics are listed in the [Table 1](#).

Table 1. Key port metrics

Metric	Description
Bandwidth Percentage (Send)	The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Bandwidth Percentage (Receive)	The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Bandwidth Percentage (Overall)	The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.
Data Rate (Send)	The average rate at which data is sent by the port. A send operation is a read operation that is processed, or a write operation that is initiated by the port. The rate is measured in MiB per second.
Data Rate (Receive)	The average rate at which data is received by the port. A receive operation is a write operation that is processed, or a read operation that is initiated by the port. The rate is measured in MiB per second.
Data Rate (Total)	The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Metric	Description
Total Physical Port Error Rate (cnt/s)	<p>The sum of all the physical error rates such as Error Frames, CRC Errors, Short Frames, and Link Failures that are detected on the switch port. Total Physical Port Error Rate is the sum of the following physical error rates:</p> <ul style="list-style-type: none"> Error Frame Rate CRC Error Rate Short Frame Rate Long Frame Rate Bad EOF CRC Error Rate Link Failure Rate Loss of Sync Rate Loss of Signal Rate Primitive Sequence Protocol Error Rate Invalid Word Transmission Rate
Total Logical Port Error Rate (cnt/s)	<p>The sum of all the logical error rates such as F-BSY Frames, F-RJT Frames, Discarded Frames, and Encoding Disparity that are detected on the switch port. Total Logical Port Error Rate is the sum of the following logical error rates:</p> <ul style="list-style-type: none"> F-BSY Frame Rate F-RJT Frame Rate Discarded Class 3 Frame Rate Discarded Frame Rate Link Reset Transmitted Rate Link Reset Received Rate Class 3 Send Timeout Frame Rate Class 3 Receive Timeout Frame Rate Encoding Disparity
Total Port Error Rate	The average number of times per second that an error was detected on the port. This rate is a summation of all the other error rates for the port.

Table 2. I/O rates

Metric	Description
Port Frame Rate (Send)	The average number of frames per second that are sent by the port.
Port Frame Rate (Receive)	The average number of frames per second that are received by the port.
Port Frame Rate (Total)	The average number of frames per second that are transferred. This value includes frames that are sent and received by the port.

Table 3. Peak data rates

Metric	Description
Peak Data Rate (Send) ¹	The highest rate at which data is sent by the port. A send operation is a read operation that is processed, or a write operation that is initiated by the port.
Peak Data Rate (Receive) ¹	The highest rate at which data is received by the port. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Notes:

1. This metric is only available for ports on Brocade switches. You must use an SMI agent to collect data for this metric. In the Storage Management Initiative Specification (SMI-S), peak data rates for a port are reported in the CIM_FcPortRateStatistics class. For SMI-S 1.1, this is an optional class, meaning that it might not be supported by a given vendor. This can result in IBM Spectrum® Control displaying zeros for the peak rates, even when there is non-zero traffic flowing through the port. When a vendor does support this class, the peak data rate represents the peak value of the associated metric counter (as reported by the CIM agent used to access the device) over a recent, vendor-defined measurement window (for example, 20 milliseconds) of the IBM Spectrum Control measurement window (for example, 15 minutes).

Table 4. Frame error rates

Metric	Description
Bad EOF CRC Error Rate ¹	The percentage of nonsequential read operations that find data in the cache. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
CRC Error Rate	The percentage of nonsequential write operations that are handled in the cache.
Discarded Class 3 Frame Rate	The average number of class 3 frames per second that are discarded.
Error Frame Rate ¹	The average number of error frames per second that are received. An error frame is a frame that violates the Fibre Channel Protocol.
F-BSY Frame Rate ²	The average number of F-BSY frames per second that are generated. An F-BSY frame is issued by the fabric to indicate that a frame cannot be delivered because the fabric or destination N_port is busy.
F-RJT Frame Rate ²	The average number of F-RJT frames per second that are generated. An F-RJT frame is issued by the fabric to indicate that delivery of a frame was denied.
Long Frame Rate	The average number of frames that are received per second that are longer than 2140 octets. This number excludes start-of-frame bytes and end-of-frame bytes. The 2140 octet limit is calculated based on the assumption that a frame has 24 header bytes, 4 CRC bytes, and 2112 data bytes.
Short Frame Rate ²	The average number of frames that are received per second that are shorter than 28 octets. This number excludes start-of-frame bytes and end-of-frame bytes. The 28 octet limit is calculated based on the assumption that a frame has 24 header bytes, and 4 CRC bytes.

Notes:

1. This metric is only available for ports on Brocade switches.
2. This metric is only available for ports on Cisco switches.

Table 5. Port protocol error rates

Metric	Description
--------	-------------

Metric	Description
Class 3 Receive Timeout Frame Rate ¹	The average number of class 3 frames per second that were discarded after reception because of a timeout condition. The timeout condition occurs while a transmitting port waits for buffer credit from a port at the other end of the fibre. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.
Class 3 Send Timeout Frame Rate ¹	The average number of class 3 frames per second that were discarded before transmission because of a timeout condition. The timeout condition occurs while the switch or port waits for buffer credit from the receiving port at the other end of the fibre. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.
Credit Recovery Link Reset Rate	The estimated average number of link resets per second that a switch or port completed to recover buffer credits. This estimate attempts to disregard link resets that were caused by link initialization. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.
Discarded Frame Rate ¹	The average number of frames per second that are discarded because host buffers are unavailable for the port.
Link Reset Received Rate	The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR2) state.
Link Reset Transmitted Rate	The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR1) state.
Port Congestion Index	The estimated degree to which frame transmission was delayed due to a lack of buffer credits. This value is generally 0 - 100. The value 0 means there was no congestion. The value can exceed 100 if the buffer credit exhaustion persisted for an extended amount of time. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.
Zero Buffer Credit Percentage	The amount of time, as a percentage, that the port was not able to send frames between ports because of insufficient buffer-to-buffer credit. The amount of time value is measured from the last time that metadata was collected. In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports.
Zero Buffer Credit Rate	The average number of Zero Buffer Credit conditions per second that occurred. A Zero Buffer Credit condition occurs when a port is unable to send frames because of a lack of buffer credit since the last node reset. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.
Notes:	
1. This metric is available only for ports on Brocade switches.	

Table 6. Link error rates

Metric	Description
Encoding Disparity	The average number of disparity errors per second that are received.
Invalid Link Transmission Rate	The average number of times per second that an invalid transmission word was detected by the port while the link did not experience any signal or synchronization loss.
Invalid Word Transmission Rate	The average number of bit errors per second that are detected.
Link Failure Rate	The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.
Loss of Signal Rate	The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.
Loss of Sync Rate	The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled.
Primitive Sequence Protocol Error Rate	The average number of primitive sequence protocol errors per second that are detected. This error occurs when there is a link failure for a port.

Table 7. Miscellaneous port metrics

Metric	Description
Link Quality Percentage	The percentage is based on whether the port is an expansion port (E_port) or a fabric port (F_port), and on the numbers and types of errors that are detected by the port.
Port Frame Size (Overall)	The average frame transfer size. This value is measured in KiB and includes frames that are sent and frames that are received by the port.
Port Frame Size (Receive)	The average size of a frame, in KiB, that is received by the port.
Port Frame Size (Send)	The average size of a frame, in KiB, that is sent through the port.

Monitoring the capacity of resources

IBM Spectrum® Control can collect information about the capacity and space usage of block, file, and object storage resources. This information includes key metrics that can help you measure, identify, and troubleshoot capacity and space usage issues in your storage. You can view capacity metrics for storage resources, including tiers.

You can use the capacity and space usage information to complete the following tasks:

- Measure, compare, and troubleshoot the capacity and space usage of resources such as:
 - Block storage systems and pools
 - Compressed, thin-provisioned, and Easy Tier® volumes

- File systems, pools, and filesets in file storage systems
- Containers in object storage systems
- Tiers
- Review the alerts that were triggered when the capacity or space usage of a resource fell outside a specific range.
- Customize views of capacity and space usage so that you can analyze specific resources and metrics during time ranges that you specify.
- View capacity and space usage information in a chart or table format to help you quickly identify where and when issues are occurring. The chart is a visual representation of how the capacity and space usage of resources trend over time.
- Drill down into resources to view detailed information about the capacity and space usage of internal resources. For example, if a SAN Volume Controller is shown in the chart, you can quickly view and compare the capacity and space usage of its pools.
- Implement server-centric monitoring of SAN resources without requiring a Storage Resource agent. When you add an agentless server, IBM Spectrum Control correlates the server with the known host connections on monitored storage systems. If matches are found, you can view the amount of storage that is assigned to the server, and trace that storage back to the storage system. You can then view details about the internal resources of the related storage system, including capacity and space usage information.
- Export capacity and space usage information to a CSV file. A CSV file is a file that contains comma-delimited values and can be viewed with a text editor or imported into a spreadsheet application.

Before you begin

Before you can view capacity and space usage information for resources, you must complete the following tasks:

Task	 Learn more
Add storage systems for monitoring by IBM Spectrum Control.	For information about how to add these resources, see Adding storage systems .
Ensure that capacity data is being collected for a resource. Typically, data collection is scheduled when resources are added for monitoring.	For information about verifying data collection, see Collecting data .
Define capacity and capacity usage alerts to be notified if the capacity or capacity usage of a resource falls outside a specified range and might represent a potential problem.	For information about how to define capacity and capacity usage alerts, see Defining alert definitions for general attributes and capacity changes .
When you define a capacity or capacity usage alert for an alert policy or for an individual resource, select a specific metric that you want to measure. For example, you can define an alert that notifies you when the total used capacity for a storage system falls outside a specified range.	

- [Setting capacity limits](#)
If your company has a policy to maintain a reserve of available capacity, you can set a limit on the amount of capacity that is used by your storage systems and pools.
- [Viewing capacity information](#)
View the capacity and space usage information of resources such as block storage systems, volumes, and pools. You can view similar information for filesets, file systems, and file system pools as internal resources of file storage systems. You can view information for containers as internal resources of object storage systems. Additionally, you can view capacity and space usage information for resources that violated a specified capacity range and generated an alert.
- [Viewing the capacity of external storage](#)
View the used capacity and capacity of external pool storage that is used by file systems in IBM Spectrum Scale. External pools can include storage that is provided by IBM® Cloud Object Storage, Amazon Simple Storage Service (S3), OpenStack Swift, IBM Spectrum Archive, IBM Spectrum Protect, and other storage providers.
- [Viewing capacity alerts and violations](#)
View the alerts that were triggered when the capacity of a resource changes and reaches a threshold. For example, you can view alerts that are generated when the measured value of a capacity metric for a pool meets the conditions for generating an alert.
- [Capacity metrics](#)
Use IBM Spectrum Control to collect and view capacity metrics about the storage systems in your environment.

Setting capacity limits

If your company has a policy to maintain a reserve of available capacity, you can set a limit on the amount of capacity that is used by your storage systems and pools.

Before you begin

Only users with Administrator privileges can set capacity limits.

About this task

When you set a limit on the amount of capacity that is used, you can monitor whether the capacity that is used is above or below the limit that you set. You can also define alerts that notify you when you are over the capacity limit.

You can set the same capacity limit:

- For all storage systems or one or more storage systems
- For all pools or one or more pools

Alternatively, you can set different capacity limits for storage systems and pools.

Tip: FlashSystem A9000 and FlashSystem A9000R storage systems are configured to report storage consumption at the storage system rather than the pool level. So, if you want to set a capacity limit for these types of storage systems, set the capacity limit for the storage systems.

Procedure

1. To set the capacity limit for storage systems or pools, choose one of the following options:

Storage Resource	Step
Block Storage Systems	Click Storage, and then click Block Storage Systems.
Pools	Click Storage, and then click Pools.

2. Select the storage systems or pools.
Tip: To select multiple storage systems or pools, press Shift and click.
3. Right-click and click View Properties.
4. Click Edit Properties
5. Enter the percentage value for the capacity limit.
6. Save your changes.

Results

The capacity limit is set and can be shown as a percentage value or GiB value. Just right-click any column heading and add Capacity Limit (%) or Capacity Limit (GiB) to the Block Storage Systems or Pools pages. You can also add the Adjusted Used Capacity (%) column which tells you how much used capacity is left based on the capacity limit. By default, the Capacity-to-Limit (GiB) column is shown on the Block Storage Systems and Pools pages so that you can see how much available capacity you have left before you reach the capacity limit.

Zero capacity: When you set the capacity limit for pools, the values shown for Zero Capacity are readjusted to take into account the capacity limit of the pool. The date will represent when the capacity limit of the pool is reached. If the pool has already reached the capacity limit, Depleted is shown. None is shown when a trend in storage consumption can't be detected because the pool's storage isn't being consumed or because not enough data was collected to predict storage consumption.

- [Tutorial: Investigating compliance with the capacity limit](#)
Track the compliance of your block storage systems with the capacity limit.
- [Removing the capacity limit](#)
Remove the capacity limit that was set for your storage systems and pools.
- [Capacity limit metrics](#)
Monitor how much capacity is available for storing data when you set a capacity limit for your storage systems and pools.

Tutorial: Investigating compliance with the capacity limit

Track the compliance of your block storage systems with the capacity limit.

About this task

In this tutorial, you set the capacity limit for the storage systems on your production platform to 80%. Today, you want to create a chart that plots the compliance of your block storage systems with the capacity limit that was set.

Because you want to track capacity in relation to the capacity limit, you remove the Capacity (GiB) metric from the chart. And, you add the following metrics to track whether the available capacity of each storage system is over or under the capacity limit:

- Capacity Limit (GiB)
- Capacity-to-Limit (GiB)

Procedure

1. From the Storage menu, click Block Storage Systems.
2. Click the Capacity tab.
3. Select the storage systems that you want to add to the capacity chart.
To select multiple storage systems, press shift and click. You can add up to 10 storage systems at a time to the capacity chart.
4. Click the Select Chart Metrics button, add Capacity Limit (GiB) and Capacity-to-Limit (GiB), and click Save.

Tip: To see the capacity metrics for a single resource, click a storage system in the Selected Resources section of the chart. And, if you want to focus on a specific period, you can change the default date range of a month to a week, or select start and end dates.

Results

You can identify the storage systems that comply with the capacity limit that was set.

Removing the capacity limit

Remove the capacity limit that was set for your storage systems and pools.

About this task

Only users with Administrator privileges can remove the capacity limit.

Procedure

1. To remove the capacity limit for storage systems or pools, choose one of the following options:

Storage Resource	Step
Block Storage Systems	Click Storage, and then click Block Storage Systems.
Pools	Click Storage, and then click Pools.

2. Select the storage systems or pools.
Tip: To select multiple storage systems or pools, press shift and click.
3. Right-click, and then click View Properties.
4. Click Edit .
5. Complete one of the following action:
 - If the pools or storage systems have the same capacity limit, delete the capacity limit.
 - If the pools or storage systems have different capacity limits, enter 0 in the Capacity Limit (%) field and press the Backspace key.
6. Save your changes.

Capacity limit metrics

Monitor how much capacity is available for storing data when you set a capacity limit for your storage systems and pools.

Capacity Limit (%)

As an Administrator, you can set a Capacity Limit (%) for block storage systems, or pools, or both. In this scenario, you want to keep 20% of your usable capacity in reserve so you set the capacity limit to 80%.

Example: Administrator Sets Capacity Limit to 80%

To see the GiB or percentage value for the capacity limit, right-click any column heading on the Block Storage Systems or the Pools pages and add them.

To monitor how much capacity is available in relation to the capacity limit that you set, the used and available capacity values are adjusted and are shown in the following columns:

- Adjusted Used Capacity (%)
- Capacity-to-Limit (GiB)

To see the values for Adjusted Used Capacity (%), right-click any column heading on the Block Storage Systems page or Pools page and add it.

Adjusted Used Capacity (%)

To know how much capacity can be used without exceeding the capacity limit, monitor the value for Adjusted Used Capacity (%).

Example: Adjusted Used Capacity

The formula for calculating Adjusted Used Capacity (%) is (Used Capacity in GiB/Capacity Limit in GiB)*100. Using the values that are shown in the illustration above, the value is (40 GiB/80 GiB)*100 or 50%. So, in this scenario, you can use 30% or 40 GiB of the usable capacity of the resource before you reach the capacity limit.

If the used capacity exceeds the capacity limit, the value for Adjusted Used Capacity (%) is over 100%.

Capacity-to-Limit (GiB)

Use the value for Capacity-to-Limit (GiB) to monitor how much available capacity is left before the capacity limit is reached.

Example: Capacity-to-Limit

The formula for calculating Capacity-to-Limit (GiB) is (Capacity Limit in GiB - Used Capacity in GiB). Using the values that are shown in the illustration above, the value is (80 GiB - 40 GiB) or 40 GiB.

If the capacity limit is exceeded, a negative value is shown for Capacity-to-Limit (GiB).

Viewing capacity information

View the capacity and space usage information of resources such as block storage systems, volumes, and pools. You can view similar information for filesets, file systems, and file system pools as internal resources of file storage systems. You can view information for containers as internal resources of object storage systems. Additionally, you can view capacity and space usage information for resources that violated a specified capacity range and generated an alert.

Before you begin

Before you view the capacity and space usage of resources, ensure that capacity data was collected for those resources during the time ranges that you want to analyze. Data collection is usually scheduled when resources are added for monitoring by IBM Spectrum Control.

About this task

You can view the following capacity information:

- [Capacity charts for block storage](#)
- [Capacity charts for file storage](#)
- [Capacity charts for object storage](#)
- [Capacity charts for tiers](#)

Capacity charts for block storage

How capacity information is displayed

The capacity view is displayed when you view the capacity of resources, such as block storage systems or pools, including the capacity of resources in alert violations. Information in the capacity view is organized into a chart or table and a legend.

Capacity chart

The top section of the capacity view shows information about the selected resources, such as block storage systems or pools. You can view this information in the following formats:

Chart

The chart shows a visual representation of how the capacity of a resource trends over time. Each line on the chart represents a metric and a resource. For example, if you select two metrics and three resources, six lines are shown on the chart. The y-axis shows the unit of measurement for a metric. If more metrics were selected with a different unit of measurement, an extra y-axis is shown on the right side of the chart window.

Table

The table shows capacity information that is formatted into rows and columns. Each row represents a resource and a time stamp from the chart; each column represents a metric from the chart. For example, if two metrics and three resources are displayed on a chart, and each of the lines on the chart have 10 data points, 30 rows and 2 columns are shown in the table.

To view other metrics and asset information for a resource, right-click anywhere in the header row of the table and select extra columns. The type of resource determines the metrics and information that is available.

Capacity chart legend

The bottom section of the capacity view shows more information about the resources in the chart. The information is formatted into rows and columns. Each row represents a resource that was selected for the view. Each column provides capacity and space usage information about a resource.

You can also view information about the resources that are related to the resources in the legend. For example, in the capacity view for block storage systems, if a SAN Volume Controller is listed in the legend, right-click it to view the capacity of its internal resources, such as pools.

Tip:

- If you hide a resource in the capacity chart, the row for that resource remains visible in the chart legend.
- In the chart legend, information about a resource represents the state of that resource during the selected time range. Specifically, this information does not represent the current state of a resource, but instead shows the final state of the resource during the selected time range. For example, if the current date is January 1, and you view a pool with the time range set to December 1 to December 7, the legend shows the capacity of that pool on December 7. If the capacity of the pool was changed between December 7 and January 1, this historical capacity is different from the current capacity of the pool on January 1.

- **[Controls for capacity views](#)**

Each capacity view includes controls for customizing how information is displayed. The type of view and the resources that you are viewing determine which controls are available.

- **[Resources in the capacity chart legend](#)**

In the capacity view, capacity metrics and related information for resources are shown in a chart and in the chart legend. For resources in the chart legend, such as block storage systems, you can open separate capacity views for their internal resources, such as pools or volumes. The separate capacity views use the same time range as the capacity view in the main window of the GUI.

Related reference

- [Capacity metrics](#)

Controls for capacity views

Each capacity view includes controls for customizing how information is displayed. The type of view and the resources that you are viewing determine which controls are available.

View chart

View capacity information in a chart format. The chart shows a visual representation of how resource capacity trends over time. Each line on the chart represents a metric and a resource. The y-axis shows the unit of measurement for a metric. If more metrics were selected with a different unit of measurement, an extra y-axis is shown on the right side of the chart window.

Hover the mouse pointer over points on a line to view a snapshot of capacity information at a specific time.

View table

View capacity information in a table format. Each row represents a resource and a time stamp. Each column represents a metric. You can view other metrics and information for a resource by right-clicking anywhere in the header row for the table and selecting more columns. The type of resource determines the metrics and information that are available.

For information how to filter, sort, and customize the columns in a table, see [Customizing lists](#).

Metrics

Add metrics to the capacity chart. On the Select Chart Metrics dialog, the metrics that are available depend on the type of resource that is being shown in the chart. The number next to the name of the metrics type represents the number of metrics that are currently selected.

You can select multiple metrics at the same time, but you cannot include more than two unit types in the same view. For example, if you select metrics that use % and ops/s as units of measurement, you cannot select more metrics that use different units of measurement such as KiB/op or MiB/s.

For a list of metrics that you can view for resources, see [Capacity metrics](#).

Hide and show resources

When the chart includes multiple resources, you can click the icon next to a resource to show only the line for that resource. Each icon is shown in a different color to match the color of line for the resource.

You can also show and hide resources in the chart by selecting resources in the chart legend. To select multiple resources at the same time, press Shift or Ctrl and click those resources. Press Shift and click to select consecutive rows in the legend; press Ctrl and click to select non-consecutive rows.

You can show up to 10 resources in a chart at the same time.

Specify a time range

The time range of the capacity information is shown below the chart. You can change this range to display information for different times when data was collected. When you first access the capacity view, the default time range is the last month.

Ensure that capacity data was collected during the time range that you select. If data was not collected during the time range, the chart and table are blank. If data collection was interrupted during the time range, the chart and table show gaps for the time increments when data was not collected.

For example, if you select a time range for the last 7 days, but data was not collected on days 4 and 5, the lines in the chart do not show data for days 4 and 5.

Export information about the chart to a file

Export information on a capacity view to a CSV file.

Open the capacity view in a separate web browser window

Open a duplicate of the current capacity view in a separate web browser window. You can change the information that is displayed in this separate window while retaining the original capacity view for comparison.

Actions for managing the resources in the chart legend

The chart legend in bottom section of the view shows more information about the selected resources. This information is organized into rows and columns, where each row represents a resource.

When you select one or more resources in the legend, the following actions are available in the Actions menu:

View Properties

View key details about a resource, including asset, status, configuration, and capacity information.

View *resource* Capacity

View the capacity of resources that are internal or related to a resource in the chart legend. For example, when you view the capacity of a SAN Volume Controller, you can right-click it and view the capacity of its internal resources, such as pools.

Information about an internal or related resource is shown in a separate web browser window. This window uses the same time range as the capacity view in the main window of the GUI.

Resources in the capacity chart legend

In the capacity view, capacity metrics and related information for resources are shown in a chart and in the chart legend. For resources in the chart legend, such as block storage systems, you can open separate capacity views for their internal resources, such as pools or volumes. The separate capacity views use the same time range as the capacity view in the main window of the GUI.

For example, when you view the capacity of a SAN Volume Controller, you can right-click it in the chart legend to open a capacity view for its internal resources, such as pools or volumes.

You can view capacity metrics for the following resources:

- Block storage systems
- Internal resources of block storage systems: volumes and pools
- Internal resources of file storage systems: filesets, file systems, and file system pools
- Internal resources of object storage systems: containers
- Tiers

The following table summarizes the resources and the internal resources for which you can view capacity metrics.

Table 1. Internal resources for which you can view capacity metrics

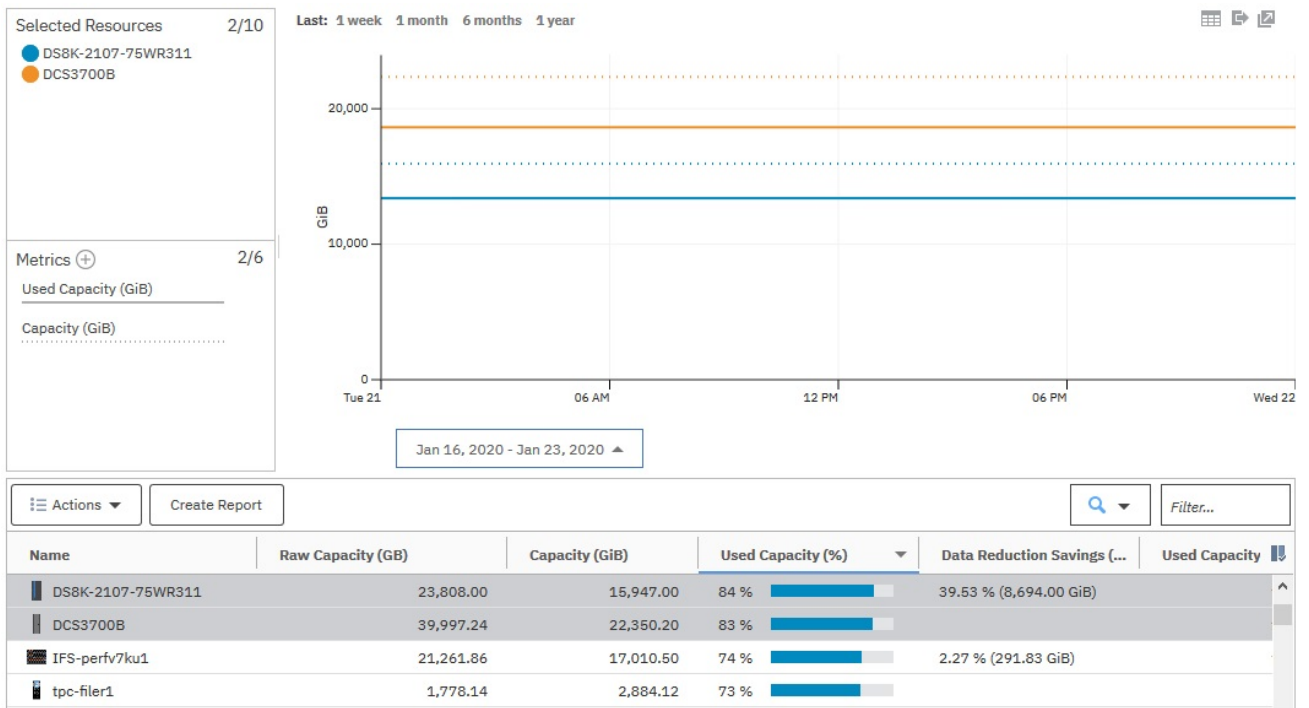

Resource	Internal resources
Block storage system	<ul style="list-style-type: none">• Volumes• Pools
File storage system	<ul style="list-style-type: none">• Filesets• File systems• File system pools
Object storage system	<ul style="list-style-type: none">• Containers

Investigating capacity trends for block storage systems

Use the capacity charts and the information that is shown in the tables for the block storage systems to check which storage systems have the highest growth rates and which storage systems might need more capacity.

Procedure

1. From the Storage menu, click Block Storage Systems.
2. Click Capacity and select the storage systems and the capacity metrics that you want to review.

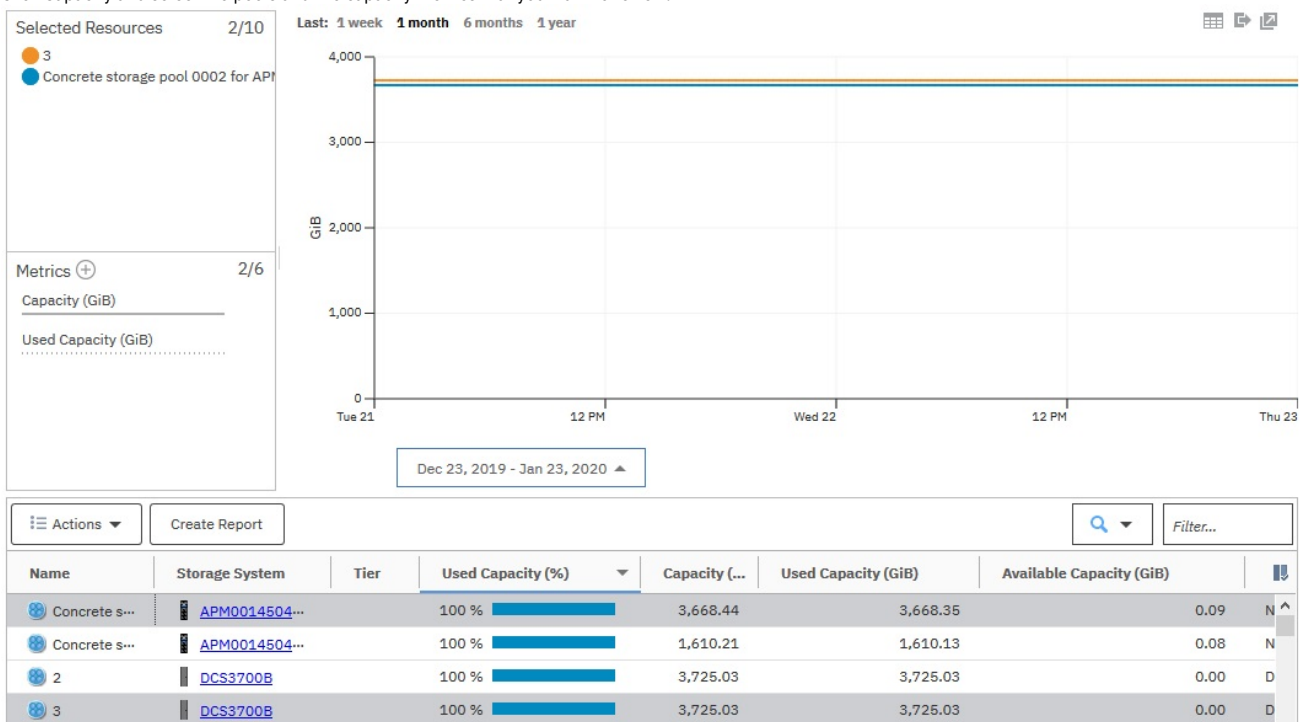

Tip: To check which pools consume the most storage, right-click the storage systems and click Capacity.

Investigating capacity trends for block storage pools

Use the capacity charts and the information that is shown in the tables for the block storage pools to check which storage pools have the highest growth rates, which storage pools might need more capacity, and which storage pools are at risk because too much capacity is committed to the thin-provisioned volumes.

Procedure

1. From the Storage menu, click Block Storage Systems.
Alternatively, you can click Storage > Pools.
2. Right-click the storage system and click View Details.
3. In the navigation pane, click Pools.
4. Click Capacity and select the pools and the capacity metrics that you want to review.

Tip: To investigate the pools with the highest shortfall rates, right-click the pools in the table and click Volume Capacity.

Investigating capacity trends for volumes

Use the capacity charts and the information that is shown in the tables to check the rate at which the thin-provisioned volumes consume capacity, the compression savings for the volumes that were converted to compressed volumes, and the changes in the distribution of Easy Tier® volumes across the SSD, Enterprise HDD, and Nearline HDD drives.

Procedure

- 1. From the Storage menu, click Block Storage Systems.
- 2. Right-click the storage system and click View Details.
- 3. In the navigation pane, click Volumes.
- 4. Click Capacity and select the volumes and the capacity metrics that you want to review.

Tip: To check the distribution of Easy Tier volumes, click Select Chart Metrics and add the Easy Tier metrics to the chart.

Investigating capacity trends for file systems

Use the capacity charts and the information that is shown in the tables for the file systems to check which file systems have the highest growth rates and which file systems might require additional capacity.

Procedure

- 1. From the Storage menu, click File Storage Systems.
- 2. Right-click the storage system and click View Details.
- 3. In the navigation menu, click File Systems.
- 4. Click Capacity and select the file systems and the capacity metrics that you want to review.

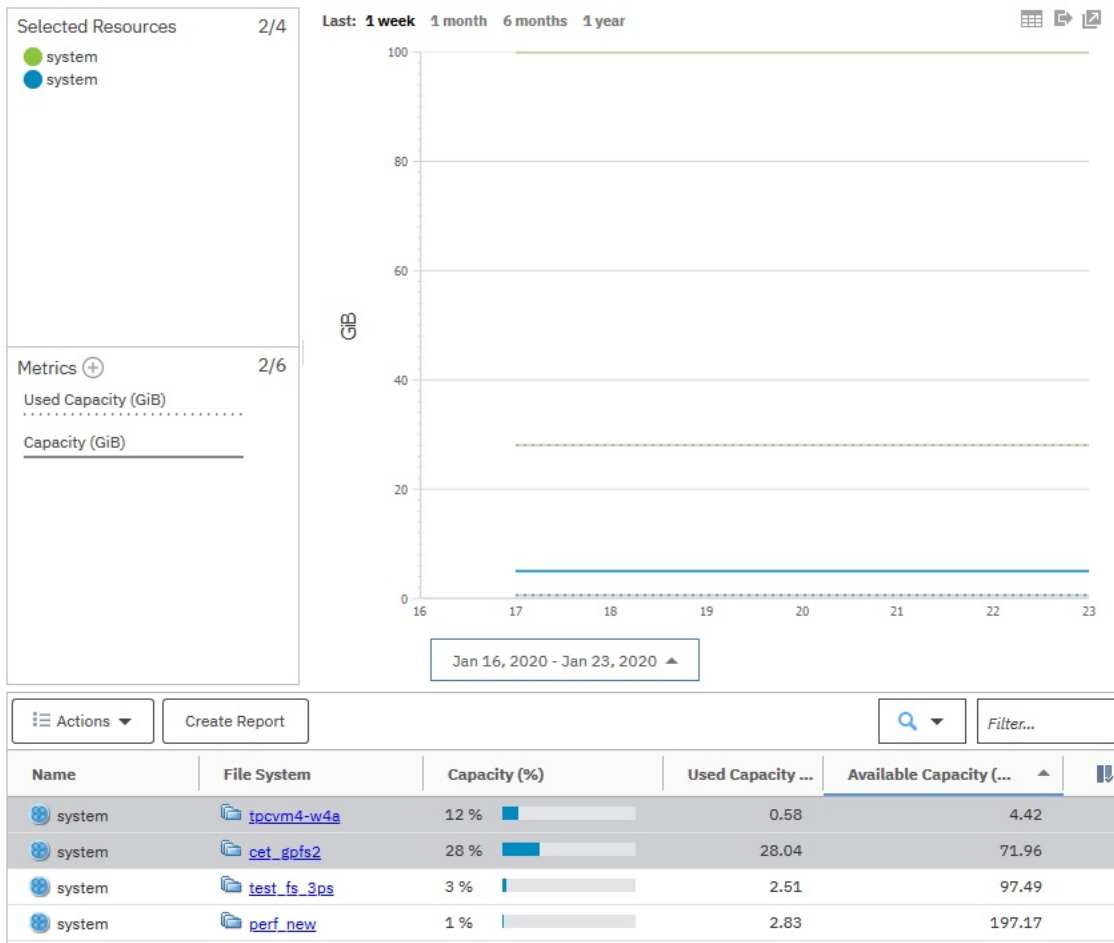

Tip: To check which pools consume the most storage, right-click the file systems and click File System Pool Capacity.

Investigating capacity trends for file system pools

Use the capacity charts and the information that is shown in the tables for the file system pools in your storage systems to check which storage pools have the highest growth rates so that you can plan future storage requirements.

Procedure

1. From the Storage menu, click File Storage Systems.
2. Right-click the storage system and click View Details.
3. In the navigation menu, click File System Pools.
4. Click Capacity and select the pools and the capacity metrics that you want to review.

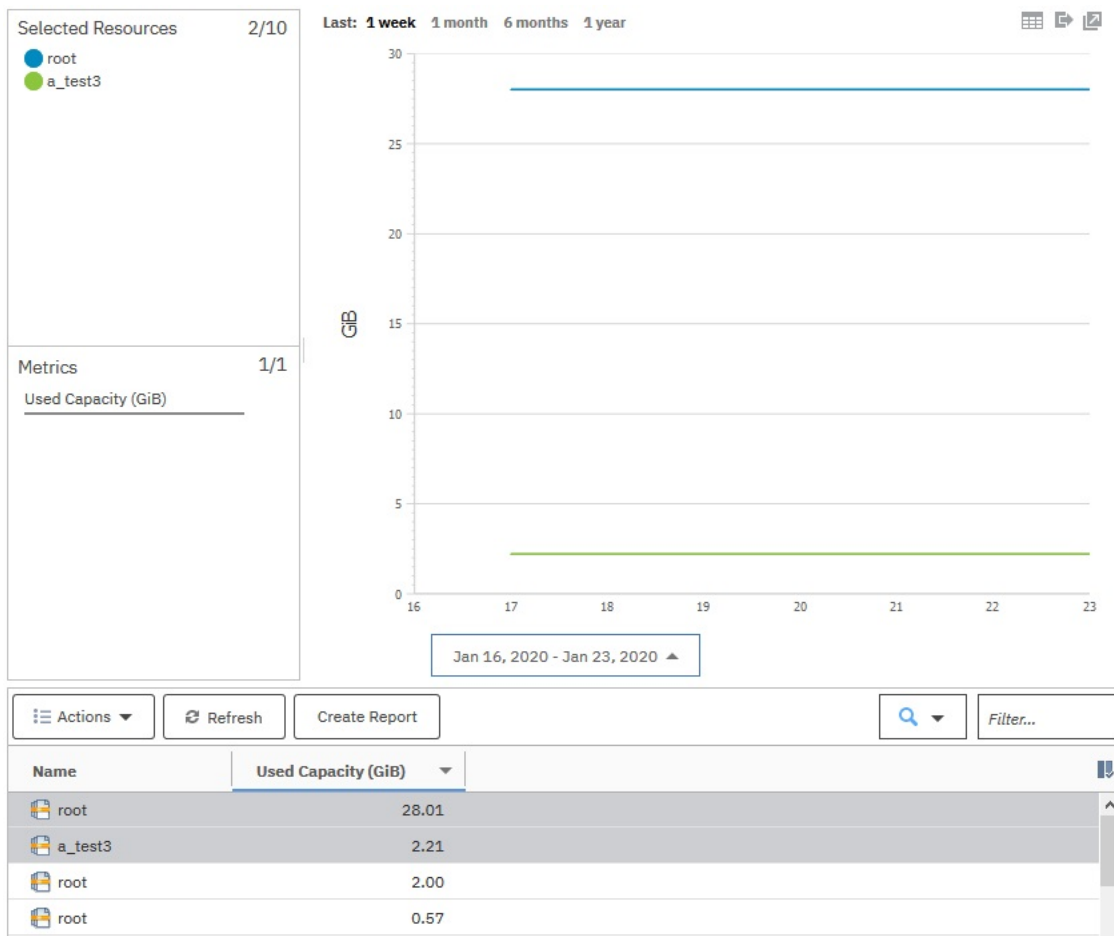

Investigating capacity trends for filesets

Use the capacity charts to check which filesets have the highest growth rates in your file storage systems.

Procedure

1. From the Storage menu, click File Storage Systems.
2. Right-click the storage system and click View Details.
3. In the navigation menu, click Filesets.
4. Click Capacity and select the filesets that you want to review.

Investigating capacity trends for containers

Use the capacity charts to check which containers have the highest growth rates in your object storage systems.

Procedure

1. From the Storage menu, click Object Storage Systems.
2. Right-click the storage system and click View Details.
3. In the navigation menu, click Containers.
4. Click Capacity and select the objects that you want to review.

Investigating capacity trends for tiers

Use the capacity charts and the information that is shown in the tables to check which tiers have the highest growth rates and which tiers might require more capacity.

Procedure

1. From the Groups menu, click Tiers.
2. Click Capacity.

Investigating capacity trends for servers

Use the capacity charts and the information that is shown in the tables for the servers to check which servers have the highest growth rates for mapped and used SAN capacity. Use this information to help determine and compare the capacity usage rate of servers and which ones might need more capacity.

Procedure

1. From the Servers menu, click Servers.
2. Click Capacity and select the servers and the capacity metrics that you want to review.

Creating bookmarks for URLs of capacity views

You can create a bookmark for the URL of a capacity view. You can also open a duplicate of the capacity view to change and compare views.

About this task

The bookmark stores details of the capacity view, such as the resources, metrics, interval, and other details. It also stores the time period that is specified in the time selector at the top of the chart.

Procedure

To create a bookmark for a capacity view, follow these steps:

1. Open the capacity view for which you want to create a bookmark.
2. Right-click and click the relevant option for creating a bookmark.
Tip: To open a duplicate of the current capacity view, click the icon for opening a new browser window. You can change the information that is displayed in the new window while retaining the original capacity view for comparison.

Viewing the capacity of external storage

View the used capacity and capacity of external pool storage that is used by file systems in IBM Spectrum Scale. External pools can include storage that is provided by IBM® Cloud Object Storage, Amazon Simple Storage Service (S3), OpenStack Swift, IBM Spectrum Archive, IBM Spectrum Protect, and other storage providers.

About this task

For all external storage that is being used by IBM Spectrum Scale file systems, you can complete the following tasks:

- View used capacity to understand how much data is being migrated from those file systems to external storage.
- Charge back storage costs to the departments within your organization.
- Gauge shortfall in case you need to recall data from external pools.

For external storage that is provided by IBM Cloud Object Storage, you can also view capacity information, including the percentage of space (active and inactive) that is being used. Use this information to complete the following tasks:

- View how storage space is distributed between internal and external storage tiers.
- Identify the external pools that are running out of space.
- Determine when you need to reconcile files between an IBM Spectrum Scale and an external storage tier. For example, when you remove files from a file system, no policy is available to automatically remove the cloud objects that are created. This situation might cause orphan objects (inactive data) on the cloud. To clean up inactive data and keep the cloud in sync with the file system, you can reconcile files.

The following figure illustrates the relationship between IBM Spectrum Scale and the IBM Cloud Object Storage system that provides storage for external pools:

Procedure

To view the used capacity and capacity of external storage, complete the following steps:

1. From the Storage menu, click File Storage Systems.
2. Right-click a IBM Spectrum Scale storage system and click View Details.
3. In the navigation pane, click Pools.
4. View the following columns for information about the used capacity and capacity of external pools:

Capacity (%)

The percentage of used capacity in the file system pool. Hover over the bar for a specific pool to view statistics about its used and available capacity.

For external pools that are connected to cloud services or storage providers, only the amount of used capacity is shown. Cloud services and other storage providers might include IBM Spectrum Protect, IBM Spectrum Archive, Amazon Simple Storage Service (S3), or OpenStack Swift.

For external pools that are connected to vaults in IBM Cloud Object Storage, the percentage of used capacity includes active and inactive data. Space values are determined from the usable vault capacity that is associated with the cloud account and the hard quota value (if a hard quota is configured). Hover over the bar for a specific pool to view statistics about its used active space, used inactive space, and available capacity.

Active and inactive data in external pools

Active data is data that has corresponding stub files on the GPFS file system. Inactive data is data that exists in the external pool but is not accessible in the GPFS file system. Data is classified as inactive under these conditions:

- When you migrate a file off a GPFS file system, its data is still visible and accessible through its stub file. When the stub file is deleted, the data in the external pool is no longer accessible and is considered inactive.
- When you modify a migrated file, it's recalled from the external pool and modified locally. The previous data for the file remains in the external pool but is no longer accessible through the GPFS file system and is considered inactive.

Tip: To keep the files in sync between an external pool and a GPFS file system and clean up inactive data, you can run the IBM Spectrum Scale `mmcloudgateway files reconcile` command. For more information, see [Reconciling files between IBM Spectrum Scale file system and cloud storage tier](#).

External Used Capacity (GiB)

The amount of used capacity on an external pool. This value includes active data and inactive data. Active data is data that has corresponding stub files on the GPFS file system. Inactive data is data that exists in the external pool but is not accessible in the GPFS file system.

Availability: External pools that are provided by IBM Cloud Object Storage.

Inactive Used Capacity

The amount of inactive used capacity on an external pool. Inactive data is data that exists in the external pool but is not accessible in the GPFS file system.

Available for external pools that are provided by Cloud Object Storage only.

Availability: External pools that are provided by IBM Cloud Object Storage.

Used Capacity

The amount of capacity in the file system pool that is being used. For external pools, used capacity includes active data only. Active data is data that has corresponding stub files on the GPFS file system.

Availability: All storage systems.

- **Identifying shortfall before data is recalled from external storage**

View the percentage of migrated data in external pools that does not fit into the available capacity on an IBM Spectrum Scale file system.

Related information

- [Introduction to Transparent Cloud Tiering for IBM Spectrum Scale](#)

Identifying shortfall before data is recalled from external storage

View the percentage of migrated data in external pools that does not fit into the available capacity on an IBM Spectrum Scale file system.

About this task

This percentage, called *shortfall*, represents the relative risk of not having enough internal file system space if you recall all data from the associated external pools. The higher the percentage, the higher the amount of migrated data that does not fit.

Procedure

To view the potential shortfall for a file system, complete the following steps:

1. From the Storage menu, click File Storage Systems.
2. Right-click a IBM Spectrum Scale storage system and click View Details.
3. Under Internal Resources, click File Systems.
4. Locate the file system that you want to check and view the value in the Shortfall column.

To calculate shortfall, the following formula is used:

$$[(\text{External Pool Migrated Data} - \text{Available Capacity}) \div \text{External Pool Migrated Data}] \times 100$$

For example, if the available capacity on a file system is 200 GiB, but the used capacity of migrated data on external pools is 500 GiB, the shortfall percentage is 60% (300 GiB). In this case, consider adding capacity to the file system before recalling data.

$$[(500 - 200) \div 500] \times 100 = 60\%$$

If the file system has sufficient available capacity to contain all the migrated data in external pools, no shortfall exists. For example, if the available capacity on a file system is 500 GiB, and the used capacity in external pools is only 200 GiB, the shortfall is 0%.

Tip: Only the space that is used by migrated data in external pools is included in the calculation for shortfall. Pre-migrated data is not included because it exists in both the internal and external pools.

Viewing capacity alerts and violations

View the alerts that were triggered when the capacity of a resource changes and reaches a threshold. For example, you can view alerts that are generated when the measured value of a capacity metric for a pool meets the conditions for generating an alert.

Before you begin

To view alert violations for the capacity of a resource, you must collect capacity data and define capacity alerts for that resource or for the alert policy that manages the resource.

Procedure

1. For block storage systems, go to Storage > Block Storage Systems. For file storage systems, go to Storage > File Storage Systems.
2. Right-click a storage system and click View Details.
3. In the navigation menu, click Alerts.
4. Right-click the resource alert that you want to view, such as an alert that was defined for a capacity metric for the resource, and click View Alert.

Capacity metrics

Use IBM Spectrum® Control to collect and view capacity metrics about the storage systems in your environment.

- [Capacity metrics for block storage systems](#)
To review trends in capacity and space usage for storage, you add metrics to capacity charts. You use the charts to detect capacity shortages and space usage trends.

- [Capacity metrics for file storage systems](#)
To review trends in capacity and space usage for file storage systems, you add metrics to capacity charts. You use the charts for filesets, file systems, and file system pools to detect capacity shortages and space usage trends.
- [Capacity metrics for object storage systems](#)
To review trends in capacity and space usage for object storage systems, you add metrics to capacity charts. Use the charts for containers to detect capacity shortages and space usage trends for the containers in your object storage systems.
- [Capacity metrics for tiers](#)
Review trends in the capacity and space usage for tiers. You use the charts to detect capacity shortages and space usage for the tiers in your storage environment.

Capacity metrics for block storage systems

To review trends in capacity and space usage for storage, you add metrics to capacity charts. You use the charts to detect capacity shortages and space usage trends.

Alphabetical lists of the capacity and space usage metrics that you can add to charts are provided in the following sections:

- [Storage system capacity metrics](#)
- [Pool capacity metrics](#)
- [Volume capacity metrics](#)

Tip: IBM Spectrum® Control displays capacity values in base 2 (GiB), while the XIV® management GUI displays capacity values in base 10 (GB, TB). Even though different units of measurement are used, the storage values are equivalent. For more information about units of measurement, see [Units of measurement for storage data](#).

Storage system capacity metrics

To detect capacity shortages and investigate space usage trends, you can add the following metrics to the capacity chart for storage systems:

Adjusted Used Capacity (%)

The amount of capacity that can be used without exceeding the capacity limit.

Example: Adjusted Used Capacity

Before Capacity Limit Was Set

■ Used Capacity = 40 GiB
■ Available Capacity = 60 GiB

After Capacity Limit Was Set

— Capacity Limit = 80% or 80 GiB
■ Adjusted Used Capacity = 50% or 40 GiB
└─ Capacity-to-Limit = 30% or 40 GiB

The formula for calculating Adjusted Used Capacity (%) is $(\text{Used Capacity in GiB} / \text{Capacity Limit in GiB}) * 100$. For example, if the capacity is 100 GiB, the used capacity is 40 GiB, and the capacity limit is 80% or 80 GiB, then the value for Adjusted Used Capacity (%) is $(40 \text{ GiB} / 80 \text{ GiB}) * 100$ or 50%. So, in this example, you can use 30% or 40 GiB of the usable capacity of the resource before you reach the capacity limit.

If the used capacity exceeds the capacity limit, the value for Adjusted Used Capacity (%) is over 100%.

To add the Adjusted Used Capacity (%) column, right-click any column heading on the Block Storage Systems page.

See these related values for more information Capacity Limit (%), and Capacity-to-Limit (GiB).

This metric is not available for all storage systems, such as Dell EMC VMAX.

Available Capacity (GiB)

(Previously known as Available Pool Space) The total amount of the space in the pools that is not used by the volumes in the pools. To calculate available capacity, the following formula is used:

(pool capacity - used capacity)

For XIV systems, pool capacity is the physical capacity of the pools and does not include the provisioned capacity of the pools.

Availability: All storage systems.

Available Volume Capacity (GiB)

(Previously known as Effective Unallocated Volume Space) The total amount of remaining space that can be used by the volumes in the pools. The following formula is used to calculate this value:

[Provisioned Capacity - Used Capacity]

The capacity that is used by thin-provisioned volumes is typically less than their provisioned capacity. Therefore, the available capacity represents the difference between the provisioned capacity and the used capacity for all the volumes in the pools. For Hitachi VSP non-thin provisioned pool capacity, the available capacity is always zero.

Availability: All storage systems.

Capacity (GiB)

(Previously known as Pool Capacity) The total amount of storage space in the pools. For XIV systems and IBM Spectrum Accelerate, capacity represents the physical ("hard") capacity of the pool, not the provisioned ("soft") capacity. Pools that are allocated from other pools are not included in the total pool space.

Availability: All storage systems.

Capacity Limit (%) and Capacity Limit (GiB)

The limit that was set on the capacity that is used by your storage systems. For example, the policy of your company is to keep 20% of the usable capacity of your storage systems in reserve. So, you log into the GUI as Administrator and set the capacity limit to 80%.

Example: Administrator Sets Capacity Limit to 80%

Click the illustration above to find out how to set capacity limits.

The GiB value for the capacity limit for the storage system is calculated when you set the value for the Capacity Limit (%).

To add the Capacity Limit (%) and the Capacity Limit (GiB) columns, right-click any column heading on the Block Storage Systems page.

See these related values for more information Adjusted Used Capacity (%) and Capacity-to-Limit (GiB).

This metric is not available for all storage systems, such as Dell EMC VMAX.

Capacity-to-Limit (GiB)

The amount of capacity that is available before the capacity limit is reached.

Example: Capacity-to-Limit

The formula for calculating Capacity-to-Limit (GiB) is (Capacity Limit in GiB - Used Capacity in GiB). For example, if the capacity limit is 80% or 80 GiB and the used capacity is 40 GiB, then the value for Capacity-to-Limit (GiB) is (80 GiB - 40 GiB or 80% - 50%) which is 30% or 40 GiB.

See these related values for more information Capacity Limit (%) and Adjusted Used Capacity (%).

This metric is not available for all storage systems, such as FlashSystem A9000, FlashSystem A9000R, and Dell EMC VMAX.

Compression Savings (%)

The estimated amount and percentage of capacity that is saved by using data compression, across all pools on the storage system. The percentage is calculated across all compressed volumes in the pools and does not include the capacity of non-compressed volumes.

For storage systems with drives that use inline data compression technology, the Compression Savings does not include the capacity savings that are achieved at the drive level.

The following formula is used to calculate the amount of storage space that is saved:

$$\text{written capacity} - \text{compressed size}$$

The following formula is used to calculate the percentage of capacity that is saved:

$$((\text{written capacity} - \text{compressed size}) \div \text{written capacity}) \times 100$$

For example, the written capacity, which is the amount of data that is written to the volumes before compression, is 40 GiB. The compressed size, which reflects the size of compressed data that is written to disk, is just 10 GiB. Therefore, the compression savings percentage across all compressed volumes is 75%.

Availability: FlashSystem A9000 and FlashSystem A9000R, IBM Spectrum Accelerate, XIV storage systems with firmware version 11.6 or later, and resources that run IBM Spectrum Virtualize.

For FlashSystem A9000 and FlashSystem A9000R, all volumes in the pools are compressed.

Deduplication Savings (%)

The estimated amount and percentage of capacity that is saved by using data deduplication, across all data reduction pools on the storage system. The percentage is calculated across all deduplicated volumes in the pools and does not include the capacity of volumes that are not deduplicated.

The following formula is used to calculate the amount of storage space that is saved:

$$\text{written capacity} - \text{deduplicated size}$$

The following formula is used to calculate the percentage of capacity that is saved:

$$((\text{written capacity} - \text{deduplicated size}) \div \text{written capacity}) \times 100$$

For example, the written capacity, which is the amount of data that is written to the volumes before deduplication, is 40 GiB. The deduplicated size, which reflects the size of deduplicated data that is written to disk, is just 10 GB. Therefore, data deduplication reduced the size of the data that is written by 75%.

This metric is available for FlashSystem A9000, FlashSystem A9000R, and resources that run IBM Spectrum Virtualize 8.1.3 or later.

Drive Compression Savings (%)

The amount and percentage of capacity that is saved with drives that use inline data compression technology. The percentage is calculated across all compressed drives in the pools.

The amount of storage space that is saved is the sum of drive compression savings.

The following formula is used to calculate the percentage of capacity that is saved:

$$((\text{used written capacity} - \text{compressed size}) \div \text{used written capacity}) \times 100$$

Availability: Storage systems that contain IBM FlashCore® Modules with hardware compression.

Mapped Capacity (GiB)

(Previously known as Assigned Volume Space) The total volume space in the storage system that is mapped or assigned to host systems, including child pool capacity.

Availability: All storage systems.

Overprovisioned Capacity (GiB)

(Previously known as Unallocatable Volume Space) The capacity that cannot be used by volumes because the physical capacity of the pools cannot meet the demands for provisioned capacity. The following formula is used to calculate this value:

$$[\text{Provisioned Capacity} - \text{Capacity}]$$

Availability: All storage systems.

Shortfall (%)

The percentage of space that is over committed to the pools with thin-provisioned volumes. For example, you commit 100 GiB of space to a thin-provisioned volume in a pool with a capacity of 50 GiB. As the space is used by the thin-provisioned volume in increments of 10 GiB, the space available for allocation decreases and the shortfall in capacity becomes more acute.

To calculate the shortfall, the following formula is used:

$$[(\text{overprovisioned capacity} \div \text{committed but available capacity}) \times 100]$$

A shortfall occurs when you commit more space to the volumes in the pools than is physically available to the pools. If the physical space available to the pools is less than the committed provisioned capacity, then the pools do not have enough space to fulfill the commitment to the provisioned capacity.

For example, the physical capacity of the pools is 70 GiB, but 150 GiB of provisioned capacity was committed to the thin-provisioned volumes. If the volumes are using 50 GiB, 100 GiB is committed to those volumes (150 GiB – 50 GiB) with only 20 GiB of available pool space (70 GiB – 50 GiB). Because only 20 GiB of the pool space is available, 80 GiB of the committed space cannot be allocated (100 GiB - 20 GiB). In this case, the percentage of committed space that is unavailable is 80% [(80 GiB ÷ 100 GiB × 100)].

Availability: DS8000®, FlashSystem storage systems, Dell EMC VMAX, VNX, and VNXe storage systems, Hitachi Virtual Storage Platform, SAN Volume Controller, Storwize® family storage systems that are configured with block storage, XIV systems, and IBM Spectrum Accelerate storage systems.

Provisioned Capacity (%)

(Previously known as Virtual Allocation) The percentage of the physical capacity that is committed to the provisioned capacity of the volumes in the pools. If the value exceeds 100%, the physical capacity doesn't meet the demands for provisioned capacity.

To calculate provisioned capacity percentage, the following formula is used:

$$[(\text{provisioned capacity} \div \text{pool capacity}) \times 100]$$

For example, if the provisioned capacity percentage is 200% for a storage pool with a physical capacity of 15 GiB, then the provisioned capacity that is committed to the volumes in the pools is 30 GiB. Twice as much space is committed to the pools than is physically available to the pools. If the provisioned capacity percentage is 100% and the physical capacity is 15 GiB, then the provisioned capacity that is committed to the pools is 15 GiB. The total physical capacity that is available to the pools is used by the volumes in the pools.

A provisioned capacity percentage that is higher than 100% is considered to be aggressive because insufficient physical capacity is available to the pools to satisfy the allocation of the committed space to the compressed and thin-provisioned volumes in the pools. In such cases, you can check the Shortfall (%) value to determine how critical the shortage of space is for the storage system pools.

Availability: All storage systems.

Provisioned Capacity (GiB)

(Previously known as Total Volume Capacity)

The total amount of provisioned capacity of volumes within the pool. If the pool is a parent pool, it also includes the storage space that can be made available to the volumes in the child pools.

Availability: All storage systems.

Safeguarded Capacity (GiB)

The total amount of capacity that is used to store volume backups that are created by the Safeguarded Copy feature in DS8000.

Total Capacity Savings (%)

The estimated amount and percentage of capacity that is saved by using data deduplication, pool compression, thin provisioning, and drive compression, across all volumes in the pool.

The following formula is used to calculate the amount of storage space that is saved:

$$[\text{Provisioned Capacity} - \text{Used Capacity}]$$

The following formula is used to calculate the percentage of capacity that is saved:

$$((\text{Provisioned Capacity} - \text{Used Capacity}) \div \text{Provisioned Capacity}) \times 100$$

This metric is available for FlashSystem A9000 and FlashSystem A9000R, IBM Spectrum Accelerate, XIV storage systems with firmware version 11.6 or later, and storage systems that run IBM Spectrum Virtualize.

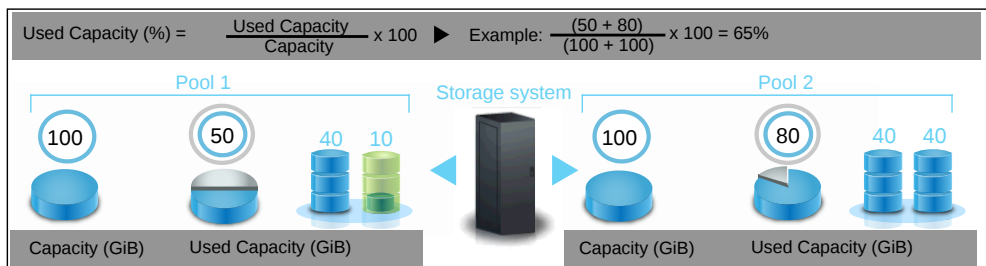

Unmapped Capacity (GiB)

(Previously known as Unassigned Volume Space) The total amount of space in the volumes that are not assigned to hosts.

Availability: All storage systems.

Used Capacity (%)

(Previously known as Physical Allocation)

The percentage of physical capacity in the pools that is used by the standard-provisioned volumes, the thin-provisioned volumes, and the volumes in child pools. Check the value for used capacity percentage to see:

- Whether the physical capacity of the pools is fully allocated. That is, the value for used capacity is 100%.
- Whether you have sufficient capacity to provision new volumes with storage
- Whether you have sufficient capacity to allocate to the compressed and thin-provisioned volumes in the pools

Availability: All storage systems.

Used Capacity (GiB)

(Previously known as Allocated Space) The amount of space that is used by the standard- and thin-provisioned volumes in the pools. If the pool is a parent pool, the amount of space that is used by the volumes in the child pools is also calculated.

The capacity that is used by for thin-provisioned volumes is less than their provisioned capacity, which is shown in the Provisioned Capacity (GiB) column. If a pool doesn't have thin-provisioned volumes, the value for used capacity is the same as the value for provisioned capacity.

Availability: All storage systems.

Pool capacity metrics

If sufficient data is collected, you can view charts that compare the capacity, used capacity, and available capacity of the pools in your data center.

In the Zero Capacity column on the Pools page, you can see the date, based on the storage usage trends for the pool, when the pool will run out of available capacity.

Zero Capacity: The capacity information that is collected over 180 days is analyzed to determine, based on historical storage consumption, when the pools will run out of capacity. The pools that have already run out of capacity are marked as depleted. For the other pools, a date is provided so that you know when the pools are projected to run out of capacity. If sufficient information isn't collected to analyze the storage usage of the pool, *None* is shown as the value for zero capacity. If a capacity limit is set for the pool, the date shown in the Zero Capacity column is the date when the available capacity based on the capacity limit will be depleted. For example, if the capacity limit for a 100 GiB pool is 80%, it is the date when the available capacity of the pool is less than 20 GiB. *Depleted* is shown in the column when the capacity limit is reached.

To detect capacity shortages and investigate trends in storage usage, you can add the following metrics to the capacity chart for pools:

Adjusted Used Capacity (%)

The amount of capacity that can be used without exceeding the capacity limit.

Example: Adjusted Used Capacity

Before Capacity Limit Was Set

100 GiB Capacity

■ Used Capacity = 40 GiB

■ Available Capacity = 60 GiB

After Capacity Limit Was Set

100 GiB Capacity

— Capacity Limit = 80% or 80 GiB

■ Adjusted Used Capacity = 50% or 40 GiB

▨ Capacity-to-Limit = 30% or 40 GiB

The formula for calculating Adjusted Used Capacity (%) is (Used Capacity in GiB/Capacity Limit in GiB)*100. For example, if the capacity is 100 GiB, the used capacity is 40 GiB, and the capacity limit is 80% or 80 GiB, then the value for Adjusted Used Capacity (%) is (40 GiB/80 GiB)*100 or 50%. So, in this example, you can use 30% or 40 GiB of the usable capacity of the resource before you reach the capacity limit.

If the used capacity exceeds the capacity limit, the value for Adjusted Used Capacity (%) is over 100%.

To add the Adjusted Used Capacity (%) column, right-click any column heading on the Pools page.

See these related values for more information Capacity Limit (%) and Capacity-to-Limit (GiB).

Availability: This metric is not available for all storage systems, such as Dell EMC VMAX.

Available Capacity (GiB)

(Previously known as Available Pool Space) The amount of physical space that is available in the pool. If the pool is a parent pool, the amount of space that is used by the volumes in the child pools is also included.

Availability: All storage systems. For FlashSystem A9000 and FlashSystem A9000R, this value represents provisioned capacity rather than physical space.

Available Repository Capacity (GiB)

The available, unallocated storage space in the repository for Track Space-Efficient (TSE) thin-provisioning.

Availability: DS8000 thin-provisioned pools.

Available Soft Capacity (GiB)

The amount of virtual storage space that is available to allocate to volumes in a storage pool.

Availability: XIV systems, and IBM Spectrum Accelerate storage systems.

Available Volume Capacity (GiB)

(Previously known as Effective Unallocated Volume Space) The total amount of remaining capacity that can be used by the existing volumes in the pools. The following formula is used to calculate this value:

Provisioned Capacity - Used Capacity

The capacity that is used by thin-provisioned volumes is typically less than their provisioned capacity. Therefore, the available capacity represents the difference between the provisioned capacity and the used capacity for all the volumes in the pool. For Hitachi VSP non-thin provisioned pool capacity, the unused volume capacity is always zero.

Availability: All storage systems, except FlashSystem A9000 and FlashSystem A9000R.

Available Written Capacity (GiB)

(Previously known as Effective Used Capacity) The amount of capacity that can be written to the pools before inline compression is applied. If the pools are not compressed, this value is the same as Available Capacity.

Important: Because data compression is very efficient, a pool can run out of Available Written Capacity while physical capacity is still available. To stay aware of your capacity needs, monitor this value and Available Capacity.

Capacity (GiB)

The total amount of storage space in the pool. For XIV systems and IBM Spectrum Accelerate, capacity represents the physical or ("hard") capacity of the pool, not the provisioned ("soft") capacity.

Availability: All storage systems.

Capacity Limit (%) and Capacity Limit (GiB)

The limit that was set on the capacity that is used by your pools. For example, the policy of your company is to keep 20% of the usable capacity of your pools in reserve. So, you log into the GUI as Administrator and set the capacity limit of your pools to 80%.

Example: Administrator Sets Capacity Limit to 80%

Click the illustration above to find out how to set capacity limits.

The GiB value for the capacity limit for the pool is calculated when you set the value for the Capacity Limit (%).

To add the Capacity Limit (%) and the Capacity Limit (GiB) columns, right-click any column heading on the Pools page.

See these related values for more information Adjusted Used Capacity (%) and Capacity-to-Limit (GiB).

Zero capacity: When you set the capacity limit for pools, the values shown for Zero Capacity are readjusted to take into account the capacity limit of the pool. The date will represent when the capacity limit of the pool is reached. If the pool has already reached the capacity limit, Depleted is shown. None is shown when a trend in storage consumption can't be detected because the pool's storage isn't being consumed or because not enough data was collected to predict storage consumption.

Availability: This metric is not available for all storage systems, such as Dell EMC VMAX.

Capacity-to-Limit (GiB)

The amount of capacity that is available before the capacity limit is reached.

Example: Capacity-to-Limit

The formula for calculating Capacity-to-Limit (GiB) is (Capacity Limit in GiB - Used Capacity in GiB). For example, if the capacity limit is 80% or 80 GiB and the used capacity is 40 GiB, then the value for Capacity-to-Limit (GiB) is (80 GiB - 40 GiB or 80% - 50%) which is 30% or 40 GiB.

See these related values for more information Capacity Limit (%) and Adjusted Used Capacity (%).

This metric is not available for all storage systems, such as FlashSystem A9000, FlashSystem A9000R, and Dell EMC VMAX.

Compression Savings (%)

The estimated amount and percentage of capacity that is saved by using data compression. The percentage is calculated across all compressed volumes in the pool and does not include the capacity of non-compressed volumes.

For storage systems with drives that use inline data compression technology, the Compression Savings does not include the capacity savings that are achieved at the drive level.

The following formula is used to calculate the amount of storage space that is saved:

written capacity - compressed size

The following formula is used to calculate the percentage of capacity that is saved:

((written capacity - compressed size) ÷ written capacity) × 100

For example, the written capacity, which is the amount of data that is written to the volumes before compression, is 40 GiB. The compressed size, which reflects the size of compressed data that is written to disk, is just 10 GiB. Therefore, the compression savings percentage across all compressed volumes is 75%.

Availability: IBM Spectrum Accelerate, XIV storage systems with firmware version 11.6 or later, and resources that run IBM Spectrum Virtualize.

Deduplication Savings (%)

The estimated amount and percentage of capacity that is saved by using data deduplication. The percentage is calculated across all deduplicated volumes in the pool and does not include the capacity of volumes that are not deduplicated.

The following formula is used to calculate the amount of storage space that is saved:

written capacity - deduplicated size

The following formula is used to calculate the percentage of capacity that is saved:

((written capacity - deduplicated size) ÷ written capacity) × 100

For example, the written capacity, which is the amount of data that is written to the volumes before deduplication, is 40 GiB. The deduplicated size, which reflects the size of deduplicated data that is written to disk, is just 10 GB. Therefore, data deduplication reduced the size of the data that is written by 75%.

Availability: Storage systems that run IBM Spectrum Virtualize 8.1.3 or later.

Drive Compression Savings (%)

The amount and percentage of capacity that is saved with drives that use inline data compression technology. The percentage is calculated across all compressed drives in the pools.

The amount of storage space that is saved is the sum of drive compression savings.

The following formula is used to calculate the percentage of capacity that is saved:

((used written capacity - compressed size) ÷ used written capacity) × 100

Availability: Storage systems that contain IBM FlashCore Modules with hardware compression.

Enterprise HDD Available Capacity (GiB)

The amount of storage space that is available on the Enterprise hard disk drives that can be used by Easy Tier® for re-tiering the volume extents in the pool.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Enterprise HDD Capacity (GiB)

The total amount of storage space on the Enterprise hard disk drives that can be used by Easy Tier for re-tiering the volume extents in the pool.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Mapped Capacity (GiB)

(Previously known as Assigned Volume Space) The total amount of space in the volumes that is assigned to hosts. For Hitachi VSP non-thin provisioning pool space, this value is the sum of assigned regular host-accessible volumes. Volumes that are used for thin-provisioning (pool volumes) are not included.

Availability: All storage systems.

Nearline HDD Available Capacity (GiB)

The amount of storage space that is available on the Nearline hard disk drives that can be used by Easy Tier for re-tiering the volume extents in the pool.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Nearline HDD Capacity (GiB)

The total amount of storage space on the Nearline hard disk drives that can be used by Easy Tier for re-tiering the volume extents in the pool.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Overprovisioned Capacity (GiB)

(Previously known as Unallocatable Volume Space) The capacity that cannot be used by volumes because the physical capacity of the pool cannot meet the demands for provisioned capacity. The following formula is used to calculate this value:

[Provisioned Capacity - Capacity]

In thin-provisioned environments, it is possible to over commit (over provision) storage in a pool by creating volumes with more provisioned capacity than can be physically allocated in the pool. This value represents the amount of volume capacity that cannot be allocated based on the current capacity of the pool. For Hitachi VSP non-thin provisioned pool capacity, this value is always zero.

Availability: All storage systems, except FlashSystem A9000, FlashSystem A9000R, XIV, and IBM Spectrum Accelerate.

Provisioned Capacity (%)

(Previously known as Virtual Allocation) The percentage of the physical capacity that is committed to the provisioned capacity of the volumes in the pool. If the value exceeds 100%, the physical capacity doesn't meet the demands for provisioned capacity. The following formula is used to calculate this value:

[(Provisioned Capacity ÷ Capacity) × 100]

This value is available for all pools.

For Hitachi VSP non-thin provisioned pool space, the following formula is used to calculate this value:

[(Used Capacity ÷ Capacity) × 100]

Example: If the provisioned capacity percentage is 200% for a total storage pool size of 15 GiB, then the provisioned capacity that is committed to the volumes in the pool is 30 GiB. This configuration means that twice as much capacity is committed than is physically contained in the pool. If the provisioned capacity percentage is 100% for the same pool, then the provisioned capacity that is committed to the pool is 15 GiB. This configuration means that all the physical capacity of the pool is already used by volumes.

A provisioned capacity percentage that is higher than 100% is considered aggressive because insufficient physical capacity is available in the pool to satisfy the maximum allocation for all the thin-provisioned volumes in the pool. In such cases, you can use the value for Shortfall (%) to estimate how critical the shortage of capacity is for a pool.

You can hover the mouse pointer over the percentage bar to view values for the provisioned capacity and capacity.

Availability: All storage systems.

Provisioned Capacity (GiB)

(Previously known as Total Volume Capacity) The total amount of storage capacity that can be made available to the standard- and thin-provisioned volumes in the pool. If the pool is a parent pool, it also includes the storage capacity that can be made available to the volumes in the child pools. For Hitachi VSP non-thin provisioned pool capacity, this value is the sum of the capacity of regular host-accessible volumes. Volumes that are used for thin-provisioning (pool volumes) are not included.

Availability: All storage systems.

Repository Capacity (GiB)

The total storage capacity of the repository for Track Space-Efficient (TSE) thin-provisioning.
Availability: DS8000 thin-provisioned pools.

Reserved Volume Capacity

(Previously known as Unused Space) The amount of pool capacity that is reserved but has not been used yet to store data on the thin-provisioned volume.
Availability: Resources that run IBM Spectrum Virtualize.

Safeguarded Capacity (GiB)

The total amount of capacity that is used to store volume backups that are created by the Safeguarded Copy feature in DS8000.

SCM Available Capacity (GiB)

The available capacity on Storage Class Memory (SCM) drives in the pool. Easy Tier can use these drives to retire the volume extents in the pool.

Availability: IBM Spectrum Virtualize systems, such as FlashSystem 9100, FlashSystem 7200, and Storwize family storage systems that are configured with block storage.

SCM Capacity (GiB)

The total capacity on Storage Class Memory (SCM) drives in the pool. Easy Tier can use these drives to retire the volume extents in the pool.

Availability: IBM Spectrum Virtualize systems, such as FlashSystem 9100, FlashSystem 7200, and Storwize family storage systems that are configured with block storage.

Shortfall (%)

The difference between the remaining unused volume capacity and the available capacity of the associated pool, expressed as a percentage of the remaining unused volume capacity. The shortfall represents the relative risk of running out of space for overallocated thin-provisioned volumes. If the pool has sufficient available capacity to satisfy the remaining unused volume capacity, no shortfall exists. As the remaining unused volume capacity grows, or as the available pool capacity decreases, the shortfall increases and the risk of running out of space becomes higher. If the available capacity of the pool is exhausted, the shortfall is 100% and any volumes that are not yet fully allocated have run out of space.

If the pool isn't thin-provisioned, the shortfall percentage equals zero. If shortfall percentage isn't calculated for the storage system, the field is left blank.

The following formula is used to calculate this value:

Overprovisioned Capacity ÷ Committed but Unused Capacity

You can use this percentage to determine when the amount of over-committed space in a pool is at a critically high level. Specifically, if the physical space in a pool is less than the committed provisioned capacity, then the pool does not have enough space to fulfill the commitment to provisioned capacity. This value represents the percentage of the committed provisioned capacity that is not available in a pool. As more space is used over time by volumes while the pool capacity remains the same, this percentage increases.

Simplifying storage, deploying new applications, and controlling costs with IBM Spectrum Storage

 Simplifying storage, deploying new applications, and controlling costs with IBM Spectrum Storage

Example: The remaining physical capacity of a pool is 70 GiB, but 150 GiB of provisioned capacity was committed to thin-provisioned volumes. If the volumes are using 50 GiB, then 100 GiB is still committed to the volumes (150 GiB – 50 GiB) with a shortfall of 30 GiB (70 GiB remaining pool space – 100 GiB remaining commitment of volume space to the volumes).

Because the volumes are overcommitted by 30 GiB based on the available capacity in the pool, the shortfall is 30% when the following calculation is used:

**[(100 GiB unused volume capacity – 70 GiB remaining pool capacity)
÷ 100 GiB unused volume capacity] × 100**

Availability: DS8000, Hitachi Virtual Storage Platform, and storage systems that run IBM Spectrum Virtualize.

For FlashSystem A9000 and FlashSystem A9000R, this value is not available.

Soft Capacity (GiB)

The amount of virtual storage space that is configured for the pool.

Availability: XIV systems and IBM Spectrum Accelerate storage systems.

Tier 0 Flash Available Capacity (GiB)

The amount of storage space that is available on the Tier 0 flash solid-state drives that can be used by Easy Tier for retiring the volume extents in the pool.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Tier 0 Flash Capacity (GiB)

The total amount of storage space on the Tier 0 flash solid-state drives that can be used by Easy Tier for retiring the volume extents in the pool.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Tier 1 Flash Available Capacity (GiB)

The amount of storage space that is available on the Tier 1 flash, read-intensive solid-state drives that can be used by Easy Tier for retiring the volume extents in the pool.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Tier 1 Flash Capacity (GiB)

The total amount of storage space on the Tier 1 flash, read-intensive solid-state drives that can be used by Easy Tier for retiring the volume extents in the pool.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Tier 2 Flash Available Capacity (GiB)

The available capacity on Tier 2 flash, high-capacity drives in the pool. Easy Tier can use these drives to retire the volume extents in the pool.

Availability: DS8000 storage systems.

Tier 2 Flash Capacity (GiB)

The total capacity on Tier 2 flash, high-capacity drives in the pool. Easy Tier can use these drives to retire the volume extents in the pool.

Availability: DS8000 storage systems.

Total Capacity Savings (%)

The estimated amount and percentage of capacity that is saved by using data deduplication, pool compression, thin provisioning, and drive compression, across all volumes in the pool.

The following formula is used to calculate the amount of storage space that is saved:

Provisioned Capacity – Used Capacity

The following formula is used to calculate the percentage of capacity that is saved:

$$((\text{Provisioned Capacity} - \text{Used Capacity}) \div \text{Provisioned Capacity}) \times 100$$

Availability: FlashSystem A9000 and FlashSystem A9000R, IBM Spectrum Accelerate, XIV storage systems with firmware version 11.6 or later, and resources that run IBM Spectrum Virtualize.

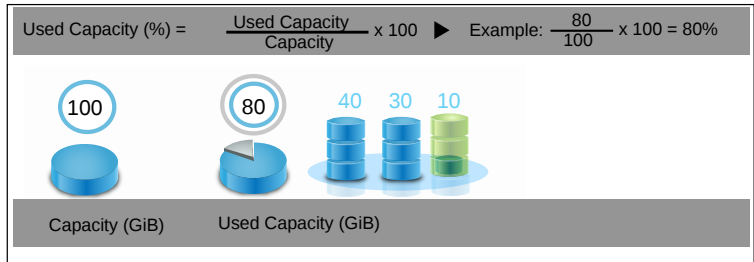

Unmapped Capacity (GiB)

(Previously known as Unassigned Volume Space) The total amount of space in the volumes that are not assigned to hosts. For Hitachi VSP non-thin provisioning pool space, this value is the sum of unassigned regular host-accessible volumes. Volumes that are used for thin-provisioning (pool volumes) are not included.

Availability: All storage systems.

Used Capacity (%)

(Previously known as Physical Allocation)

The percentage of physical capacity that is used by the volumes in the pool, including the volumes in child pools. This value is always less than or equal to 100% because you cannot allocate more physical space than is available in a pool. Check the value for used capacity to see:

- Whether the physical capacity of the pool is fully allocated. That is, the value for used capacity is 100%.
- Whether you have sufficient capacity to provision new volumes with storage
- Whether you have sufficient capacity to allocate to the compressed and thin-provisioned volumes in the pool

Availability: All storage systems, except FlashSystem A9000 and FlashSystem A9000R.

Used Capacity (GiB)

(Previously known as Allocated Space) The amount of physical capacity that is used by the volumes in the pool. If the pool is a parent pool, the amount of space that is used by the volumes in the child pools is also included.

The capacity that is used by thin-provisioned volumes is less than their provisioned capacity, which is shown in the Provisioned Capacity column. If a pool does not contain thin-provisioned volumes, this value is the same as Provisioned Capacity.

Availability: All storage systems, except FlashSystem A9000 and FlashSystem A9000R.

Used Written Capacity (%)

(Previously known as Effective Used Capacity) For devices with inline hardware compression, the effective used capacity percentage is the percentage of capacity that is provisioned to the standard-provisioned volumes and the thin-provisioned volumes, given the drive compression savings.

Used Written Capacity (GiB)

(Previously known as Effective Used Capacity) The amount of capacity that is written to the volumes in a pool before inline disk compression is applied. If a pool is not compressed, this value is the same as Used Capacity.

Written Capacity Limit (GiB)

(Previously known as Effective Capacity) The maximum of amount of capacity that can be written to a pool before inline-disk compression is applied. If a pool is not compressed, this value is the same as Capacity.

Volume capacity metrics

You use the capacity chart to detect capacity shortages for the following types of volumes:

- Space-efficient volumes such as compressed volumes and thin-provisioned volumes
- Standard-provisioned volumes that use Easy Tier to re-tier volume extents

You can review the capacity usage by space-efficient volumes to detect capacity shortfalls. You can also review the capacity usage of volumes that use Easy Tier to distribute volume extents across Enterprise HDD, Nearline HDD, and SSD drives.

To detect capacity shortages and investigate capacity usage trends, you can add the following metrics to the chart for volumes:

Capacity (GiB)

The capacity of the compressed or the thin-provisioned volume, which comprises the sum of the used and available capacity. For thin-provisioned volumes in XIV systems pools or IBM Spectrum Accelerate pools, capacity is the physical ("hard") capacity of the volume.

Availability: All storage systems.

Compression Savings (%)

The estimated amount and percentage of capacity that is saved by using data compression.

The following formula is used to calculate the amount of storage space that is saved:

$$\text{written capacity} - \text{compressed size}$$

The following formula is used to calculate the percentage of capacity that is saved:

$$((\text{written capacity} - \text{compressed size}) \div \text{written capacity}) \times 100$$

Availability: FlashSystem A9000 and FlashSystem A9000R, IBM Spectrum Accelerate, XIV storage systems with firmware version 11.6 or later, and resources that run IBM Spectrum Virtualize.

Exception: For compressed volumes that are also deduplicated, on storage systems that run IBM Spectrum Virtualize, this column is blank.

Enterprise HDD Capacity (GiB)

The amount of volume capacity that Easy Tier has placed on Enterprise hard disk drives.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Nearline HDD Capacity (GiB)

The amount of volume capacity that Easy Tier has placed on Nearline hard disk drives.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Safeguarded Capacity (GiB)

The amount of capacity that is used to store volume backups that are created by the Safeguarded Copy feature in DS8000.

SCM Capacity (GiB)

The amount of volume capacity that Easy Tier has placed on Storage Class Memory (SCM) drives.

Availability: IBM Spectrum Virtualize systems, such as FlashSystem 9100, FlashSystem 7200, and Storwize family storage systems that are configured with block storage.

Tier 0 Flash Capacity (GiB)

The amount of volume capacity that Easy Tier has placed on Tier 0 flash drives.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Tier 1 Flash Capacity (GiB)

The amount of volume capacity that Easy Tier has placed on Tier 1 flash, read-intensive drives.

Availability: DS8000 and storage systems that run IBM Spectrum Virtualize.

Tier 2 Flash Capacity (GiB)

The amount of volume capacity that Easy Tier has placed on Tier 2 flash, high-capacity drives.

Availability: DS8000 storage systems.

Used Capacity (GiB)

(Previously known as Allocated Space) The amount of space that is used by the compressed, thin-provisioned, or the Easy Tier volume. Typically, the space that is used by the compressed or thin-provisioned volume is less than the capacity of the volume. For Easy Tier volumes, used capacity is the capacity that is used by the volume's extents on the Enterprise HDD, Nearline HDD, or SSD drives.

Availability: All storage systems.

Written Capacity (GiB)

(Previously known as Written Space) The amount of data that is written from the assigned hosts to the volume before compression or data deduplication are used to reduce the size of the data. For example, the written capacity for a volume is 40 GiB. After compression, the volume used space, which reflects the size of compressed data that is written to disk, is just 10 GiB.

Limitations and known issues

Zero values are displayed for some metrics on storage systems that run IBM Spectrum Virtualize

Storage systems that run IBM Spectrum Virtualize with firmware 8.2 or earlier might show zero values for some capacity values. This issue occurs because the capacity values for these storage systems were changed to rely on physical capacity values.

The issue is resolved in newer versions of firmware, starting with the following versions:

- 8.1.3.6
- 8.2.1.4

For more information, see [APAR HU01916: The GUI Dashboard and the CLI lssystem command report physical capacity incorrectly](#).

- [Key capacity concepts](#)

Understand the terms that are used to measure and plan capacity.

- [Key storage values for pools](#)

The metadata that is collected about storage systems is used to calculate key capacity values for pools. Use these values to monitor storage usage and to detect and identify capacity issues.

Key capacity concepts

Understand the terms that are used to measure and plan capacity.

Scenarios are used to explore the following capacity concepts for block storage systems:

- [Standard provisioning](#)
- [Thin-provisioning](#)
 - [Thin-provisioning savings](#)
 - [Data reduction savings](#)
 - [Total capacity savings](#)
 - [Effective capacity](#)

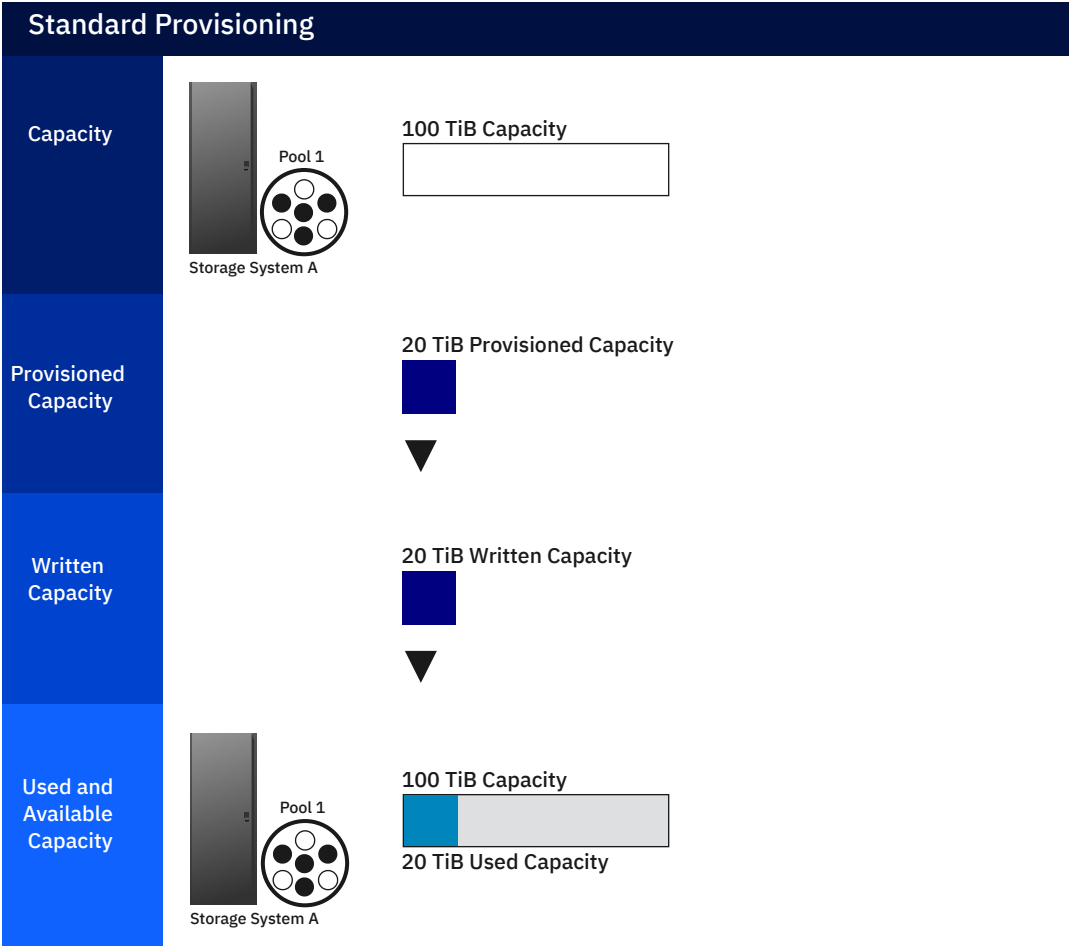

Tip: To review the capacity terms and definitions that are used, click [Definitions for the key capacity terms and concepts](#).

Standard provisioning

You add Storage System A with a capacity of 100 TiB to IBM Spectrum® Control for monitoring.

Then, you add a standard-provisioned volume with a capacity of 20 TiB.

You create standard-provisioned volumes when you want to dedicate the usable capacity of the storage system to the device that writes to it. From the perspective of the pool and storage system, the capacity is used and is no longer available to the storage system and pool.

The capacity values that are reported by the storage system for standard-provisioned volumes are as follows:

- Used Capacity (%) is reported as fully allocated, and Used Capacity (GiB) has the same value as the provisioned capacity of the volume.
- Available Capacity (%) is reported as 00.00.

The capacity of the data that is written to standard-provisioned volumes is not measured by the storage system. However, the written capacity of standard-provisioned volumes is included in the calculation of the total written capacity of the volumes. Because the data that is written to standard-provisioned volumes isn't reduced when data is stored, the written capacity has the same value as the provisioned capacity of the volume.

Figure 1. Overview chart: Written capacity of standard and thin-provisioned volumes

Tip: From the Storage menu, click Block Storage Systems. Double-click a storage system and check the Provisioned Capacity chart.

Thin-provisioning

Unlike standard-provisioned volumes, the capacity of thin-provisioned volumes is not dedicated to the device that writes to it. Devices get the capacity when they write data to the thin-provisioned volumes. Depending on the data reduction techniques that are supported by the storage system, the data that is written to the thin-provisioned volumes can be reduced before it is stored on the volumes.

Thin-provisioning savings

Thin-provisioning savings are the total amount of capacity that is saved in a pool, system, or volume by using capacity when needed as a result of write operations. The capacity that is saved is the difference between the provisioned capacity and the written capacity.

In this scenario, you add four thin-provisioned volumes with a total capacity of 200 TiB to Storage System B, which has a capacity of 100 TiB.

Thin-provisioning savings are the difference between the 200 TiB total provisioned to the thin-provisioned volumes and the 150 TiB of data that is written to the volumes, which is 50 TiB.

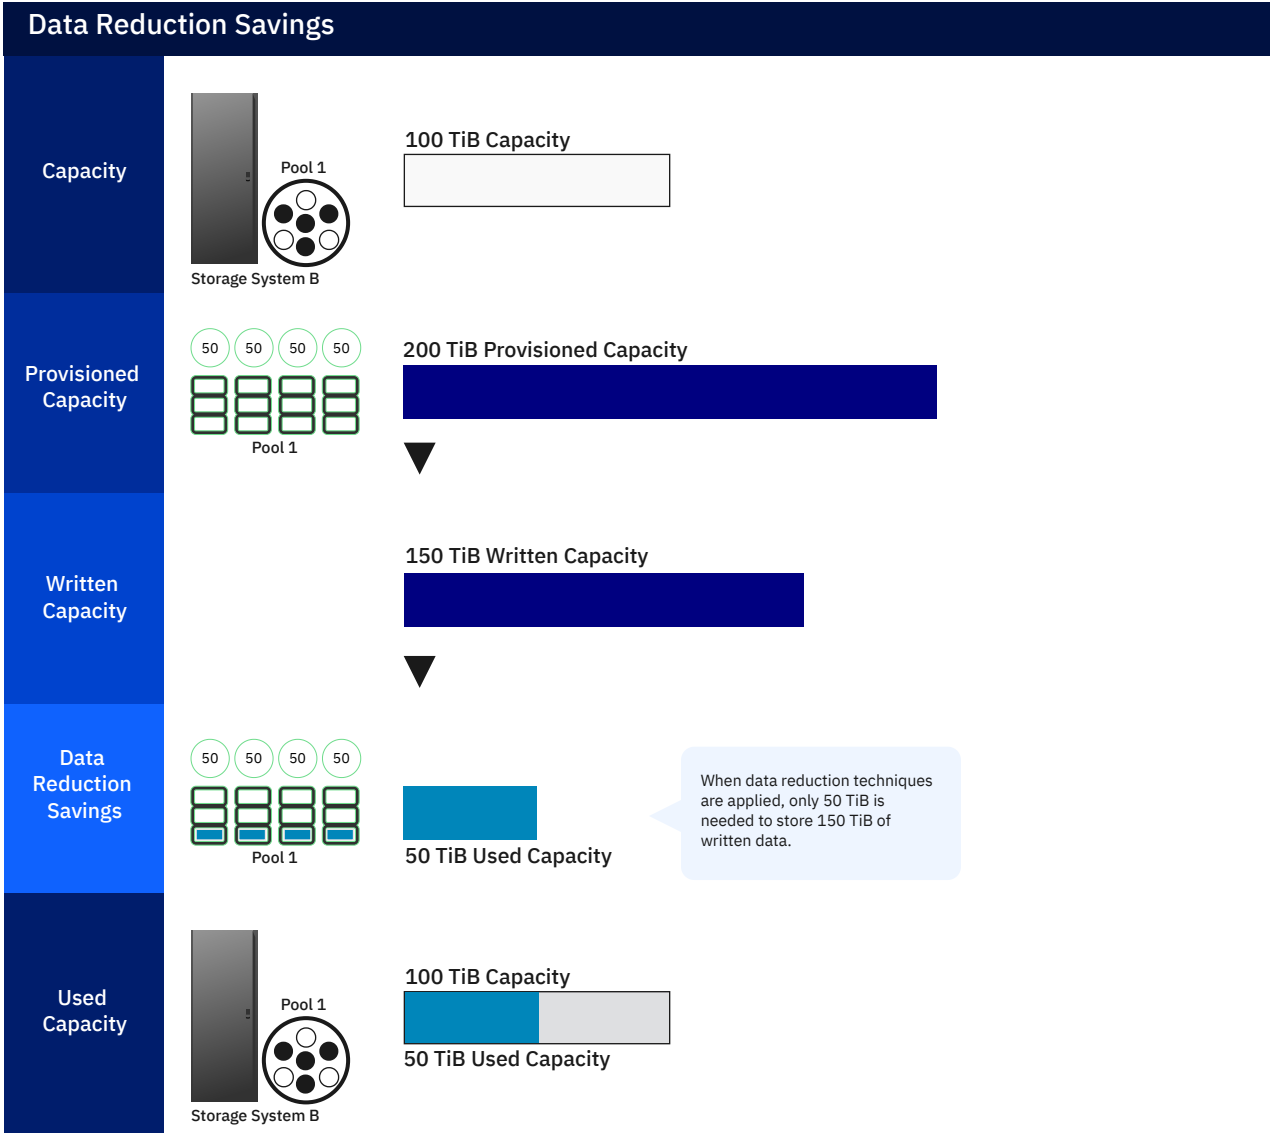

Measuring the capacity data reduction savings of thin-provisioned volumes  Measuring the capacity data reduction savings of thin-provisioned volumes

(To enlarge, right-click the video and select the full screen or new tab option.)

Data reduction savings

Data reduction savings are the total amount of usable capacity that is saved in a pool, system, or volume through the application of data reduction algorithms on the written data, such as compression and deduplication. This saved capacity is the difference between the written capacity and the used capacity.

Before data is stored on thin-provisioned volumes, it can be reduced. For example, if your storage system supports compression and deduplication, these data reduction techniques are applied to reduce the amount of capacity that is needed to store the data.

In this scenario, the data reduction savings are the difference between the written capacity (150 TiB), and the used capacity(50 TiB), which is 100 TiB or 67%.

Total capacity savings

Total capacity savings are the amount of capacity that is saved in a pool, system, or volume through thin-provisioning and data reduction techniques.

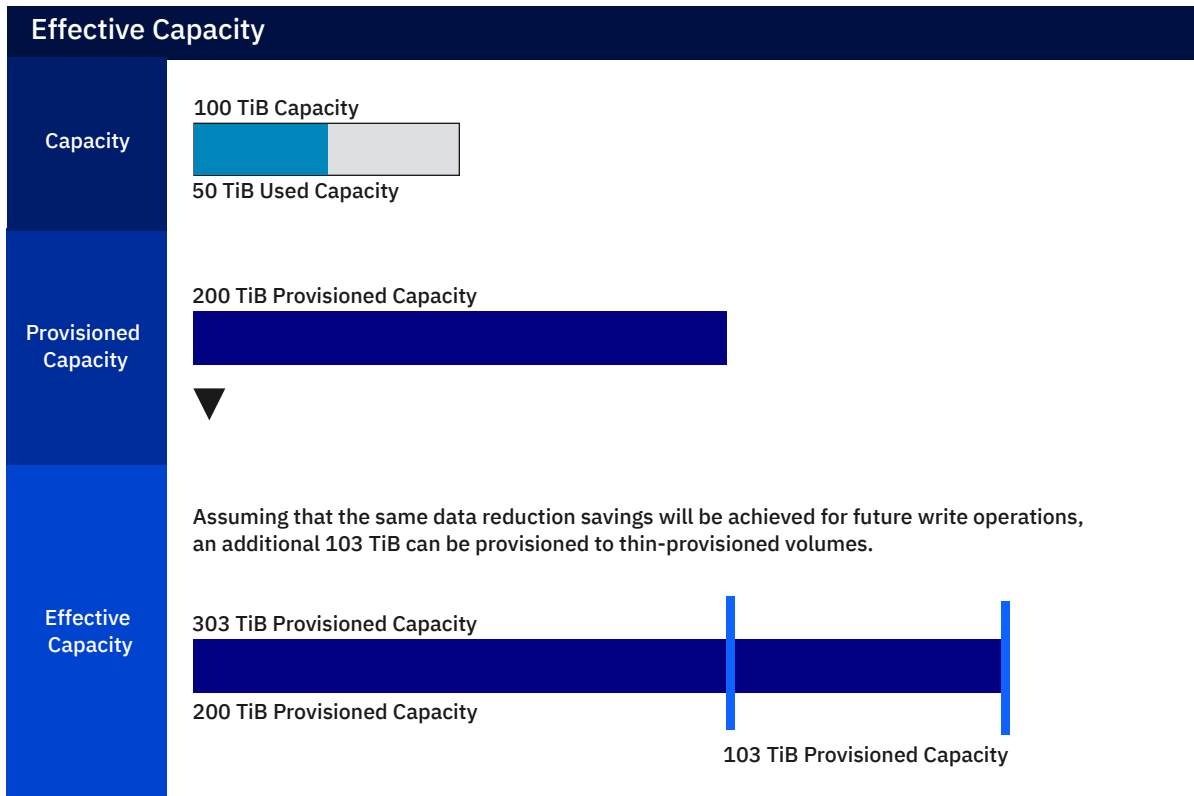

In the scenario illustrated above, the thin-provisioning savings are (200 TiB - 150 TiB), which is 50 TiB. The data reductions savings are (150 TiB - 50 TiB), which is 100 TiB. So, the total capacity savings are 150 TiB.

Effective capacity

Effective capacity is the amount of provisioned capacity that can be created in a system or pool without running out of capacity given the current data reduction savings that are being achieved. To calculate effective capacity, you divide the capacity of the storage system or pool by the data reduction savings percentage.

Note: In some storage systems, restrictions in the system determine the maximum provisioned capacity that is allowed in a pool or system. In these cases, the effective capacity cannot exceed this limit.

You can use effective capacity to estimate how much capacity you can provision to your thin-provisioned volumes without running out of usable capacity.

In the scenario illustrated above, the storage system has a capacity of 100 TiB and a current data reduction savings of 66%. So, the effective capacity is $100 / (1.00 - 0.67)$, which is 303 TiB. Currently, the provisioned capacity of the volumes is 200 TiB. Assuming that the same data reduction savings are achieved for subsequent write operations, more thin-provisioned volumes can be created with a total capacity of 303 TiB.

Definitions for the key capacity terms and concepts

These are capacity terms and concepts that are used:

Available capacity

The amount of usable capacity that is not yet used in a system, pool, array, or MDisk.

Capacity

The amount of usable capacity that is available for storing data on a system, pool, array, or managed disk after formatting and RAID techniques are applied.

Compression

A function that removes repetitive characters, spaces, strings of characters, or binary data from the data being processed and replaces characters with control characters. Compression reduces the amount of storage space that is required for data.

Data deduplication

A method of reducing storage needs by eliminating redundant data. Only one instance of the data is retained on storage media. Other instances of the same data are replaced with a pointer to the retained instance.

Data reduction

A set of techniques that can be used to reduce the amount of usable capacity that is required to store data. Examples of data reduction include data deduplication and compression.

Data reduction savings

The total amount of usable capacity that is saved in a pool, system, or volume through the application of data reduction algorithms on the written data, such as compression and deduplication. This saved capacity is the difference between the written capacity and the used capacity.

Effective capacity

The amount of total provisioned capacity that can be created in a system or pool without running out of usable capacity given the current data reduction savings that are being achieved. This capacity equals the usable capacity that is divided by the data reduction savings percentage. In some storage systems, restrictions in the system determine the maximum provisioned capacity that is allowed in a pool or system. In those cases, the effective capacity cannot exceed this limit.

Provisioned capacity

The total capacity of all volumes in a pool or system.

Standard-provisioned volumes

Unlike thin-provisioned volumes, which use capacity when it is needed, the capacity that is provisioned to standard-provisioned or thick volumes is no longer available to the pool. Standard-provisioned volumes are fully allocated, and their capacity is reported as used because their capacity is no longer available to the pool and storage system.

Thin-provisioning

The ability to defer capacity allocation on a storage resource until data is actually written to it.

Thin-provisioning savings

The total amount of usable capacity that is saved in a pool, system, or volume by using usable capacity when needed as a result of write operations. The capacity that is saved is the difference between the total provisioned minus the written capacity.

Total capacity savings

The total amount of capacity that is saved in a pool, system, or volume through thin-provisioning and data reduction techniques. This saved capacity is the difference between the used capacity and the provisioned capacity.

Used capacity

The amount of capacity that is taken up by data in a system, pool, array, or MDisk after data reduction techniques have been applied.

Written capacity

The amount of usable capacity that would have been used to store written data in a pool or system if data reduction was not applied.

Key storage values for pools

The metadata that is collected about storage systems is used to calculate key capacity values for pools. Use these values to monitor storage usage and to detect and identify capacity issues.

The following diagram shows the relationships between the key storage values for pools:

The following table describes the values on the diagram and how they are calculated:

Storage value	Formula	Description
Capacity	A	The total amount of physical and usable capacity in a pool.
Used Capacity	B	The amount of physical capacity that is used by the volumes in a pool, including the volumes in child pools.
Available Volume Capacity	$PC - B$	The amount of the Provisioned Capacity (PC) in the pool that is not used.
Used Capacity %	$B \div A \times 100$	The percentage of physical capacity that is used by the volumes in a pool, including the volumes in child pools.
Provisioned Capacity %	$PC \div A \times 100$	The percentage of the physical capacity that is committed or reserved for the provisioned capacity of the volumes in the pool.
Reserved Volume Capacity	$B - C$	The amount of pool capacity that is reserved but has not been used yet to store data on the thin-provisioned volume.
Provisioned Capacity (PC)	Sum of volume capacities	The total storage capacity on all the volumes in a pool, which includes thin-provisioned and standard-provisioned volumes.
Overprovisioned Capacity %	$E = PC - A$	The amount of capacity by which the Provisioned Capacity exceeds the physical capacity of a pool.
Shortfall %	$((E \div (D + E)) \times 100$ $E =$ Overprovisioned Capacity %	The percentage of the remaining capacity in a pool that is not available to be used. The higher the percentage, the more critical the shortfall of pool capacity.
Reserved Capacity	F	The amount of unused capacity in a pool that is reserved by provisioning and optimization tasks. Pool capacity is reserved when a provisioning or optimization task is created, and used when the task is run.

Capacity metrics for file storage systems

To review trends in capacity and space usage for file storage systems, you add metrics to capacity charts. You use the charts for filesets, file systems, and file system pools to detect capacity shortages and space usage trends.

Alphabetical lists of the capacity and space usage metrics that you can add to charts are provided in the following sections:

- [Capacity metrics for filesets](#)
- [Capacity metrics for file systems](#)
- [Capacity metrics for file system pools](#)

Capacity metrics for filesets

If sufficient data is collected about the filesets in your file storage systems, you can view charts that compare the used capacity of the filesets. The following metric is displayed in the capacity chart for filesets:

Used Capacity (GiB)

The amount of storage capacity that is used by the fileset. Used capacity is not provided for filesets that are cache targets.

Availability: All storage systems.

Capacity metrics for file systems

To detect capacity shortages and investigate capacity usage trends, you can add the following metrics to the capacity chart for file systems:

Available Inodes

The number of inodes that are available in a file system.

Available Capacity (GiB)

The amount of storage capacity that is available (not allocated) on a file system.

Capacity (%)

The percentage of the total storage space on the file system that is used by files and directories.

Available for: All storage systems.

Capacity (GiB)

(Previously known as Total Capacity) The capacity on the file system.

Available for: All storage systems.

Maximum Inodes

The total number of inodes that the file system can contain. This value consists of the available inodes and the used inodes for the file system.
Available for: All storage systems.

Physical Capacity (GiB)

The raw capacity of the partition where a file system resides.

Used Inodes

The number of used inodes on a file system. An inode is the internal structure that describes the individual files or directories in the file system metadata. An inode contains the node, type, owner, and location of a file or directory.

Availability: All storage systems.

Used Inodes (%)

The percentage of inodes that are already used on the file system. Each time that you create a file or directory on the file system, an inode is allocated to the file or directory.

Available for: All storage systems.

Internal Used Capacity (GiB)

The amount of storage space that is unavailable (allocated) on a file system. For IBM Spectrum Scale, this value does not include the space that is used by migrated data on external pools.

Capacity metrics for file system pools

If sufficient data is collected about the file system pools in your data center, you can view charts that compare the capacity of the pools with the space that is allocated to the pools and the space that is still available in the pools.

The internal resource for IBM Spectrum Scale storage systems is called Pools. For all other file storage systems, the internal resource is called File System Pools.

To detect capacity shortages and investigate space usage trends, you can add the following metrics to the capacity chart for file system pools:

Available Capacity (GiB)

The amount of unallocated storage capacity in the pool. Available capacity usually comprises the space that can be used for storage. However, if the pool is not formatted, the amount of overhead capacity might also be included in the calculation.

Availability: All storage systems.

Capacity (%)

The percentage of space in the file system pool that is being used.

Available for: All storage systems.

Capacity (GiB)

(Previously known as Total Capacity) The capacity in the storage pool.

Available for: All storage systems.

Used Capacity (GiB)

The amount of space in the file system pool that is being used.

Available for: All storage systems.

Capacity metrics for object storage systems

To review trends in capacity and space usage for object storage systems, you add metrics to capacity charts. Use the charts for containers to detect capacity shortages and space usage trends for the containers in your object storage systems.

Capacity metrics for containers

If sufficient data is collected about the containers in your object storage systems, you can view charts that compare the used capacity of the containers. You can add the following metrics to the capacity chart for containers:

Available Objects

The number of objects that you can add to the container on the object storage system.

Available for: IBM Spectrum Scale storage systems.

Available Capacity (GiB)

The amount of file system capacity that can be used to store object data for the container.

Available for: IBM Spectrum Scale storage systems.

Capacity Quota (%)

The percentage of the capacity quota for the container that was used when the storage system was last probed. The quota limits the amount of file system capacity that can be used by the container. This column contains a value only if a capacity quota is defined for the container on the OpenStack Swift object storage system. If the used capacity value for the container exceeds the capacity quota value, the percentage exceeds 100%. The used capacity can exceed the capacity quota if the quota is set after object files are uploaded to the file system or if an object file without size information is uploaded to the file system.

Available for: IBM Spectrum Scale storage systems.

Capacity Quota (GiB)

The amount of file system capacity that can be used to store object data for the container. This column contains a value only if a capacity quota is defined for the container on the OpenStack Swift object storage system.

Available for: IBM Spectrum Scale storage systems.

Objects

The number of objects in the container on the object storage system.

An object stores data content, such as files, videos, images, virtual machine snapshots, and other unstructured data. In IBM Spectrum Scale, objects are stored as files on the GPFS file system.

Available for: IBM Spectrum Scale storage systems.

Objects Quota

The number of objects that can be stored in the container. This column contains a value only if an objects quota is defined for the container on the OpenStack Swift object storage system.

Available for: IBM Spectrum Scale storage systems.

Objects Quota (%)

The percentage of the objects quota for the container that was used when the storage system was last probed. The quota limits the number of objects that can be stored in the container. This column contains a value only if an objects quota is defined for the container on the OpenStack Swift object storage system. If the number of objects that are used exceeds the objects quota, the percentage exceeds 100%. The number can exceed the quota if the quota is configured after the object files are stored on the file system.

Available for: IBM Spectrum Scale storage systems.

Used Capacity (GiB)

The amount of file system capacity that is used by the objects in the container. If a probe is run immediately after objects are added to a container, the used capacity value might not reflect the updates until after the next scheduled probe is run.

Available for: IBM Spectrum Scale storage systems.

Capacity metrics for tiers

Review trends in the capacity and space usage for tiers. You use the charts to detect capacity shortages and space usage for the tiers in your storage environment.

Based on historical space usage, you can plan the capacity growth for tiers.

You can view values for the following metrics in the tier charts:

Capacity (GiB)

The total amount of storage space in the tier, which comprises the total storage space of the pools in the tier.

Used Capacity (GiB)

The capacity that is used by pools in the tier.

Monitoring and administering applications, departments, and general groups

You create applications to monitor the storage capacity, space usage, and performance of applications, and you create departments to monitor the space usage of the applications in the department. You can structure your applications and departments hierarchically to match the structure of your business organization.

You can map the application to the storage resources that the application uses to do capacity trending, health monitoring, and performance troubleshooting tasks. For example, a department might use 15 applications and be part of another five departments. Also a department might share storage resources with another department, subdepartment or application even if they do not belong in the same business hierarchy. Another example, might be if you are contacted because an application within a department is experiencing a performance issue. You carry out tasks like capacity reporting or trending on the behalf of the application.

Create general groups to quickly view information about storage resources that have common characteristics. For example, you might group the subset of ports on a SAN Volume Controller that are used for inter-node communication, or all the storage systems with lease agreements that end in the current year, or the storage systems that are used by a critical business application.

Application administration

Go to the pages for creating and administering the applications that you want to monitor.

Table 1. Create and administer applications and subcomponents

Actions	Navigation
Create applications and assign storage resources directly to the application.	<ol style="list-style-type: none">1. In the menu bar, go to Groups > Applications.2. On the Applications page, click Create Application.3. On the Select a Method page, click Assign storage resources to the application.
Create subcomponents that can have its own storage resources.	<ol style="list-style-type: none">1. In the menu bar, go to Groups > Applications.2. On the Applications page, click Create Application.3. On the Select a Method page, click Create a subcomponent that can have its own set of storage resources.
Create a filter to use in assigning resources.	<ol style="list-style-type: none">1. In the menu bar, go to Groups > Applications.2. On the Applications page, right-click a row in the Applications list and click View Details.3. In the Members section, click Filters.4. On the Filters page, click Create Filter.
Add applications as subcomponents to an application.	<ol style="list-style-type: none">1. In the menu bar, go to Groups > Applications.2. Right-click the applications that you want to add as subcomponents, and then click Add to.. > Application.3. On the Add to Application page, select the applications and click Save.
Add applications to departments.	<ol style="list-style-type: none">1. In the menu bar, go to Groups > Applications.2. On the Applications page, select one or more applications, right-click and then click Add to.. > Department.3. On the Add to Department page, select the applications that you want to add as members and click Save.
Add applications to subdepartments.	<ol style="list-style-type: none">1. In the menu bar, go to Groups > Departments.2. Right-click the department, and then click View Details.3. In the General section, click Subdepartments.4. Right-click the subdepartment, and click View Details.5. In the General section, click Applications.6. Click Create Application.
Remove applications and subcomponents that you do not want to monitor.	<ol style="list-style-type: none">1. In the menu bar, go to Groups > Applications.2. On the Applications page, select one or more applications, and click Delete.3. If you select Delete subcomponents, the subcomponents that belong only to that application are removed.

Actions	Navigation
Remove subcomponents within direct context of an application that you do not want to monitor.	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Applications. 2. Right-click the application and click View Details. 3. In the General section, click Subcomponents. 4. Right-click the subcomponent, and click Remove from Application.
Remove selected resources from applications or subcomponents	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Applications. 2. Right-click the application and click View Details. 3. In the Related Resources section, click an eligible resource. 4. Optional: In the Members section, click the storage resource that is part of the application. 5. On the resource page, right-click the resource, and click Remove from Application.
Troubleshoot applications	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Applications . 2. Right-click the application, and then click View Details. <p>Investigate the performance of the application and the storage resources that are associated with the application by viewing the charts on the Overview page. You can investigate the performance of related resources by clicking the resource and clicking the Performance tab.</p>
Troubleshoot subcomponents	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Applications . 2. Right-click the application, and then click View Details. 3. In the General section, click Subcomponents. 4. Right-click the subcomponent, and click View Details. <p>Investigate the performance of the storage resources that are associated with the subcomponent by viewing the charts on the Overview page. You can investigate the performance of related resources by clicking the resource and clicking the Performance tab.</p>

Department administration

Go to the pages for creating and administering the departments that you want to monitor.

Table 2. Create and administer departments and subdepartments

Actions	Navigation
Create departments and associate members (applications and departments) to create a hierarchal structure.	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Departments. 2. On the Departments page, click Create Department. 3. On the Add Members page, click Add one or more applications or Create subdepartment.
Add departments as subdepartments to a department.	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Departments. 2. On the Departments page, right-click the departments that you want to add as subdepartments, and then click Add to Department.
Add applications to departments.	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Departments. 2. Right-click the department, and then click View Details. 3. In the General section, click Applications. 4. Click Create Application.
Add applications to subdepartments.	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Departments. 2. Right-click the department, and then click View Details. 3. In the General section, click Subdepartments. 4. Right-click the subdepartment, and click View Details. 5. In the General section, click Applications. 6. Click Create Application.
Remove departments, subdepartments, and applications, that are members of the department.	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Departments. 2. On the Departments page, right-click one or more departments and click Delete. 3. If you select Delete subdepartments and applications, the subdepartments and applications that belong only to the department, that is being removed, are removed.
Remove applications from a department or subdepartment.	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Departments. 2. Right-click the department, and then click View Details. 3. In the General section, click Subdepartments. 4. Right-click the subdepartment, and click View Details. 5. In the General section, click Applications. 6. Select and right-click the applications, and then click Delete or Remove from Department.
Remove subdepartments within direct context of a department that you do not want to monitor.	<ol style="list-style-type: none"> 1. In the menu bar, go to Groups, > Departments. 2. Right-click the department, and then click View Details. 3. In the General section, click Subdepartments. 4. Right-click the subdepartments that you want to remove, and then click Remove from Department.

General group administration

Administer the general groups that you use to organize storage resources with common characteristics.

Table 3. Administering general groups

Actions	Navigation
---------	------------

Actions	Navigation
Create a general group and add resources.	<ol style="list-style-type: none"> 1. In the menu bar, click the resource list page for the resources that you want to add. For example, if you want to add file storage systems, click Storage > File Storage Systems. 2. Right-click one or more resources and click Add to General Group. 3. Click Add to new group, specify a name and description for the new group, and click Save.
Add resources to general groups.	<ol style="list-style-type: none"> 1. In the menu bar, click the resource list page for the resources that you want to add. For example, if you want to add block storage systems, click Storage > Block Storage Systems. 2. Right-click one or more resources and click Add to General Group. 3. Take one of the following actions: <ol style="list-style-type: none"> a. To add the resources to one or more existing groups, click Add to existing groups, click the appropriate groups in the list, and click Save. b. To add the resources to a new group, click Add to new group, specify a name and description for the new group, and click Save.
Set which alert policy manages a general group Learn more	<ol style="list-style-type: none"> 1. Go to the details page for the general group for which you want to set the policy. In the menu bar, click Groups > General Groups. 2. Right-click one of the general groups, then click View Details. 3. Click Alerts in the General section. 4. Click Set Policy from the Policy Actions menu. <p>To set the alert policy for multiple general groups, go to Settings > Alert Policies. Double-click the policy, click the resources tab, then click Edit Resources.</p>
Create an alert policy from the alert definitions and notification settings in a general group	<ol style="list-style-type: none"> 1. Go to the details page for the general group from which you want to create the policy. In the menu bar, click Groups > General Groups. 2. Right-click one of the general groups, then click View Details. 3. Click Alerts Definitions in the General section. 4. Click Create Policy from the Policy Actions menu.
View or modify the alert policy that manages a general group Learn more about defining alerts and notification settings	<ol style="list-style-type: none"> 1. Go to the details page for the general group whose policy you want to view. In the menu bar, click Groups > General Groups. 2. Right-click one of the general groups, then click View Details. 3. Click Alerts in the General section. 4. Click View Policy from the Policy Actions menu.
Delete general groups.	<ol style="list-style-type: none"> 1. In the menu bar, click Groups > General Groups. 2. Right-click one or more general groups and click Delete. 3. To delete subgroups, ensure that the Delete subgroups? check box is selected. <p>When a group is deleted, the information that is associated with the group, such as alerts and alert definitions, is removed from the product. The resources that were members of the group are removed from the group but are still monitored by the product.</p>
Remove resources from a general group.	<ol style="list-style-type: none"> 1. In the menu bar, click Groups > General Groups. 2. Right-click a general group and click View Details. 3. In the Members section, click the type of resource that you want to remove. For example, if you want to remove some of the volumes from the group, click Volumes. 4. Right-click the resources that you want to remove and click Remove from General Group. 5. Click OK to confirm that you want to remove the resources from the general group and from all of its subgroups.
Add general groups as subgroups.	<ol style="list-style-type: none"> 1. In the menu bar, click Groups > General Groups. 2. Right-click one or more general groups and click Add to General Group. 3. Take one of the following actions: <ol style="list-style-type: none"> a. To add the groups as subgroups of existing groups, click Add to existing groups, click one or more groups in the list, and click Save. b. To add the groups as subgroups of a new group, click Add to new group, specify a name and description for the new group, and click Save.
Remove subgroups from a group hierarchy.	<ol style="list-style-type: none"> 1. In the menu bar, click Groups > General Groups. 2. Right-click a general group and click View Details. 3. Click Subgroups in the General section. 4. Right-click the general groups that you want to remove and click Remove from General Group. <p>When you remove a subgroup from its parent group, the subgroup is moved to the same level in the hierarchy as the parent group. The subgroup is still monitored by the product.</p>
Create a subgroup.	<ol style="list-style-type: none"> 1. In the menu bar, click Groups > General Groups. 2. Right-click the general group that you want to create a subgroup for and click View Details. 3. Click Subgroups in the General section. 4. Click Create Subgroup. 5. Specify a name and description for the new group. 6. Customize the icon for the group by clicking the existing icon and selecting another icon. 7. Click Create.

Actions	Navigation
Delete subgroups.	<ol style="list-style-type: none"> 1. In the menu bar, click Groups > General Groups. 2. Right-click the general group that contains the subgroups that you want to delete and click View Details. 3. Click Subgroups in the General section. 4. Right-click one or more subgroups and click Delete. 5. To delete further subgroups, ensure that the Delete subgroups? check box is selected. <p>When a group is deleted, the information that is associated with the group, such as alerts and alert definitions, is removed from the product. The resources that were members of the group are removed from the group but are still monitored by the product.</p>

- [Applications](#)
View information about storage area network resources that you can model by using applications in your business environment. The monitoring and management of applications enables you to perform capacity trending, health monitoring, and performance troubleshooting tasks.
- [Departments](#)
View information about departments and structure the hierarchy to mirror your business organization. Monitor the detailed information about capacity and space usage that is collected for departments and subdepartments, and monitor the performance of the applications and the application subcomponents that are added to departments and subdepartments.
- [Application and department hierarchies](#)
The interactive breadcrumb on the Overview page provides a visual representation of the hierarchical relationships for applications and departments and enables you to navigate quickly between the elements in the hierarchy.
- [Exporting information about applications and departments](#)
You can save information about applications and departments to a PDF, CSV, or HTML file. Information that you can export from the GUI includes all the values that are being shown in the columns for a list of applications and departments.
- [General groups](#)
View and administer the general groups that are used to alert on logically related storage resources. You can define alerts for a general group to notify you about changes in the configuration, attributes, and performance of the resources in the group.

Applications

View information about storage area network resources that you can model by using applications in your business environment. The monitoring and management of applications enables you to perform capacity trending, health monitoring, and performance troubleshooting tasks.

An application can be part of a department and have subcomponents that can contain a five level deep hierarchy. Applications that are grouped together can range from large line of business systems to specialized software, in a department that runs on either client computers or servers. For example, an application might be an automated billing system in the Finance department, VMware running in the Information Technology department or an email marketing system that is part of the Marketing department.

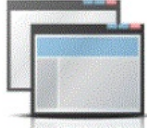

Another example might be an application named *Database* and the database contains logs and data, and a best practice is to place the logs and data on separate volumes. You might create subcomponents for the logs and data and these subcomponents become part of the *Database* application.

A storage administrator can use applications for planning purposes to diagnose how much storage a particular application is consuming in relation to the other applications in the business hierarchy. Another applicable usage for applications might be troubleshooting performance issues. The administrator checks the related resources that make up the application to see if there is a health status issue or can examine the performance of volumes that are used by the application.

The Applications page shows capacity information about the applications that are monitored and the actions that you can use to view and manage them. To see more detailed information, view properties and details for the application. If the application is associated with a department, information about that department is also shown.

The following information shows the resources and objects that can be added to the application.

Table 1. Resources and objects that can be added to the application

Object	Resources or objects that can be added to the application
 Application	<ul style="list-style-type: none"> • Applications • Data stores • Hypervisors • File Systems (Only file systems that are monitored through a Storage Resource Agent.) • Filesets • Servers • Shares • Vaults (IBM® Cloud Object Storage) • Virtual Machines (Only can be added with the CLI modifyappgroup command) • Volumes • Volume Groups

Creating an application hierarchy

To monitor, the capacity, space usage, and performance of the storage resources that your applications use, create application models.

About this task

In this scenario, you want to monitor the capacity, space usage, and performance of a Db2® application.

The Db2 application has two subcomponents, which you want to monitor separately:

- logs
- data

To monitor the Db2 applications and the data and logs subcomponents, complete these tasks:

- Create an application that is named Db2.
- Create applications that are named data and logs
- Associate storage resources with the data and logs applications. For example, in this case, associate the volumes that the data application uses, type **data_vol***. For the logs application, type **logs_vol*** in the Volumes field of A selection of volumes that match a pattern filter. Then click Belonging to and click Storage System. Type the name of the storage system or the pattern that matches the name of the storage system.
- Add the data application and the logs application as subcomponents to the Db2 application.

Tip:

When you create complex application models for applications, it is not necessary to create a filter to associate storage resources with the application because the application inherits the storage resources that are associated with its subcomponents. However, if you want to monitor storage resources that are not associated with the subcomponents, you must create a filter that associates the additional storage resources that you want to monitor with the application.

Results

You can now view information about the capacity, space usage, and performance of the storage resources on the Overview page for the application and subcomponents.

What to do next

You can create departments and add applications to the departments.

1. [Creating applications](#)

To monitor storage capacity, troubleshoot performance, and view storage area network dependencies for applications, you can create applications for monitoring in IBM Spectrum® Control.

2. [Using filters to assign resources to applications](#)

Instead of manually adding the resources that you want to assign to new or existing applications, you can create filters to assign resources based on name pattern matching.

3. [Adding subcomponents](#)

You created a new application and a subcomponent, with their own set of resources and added it to your business hierarchy. You now want to add another level to your business hierarchy.

Related concepts

- [Application and department hierarchies](#)

Creating applications

To monitor storage capacity, troubleshoot performance, and view storage area network dependencies for applications, you can create applications for monitoring in IBM Spectrum Control.

About this task

Use the GUI to create applications, assign resources, and subcomponents for monitoring by IBM Spectrum Control.

To determine the storage capacity usage by the storage resources that the applications use, you create a data model of the applications for your storage environment.

Procedure

To create an application, complete these steps:

1. In the menu bar, go to Groups > Applications.
2. On the Applications page, click Create Application.
3. On the Create Application page, enter information about the application.

Note: You cannot have a duplicate application name on the same level in your application hierarchy. For example, you create an application named *Finance* and create a subcomponent named *Business*. You can create another application named *Business* as a top level application, but you cannot add the new *Business* application as a subcomponent of the *Finance* application.

You can customize the icon for your application by clicking the existing icon on the Create Application page and selecting another icon from the Customize Icon page.

4. Click Create.
5. Optional: On the Select a Method page, select Assign storage resources to the application that was created and follow the instructions to add the resources directly to the application.
6. Click Preview to see a list of filter matches before you finalize your filtering criteria, otherwise, click Save.
7. Optional: Select Create a subcomponent that can have its own set of storage resources and follow the instructions to create a subcomponent of the application.
8. Click Create.

Results

When the application creation is created, you can view status information, block and file capacity and additional data on the Applications page and in properties. If the View Performance action is available, you can view the aggregated information for all of the volumes in the application on the performance view. By default, the Total I/O Rate and the Total Data Rate are displayed in the performance chart. You can also select to display the read and write I/O rates, and the read and write data rates in the chart.

Note: The application performance feature isn't available to all IBM Spectrum Control users. Look for news from IBM® about when this feature will be available to you. For a detailed view of the application and related resources, on the Applications page, right-click the application and select View Details. To see the subcomponents for the application, click Subcomponent on the application details page.

- [Using filters to assign resources to applications](#)
- [Viewing information about applications](#)

Using filters to assign resources to applications

Instead of manually adding the resources that you want to assign to new or existing applications, you can create filters to assign resources based on name pattern matching.

About this task

When you create a filter to assign storage resources to applications, the resources that match the criteria that are defined in the filter are automatically added to the application or subcomponent (member application).

The use of wildcard characters enables you to customize and expand your search to add related resources. The asterisk (*) and the question mark (?) can be used as wildcard characters. The asterisk matches one or more characters. The question mark matches a single character. Use a comma-separated list to add multiple resources. As new resources are added or modified and they match the existing filter, they automatically become part of the application. For example, a new server is added, a volume is renamed or a share is mounted on a server.

If you edit a filter, the resources that no longer match the filter are removed from the application and the resources that now match the filter are added to the application.

If you remove the filter, all storage resources that match the filter criteria are removed from the application.

Filtering is extremely useful in storage environments where resources are predefined and named in a consistent format. Instead of adding each resource separately, you create filtering criteria that matches your naming format in your environment. You can use filtering when you create a new application or directly from the details page for an existing application.

You can only select one resource type filter at a time during the creation workflow, but you can create multiple filters for applications.

Tip: For any volume that you add to an application, the performance information for that volume, including historical information, is aggregated with the information for the existing volumes.

Note: The application performance feature isn't available to all IBM Spectrum® Control users. Look for news from IBM® about when this feature will be available to you. The filters are divided into the following categories:

All storage that belongs to a set of servers/hypervisors

You can add servers or hypervisors to the application or subcomponent (member application).

For example, in the Define Name Patterns section, enter ***blade**, in the Server/Hypervisor field and click Save. The filter adds all known servers or hypervisors that have a name that ends with **blade** to the application.

If you enter **server???.abc.com**, in the Server/Hypervisor field, the filter adds all servers, in the domain with names that begin with **server** followed by three characters and ends with **.abc.com** to the application. If you enter, **accounting*. ***, the filter adds all servers with names that begin with **accounting** regardless of the domain the system belongs to.

If you enter **cs-blade47.1ab.abc.com**, **cs-blade49.1ab.abc.com** or **cs-blade47***, **cs-blade49***, the filter adds multiple servers to the application.

A selection of volumes that match a pattern

You can add volumes of a certain name format, volumes that belong to a server or hypervisor, volumes from a specific storage system or volumes from a pool to the application or subcomponent. You can only select one resource option per filter creation.

For example, in the Define Name Patterns section, if you enter ***vo1**, in the Volumes field, mark the Belonging to box, click Server/Hypervisor, enter ***.lab.abc.com** and click Save. The filter adds all volumes that have a name that ends with **vo1** and are mapped to servers that have a name that ends with **.lab.abc.com** to the application.

If you enter ***vo1**, in the Volumes field, mark the Belonging to box, click Storage System, and enter **ds8000**. The filter adds all volumes that have a name that ends with **vo1** that belong to the **ds8000** storage system.

A selection of shares that match a pattern

You can add shares and exports that are mounted on a server or hypervisor, or shares and exports that are exported from a specific storage system to the application or subcomponent. You can select only one resource option per filter creation.

For example, in the Define Name Patterns section, if you enter ***share** in the Shares field, mark the Belonging to box, click Server/Hypervisor, enter ***.lab.abc.com** and click Save. The filter adds shares that have a name that ends with **share** that are mounted on servers that have a name that ends with **.lab.abc.com**.

If you enter **share3** in the Shares field, mark the Belonging to box, click Storage System and enter **netapp**, the filter adds all the shares that are named **share3** and are exported from the **netapp** storage system.

A selection of filesets that match a pattern

You can add filesets that are associated with file systems, from a storage system to the application or subcomponent. You can select only one resource option per filter creation.

For example, in the Define Name Patterns section, if you enter ***** in the Filesets field, mark the Belonging to box, click Storage System, enter **scale*** and click Save, the filter adds all the filesets that are exposed by storage systems that have names that begin with **scale** to the application.

If you enter ***** in the Filesets field, mark the Belonging to box, click File System and enter **fs1**, the filter adds all the filesets that are associated with the file systems named **fs1** to the application.

A selection of vaults that match a pattern

You can add vaults of a certain name format and vaults that belong to a specific IBM Cloud Object Storage system.

For example, in the Define Name Patterns section, if you enter ***v_cloud*** in the Vault field, select Belonging to, and enter ***.lab.abc.com** in the Cloud Object Storage System field, the filter adds all vaults that have a name that includes **v_cloud** and belong to IBM Cloud Object Storage systems with names that end in **.lab.abc.com**.

If you enter ***v_cloud_ibm** in the Vaults field, select Belonging to, and enter **COS_storage** in the Cloud Object Storage System field, the filter adds all vaults that have a name that ends with **v_cloud_ibm** and belong to the **COS_storage** storage system.

Procedure

To create a filter, complete these steps:

1. In the menu bar, go to Groups>Applications.
2. On the Applications page, right-click a row in the Applications list and click View Details.
3. In the Members section, click Filters.
4. On the Filters page, click Create Filter.
5. On the Create Filter page, select a resource type filter and enter the necessary information.
6. Click Preview to see a list of filter matches before you finalize your filtering criteria.
7. On the Filter Matches page, click Save to create the filter.

Results

The Members section of the details page shows the number of filters that you created, for example, Filters (6). Click Filters to access the Filters page and see the filters that were created. For example, The number of matches: 26, which indicates there are 26 matches for the filter criteria. Click the link to see the resources for the filter matches that are available.

Tip: To view a description of a field on the Create Filter page, hover the mouse pointer over the help icon  for that field.

Next topic: [Adding subcomponents](#)

Related tasks

- [Creating applications](#)
- [Adding subcomponents](#)

Adding subcomponents

You created a new application and a subcomponent, with their own set of resources and added it to your business hierarchy. You now want to add another level to your business hierarchy.

Procedure

To create a subcomponent for an existing application, complete these steps:

1. In the menu bar, go to Groups>Applications.
2. On the Applications page, select one or more applications, right-click and then, click Add to...>Application.
3. On the Add to Application page, choose the applications that you want to become subcomponents of your selected applications.

- The Hierarchy column shows the path of only the ancestor applications; it does not show departments.
4. Click Save.
 5. Optional: On the details page for the application, click Subcomponents.
 6. On the Subcomponents page, click Create Subcomponent.
 7. On the Create Subcomponent page, enter information including name, description, type, and subtype.
 8. Click Create.

Results

After the subcomponent is created, you can view the results on the Subcomponent page and in the properties. For a more detailed view of the subcomponent, select the subcomponent from the Subcomponent page and click Actions, > View Details.

Previous topic: [Using filters to assign resources to applications](#)

Adding resources manually to applications

You can add resources directly from a resource page to your applications.

About this task

Only the following resources can be added directly to applications:

- Data stores
- Hypervisors
- File Systems (Only server file systems that are monitored through a Storage Resource Agent.)
- Filesets
- Servers
- Shares
- Vaults (Cannot be added with the CLI)
- Virtual Machines (Only can be added with the CLI **modifyappgroup** command)
- Volumes
- Volume Groups

Tip: For any volume that you add to an application, the performance information for that volume, including historical information, is aggregated with the information for the existing volumes.

Note: The application performance feature isn't available to all IBM Spectrum Control users. Look for news from IBM® about when this feature will be available to you.

Procedure

To add a resource directly to an application, complete these steps:

1. On a resource page, right-click a resource and click Add to Application.
For example, to add a server to an application, in the menu bar, go to Groups, > Servers. On the Servers page, select a server from the Servers list, right-click and click Add to Application.
2. On the Add to Application page, select one or more applications to assign the resource to.
3. Click Save.

Results

The resource is added to the application and is displayed on the Applications page.

Related tasks

- [Using filters to assign resources to applications](#)

Adding resources with the command line interface

You can use the **modifyappgroupviafile** command-line interface (CLI) command to automate your bulk assignment of eligible storage resources to applications. To add a single resource to an application, use the **modifyappgroup** command.

Related reference

- [modifyappgroupviafile command](#)
- [modifyappgroup command](#)

Viewing information about applications

You can view information about the application that you created as related resources, filters that are used to populate the application with resources, any subcomponents, capacity trending and performance information.

Procedure

To view the details of an application, use these steps:

1. In the menu bar, go to Groups > Applications.
2. On the Applications page, right-click an application and select View Details.

Results

The details page shows information about the specific application. The information is available from the following sections on the page:

- Overview: The overall capacity trending about the application and performance information. An interactive breadcrumb that shows the hierarchy of applications and departments and a list of all the top level applications.
- Properties: The key information about the application.
- Subcomponents: The number of subcomponents that are a members of the selected application. If there is more than one subcomponent, the number of subcomponents is displayed.
- Members: The information on the resource types that were added directly to the application or subcomponent. The number next to the resource type, for example, Servers (2), shows the number of resources of that type in the application.
- Filters: The number of filters created and the filtering criteria used for the resources that were added to the application.
- Related Resources: The information about the resources that are related to the application.

Tip: To view descriptions of the information that is available on an application details page, click the Help icon  in the upper-right corner of the page.

Removing applications and subcomponents

You can remove applications and their subcomponents. The data that was collected to monitor the applications is also removed from the database repository.

Procedure

To remove applications and subcomponents from a level of the business hierarchy, complete the following steps:

1. In the menu bar, go to Groups > Applications.
2. On the Applications page, select one or more applications, and click Delete.
 - a. If you select Delete Subcomponents, the subcomponents that belong only to the application are removed.
 - b. If you do not select Delete Subcomponents, any subcomponents of the application, that is being removed, then become members of the parent application or department. If the application is a top level application, and, the subcomponents are not members of any other application, the subcomponents become top level applications.

Results

The applications and subcomponents are removed and are no longer displayed on the Applications page.

To remove subcomponents from within the direct context of the application, use these steps:

1. In the menu bar, go to Groups > Applications.
2. On the Applications page, select an application from the Application list and right-click View Details.
3. Optional: Select a application from the Applications page and right-click View Properties.
 - a. Click the Subcomponents tab and continue with steps 5-6.
4. On the application details page, click Subcomponents in the General section.
5. On the Subcomponents page, select the subcomponent and right-click Remove from Application.
6. Confirm that you want to remove the subcomponent and click OK.

Removing resources from applications

Related resources within the context of an application can be removed from applications. The action is only available when viewing the related resources that belong to an application on the details page.

About this task

The following resources can be removed from an application:

- Volumes
- Shares
- Servers

- File systems (Only server file systems that are monitored through a Storage Resource Agent.)
- Filesets
- Volume Groups
- Hypervisors
- Data Stores

Resources that were added through a filter match are removed if the filter is modified and no longer includes the resource, the filter is removed from IBM Spectrum® Control, or the resource is removed from IBM Spectrum Control. Resources can be added back to the application if the filter is modified and includes the resource that was originally removed, a new filter is created that matches the resource, the resources are added to IBM Spectrum Control, or you use the Add to Application action.

For example, a server named, `abc.xyz.com` is added to an application named, `ApplicationABC` because it matched the server name filter, `abc*`. You decide to remove the `abc.xyz.com` server from the `ApplicationABC` application and remove the `abc.xyz.com` server from IBM Spectrum Control. Later you want to add the `abc.xyz.com` server back to IBM Spectrum Control. The `abc.xyz.com` server is added to the `ApplicationABC` application because the name matches the server resource filter that you originally created for the `ApplicationABC` application. If you do not want the resource added back to the application, you can further refine your filters. Click the View Filters link on the confirmation dialog to make any adjustments to the filtering criteria before creation.

Resources that are automatically added to an application because they are related to resources that were explicitly added to the application *are not* removed from the application. The resources are automatically removed when the corresponding related resource that was added to the application, is also removed from the application.

For example, you add a server to the application that has one volume from a storage system. The volume is added as a related resource of that server in the application. If you attempt to remove the volume from the application, the volume is *not* removed since it is a related resource. The volume is only removed when the server, that was explicitly added to the application, is removed.

Procedure

To remove resources directly from an application, use these steps

1. In the menu bar, go to Groups > Applications.
2. On the Applications page, select an application from the Application list and right-click View Details.
3. On the application details page, click an eligible resource in the Related Resource section.
4. On the resource page, select the resource from the list, and right-click Remove from Application.
5. Confirm that you want to remove the resource.
6. Click Remove.

Results

The resources that were added to the application are removed from the application.

Tip: When you remove a member volume from an application, the performance information for that volume, including historical information, is no longer aggregated with the information for the existing volumes.

Note: The View Performance feature for applications isn't available to all IBM Spectrum Control users. Look for news from IBM® about when this feature will be available to you.

Departments

View information about departments and structure the hierarchy to mirror your business organization. Monitor the detailed information about capacity and space usage that is collected for departments and subdepartments, and monitor the performance of the applications and the application subcomponents that are added to departments and subdepartments.

A department can be hierarchical in its organizational layout. For example, a department might use 15 applications and be part of another five departments. A department might share storage resources with another department, subdepartment or application even if they do not belong in the same hierarchy. For example, in a collaboration scenario, a single IBM® SAN Volume Controller might be shared by multiple departments. You can provide reports on the storage capacity that is used at different levels of your business hierarchy to regulate and compare the capacity storage, and in turn, track the trending of storage usage by specific departments.

The Departments page shows storage capacity information about the top level departments, the subdepartments and any applications that belong to the department that are monitored by IBM Spectrum® Control and the actions that you can use to view and manage the resources that are defined to them. To see more detailed information, view properties and details for the department.

The following information shows the objects that you can add using the Add to Department function.

Table 1. Objects that can be added to the department

Object	Objects that can be added to the department
 Department	<ul style="list-style-type: none"> • Applications • Departments

- [Creating a department hierarchy](#)

To monitor the capacity and space usage of the department, you want to create a department hierarchy and associate applications with the department hierarchy. You can also monitor the performance of the storage resources that are associated with the applications that you add to the department hierarchy.

- [Viewing information about departments](#)

You can view detailed information about departments for use in storage capacity monitoring and performance troubleshooting. You can view additional information on the applications and subdepartments that are used to establish a hierarchical business structure.

- [Removing departments and subdepartments](#)

You can remove departments, subdepartments and applications that are members of the department. The data that is collected about the departments, subdepartments and applications is removed from the database repository.

- [Removing applications from a department](#)

You can remove an application from within a department. This action is only available from the department detail page or the properties for the department.

Creating a department hierarchy

To monitor the capacity and space usage of the department, you want to create a department hierarchy and associate applications with the department hierarchy. You can also monitor the performance of the storage resources that are associated with the applications that you add to the department hierarchy.

About this task

In this scenario, you want to monitor the capacity and space usage of departments in a business organization that sells books. You also want to monitor the performance of the storage resources that are associated with the applications or application subcomponents that are used by the departments.

The sales department of the organization, Book Sales, has these subdepartments:

- Wholesale
- Retail
- Online

To monitor the storage resources that the Books Sales department uses and that each of its subdepartments use, complete these tasks:

- Create a department for Book Sales.
- Create the Wholesale, Retail, and Online subdepartments that you want to add to the department:
 - Create the subdepartments as departments.
 - Add the departments as subdepartments to the department.
 - Add the applications to the subdepartments.

Results

You can now view charts and information about the capacity and space usage of the department and each of the subdepartments on the Departments page and the Subdepartments page. You can also view charts and information about the performance of the storage resources that are associated with the applications or application subcomponents that the departments and subdepartments use.

Tip: In the Subdepartments column for the department on the Departments page, the name of the subdepartment is shown. If you add two or more departments to a subdepartment, the number of subdepartments is shown. To view information about the subdepartments, click the name of the subdepartment or the number.

What to do next

You can view the total capacity and space usage for the department and the capacity and space usage for each of the subdepartments. You can add to your department hierarchy by adding more applications and departments.

1. [Creating departments](#)

To model the storage capacity that is consumed in a department for your business environment, in accordance with other department and application members, create departments for monitoring in IBM Spectrum® Control.

2. [Adding and creating subdepartments](#)

To further enhance your data modeling at the department level and to add to your overall business hierarchy for monitoring, add an existing subdepartment or create a new subdepartment.

3. [Adding applications to departments](#)

To further enhance the data storage modeling in a business environment and see the storage capacity that is used at the different levels of your business hierarchy, add applications to departments. The departments you select from the Add to Department page become parents of the selected applications.

Creating departments

To model the storage capacity that is consumed in a department for your business environment, in accordance with other department and application members, create departments for monitoring in IBM Spectrum Control.

About this task

Use the web-based GUI to create departments, subdepartments (member departments) and add applications for monitoring different levels of a business hierarchy.

Procedure

To create a department, complete these steps:

1. In the menu bar, go to Groups > Departments.
2. On the Departments page, click Create Department.
3. On the Create Department page, enter information about the department.

You cannot have a duplicate department name on the same level in your department hierarchy. For example, you create a department named *Finance* and create a subdepartment named *Business*. You can create another department named *Business* as a top level department, but if you want to make your new *Business* department a subdepartment of the *Finance* department, you see a message that indicates there is already a department named *Business* that is a member of the *Finance* department; your department creation is denied.

You can customize the icon for your department by clicking the existing icon on the Create Department page and selecting another icon from the Customize Icon page.

4. Click Create and then Close.
5. Optional: On the Add Members page, click Add one or more applications .
 - a. On the populate page, select the applications that to add to your department.
If you do not want to add any of the applications that are listed, click Create Application to create a new application to add to the department.
 - b. Click Finish.
6. Optional: On the Add Members page, click Create subdepartment .
 - a. On the Create Subdepartment page, enter your information.
 - b. Click Create.

Results

To view the newly created department, go to the Departments page.

To see the applications that you added to your department, see the details page and click Applications.

To see the subdepartment you created, see the Subdepartments column on the Departments page or see the details page and click Subdepartments.

What to do next

Continue to add to your department hierarchy by adding applications and departments.

Next topic: [Adding and creating subdepartments](#)

Related tasks

- [Adding and creating subdepartments](#)
- [Adding applications to departments](#)

Adding and creating subdepartments

To further enhance your data modeling at the department level and to add to your overall business hierarchy for monitoring, add an existing subdepartment or create a new subdepartment.

Procedure

To add a subdepartment to the department level hierarchy, use these steps:

1. In the menu bar, go to Groups > Departments.
2. On the Departments page, select one or more departments, right-click and click Add to Department.
3. On the Add to Department page, select one or more departments from the list and click Save.
The department or departments you select from the Add to Department page become parents of the selected department. The Hierarchy column shows the longest ancestry path of the department. You can also view the applications that are members of the department on the Departments page.
4. Optional: Create a new subdepartment:
 - a. Click Create Department to open the Create Department page.
 - b. Enter information about the department.
 - c. Click Create.
 - d. On the Add Members page, click Create a subdepartment.
 - e. On the Create Subdepartment page, enter your information.
 - f. Click Create.
5. Optional: Create a new subdepartment from the details page of the existing department:
 - a. In the General section, click Subdepartments to open the Subdepartments page.
 - a. Click Create Subdepartment to open the Create Subdepartment page.
 - b. Enter information about the subdepartment.
 - c. Click Create.

Results

To see the subdepartment you created, see the Subdepartments column on the Departments page or click Subdepartments on the details page.

What to do next

You can continue to create or add subdepartments to the department or add applications to the department.

Removing departments and subdepartments

You can remove departments, subdepartments and applications that are members of the department. The data that is collected about the departments, subdepartments and applications is removed from the database repository.

Procedure

To remove departments, subdepartments, and applications, that are members of the department, from a level of the business hierarchy, complete these steps:

1. In the menu bar, go to Groups > Departments.
2. On the Departments page, select one or more departments, right-click and click Delete.
3. Confirm the information and click Delete.
 - a. If you select Delete subdepartments and applications, the subdepartments and applications that belong only to the department, that is being removed, are removed.
 - b. If you do not select Delete subdepartments and applications, the subdepartments and applications of the department that are being removed become members of the parent department. If the department is a top level department, and the subdepartments are not members of any other department, they become top level departments.

Results

The departments, subdepartments and applications are removed from the business level hierarchy and are no longer displayed on the Departments page. To remove subdepartments from within the direct context of a department, use these steps:

1. In the menu bar, go to Groups > Departments.
2. On the Departments page, select a department from the list and right-click View Details.
3. Optional: Select a department from the Departments page and right-click View Properties.
 - a. Click the Subdepartments tab and continue with steps 5 and 7.
4. On the department details page, click Subdepartments in the General section.
5. On the Subdepartments page, select the subdepartment and right-click Remove from Department.
6. Optional: On the Subdepartments page, select the subdepartment and click Delete.
7. Reply to the confirmation message and click OK.

Removing applications from a department

You can remove an application from within a department. This action is only available from the department detail page or the properties for the department.

Procedure

To remove applications from within the context of a department, use these steps:

1. In the menu bar, go to Groups > Departments.
2. On the Departments page, select a department from the list and right-click View Details.
3. Optional: Select a department from the Departments page and right-click View Properties.
 - a. Click the Applications tab and continue with steps 5-7.
4. On the department details page, click Applications from the General section.
5. On the Applications page, select the application and right-click Remove from Department.
6. Confirm the information.
7. Click OK.

Results

The applications that were added within the context of a department are eligible for removal from within department.

- [Viewing information about departments](#)

Application and department hierarchies

The interactive breadcrumb on the Overview page provides a visual representation of the hierarchical relationships for applications and departments and enables you to navigate quickly between the elements in the hierarchy.

The breadcrumb uses default or customized icons to represent the related applications and departments. The greater-than sign (>) serves as the hierarchy separator and ends with the name of the selected application or department. Only the ancestor names of the selected application are shown.

Overview

Multiple (2) V DB2 > Data
Epic
Records

When you move your mouse pointer over an icon in the breadcrumb, you see the siblings for that application or department. If you move your mouse pointer, for example, over the Data subcomponent, the related application and department elements are shown.

The visual representation of the hierarchy stops when either there are no additional parents or multiple parents are encountered from the selected application or department. When multiple parents are encountered, the number of parents are shown in parenthesis. For example, *Multiple (2)*. Moving the mouse pointer over *Multiple* shows a list of the parents. The siblings of multiple parents are *not* shown.

Move your mouse pointer over a sibling in the breadcrumb and it becomes a name link. Click the application or department name link to navigate to the details for that application or department and view the breadcrumb if it exists.

You can add resources directly on the Overview page for applications from the breadcrumb. For example, in this case, you create an application named Db2® and create two subcomponents, Logs and Data. On the Overview page for the Logs subcomponent, click the Logs subcomponent name link in the breadcrumb and click Filters to create a resource filter for that subcomponent. Then, click the Data subcomponent name link and create a resource filter for that application subcomponent. To see a visual representation of the hierarchy for applications, subcomponents, departments, and subdepartments click View Details.

Exporting information about applications and departments

You can save information about applications and departments to a PDF, CSV, or HTML file. Information that you can export from the GUI includes all the values that are being shown in the columns for a list of applications and departments.

Before you begin

The information that you export to a file is organized according to the sorting, filtering, and column order that is defined for a list. Before you export information, complete the following tasks to configure a list:

- Change the order of columns in the list as you want them to appear in the generated file.
- Hide columns in the list that you do not want to include in the generated file. Information in hidden columns is not exported.
- Sort the rows in the list as you want them to appear in the generated file. Each list in the GUI has a column or set of columns that determines the order of its rows.
- Filter the list to show only the applications and departments that you want to export. Use filtering to limit the rows that are shown in a list based on value in a specific column or set of default columns.

About this task

You can export information that is shown on the application and department list and detail pages.

Applications and departments list and detail pages

You can export information about the top level applications and departments and the related resources that are shown on application and department list and detail pages.

For example, you can export information about monitored applications and their subcomponents and departments on the Applications page. When you select the export action, the generated file includes the column values for each monitored application in the list.

For example, you can export information about the servers that are associated with an application on the details page.

Procedure

1. In the GUI, go to the Applications or Departments page and select applications or departments for which you want to export information.
2. Click Actions and select Export. *file_format*, where **file_format** represents the format that you want to use for a file.

The following formats are available:

CSV (comma-separated values)

A CSV file is a file that contains comma-delimited values and can be viewed with a text editor or imported into a spreadsheet application. The information in a CSV file has the following format:

```
"Column_name", "Column_name", "Column_name", "Column_name", "Column_name", "Column_name"
"data", "data", "data", "data", "data", "data"
```

where **Column_name** represents the name of a column in a table and **data** represents the data that is associated with a column.

PDF

You can view a PDF file with Acrobat reader. The information that you export to a PDF file is formatted into a table.

Tip: When you export a table of data that contains many columns, the rows in that table might span multiple pages in the resulting PDF. For example, if a table contains 20 columns, then the row for a specific resource might be shown on more than one page (10 columns on the first page and 10 columns on the second page).

To reduce the number of pages that a table spans, before you select the export action, hide the columns that you do not want to include in the PDF. Continue hiding columns until the table no longer spans multiple pages.

HTML

You can view an HTML file with a web browser. The information that you export to an HTML file is formatted into a table.

3. Optional: Depending on how your web browser is configured, you can specify the name and location of the generated file.
4. Click the save option to export the information to a file.

General groups

View and administer the general groups that are used to alert on logically related storage resources. You can define alerts for a general group to notify you about changes in the configuration, attributes, and performance of the resources in the group.

Organizing your resources into general groups can be helpful in the following situations:

- When you want to receive alert notifications about changes for a subset of the resources of a particular type. For example, you want to detect when the ports that are used for replication on your SAN Volume Controller have insufficient buffer-to-buffer credit. You do not want the alerts to apply to other ports on your SAN Volume Controller. You can group the ports that are used for replication and then define alerts for the group.
- When you want to receive alert notifications about changes for a group of resources that are logically related. Examples include all the servers that use a particular operating system or all the storage systems at a specific location.

General group hierarchies

Organizing resources into general groups and their subgroups can be helpful when you want to quickly view information about a group of resources, but you also want to view information about subgroups of resources within the group.

Only top-level groups in the general group hierarchy are shown on the General Groups page. If the general group has a subgroup, the name of the subgroup is shown in the Subgroups column. If the general group has more than one subgroup, click the number of groups in the Subgroups column to view the subgroups.

Creating a general group hierarchy

Organizing resources into general groups and their subgroups can be helpful when you want to quickly view information about a group of resources, but you also want to view information about subgroups of resources within the group.

About this task

In this scenario, you want to monitor all the ports on your SAN Volume Controller but you also want to separately monitor the following subsets of ports on the SAN Volume Controller:

- Ports that are used for inter-node communication
- Ports that are used for host I/O exchanges

To add the ports to a general group hierarchy, complete the following steps:

1. Add the ports that are used for inter-node communication to a general group, SVC Inter Node Ports.
2. Add the ports that are used for host I/O exchanges to another general group, SVC Host I/O Ports.
3. Add the groups as subgroups of a parent general group, SVC All Ports.

You can now quickly view information about the resources in the hierarchy on the details page for the general groups.

When you view the SVC Inter Node Ports or SVC Host I/O Ports groups, you see information about the specific ports that are members of that subgroup.

When you view the parent group, SVC All Ports, you see information about the ports that are members of the parent group and also the ports in the subgroups.

Creating general groups and adding resources

When you create and associate storage resources with a general group, you can quickly view information about the group and its resources.

About this task

You can add the following resources and their internal resources to a general group:

- Storage systems
- Servers
- Hosts
- Hypervisors
- Switches
- Fabrics
- Other general groups

Only resources that you specifically add to a group are included as members of the group. For example, if you add a SAN Volume Controller, the internal resources of the SAN Volume Controller, such as volumes and pools, are not automatically added to the group. To add the volumes and pools, you must specifically select those resources and add them to the group.

Procedure

To create a general group and add resources to the group, complete these steps:

1. Take one of the following actions to go to the list page for the resource or group that you want to add:
 - To add top-level resources such as storage systems, servers, hypervisors, switches, or fabrics, go to the appropriate resource page. For example, to add servers, in the menu bar, click Servers >> Servers.
 - To add internal resources of top-level resources, complete the following steps:
 - Go to the resource list page for the top-level resource. For example, to add internal resources of a SAN Volume Controller, in the menu bar, click Storage >> Block Storage Systems.
 - Right-click the resource and click View Details.
 - In the Internal Resources section, click the type of resource that you want to add, for example, volumes or pools.
 - To add general groups, in the menu bar, click Groups >> General Groups.
2. Right-click one or more resources or groups and click Add to General Group.
3. Click Add to new group and specify a name and description for the new group.
4. Optional: Customize the icon for a new group by clicking the existing icon and selecting another icon.
5. Click Save.

Results

You can now quickly view information about the resources in the general group hierarchy on the details page for the general group.

Adding resources to general groups

Add resources to general groups so that you can receive alert notifications about changes in the configuration, attributes, and performance of the resources in the group. You can add resources to one or more existing groups or you can create a new group.

About this task

The following resources and their internal resources can be added to a general group:

- Storage systems*
- Hosts
- Hypervisors
- Switches
- Fabrics
- Other general groups

Tip: * For IBM® Cloud Object Storage, only vaults can be added to general groups.
Only resources that you specifically add to a group are included as members of the group. For example, if you add a SAN Volume Controller, the internal resources of the SAN Volume Controller, such as volumes and pools, are not automatically added to the group. To add the volumes and pools, you must specifically select those resources and add them to the group.

You can create a general group hierarchy by adding one or more general groups as subgroups of a general group. When you define a general group alert for a resource such as a volume, the alert applies to all the volumes that belong to that group and all its subgroups.

Procedure

To add resources to a general group, complete these steps:

1. Take one of the following actions to go to the list page for the resource or group that you want to add:
 - To add top-level resources such as storage systems, servers, hypervisors, switches, or fabrics, go to the appropriate resource page. For example, to add servers, in the menu bar, click Servers. >> Servers.
 - To add internal resources of top-level resources, complete the following steps:
 - Go to the resource list page for the top-level resource. For example, to add internal resources of a SAN Volume Controller, in the menu bar, click Storage. >> Block Storage Systems.
 - Right-click the resource and click View Details.
 - In the Internal Resources section, click the type of resource that you want to add, for example, volumes or pools.
 - To add general groups, in the menu bar, click Groups. >> General Groups.
2. Right-click one or more resources or groups and click Add to General Group.
3. Take one of the following actions:
 - To add the resources or groups to a new group, click Add to new group and specify a name and description for the new group.
 - To add the resources or groups to one or more existing groups, click Add to existing groups and click the appropriate groups in the list.
4. Optional: Customize the icon for a new group by clicking the existing icon and selecting another icon.
5. Click Save.

What to do next

To view the resources and subgroups that are members of the group, complete the following steps:

1. Go to Groups. >> General Groups.
2. Right-click the general group and select View Details.
On the general group details page, all the different resource types, such as volumes or pools, that are members of the group or members of its subgroups are shown in the Members section.
3. Click the resource type to view the specific resources. For example, click Volumes to view all the volumes that are in the general group or in its subgroups.
4. Click Subgroups to view the child groups.

To define alerts for the general group, use the View Alert Definitions action on the General Groups page.

Provisioning storage

You can assign storage to servers, hypervisors, and clusters on servers and hypervisors in the GUI.

About this task

Discontinued support: Provisioning is no longer supported in IBM Spectrum® Control. While the feature might still work in this release, it's recommended that you use another tool for your provisioning needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

You can also assign the following types of storage to servers, hypervisors, and clusters on servers and hypervisors:

- Volumes
- NAS file shares

When you assign storage, you must associate the storage with a service class. You can associate the storage with a default service class such as gold, silver, or bronze, or you can create a user-defined service class. You can also create capacity pools to restrict the provisioning of storage to a defined set of storage resources such as pools on a storage system in a particular location.

- [Configuring IBM Spectrum Control for provisioning](#)
- [Provisioning storage with the IBM Spectrum Control GUI](#)

You can provision volumes or shares to servers, hypervisors, and clusters in IBM Spectrum Control.

Configuring IBM Spectrum Control for provisioning

Before you can use the simplified provisioning capabilities that are provided with IBM Spectrum® Control, you must configure your environment.

Before you begin

Discontinued support: Cloud configuration, provisioning, and optimization are no longer supported in IBM Spectrum Control. While these features might still work in this release, it's recommended that you use another tool for your provisioning and optimization needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

About this task

To provision storage, you are required to specify only the storage capacity and storage quality that is required. After volumes are created, IBM Spectrum Control can analyze and optimize volume performance.

Procedure

To configure IBM Spectrum Control for provisioning, complete the following tasks:

1. Assign storage pools to tiers by setting the tier level of each storage pool. The tier levels are number tags that can reflect any tier structure in the environment. You must assign storage pools to tiers to later provision volumes that require a certain tier level and to optimize the placement of volumes. Storage pools do not need to be assigned to tiers to provision volumes that do not require a tier level, or to provision file shares.
 2. Create service classes. A service class is a set of properties that describe capabilities and characteristics of storage resources. A service class typically describes a particular quality of service, and is used during provisioning to describe storage requirements. For example, a block-storage service class specifies properties such as a required RAID level, and whether storage resources must be able to encrypt or thin provision volumes.
 3. Optional: Create capacity pools. You can restrict provisioning requests to a capacity pool. Capacity pools are groups of storage resources. You can use capacity pools to separate storage resources in any way that serves the needs of your environment or business. For example, a capacity pool might contain the storage resources that are allocated to a particular department or division of your business, or to a particular application.
- [Configuring service classes](#)
Configure service classes to represent the different levels or types of storage quality that you want to provision. When you are configuring service classes for your installation, consider whether certain storage requests must always be satisfied from a particular set of resources. Also, consider whether you want to allow users without administrator privileges to provision storage, and whether you want their provisioning requests to require administrator approval.
 - [Configuring capacity pools](#)
Configure capacity pools to track the used and available capacity for block and file storage on any set of storage resources. Provisioning requests can also be restricted to resources in a capacity pool.
 - [Block storage: Calculating available capacity and determining the placement of volumes](#)
For each block-storage service class, IBM Spectrum Control calculates the amount of available capacity for volumes of that service class. When you request volumes of a particular service class, IBM Spectrum Control recommends the best location for the volumes from the available capacity.
 - [File storage: Calculating available capacity and determining the placement of shares](#)
For each file-storage service class, IBM Spectrum Control calculates the amount of available capacity for NAS file shares of that service class. When you request file shares of a particular service class, IBM Spectrum Control recommends the best location for the shares from the available capacity.
 - [Changing the default host definition for provisioned storage](#)
Use the `setdscfg` command to change the default host definition for fibre-channel ports when provisioning storage from resources that run IBM Spectrum Virtualize.

Configuring service classes

Configure service classes to represent the different levels or types of storage quality that you want to provision. When you are configuring service classes for your installation, consider whether certain storage requests must always be satisfied from a particular set of resources. Also, consider whether you want to allow users without administrator privileges to provision storage, and whether you want their provisioning requests to require administrator approval.

Before you begin

Discontinued support: Cloud configuration, provisioning, and optimization are no longer supported in IBM Spectrum® Control. While these features might still work in this release, it's recommended that you use another tool for your provisioning and optimization needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

A service class can specify tags to create custom requirements for provisioning. Add the same tags to storage resources that satisfy the custom requirements. When the service class is specified during provisioning, only the tagged resources are candidates for provisioning.

Creating service classes

Create service classes to specify storage requirements for future provisioning requests. A service class describes attributes and capabilities of block storage or file storage resources, and typically describes particular quality of service.

Before you begin

You must have Administrator privileges to create a service class.

About this task

The IBM Spectrum® Control GUI guides you through the steps to create a service class. When you provision a volume or share, you define storage requirements by specifying a service class. A block-storage service class specifies the requirements for the block-storage resource from which a new volume is allocated. A file-storage service class defines requirements for the file storage resources from which a new share is allocated.

You can associate a service class with one or more capacity pools. If you do, future provisioning requests can be satisfied only by storage resources in the specified capacity pools.

You can selectively grant users who do not have administrator privileges permission to provision storage by using the service class.

Restrictions:

- To create a block-storage service class, you must have the IBM Spectrum Control Advanced Edition license.
- To associate the service class with a capacity pool, one or more capacity pools must be defined in the IBM Spectrum Control database. If no capacity pool is defined, the Specify Capacity Pool page is not displayed.

Procedure

Start this task at the Service Classes page. To open the Service Classes page, select Advanced Analytics > Cloud Configuration > Work With Service Classes. To create a service class, complete the following steps:

1. From the Service Classes page, click Create Service Class.
2. Select the type of service class that you want to create:
 - To create a block-storage service class, click the Block icon.
 - To create a file-storage service class, click the File icon.
3. In the Define Properties page, complete the following steps:
 - a. Specify a name for the service class.
 - b. Optional: Specify a service class description.
Descriptions are displayed in the table of service classes on the Service Classes page.
 - c. Specify the general attributes of the service class.
Most of the general properties specify requirements for provisioning. Some of the general properties specify configuration instructions for the storage resources or for the volumes or shares that are provisioned from them.
Tip: To display help information about a service class property, move the mouse pointer over the field or control. Then, move the mouse pointer over the question mark icon displayed next to the field.
4. Optional: Specify or modify the advanced properties of the service class.
 - a. From the Define Properties page, click Advanced.
 - b. If you are creating a block-storage service class, and thin provisioning is enabled for the service class, specify configuration instructions for thin provisioning.
 - c. If you are creating a block-storage service class, select how the multipath driver on the host is configured. For hypervisors, the multipath driver is configured only if provisioning is initiated from the vSphere Web Client extension for IBM Spectrum Control.
 - d. Create custom requirements for the service class by specifying up to three custom tags. To provide the service class, storage resources must have all the same tags that are specified in the service class.
5. Optional: In the Specify Capacity Pool page, associate the service class with one or more capacity pools.
If capacity pools are associated with the service class, future provisioning requests that specify the service class can be satisfied only by storage resources in the capacity pools.
6. Optional: Grant permission to individual users, who do not have administrator privileges, to provision storage by using the service class.
By default, users must be assigned to the Administrator role to provision storage. However, you can selectively grant users who are limited to the Monitor or External Application role permission to provision by using this service class. You can also specify whether administrator approval is required to run provisioning tasks that are created by these users.
7. Click Finish
The new service class is listed in the table of service classes on the Service Classes page, and can be specified in future provisioning requests.

Viewing the details of service classes

You can view the provisioning requirements and storage constraints that a service class defines. You can also view the volumes or shares that were provisioned by using the service class.

About this task

From the Service Classes page, you can open a properties page to view the following information for a service class:

- The properties of a service class, such as the required RAID level or storage tier for a block-storage service class.
- The storage constraints that are imposed by the service class. The service class can allow provisioning from all available storage, or can limit provisioning to one or more capacity pools.
- The users who can provision storage by using the service class.
- The volumes or shares that were provisioned by using the service class.
- The candidate storage for the service class. The *candidate storage* is the set of storage resources that can provide the service class.

Procedure

To open the service class properties window from the Service Classes page, complete the following steps:

1. In the menu bar in the web-based GUI, go to Advanced Analytics > Cloud Configuration, and click Work With Service Classes.
The Service Classes page is displayed.
2. From the list of service classes, select the service class, and then select Actions > View / Modify.
The service class properties window is displayed.

Modifying service classes

You can modify the attributes of a service class to change the provisioning requirements, capacity pool storage constraints, user permissions, and service class name.

Before you begin

You must have Administrator privileges to modify a service class.

About this task

Important: When volumes or shares are provisioned by specifying a service class, they are associated with the service class. The Volumes page and the Shares page in the web-based GUI can display the name of the service class that was used to provision the volume or share. If you modify a service class, the volumes or shares are still associated with the service class, but might be on storage resources that no longer satisfy the requirements of the service class. Depending on your changes to the service class, users might incorrectly assume that the new volumes or shares have attributes that they do not possess.

Procedure

Start this task at the Service Classes page. To open the Service Classes page, select **Advanced Analytics** > **Cloud Configuration** > **Work With Service Classes**. To modify a service class, complete the following steps:

1. From the list of service classes, select a service class and then select **Actions** > **View / Modify**.
The service class properties window is displayed.
2. Optional: Click the General tab to modify the general attributes of the service class.
Most of the general properties specify requirements for provisioning. Some of the general properties specify configuration instructions for the storage resources or for the volumes or shares that are provisioned from them.
Tip: To display help information about a service class property, move the mouse pointer over the field or control. Then, move the mouse pointer over the question mark icon displayed next to the field.
3. Optional: Specify or modify the advanced properties of the service class.
 - a. From the General tab, click **Advanced**.
 - b. If you are modifying a block-storage service class, and thin provisioning is enabled for the service class, specify configuration instructions for thin provisioning.
 - c. If you are modifying a block-storage service class, select how the multipath driver on the host is configured.
 - d. Create custom requirements for the service class by specifying up to three custom tags. To provide the service class, storage resources must have all the same tags that are specified in the service class.
4. Optional: Modify storage constraints.
If one or more capacity pools are defined in the IBM Spectrum® Control database, you can associate the service class with one or more capacity pools. If capacity pools are associated with the service class, future provisioning requests that specify the service class can be satisfied only by storage resources in the capacity pools. If a capacity pool was previously associated with the service class, you can disassociate it from the service class.
5. Optional: Modify user permissions.
By default, users must be assigned to the Administrator role to provision storage. However, you can selectively grant users who are limited to the Monitor or External Application role permission to provision by using this service class. You can also specify whether administrator approval is required to run provisioning tasks that are created by these users.
If users in the Monitor or External Application roles have permission to provision by using the service class, you can revoke that permission. You can specify that only administrators can provision by using the service class, or you can selectively remove users. To remove a user, right-click the user name in the table and then select **Remove** from the context-sensitive menu.

Deleting service classes

You can delete a service class that is no longer needed.

Before you begin

You must have Administrator privileges to delete a service class.

About this task

Deleting a service class does not affect the storage volumes or NAS shares that are already provisioned by using the service class. However, the storage volumes or NAS shares are no longer associated with any service class. When a volume that is not associated with a service class is optimized, the volume can be migrated to any available storage pool. The storage pool to which the volume is migrated might not satisfy the requirements of the service class that was specified when the volume was provisioned.

Procedure

To delete a service class from the Service Classes page, complete these steps:

1. In the menu bar, go to **Advanced Analytics** > **Cloud Configuration**, and click **Work With Service Classes**.
The Service Classes page is displayed.
2. From the list of service classes, select the service class, and then select **Actions** > **Delete**.

Tagging resources to satisfy custom requirements

A service class can specify tags to create custom requirements for provisioning. Add the same tags to storage resources that satisfy the custom requirements. When the service class is specified during provisioning, only the tagged resources are candidates for provisioning.

Before you begin

You must have Administrator privileges to tag storage resources.

About this task

When you provision storage, you indicate your storage requirements by specifying a service class. Certain properties of the service class describe capabilities that storage resources must have to be a candidate for provisioning. In addition to the default properties, a service class can define custom requirements by specifying up to three custom tags. To provide the service class, a storage resource must have all the same tags as the service class. The ability to define custom requirements by tagging service classes and storage resources gives you more control over the selection of storage resources during provisioning. By using tags, you can filter the candidates for provisioning by using any criteria that you choose.

When you provision volumes, you specify the requirements by using a block-storage service class. Based on the requirements of the service class, IBM Spectrum® Control identifies a storage pool for the volume. If the service class specifies tags, only pools that have all the same tags are candidates for provisioning. If a pool is not tagged, any tags on the containing storage system also apply to the pool.

When you provision shares, you specify the requirements by using a file-storage service class. Based on the requirements of the service class, IBM Spectrum Control identifies a file system or Network Shared Disk (NSD) for the share. If the service class specifies tags, only file systems and NSDs that have all the same tags are candidates for provisioning. If a file system or NSD is not tagged, any tags on the containing storage system also apply to the internal resource.

Procedure

Tag only the storage resources that satisfy the intended custom requirements of the service class. During provisioning, only the tagged resources can provide the service class.

1. Open the resource list page for the type of storage resource that you want to tag. To satisfy the custom tag requirements of a block-storage service class, you can tag a storage pool or its containing block storage system. To satisfy the custom tag requirements of a file-storage service class, you can tag a file system or NSD, or the containing file storage system.

Important: The tags on a containing storage system apply to an internal pool, file system, or NSD resource only if the internal resource is not tagged.

- If you are tagging a storage pool, from the menu bar, go to Storage > Pools.
 - If you are tagging the block storage system that contains the pools, complete the following steps:
 - In the menu bar, go to Storage > Block Storage Systems.
 - Click the Block Storage tab.
 - If you are tagging a file system or NSD, complete the following steps:
 - In the menu bar, go to Storage > Block Storage Systems.
 - Click the File Storage tab.
 - From the list of storage systems, select the storage system that contains the file system or NSD, and then select View Details. Alternatively, you can select Actions > View Details.
 - In the Internal Resources area, click File Systems or Network Shared Disks.
 - If you are tagging the file storage system that contains the file systems or NSDs, complete the following steps:
 - In the menu bar, go to Storage > Block Storage Systems.
 - Click the File Storage tab.
2. In the table of storage systems, pools, file systems, or NSDs, select the storage resource that you want to tag, and then select View Properties. Alternatively, you can select Actions > View Properties.
 3. In the properties notebook for the storage system, pool, file system, or NSD, click Edit.
 4. In the custom tag fields of the properties notebook, specify tags that match the tags that are specified in the service class. To provide the service class, the resource must have all of the same tags.
 5. In the properties notebook, click Save.

Configuring capacity pools

Configure capacity pools to track the used and available capacity for block and file storage on any set of storage resources. Provisioning requests can also be restricted to resources in a capacity pool.

Before you begin

Discontinued support: Cloud configuration, provisioning, and optimization are no longer supported in IBM Spectrum® Control. While these features might still work in this release, it's recommended that you use another tool for your provisioning and optimization needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

- **[Adding resources to capacity pools](#)**
Divide storage resources into capacity pools to later restrict provisioning or optimization to a specific set of resources. You can also use capacity pools to track the used and available capacity for block and file storage on any set of storage resources. You can add resources to an existing capacity pool, or you can create a new capacity pool.
- **[Viewing the details of capacity pools](#)**
You can view details of a capacity pool, such as its total capacity, used and available capacity, and member resources.
- **[Modifying capacity pools](#)**
You can modify the attributes of a capacity pool such as its name and description, and you can remove storage resources from a capacity pool.
- **[Deleting capacity pools](#)**
You can delete a capacity pool that is no longer needed.

Adding resources to capacity pools

Divide storage resources into capacity pools to later restrict provisioning or optimization to a specific set of resources. You can also use capacity pools to track the used and available capacity for block and file storage on any set of storage resources. You can add resources to an existing capacity pool, or you can create a new capacity pool.

Before you begin

You must have Administrator privileges to perform this task.

About this task

You can add storage resources to a capacity pool from resource list pages such as the Storage Systems page and the Pools page.

You can add the following resource types to a capacity pool:

- Storage systems
- Storage pools
- File systems of file storage systems

When you add a storage system to a capacity pool, any storage pool or file system that is an internal resource of that storage system is also indirectly assigned to the capacity pool.

Restriction: A resource can be assigned to only one capacity pool. When you attempt to add one or more resources to a capacity pool that are already assigned to different capacity pool, IBM Spectrum® Control displays a message that lists the resources and their capacity pool assignments. When a message is displayed, ensure that you want to change the capacity pool assignments for the listed resources.

Procedure

To add one or more resources to a capacity pool, complete these steps:

1. Open the appropriate list page for the resource you want to add. You can add an entire storage system, or you can add individual pools or file systems.
 - To add a storage system, in the menu bar, go to Storage > Block Storage Systems or Storage > File Storage Systems.
 - To add a storage pool, in the menu bar, go to Storage > Pools.
 - To add a file system, complete the following steps:
 - In the menu bar, go to Storage > File Storage Systems.
 - Select the storage system that contains the file system, then select View Details from the context-sensitive menu.
 - From the Internal Resources list, click File Systems or Network Shared Disks.
2. To add one or more resource to a capacity pool, select the resources in the list, and then select Actions > Add to Capacity Pool.
If one or more capacity pools are defined, a list of capacity pools is displayed. If no capacity pools are defined, the Create Capacity Pool window is displayed so that you can add resources to a new capacity pool.
Tip: The list of capacity pools and the Create Capacity Pool window shows capacity information. For the list of capacity pools, the Capacity column shows a bar that summarizes the used and free space in each capacity pool. In the Create Capacity Pool window, a capacity bar summarizes the used and free space of the resources that are being added to the new capacity pool. Move the mouse pointer over the bar to display a text summary and details of the capacity usage.
3. Take one of the following actions:
 - If the Create Capacity Pool window is displayed, go to step 4.
 - If a list of capacity pools is displayed, add the selected resources to an existing capacity pool or to a new capacity pool.
 - To add the selected resource or resources to an existing capacity pool, select the appropriate row in the list of capacity pools, and click Save.
 - To add the selected resource to a new capacity pool, click Create Capacity Pool. The Create Capacity Pool window is displayed.
4. In the Create Capacity Pool window, specify a name for the capacity pool.
5. Optional: Specify a capacity pool description.
Capacity pool descriptions appear in the list of capacity pools on the Capacity Pools page.
6. Optional: Specify custom tags to associate any significant information with the capacity pool.
You can specify up to three custom tags. The custom tags can be displayed in the list of capacity pools on the Capacity Pools page.
7. Save the new capacity pool by clicking OK.

Viewing the details of capacity pools

You can view details of a capacity pool, such as its total capacity, used and available capacity, and member resources.

About this task

The Capacity Pools page lists all of the capacity pools that are defined in IBM Spectrum® Control. For any capacity pool in the list, you can open a window to view more details about the capacity pool and its storage resources.

Procedure

To view details of a capacity pool, complete these steps:

1. In the menu bar, go to Advanced Analytics > Cloud Configuration, and click Work With Capacity Pools.
The Capacity Pools page is displayed.
2. From the list of capacity pools, select the capacity pool, and then select Actions > View / Modify.
A window is displayed, showing the following details:
 - A bar summarizing the used and free space in the capacity pool in gibibytes. The bar represents the total capacity of the capacity pool. The bar is divided into sections that represent the following measurements:
 - The amount of capacity that is used for file storage
 - The amount of available capacity for file storage
 - The amount of capacity that is used for block storage
 - The amount of block storage capacity that is not used for volumes, and is not reserved by pending or scheduled provisioning tasks.

- The amount of block storage capacity that is reserved by pending or scheduled provisioning tasks
- Move the mouse pointer over the bar to display a text summary and details of the capacity usage, and a legend for interpreting the colors on the bar.
- A table that lists the storage systems, storage pools, and file systems that are in the capacity pool. To view details of any of these resources, select the resource, and then select Actions > View Properties.

Modifying capacity pools

You can modify the attributes of a capacity pool such as its name and description, and you can remove storage resources from a capacity pool.

Before you begin

You must have Administrator privileges to perform this task.

Procedure

To modify a capacity pool, complete these steps:

1. In the menu bar in the web-based GUI, go to Advanced Analytics > Cloud Configuration, and click Work With Capacity Pools.
The Capacity Pools page is displayed.
2. From the list of capacity pools, select the capacity pool, and then select Actions > View / Modify.
A window that shows details of the capacity pool is displayed. A table lists the storage systems, storage pools, and file systems that are in the capacity pool.
3. Optional: Modify attributes of the capacity pool.
4. Optional: Remove one or more resources from the capacity pool. Removing a storage resource from a capacity pool does not delete the storage resource, but does remove its capacity from the capacity pool. To remove resources, select the appropriate resources in the list, and then select Actions > Remove.
The resources are removed from the list, but are not removed from the capacity pool until you save your changes.
5. Click Save.

Deleting capacity pools

You can delete a capacity pool that is no longer needed.

Before you begin

You must have Administrator privileges to perform this task.

About this task

When you delete a capacity pool, the storage resources that were added to the capacity pool are no longer members of any capacity pool. Deleting a capacity pool does not affect any volumes or NAS shares that were provisioned from the capacity pool. However, the volumes or NAS shares are no longer associated with a capacity pool.

Procedure

To delete a capacity pool, complete the following steps:

1. In the menu bar in the web-based GUI, go to Advanced Analytics > Cloud Configuration, and click Work With Capacity Pools.
The Capacity Pools page is displayed.
2. From the list of capacity pools, select the capacity pool, and then select Actions > Delete
3. In the confirmation window, click Delete.

Block storage: Calculating available capacity and determining the placement of volumes

For each block-storage service class, IBM Spectrum® Control calculates the amount of available capacity for volumes of that service class. When you request volumes of a particular service class, IBM Spectrum Control recommends the best location for the volumes from the available capacity.

Discontinued support: Cloud configuration, provisioning, and optimization are no longer supported in IBM Spectrum Control. While these features might still work in this release, it's recommended that you use another tool for your provisioning and optimization needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

The Service Classes page in the GUI displays the available capacity for each block-storage service class. The available capacity is the amount of space that is available across storage pools for new volumes of the service class. Typically, not all pools are used in the available-space calculation. Some pools might be eliminated because of the consolidated status of the pool or its storage system. Other pools might be eliminated because they do not satisfy the requirements of the service class. The set of storage pools that are used to calculate the available capacity are also the candidates for provisioning by using the service class.

When you request storage volumes by using the Provision Storage wizard, you specify the capacity that is required for one or more volumes, and you specify a service class. You can also specify a capacity pool from which the volumes must be provisioned. Based on the volume size that is requested and if a capacity pool is specified, the candidates for provisioning are further refined to include only the pools that have enough available capacity and are in the specified capacity pool. From the remaining candidates for provisioning, IBM Spectrum Control creates a provisioning task that identifies the best location for the new volumes.

How available capacity for a block-storage service class is calculated

For each block-storage service class, IBM Spectrum Control calculates the available capacity for volumes of that service class. Only storage pools that are candidates for provisioning by using the service class are used to calculate the available capacity.

Identifying candidates for provisioning is a filtering process. For example, if the service class specifies that RAID 10 is required, then any storage pool that is not configured at RAID 10 is eliminated as a candidate for provisioning. IBM Spectrum Control filters the set of available storage resources against certain properties of the service class until only the storage resources that can satisfy all of the requirements remain. These remaining storage resources are the candidates for provisioning. Only certain properties of a service class are used to identify candidates for provisioning. More advanced properties contain configuration instructions, and are not used to identify candidates for provisioning.

The candidates for provisioning are identified by eliminating storage pools that cannot provide the service class, as follows:

- If a storage pool is a primordial pool or if it is formatted for count key data (CKD) volumes, it is not a candidate for provisioning.
- If a storage system has a condition of Error or Unreachable, none of its internal storage pools are candidates for provisioning. If a storage pool has a status of Error, it is not a candidate for provisioning.

Remember: *Status* is different from *condition*. Status is the status reported by a storage resource without considering the status of its internal resources. Condition is the combined status of the monitored, internal resources for the higher-level resource, and the status of the higher-level resource itself. The condition of a storage system is shown on the Storage Systems page and the condition for a pool is shown on the Pools page. The condition of a resource might not have the same value as the status, which is used to eliminate pools as candidates for provisioning.

Although the condition of a resource might not have the same value as its status, the condition is always at least as severe as the status. The condition reflects the most severe status of any internal resource or the status of the resource itself. If the condition of a resource is Normal, then its status is also Normal.

Tip: The Service Classes page in the GUI displays both the available capacity and the unavailable capacity for a service class. The Unavailable Capacity column shows the amount of storage that satisfies the requirements of the service class, but is unavailable because of the consolidated status of the storage system or its internal resources.

- If a service class allows provisioning only from certain capacity pools, any storage pool that is not in a specified capacity pool is eliminated as a candidate for provisioning.

Tip: You can see whether a service class restricts provisioning to one or more capacity pools from the Service Classes page. On the Service Classes page, show the Capacity Pools column, which is hidden by default.

- A storage pool must satisfy the requirements of every service class property in the following table to be a candidate for provisioning. Other properties of a service class are instructions for provisioning and do not affect whether the storage pool is a candidate for provisioning.

Table 1. Filtering candidates for provisioning based on service class properties

Service class property:	Candidates for provisioning:
Storage tier	If specified in the service class, storage pools that are assigned to any storage tier within the specified range are candidates for provisioning.
RAID level	If a RAID level is specified, only storage pools that are configured at the specified RAID level are candidates for provisioning. Exception: The IBM® XIV® Storage System uses a nontraditional approach to data redundancy and does not support any of conventional RAID levels. IBM Spectrum Control always considers XIV storage pools to be configured at RAID 10. Restriction: Storage pools that support multiple RAID levels are not candidates for provisioning when a service class specifies a RAID level. Storage pools that support multiple RAID levels are not candidates even when the specified RAID level is one of the RAID levels that are supported by the storage pool. Storage pools that support multiple RAID levels are only candidates for provisioning when the service class specifies that any RAID level is allowed.
Virtualization	If virtualization is required by the service class, only storage pools on IBM storage virtualizers are candidates for provisioning. The IBM storage virtualizers are SAN Volume Controller, Storwize® V7000, Storwize V7000 Unified, FlashSystem 9100, and FlashSystem V9000. If virtualization is not allowed by the service class, only storage pools that are not on IBM storage virtualizers are candidates for provisioning.
Encryption	If encryption is required by the service class, only storage pools on DS8000® storage systems that are encrypted and configured to use the encryption group that is specified in the service class are candidates for provisioning. If encryption is not allowed by the service class, only pools that are not encrypted are candidates for provisioning.
Thin provisioning	If thin provisioning is required by the service class, only storage pools that are configured for thin provisioning are candidates for provisioning. Thin provisioning is supported by the XIV, DS8000, and storage systems that run IBM Spectrum Virtualize. During provisioning, a thin-provisioned volume is created. If thin provisioning is not allowed by the service class, any storage pool that is not thin provisioned is a candidate for provisioning. In addition, any storage pool on DS8000 or a storage system that runs IBM Spectrum Virtualize is a candidate for provisioning, regardless of whether it is configured for thin provisioning. During provisioning, the volume that is created is not thin provisioned.
Compression	If compression is required by the service class, at least one I/O group of an IBM storage virtualizer must be enabled for compression. Only pools of the IBM storage virtualizer are candidates for provisioning.
Overallocation limit	If thin provisioning is required by the service class, IBM Spectrum Control identifies the storage pools that can thin provision volumes as candidates for provisioning. If an overallocation limit is specified, IBM Spectrum Control refines that list to include only the storage pools that have an overallocation percentage that does not exceed the overallocation limit. The overallocation percentage for a pool is determined by using the following measurements, as shown on the Pools page: <ul style="list-style-type: none">◦ For an XIV storage pool, the Soft Capacity divided by the Capacity.◦ For other storage system pools, the Provisioned Capacity.
Resource Tags	Resource tags further refine the candidates for provisioning. A service class can specify up to 3 resource tags. If resource tags are specified for the service class, only pools that have all the same tags are candidates for provisioning. If a pool is not tagged, any tags on the containing storage system also apply to the pool.

After the storage pools that can provide the service class are identified, IBM Spectrum Control calculates the amount of space that is available for provisioning new volumes of the service class. The calculated volume capacity is shown in the Available Capacity column on the Service Classes page.

The available-space calculation differs depending on whether the block-storage service class requires thin provisioning, as follows:

- If thin provisioning is not allowed, the available capacity is the sum of the following measurements, as shown on the Pools page:
 - For each XIV System pool, the Available Soft Capacity minus any Reserved Capacity
 - For other storage system pools, the Available Capacity minus any Reserved Capacity.
- If thin provisioning is required, the available capacity is the total of the following measurements, as shown on the Pools page, and calculations:
 - For each XIV System pool, the Available Soft Capacity minus any Reserved Capacity
 - For other storage system pools, the pool Capacity multiplied by the overallocation limit that is specified in the service class, minus the Provisioned Capacity. Any Reserved Capacity is subtracted from the result. For DS8000 storage pools, any space that is used by Track Space Efficient (TSE) volumes is subtracted

from the calculated available capacity.

How the recommended placement of storage volumes is determined

When you request one or more new volumes by using the Provision Storage wizard, the candidates for provisioning are further refined and a provisioning task is created which shows the recommended placement of the new volumes. The same filtering that was used to determine the available capacity for the service class is used, and is refined further as follows:

- A provisioning request specifies the set of storage pools from which the storage can be provisioned. This set can be all the storage pools that are known to IBM Spectrum Control, or can be limited to the storage pools in a particular capacity pool. Only the storage pools in the specified set are candidates for provisioning. This set might be more restrictive than the set used to calculate the available capacity for the service class.
- Any storage pool that cannot provide the requested volume capacity is eliminated as a candidate for provisioning.
- If virtualization and VDisk mirroring are specified by the service class, then a VDisk copy of the volume must be made in a second storage pool on the same IBM storage virtualizer. If the storage pools on the IBM storage virtualizer cannot provide the requested capacity for both the volume and its mirrored copy, the pools are eliminated as candidates for provisioning.
- If an overallocation limit is specified in the service class, only the storage pools that will not exceed the limit after the new volume or volumes are provisioned are candidates for provisioning.
Remember: Storage pools that have an overallocation percentage that does not exceed the overallocation limit, are included in the available-space calculation. However, if the overallocation percentage would exceed the overallocation limit after the requested volume space is included, the pools are not candidates for provisioning.

After the storage pools that can satisfy the provisioning request are identified, IBM Spectrum Control finds the best location for the storage. The best location for the storage is based on the unused volume capacity in the pool and performance data. Preference is first given to storage pools and systems that already contain volumes for the selected server or hypervisor. Preference is given to systems that have available performance data.

File storage: Calculating available capacity and determining the placement of shares

For each file-storage service class, IBM Spectrum® Control calculates the amount of available capacity for NAS file shares of that service class. When you request file shares of a particular service class, IBM Spectrum Control recommends the best location for the shares from the available capacity.

Discontinued support: Cloud configuration, provisioning, and optimization are no longer supported in IBM Spectrum Control. While these features might still work in this release, it's recommended that you use another tool for your provisioning and optimization needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

For each file-storage service class, IBM Spectrum Control calculates the amount of available capacity for NAS file shares of that service class. When you request file shares of a particular service class, IBM Spectrum Control recommends the best location for the shares from the available capacity.

The Service Classes page displays the available capacity for each file-storage service class. The available capacity is the amount of space that is available across all IBM® Storwize® V7000 Unified file systems that are known to IBM Spectrum Control and that can satisfy the requirements of the service class. The set of file storage resources that are used to calculate the available capacity are also the candidates for provisioning by using the service class.

When you request a file share by using the Provision Storage pages, you specify the capacity that is required for the share, and you specify a service class. You can also specify a capacity pool from which shares must be provisioned. Based on the requested size of the share and whether a capacity pool is specified, the candidates for provisioning are further refined to include only the file storage resources that have enough available capacity and are in the specified capacity pool. From the remaining candidates for provisioning, IBM Spectrum Control creates a provisioning task that identifies the best location for the new share.

How available capacity for a file-storage service class is calculated

For each file-storage service class, IBM Spectrum Control calculates the available capacity for file shares of the service class. Only the file storage resources that are candidates for provisioning by using the service class are used to calculate the available capacity.

Identifying candidates for provisioning is a filtering process. File systems that could be candidates for provisioning if shared storage is allowed are eliminated as candidates for provisioning when dedicated storage is required. IBM Spectrum Control filters the set of available storage resources against each attribute of the service class until only the storage resources that can satisfy all of the requirements remain. These remaining storage resources are the candidates for provisioning.

The candidates for provisioning are identified by eliminating storage resources that cannot provide the service class, as follows:

- Only IBM Storwize V7000 Unified systems are supported for provisioning file shares. No other storage system type is a candidate for provisioning file shares.
- If a storage system has a consolidated status of Error or Unreachable, none of its internal NSDs or file systems are included in the available-space calculation.
- If an NSD or file system has a consolidated status of Error, it is not included in the available-space calculation.
Tip: The status of file systems is not displayed on the GUI. View the status on the NSD on which a file system resides to determine the file system status.
- If the storage volume or NSD on which a file system resides has a consolidate status of Error, the file system is not included in the available-space calculation.
Remember: *Status* is different from *condition*. Status is the status reported by a storage resource without considering the status of its internal resources. Condition is the combined status of the monitored, internal resources for the higher-level resource, and the status of the higher-level resource itself. The condition of a storage system is shown on the Storage Systems page, the condition of a volume is shown on the Volumes page, and the condition of an NSD is shown on the storage system details page. The condition might not have the same value as the status, which is used to eliminate file storage resources as candidates for provisioning.
Although the condition of a resource might not have the same value as its status, the condition is always at least as severe as the status. The condition reflects the most severe status of any internal resource or the status of the resource itself. If the condition of a resource is Normal, then its status is also Normal.
Tip: The Service Classes page displays both the available capacity and the unavailable capacity for a service class. The Unavailable Capacity column shows the amount of storage that satisfies the requirements of the service class, but is unavailable because of the consolidated status of the storage system or its internal resources.
- If a service class allows provisioning only from certain capacity pools, any storage resource that is not in a specified capacity pool is eliminated as a candidate for provisioning.
Tip: You can see whether a service class restricts provisioning to one or more capacity pools from the Service Classes page. On the Service Classes page, show the Capacity Pools column, which is hidden by default.
- A file system or NSD must satisfy the requirements of every service class property in the following table to be a candidate for provisioning. Other properties of a service class are instructions for provisioning and do not affect the storage placement determination.

Table 1. Filtering candidates for provisioning based on service class properties

Service class attribute:	Candidates for provisioning:
Shared storage / Dedicated storage	If the service class specifies dedicated storage, the share can be created only on an unused NSD. File systems and other file storage resources are eliminated as candidates for provisioning.
Resource tags	Resource tags further refine the candidates for provisioning. A service class can specify up to 3 resource tags. If resource tags are specified for the service class, only file systems and NSDs that have all the same tags are candidates for provisioning. If a file system or NSD is not tagged, any tags on the containing storage system also apply to the internal resource.

After the file storage resources that can provide the service class are identified, IBM Spectrum Control calculates the amount of space that is available for providing new files shares of the service class.

The available-space calculation differs depending on whether the file-storage service class requires dedicated storage or allows shared storage, as follows:

- If the file-storage service class requires dedicated storage, the available capacity is the total available capacity on unused NSDs within each storage system. You can verify that an NSD is unused, and view its available capacity, from the details page of a storage system. To view information about the NSDs that are associated with a storage system, click Network Shared Disks. If the NSD is unused, the File Systems column shows 0. The Available Capacity column shows the amount of space on the NSD, which is the measurement that is used in the available-space calculation for the service class.
- If the file-storage service class allows shared storage, the file system in which the NAS share is provisioned can contain other NAS shares. In this case the available capacity is the total of the following measurements:
 - The available capacity on unused NSDs within each storage system.
 - The available capacity for each file system within each IBM Storwize V7000 Unified storage system. You can view the file system available capacity from the details page of a file storage system. To view information about the file systems that are in a storage system, click File Systems. The Available Capacity column shows the amount of available capacity on each file system, which is the measurement that is used in the available-capacity calculation for the service class.

How the recommended placement of file shares is determined

When you request a file share by using the Provision Storage pages, the candidates for provisioning are further refined and a provisioning task is created which shows the recommended placement of the new share. The same filtering that was used to determine the available capacity for the service class is used, and is refined further as follows:

- A provisioning request specifies the set of file storage resources from which the storage can be provisioned. This set can be all the storage resources that are known to IBM Spectrum Control, or can be limited to the storage resources in a particular capacity pool. Only the storage resources in the specified set are candidates for provisioning. This set might be more restrictive than the set used to calculate the available capacity for the service class.
- Any storage resource that cannot provide the requested capacity for the share is eliminated as a candidate for provisioning.

The shares are created on file systems or NSDs. After the file systems and NSDs that can satisfy the provisioning request are identified, IBM Spectrum Control identifies the best location for the storage. The best location for the storage is based on the available capacity on the file system or NSD.

Changing the default host definition for provisioned storage

Use the **setdscfg** command to change the default host definition for fibre-channel ports when provisioning storage from resources that run IBM Spectrum Virtualize.

Before you begin

You must have Administrator authority to use the **setdscfg** command.

Discontinued support: Cloud configuration, provisioning, and optimization are no longer supported in IBM Spectrum® Control. While these features might still work in this release, it's recommended that you use another tool for your provisioning and optimization needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

About this task

When you provision storage from a storage system that runs IBM Spectrum Virtualize, which does not have an existing host definition for the fibre-channel ports, IBM Spectrum Control creates a new host definition during the provisioning task. The new host definition can access only one I/O group on the source device that you specified when you created the provisioning task. To allow the new host definition to access any I/O group on the source device, use the management application for the source device or use the IBM Spectrum Control **setdscfg** command.

To change the host definition to allow access to any I/O groups on the source device:

Procedure

1. Start the IBM Spectrum Control CLI by issuing the **tpctool** command.
2. Issue the **setdscfg** command with the following values for the -property and -context parameters:
 - a. Specify *Configuration.RestrictNewHostsToIogroup* as the property value.
 - b. Specify *DiskManager* as the context value and specify false as the context parameter.

For example, to allow the new host definition to access any I/O groups on the source device of the provisioning task:

```
tpctool setdscfg -url localhost:9550 -user ***** -pwd *****
-property Configuration.RestrictNewHostsToIogroup -context DiskManager false
```

Results

The value of Configuration.RestrictNewHostsToIogroup is set to false in the IBM Spectrum Control database. This removes the default restriction on the new host definition and allows access to any I/O groups on the provisioning source device.

Tip: To verify that the host definition restriction is changed, enter the following command:

```
tpctool getdscfg -url localhost:9550 -user ***** -pwd *****  
-property Configuration.RestrictNewHostsToIogroup -context DiskManager
```

- [setdscfg](#)
- [getdscfg](#)

Provisioning storage with the IBM Spectrum Control GUI

You can provision volumes or shares to servers, hypervisors, and clusters in IBM Spectrum® Control.

Before you begin

Discontinued support: Provisioning is no longer supported in IBM Spectrum Control. While the feature might still work in this release, it's recommended that you use another tool for your provisioning needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#). The prerequisites for provisioning storage are as follows:

- You must have the required license. [Actions that are available based on role](#)
- You must have Administrator privileges or permission to use one or more of the service classes that are created for block-storage or file-service provisioning.
- You must add and probe block-storage or file-storage resources, or both.

The following restrictions apply to volume provisioning:

- If the service class that is associated with the provisioning request requires multipathing or if automatic zoning is enabled, the fabrics and switches must be managed by IBM Spectrum Control. If the fabric is not managed by IBM Spectrum Control, the fabric-related configuration options are ignored when the provisioning task is executed.
- If you provision volumes to physical servers and servers that are virtual machines, you must create separate provisioning tasks using the GUI.
- If you provision multiple servers with storage volumes, the servers must all run on the same operating system. If the servers are virtual machines, the hypervisors that manage the servers must all run on the same operating system.
- If the provisioning request involves assigning multiple volumes to a resource, the volumes are sourced from pools in the same storage system.

NAS file shares can be provisioned only from Storwize® V7000 Unified storage systems.

About this task

Specify the capacity that is required and the service class that you want to associate with the provisioning task. For shares, you must also specify at least one file access protocol. IBM Spectrum Control identifies the storage resources that can provide the storage capacity and that meet the criteria that are specified for the service class. From the set of storage resources that can provide the capacity and service class, IBM Spectrum Control identifies the best location for the storage and creates a provisioning task. Depending on the privileges that are associated with your role, you can save, execute, or schedule the provisioning task.

- [Provisioning volumes to servers](#)
You can provision volumes to one or more servers. The GUI guides you through the steps of requesting capacity and specifying requirements by using a service class.
- [Provisioning volumes to hypervisors](#)
You can provision volumes to one or more hypervisors. To provision volumes, the GUI guides you through the steps of requesting capacity and specifying requirements by using a service class.
- [Provisioning volumes to a server cluster](#)
You can assign volumes to a cluster of servers with the GUI.
- [Provisioning volumes to a hypervisor cluster](#)
You can assign volumes to a cluster of hypervisors.
- [Provisioning shares to servers](#)
You can provision a network-attached storage (NAS) file share to one or more servers. The GUI guides you through the steps of requesting capacity, specifying requirements by using a service class, and providing information about how to export the share.
- [Provisioning shares to hypervisors](#)
You can provision a network-attached storage (NAS) file share to one or more hypervisors. The GUI guides you through the steps of requesting capacity, specifying requirements by using a service class, and providing information about how to export the share.

You can assign a network-attached storage (NAS) file share to a server cluster using the GUI.
- [Provisioning shares to a hypervisor cluster](#)
You can assign a network-attached storage (NAS) file share to a hypervisor cluster.
- [Provisioning with zone control](#)
When you provision storage, you can set a zoning policy to enable automatic zoning. When automatic zoning is enabled, IBM Spectrum Control can create zones during storage provisioning to connect a server to a storage system.

Provisioning volumes to servers

You can provision volumes to one or more servers. The GUI guides you through the steps of requesting capacity and specifying requirements by using a service class.

About this task

You can provision volumes to one or more servers. If a server is a virtual machine, the storage is provisioned to the hypervisor that is managing the server.

Procedure

1. In the menu bar, go to Servers, > Servers..
Tip: Alternatively, you can go to Advanced Analytics, > Provisioning, and click Provision to Servers.
2. Select one or more servers, and then select Actions, > Provision Storage.
3. Follow the instructions to assign the storage volumes.

Results

The GUI enables you to create a provisioning task.

Provisioning volumes to hypervisors

You can provision volumes to one or more hypervisors. To provision volumes, the GUI guides you through the steps of requesting capacity and specifying requirements by using a service class.

About this task

You can provision volumes to one or more hypervisors.

Procedure

1. Servers, > Hypervisors
Tip: Alternatively, you can go to Advanced Analytics, > Provisioning, and click Provision to Hypervisors.
2. Select one or more hypervisors, and then click Actions, > Provision Storage.
3. Follow the instructions to assign the storage volumes.

Results

The GUI creates a provisioning task.

Provisioning volumes to a server cluster

You can assign volumes to a cluster of servers with the GUI.

About this task

If the cluster is on servers that are virtual machines, the storage is assigned to the hypervisors that manage the servers. The volumes are assigned to all of the nodes in the cluster.

Procedure

1. In the menu bar, go to Servers, > Servers, and click Clusters.
Tip: Alternatively, you can go to Advanced Analytics, > Provisioning, click Provision to Servers, and click Clusters.
2. Select a cluster, and then click Actions, > Provision Storage.
3. Follow the instructions to assign the storage volumes.

Results

The GUI enabled you to create a provisioning task.

Provisioning volumes to a hypervisor cluster

You can assign volumes to a cluster of hypervisors.

About this task

The volumes are assigned to all of the nodes in the hypervisor cluster.

Procedure

1. In the menu bar, go to Servers, > Hypervisors, and click Clusters.
Tip: Alternatively, you can go to Advanced Analytics, > Provisioning, click Provision to Hypervisors and click Clusters.
2. Select a cluster, and then click Actions, > Provision Storage.
3. Follow the instructions to assign the storage volumes.

Results

The GUI created a provisioning task.

Provisioning shares to servers

You can provision a network-attached storage (NAS) file share to one or more servers. The GUI guides you through the steps of requesting capacity, specifying requirements by using a service class, and providing information about how to export the share.

About this task

You can provision a NAS file share to one or more servers. The share is made available to the selected servers, but is not automatically mounted from the selected servers.

Procedure

1. In the menu bar, go to Servers, > Servers..
Tip: Alternatively, you can go to Advanced Analytics > Provisioning, and click Provision to Servers.
2. Select one or more servers, and then select Actions > Provision Storage.
3. Follow the instructions to assign the share.

Results

The GUI enabled you to create a provisioning task.

Provisioning shares to hypervisors

You can provision a network-attached storage (NAS) file share to one or more hypervisors. The GUI guides you through the steps of requesting capacity, specifying requirements by using a service class, and providing information about how to export the share.

About this task

You can provision a NAS file share to one or more hypervisors. The share is made available to the selected hypervisors, but is not automatically mounted from the selected hypervisors.

Procedure

1. In the menu bar, go to Servers > Hypervisors.
Tip: Alternatively, you can go to Advanced Analytics > Provisioning, and click Provision to Hypervisors.
2. Select one or more hypervisors, and then select Actions > Provision Storage.
3. Follow the instructions to assign the share.

Results

The GUI enabled you to create a provisioning task.

Provisioning shares to a server cluster

You can assign a network-attached storage (NAS) file share to a server cluster using the GUI.

About this task

You can provision a NAS file share to a server cluster. The share is made available to the servers in the cluster, but is not automatically mounted from the selected servers.

Procedure

To provision a NAS file share to a server cluster, follow these steps:

1. In the menu bar, go to Servers > Servers, and click Clusters.
Tip: Alternatively, you can go to Advanced Analytics > Provisioning, click Provision to Servers, and click Clusters.
2. Select a cluster, and then select Actions > Provision Storage.
3. Follow the instructions to assign the share.

Results

A provisioning task was created for a server cluster.

Provisioning shares to a hypervisor cluster

You can assign a network-attached storage (NAS) file share to a hypervisor cluster.

About this task

You can provision a NAS file share to a hypervisor cluster. The share is made available to the hypervisors in the cluster, but is not automatically mounted from the selected hypervisors.

Procedure

To provision a NAS file share to a hypervisor cluster, follow these steps:

1. In the menu bar, go to Servers, > Hypervisors, and click Clusters.
Tip: Alternatively, you can go to Advanced Analytics > Provisioning, click Provision to Hypervisors and click Clusters.
2. Select a cluster, and then select Actions > Provision Storage.
3. Follow the instructions to assign the share.

Results

A provisioning task was created for a hypervisor cluster.

Provisioning with zone control

When you provision storage, you can set a zoning policy to enable automatic zoning. When automatic zoning is enabled, IBM Spectrum® Control can create zones during storage provisioning to connect a server to a storage system.

About this task

Discontinued support: Provisioning is no longer supported in IBM Spectrum Control. While the feature might still work in this release, it's recommended that you use another tool for your provisioning needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#). When IBM Spectrum Control creates a provisioning task, it identifies the best location for the new storage that satisfies the requirements of the service class. If automatic zoning is enabled, then, during provisioning, existing zones are used if the server already has connectivity to the storage system. Otherwise, one or more zones are created between a host initiator port and a controller, node, or module port.

IBM Spectrum Control provides the support for zone control and management of Brocade switches and fabrics that are managed by using Brocade Network Advisor, and Cisco switches and fabrics.

The Cisco support includes:

- Standard Cisco zone control capabilities
- Cisco Enhanced Zoning features.

Procedure

To set or modify the zoning policy, complete the following steps:

1. In the menu bar, go to Advanced Analytics > Provisioning, and click Set Zoning Policy.
2. Enable or disable automatic zoning:
 - Enable automatic zoning to allow IBM Spectrum Control to create zones during storage provisioning. The naming convention for new zones is *host_storage-system_suffix-number*. When you enable automatic zoning, you can specify the following options:
 - Zone name prefix
If you specify a zone name prefix, all zones that are automatically created by IBM Spectrum Control are prefixed with a string you specify. This prefix can help you identify which zones were automatically created, and which were created manually.
 - Make changes to the active zone set
Specify whether changes are made to the active zone set or to a new inactive zone set. If this check box is selected, one or more new zones are added to the active zone set. If the check box is cleared, a new inactive zone set is created and the new zone or zones are added to this new inactive zone set. The new inactive zone set will contain only the new zones.
 - Disable automatic zoning if you want IBM Spectrum Control to use only existing zones. If you disable automatic zoning, no changes will be made to the zoning for the fabric.
3. Click Save.

Optimizing storage tiering

To optimize the placement of volumes on storage tiers, analyze the tiering of volumes in your storage environment.

Before you begin

Discontinued support: Storage optimization is no longer supported in IBM Spectrum® Control. While the feature might still work in this release, it's recommended that you use another tool for your optimization and tiering needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#). Before you analyze tiering, complete the following tasks:

- Probe the storage virtualizers
- Collect performance data
- Set the tier level of the storage pools that you analyze and that you select as target pools

About this task

Analyzing tiering		
	1 Collect data Probe the storage virtualizers to collect information about the logical devices, such as the volumes and virtual disks, that are associated with the storage virtualizer.	
	2 Collect performance data Collect performance data to gauge the average workload activity of the volumes that you want to analyze.	
	3 Assign tier levels Assign tier levels to the pools that contain the volumes that you want to analyze and to the target pools.	
	4 Choose the source storage resources Select the resources that you want to analyze:  Servers  Hypervisors  Storage virtualizers  Storage pools  Volumes	
	5 Choose the target pools You select the target pools to place volumes that meet the tiering criteria that you specify.	
	6 Choose the performance data Choose the analysis period, the collection days, and time period that you want to use to analyze the tiering of the volumes.	
	7 Specify the tiering criteria Specify the tiering criteria and the pool saturation rates for the target pools.	

The purpose of analyzing tiering is to tier volumes based on the I/O rate or I/O density thresholds that you set. Depending on the conditions that are set, recommendations are generated.

Storage costs can be reduced, for example, by moving volumes with low workloads from higher and more expensive tiers to lower and less expensive tiers. Storage performance can be improved and used more efficiently by moving volumes with heavy workloads to the tiers that meet the workload requirements of the volumes. When you implement the recommendations, you ensure that the volumes are placed on the tiers that best match the workload requirements of the volumes.

You can optimize the placement of volumes on storage systems that run IBM Spectrum Virtualize.

Restriction: You cannot optimize the placement of volumes in data reduction pools.

Learn more: For information about the components that can be used with IBM Spectrum Control 5.2 (or later), see [IBM Spectrum Control interoperability matrix](#). Volumes can be moved to tiered storage pools on the same storage virtualizer, but volumes cannot be moved from one storage virtualizer pool to another storage virtualizer pool.

Optimizing volumes with service classes: Recommendations are not generated to move volumes that are assigned a service class to a destination pool that does not meet the requirements of the service class.

- [Investigating the capacity of tiered storage](#)

Investigating the capacity of tiered storage

Review the capacity that is assigned to tiered storage to see whether your system needs more storage space or whether you can re-tier storage to satisfy the capacity demands for tiered storage. View the space usage trends at the current growth rate for each tier and the projected depletion date of storage space.

Before you begin

Add the pools in your storage environment to the tiers that best meet the performance requirements of your storage data.

About this task

You can view the total capacity by tier and the capacity that is consumed by the pools that are not tiered. You can also view information about recent storage growth for each tier, including the weekly and average storage growth, and the date when the storage space of the tier is expected to run out.

Procedure

1. Click Groups > Tiers.
2. Review the information that is shown about the distribution of capacity across each tier.
3. Optional: To place pools on lower or higher tiers, complete these steps:
 - a. Click the number in the Pools column.
 - b. Select the pools that you want to re-tier.
 - c. Right-click the pools, click Set Tier, and click the tier level.
4. Optional: To assign untiered pools to tiers, click Untiered Pools.

Example

If the storage space for tier 1 pools is running out, you can down-tier the volumes in the tier-1 pools to lower tiers. Alternatively, you can add more storage to meet the requirements of your tier-1 storage data.

Setting the tier level of storage pools

To analyze tiering and to balance pools, you must set the tier level of storage pools.

About this task

Before you analyze tiering or balance pools, you must set the tier level of pools.

To analyze tiering, you must set the tier level of the source pools and the target pools. The source pools are the pools that you select for analysis. The target pools are the pools that are used to relocate volumes to lower or higher tiers of storage.

Tip: You can also set or modify the tier level of pools on the General tab of the View Properties page for the storage pool.

Child pools have the same tier level as the parent pool. So if you change the tier level of the parent pool or of the child pool, all of the pools in the parent-child relationship are set to the same tier level.

You can assign tier levels to storage systems that are not storage virtualizers. However, you cannot balance the pools or analyze the tiering of pools other than storage virtualizer pools.

Procedure

1. From the Storage menu, click Pools.
2. On the Pools page, select one or more storage pools.
3. Click Set \geq Tier, and then select a tier level.
To remove the tier level, click None.

Results

The tier level that you selected for the storage pools is shown in the Tier column.

Related tasks

- [Investigating the capacity of tiered storage](#)

Renaming tiers

Change the default names of the tiers so that they match the names of the tiers in your storage environment.

Procedure

1. From the Groups menu, click Tiers.
2. On the Tiers page, click Rename Tiers.
3. On the Rename Tiers page, click Edit.
4. Click the names of the tiers that you want to change, type the new names, and then click Save.

Related tasks

Analyzing tiering by servers

Optimize tiering by analyzing the tiering of volumes on storage virtualizers that are connected to servers.

Before you begin

The servers that you select must be connected to one or more storage virtualizers.

Procedure

1. From the Servers menu, click Servers.
2. Right-click one or more servers, and then click Analyze Tiering.
Alternatively, you can click Actions \geq Analyze Tiering.

Analyzing tiering by hypervisors

Optimize tiering by analyzing the tiering of volumes on storage virtualizers that are connected to hypervisors.

Before you begin

The hypervisors that you select must be connected to one or more storage virtualizers.

Procedure

1. From the Servers menu, click Hypervisors.
2. Right-click one or more hypervisors, and then click Analyze Tiering.
Alternatively, you can click Actions_>Analyze Tiering.

Analyzing tiering by storage virtualizers

Optimize tiering by analyzing the tiering of volumes on storage virtualizers.

Procedure

1. From the Storage menu, click Storage Systems.
2. Right-click one or more storage virtualizers, and then click Analyze Tiering.
Alternatively, you can click Actions_>Analyze Tiering.

Related tasks

- [Investigating the capacity of tiered storage](#)

Analyzing tiering by storage pools

Optimize tiering by analyzing the tiering of volumes in storage pools.

Procedure

1. From the Storage_>Pools menu, click Pools.
2. Right-click one or more storage pools, and then click Analyze Tiering.
Alternatively, you can click Actions_>Analyze Tiering.

Analyzing tiering by volumes

Optimize tiering by analyzing the tiering of volumes on storage virtualizers.

Procedure

1. From the Storage menu, click Volumes.
2. Right-click one or more volumes, and then click Analyze Tiering.
Alternatively, you can click Actions_>Analyze Tiering.

Related tasks

- [Investigating the capacity of tiered storage](#)

Tiering volumes by I/O density and I/O rate

Set thresholds for tiering volumes by I/O rate or I/O density. To gain better optimization results, you can also customize the analysis of the workload activity of the pools.

Procedure

1. Select the resources that you want to analyze.
The source storage pools that are related to the resources that you selected are analyzed to determine whether they meet the workload requirements of the volumes. If the workload requirements of the volume in its current tier are not met, the volume is a candidate for relocation.

2. Select the target storage pools.
3. Include or exclude volumes in mirrored volume relationships from the analysis.
Mirrored volumes: If you want to optimize mirrored volumes, select one or more target pools that do not contain either the primary volume or the secondary volume. Primary volumes and secondary volumes cannot be placed in the same destination pool.
4. Select the period that you want to use to analyze the performance data.
You can choose the number of days, days of the week, and hours of the day for the analysis to occur.
5. Specify whether volumes that are in the same source storage pool and that are assigned to the same server or hypervisor must be placed in the same destination storage pool.
Recommendations are only generated to move one or more of the related volumes when all of the related volumes can be placed in the same destination storage pool.
Multiple host connections to the same hypervisor or server: If the volumes in the source pool that are assigned to the same hypervisor or server are assigned to different host connections, the collocation of the volumes is affected. In such cases, if volumes require optimization, the volumes that are assigned to the same host connection are kept together. To view information about the host connection for the volume, right-click the volume, select View Details, and then click the Host Connections tab.
6. Specify the type of threshold and the threshold values for moving volumes to higher and lower tiers.
7. Click Analyze.

Results

When you complete entering the information to analyze the tiering of the volumes, recommendations for tiering are shown on the Tiering Analysis page. You can create a schedule to run the analysis that is based on the analysis criteria that you entered.

Related tasks

- [Investigating the capacity of tiered storage](#)

Modifying the criteria for analyzing tiering

When a task is created after you run the tiering analysis, you can modify the criteria for tiering the volumes.

Before you begin

You must run the tiering analysis to create a tiering analysis task.

About this task

The criteria that you modify are used to analyze the source volumes and target volumes that were selected when you created the tiering analysis.

Procedure

1. From the Home menu, click Tasks.
2. Right-click a tiering analysis task, and click Edit.
3. Modify the tiering thresholds, and then click Analyze.

Results

The source volumes are analyzed to determine whether one or more of the volumes require re-tiering based on the criteria that you specified. If one or more of the volumes require re-tiering, recommendations are generated to move the volumes to the destination pools that meet the criteria that you specified.

Optimizing storage pools

Analyze the activity of pools and resolve performance hot spots by redistributing volumes across each storage tier.

Before you begin

Discontinued support: Storage optimization is no longer supported in IBM Spectrum® Control. While the feature might still work in this release, it's recommended that you use another tool for your optimization needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

Before you balance pools, complete the following tasks:

- Probe the storage virtualizer. You must probe the storage virtualizer to collect information about the logical devices, such as volumes and virtual disks, that are associated with the storage virtualizer.
- Collect performance data. To gauge the average activity level of the volumes and pools, you must collect sufficient performance data for the storage virtualizer.
- Assign a tier level to the pools that you want to balance.

About this task

You can balance the workload of volumes in pools on the same tier on storage systems that run IBM Spectrum Virtualize.

Restriction: You cannot balance the workload of volumes in data reduction pools.

Learn more: For information about the components that can be used with IBM Spectrum Control 5.2 (or later), see [IBM Spectrum Control interoperability matrix](#).

To balance pools, you must select two or more pools on the same tier level and on the same storage virtualizer. For example, you select three tier 1 pools, and four tier 3 pools. The pools on tier 1 are analyzed and balanced, and the pools on tier 3 are analyzed and balanced.

Optimizing volumes with service classes: Recommendations are not generated to move volumes that are assigned a service class to a destination pool that does not meet the requirements of the service class.

- **Balancing pools**

You balance pools to distribute the workload of volumes across pools on the same tier and on the same storage virtualizer. To improve the performance of the pools, recommendations are generated to move volumes to other pools on the same tier and on the same storage virtualizer.

- **Modifying the criteria for balancing pools**

When a task is created after you run the analysis for balancing pools, you can modify the criteria that determine which pools are balanced.

- **Criteria for identifying the pools that require balancing**

To identify the pools that require balancing, performance data is collected to determine the activity of pools on the same tier. The performance capability of pools is preserved by setting an activity limit for each tier of storage.

Related information

- [Setting the tier level of storage pools](#)

Balancing pools

You balance pools to distribute the workload of volumes across pools on the same tier and on the same storage virtualizer. To improve the performance of the pools, recommendations are generated to move volumes to other pools on the same tier and on the same storage virtualizer.

Before you begin

Discontinued support: Cloud configuration, provisioning, and optimization are no longer supported in IBM Spectrum® Control. While these features might still work in this release, it's recommended that you use another tool for your provisioning and optimization needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

Procedure

1. From the Storage menu, click Pools.
2. Right-click two or more pools on the same tier level and on the same storage virtualizer, and then click Balance Pools.
Tip: If you want to analyze pools that contain volumes in mirrored volume relationships, select one or more pools that do not contain either the primary volume or the secondary volume. The primary volume and the secondary volume cannot be placed in the same destination pool.
3. Choose whether to analyze volumes in mirrored volume relationships.
These options are only available if you select one or more volumes with mirrored volumes.
4. Select the period that you want to use to analyze the performance data.
5. Specify the placement of optimized volumes in capacity pools.
These options are only available if you select one or more volumes in capacity pools.
6. Specify whether volumes that are in the same source storage pool and that are assigned to the same server or hypervisor must be placed in the same destination storage pool.
7. Click Analyze.

Results

When you finish entering the information for balancing the pools, a task is created that shows the recommendations on the Balance Analysis page. You can implement the recommended changes, or you can create a schedule to implement the changes later.

Analyzing volumes with service classes: Recommendations are not generated to move volumes that are assigned a service class unless the destination pool can meet the requirements of the service class.

Modifying the criteria for balancing pools

When a task is created after you run the analysis for balancing pools, you can modify the criteria that determine which pools are balanced.

Before you begin

To create a balance analysis task, you must run the analysis for balancing the pools.

About this task

The criteria that you modify are used to analyze the storage pools that you selected when you entered the criteria for balancing the pools.

Discontinued support: Cloud configuration, provisioning, and optimization are no longer supported in IBM Spectrum® Control. While these features might still work in this release, it's recommended that you use another tool for your provisioning and optimization needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

Procedure

1. From the Home menu, click Tasks.
2. Right-click a balance analysis task, and click Edit.

3. Make your changes, and then click Analyze.

Results

Based on the criteria that you specified, the pools are analyzed to determine whether the pools require balancing. If one or more pools require balancing, recommendations are generated to redistribute the volumes to pools on the same tier of storage.

Criteria for identifying the pools that require balancing

To identify the pools that require balancing, performance data is collected to determine the activity of pools on the same tier. The performance capability of pools is preserved by setting an activity limit for each tier of storage.

Discontinued support: Cloud configuration, provisioning, and optimization are no longer supported in IBM Spectrum® Control. While these features might still work in this release, it's recommended that you use another tool for your provisioning and optimization needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

To determine the activity of pools on the same tier and on the same back-end storage system, the current activity level of the pool is calculated. On the Pools page, the activity level of the pool is shown in the Activity column.

The following formulas are used to calculate the activity level of pools.

Table 1. Formulas for calculating the activity level of pools

Value calculated	Formula that is used in the calculation
Activity level of the pool	$[\text{Read I/O Rate} \times (1 - \text{Read I/O Cache Hit \%}) + \text{Write I/O Rate}] \div \text{Total Pool Capacity}$
Activity level of the pool on XIV® systems	$(\text{Total I/O Rate} \div \text{Total Capacity})$

Reclaiming storage

Use the recommendations to reclaim capacity before you plan new capacity purchases.

Before you begin

To determine which volumes can be reclaimed, capacity and performance data must be available for the reclamation analysis. To run the reclamation analysis, capacity data is collected for the previous day, and a daily aggregation of the performance data is collected for the previous 14 days.

Tip: Depending on the I/O activity of the volumes in your storage environment, you can shorten or lengthen the default period of 14 days.

Storage systems that support reclamation: To find out, go to [IBM Spectrum Control interoperability matrix](#), and then click the release number in the Storage column.

About this task

Got an alert that your storage system is running out of capacity? Or, did you click Storage > Pools, had a look at the values in the Zero Capacity column and saw that you were running out of capacity?

Instead of purchasing more capacity, click Advanced Analytics > Reclamation to see how much capacity you can reclaim.

The reclamation analysis is run daily and if sufficient data is collected recommendations are generated to reclaim the volumes that meet either one of the following criteria:

- The volume isn't assigned to a server.
- I/O activity was not detected in the data that was collected for the volume.

For example, the reclamation analysis is run, and it is determined that a volume isn't assigned to a server. The volume is identified as reclaimable even if I/O activity is detected for the volume. Alternatively, the reclamation analysis is run, and no I/O activity is detected for the volume. The volume is identified as reclaimable even if the volume is assigned to a server.

The reclamation analysis also detects if volumes are replica volumes, VDisk mirrored volumes, or FlashCopy® volumes. The same criteria are used to identify whether the volumes are reclaimable, but the process varies depending on the type of copy volume:

Replica volumes

The source volumes of volumes with replicas, such as volumes that use Metro Mirror or Global Mirror copy services, are analyzed to determine whether the volumes are reclaimable.

VDisk mirrored volumes

Both copies of the VDisk mirrored volume are analyzed to determine whether the volumes are reclaimable.

FlashCopy volumes

The target volumes of volumes in FlashCopy relationships are analyzed if the source volumes are identified as reclaimable.

After the analysis is run, you see the total capacity that can be reclaimed, which is broken down by tier, and by volume. (The reclaimable capacity for volumes in storage systems that use data reduction technologies isn't shown. See the restrictions below.) In the table, you get a list of the volumes, the volume's capacity, and the information that you need to decide whether you want to decommission the volumes.

Tip: See volumes that are identified as reclaimable, such as volumes that are used to back up data or volumes that you recently assigned to a new application? If you don't want to include these volumes in the reclamation analysis, right-click the volumes and click Exclude from Analysis.

Before you reclaim space:

It's a good practice to verify that the identified volumes are available for reclamation. Before you delete or reclaim space that was identified by IBM® Storage Insights, keep in mind the following additional considerations:

- For volumes on IBM Spectrum Accelerate and CKD volumes on DS8000®, the volumes are identified as reclaimable based on I/O activity, because information about the assignment of volumes to servers is not available.
- For non-IBM storage systems, volumes are identified as reclaimable based on I/O activity because information about their existing server assignments, replication relationships, and snapshot targets might not be available for the storage system. Check with your storage administrators to ensure that the identified volumes are available for reclamation and are not part of these other configurations.
- Volumes in storage systems that use data reduction technologies are identified as reclaimable, but the actual physical capacity of the volumes can't be determined. For example, when data is deduplicated, multiple volumes can share identical blocks of data so we don't know the actual capacity of each volume. Because we can't determine the capacity of the individual volumes, the total reclaimable capacity for each volume is displayed as zero. This applies to:
 - Volumes in IBM storage systems that support data reduction pools or volumes in storage systems that run IBM Spectrum Virtualize.
 - Volumes in IBM FlashSystem® A9000 storage systems.

Private volumes in Dell EMC storage systems are excluded from the reclamation analysis.

- **[Viewing storage reclamation](#)**
Use the storage reclamation analysis to see information about the reclaimable capacity in your data center. You can see the savings that can be made by reclaiming capacity for tiered and non-tiered storage and view a list of the reclaimable volumes.
- **[Viewing storage reclamation by storage system](#)**
Use the reclamation view of storage systems for detailed information about the reclaimable capacity in your data center. You can see the savings that can be made by reclaiming capacity for tiered and non-tiered storage and view information about the storage systems that contain the reclaimable volumes.
- **[Excluding volumes from reclamation analysis](#)**
You can select volumes to not include them in the analysis for reclamation recommendations. The volumes are excluded from the reclamation charts.

Viewing storage reclamation

Use the storage reclamation analysis to see information about the reclaimable capacity in your data center. You can see the savings that can be made by reclaiming capacity for tiered and non-tiered storage and view a list of the reclaimable volumes.

Before you begin

Before you view recommendations for reclaiming storage, complete the following tasks:

- Add the storage systems for monitoring and schedule a storage systems probe.
- If your storage environment is configured for storage tiers, ensure that the amount of available capacity on tier one is minimal.

By default, the period for analyzing performance data, which is used for generating reclamation recommendations, is set to 14 days. For a more thorough analysis, you can change this period.

About this task

View information about volumes that are analyzed and recommended for reclamation.

Procedure

1. From the Advanced Analytics menu, click Reclamation.
2. On the View by Reclaimable Capacity page, view the charts and tables for information about reclaimable storage space, volumes that are recommended for reclamation, and volumes that are excluded from analysis.

Results

On the reclamation donut chart, you can view the amount of storage space that is used and the amount of storage space that can be reclaimed. You can also see an estimate of the storage space that can be saved when the volumes that are listed in the table are reclaimed.

On the reclamation by tier bar charts, view the amount of storage space that can be reclaimed on each tier of storage that is defined in your data center.

On the Recommendations tab, view the volumes that are identified as potential candidates for reclamation.

On the Excluded tab, view the volumes that are excluded from the analysis for reclamation recommendations.

Related tasks

- [Modifying the period for analyzing performance data](#)

Viewing storage reclamation by storage system

Use the reclamation view of storage systems for detailed information about the reclaimable capacity in your data center. You can see the savings that can be made by reclaiming capacity for tiered and non-tiered storage and view information about the storage systems that contain the reclaimable volumes.

Before you begin

Before you view recommendations for reclaiming storage, complete the following tasks:

- Add the storage systems for monitoring and schedule a storage systems probe.
- If your storage environment is configured for storage tiers, ensure that the amount of unused capacity on tier one is minimal.

By default, the period for analyzing performance data, which is used for generating reclamation recommendations, is set to 14 days. For a more thorough analysis, you can change this period.

About this task

View reclamation information about storage systems that contain volumes that are analyzed and recommended for reclamation.

Procedure

1. From the Advanced Analytics menu, click Reclamation.
2. On the View by Storage Systems page, view the charts and table for information about reclaimable storage space and for information about the storage systems that contain the reclaimable volumes.

Results

On the reclamation donut chart, you can view the amount of capacity that can be reclaimed and the amount of capacity that can't be reclaimed. If you defined storage tiers, you can view the amount of storage that can be saved for each tier. You can also see an estimate of the storage space that can be saved when the volumes of the storage systems that are listed in the table are reclaimed.

On the reclamation bar chart, view the amount of storage space that can be reclaimed on each storage system in your data center.

In the table, view space, capacity, and reclamation information about each storage system.

Excluding volumes from reclamation analysis

You can select volumes to not include them in the analysis for reclamation recommendations. The volumes are excluded from the reclamation charts.

About this task

On the View by Reclaimable Capacity page, you can select a volume or multiple volumes for exclusion from the analysis for reclamation recommendations.

Procedure

1. From the Advanced Analytics menu, click Reclamation.
2. On the View by Reclaimable Capacity page, to exclude a volume from the analysis, right-click the volume on the Recommendations table, and select Exclude from Analysis.

Results

The volume is removed from the Recommendations table and added to the Excluded table, and the charts are refreshed.

Tip: To include a volume in the analysis, on the Excluded table, right-click the volume and select Include in Analysis. The volume is removed from the Excluded table and added to the Recommendations table, and the charts are refreshed.

Transforming and migrating volumes

You can transform fully allocated volumes to compressed or thin-provisioned volumes, or transform compressed or thin-provisioned volumes to fully allocated volumes. You can move volumes to other pools or to pools that are enabled for Easy Tier®.

Before you begin

Discontinued support: Storage optimization is no longer supported in IBM Spectrum® Control. While this feature might still work in this release, it's recommended that you use another tool for your volume transformation needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#). Before you transform storage, you must probe the storage virtualizers. The probe collects information about the logical devices, such as volumes and virtual disks, that are associated with the storage virtualizer.

About this task

You can convert or move volumes in pools on storage systems that run IBM Spectrum Virtualize.

For volumes in mirrored volume relationships, you can convert the primary volume, the secondary volume, or both volumes.

Restrictions: The restrictions for converting or moving volumes are as follows:

- You cannot convert or move volumes in data reduction pools.
- To move volumes, the destination pool must be on the same storage virtualizer. You cannot move a volume from a pool on one storage virtualizer to a pool on another storage virtualizer.
- To convert or move volumes, image mode volumes must be converted to managed mode volumes.
- To convert fully allocated volumes to compressed volumes, you must have the IBM® Real-time Compression license.

Procedure

1. In the menu bar in the web-based GUI, go to Storage > Volumes.
2. Click one or more storage volumes, and then select Transform Storage from the context-sensitive menu.
Alternatively, you can click Actions > Transform Storage.

Results

When you complete entering criteria for transforming storage, the Transform Plan page is opened. A task is created which you can run to implement the recommendations.

Related tasks

- [Modifying the period for analyzing performance data](#)

Modifying the period for analyzing performance data

To change the default period for analyzing performance data in storage virtualizer pools, issue the **setdscfg** command. You can extend or shorten the default period for a more accurate analysis.

Before you begin

You must have Administrator authority to use the **setdscfg** command.

About this task

By default, the period for analyzing performance data is set to 14 days. When you change the number of days, the period for analyzing performance data is modified for the advanced analytics about storage, that is, tiering, balancing, transforming, and reclamation.

When you transform storage, the performance data that is collected about the pools on storage virtualizers is analyzed. The period that is set for analyzing performance data is used to calculate the average workload activity of the volumes that are selected for analysis. To provide a more accurate analysis of the workload activity of the volumes in your storage environment, you can extend or shorten the period.

For reclamation, the performance data that is collected for the analysis period about all block storage pools is analyzed, regardless of whether the storage is virtualized.

To change the analysis period, complete the following steps:

Procedure

1. To start the IBM Spectrum® Control CLI, issue the **tpctool** command.
2. Issue the **setdscfg** command, and then set the following values by using the **-property** and the **-context** parameters:
 - a. Specify *tiering_pm_days* as the property value.
 - b. Specify *tiering* as the context value, and then specify the number of days for the analysis period.

For example, to change the analysis period from the default value of 14 days to 28 days, issue the following command:

```
tpctool setdscfg -url localhost:9550 -user ***** -pwd *****  
-property tiering_pm_days -context tiering 28
```

Results

The default value is changed to the number of days that you specified, for example 28.

Tip: To verify that the analysis period is changed, you enter the following command:

```
tpctool getdscfg -url localhost:9550 -user ***** -pwd ***** -context tiering
```

- [setdscfg command](#)
- [getdscfg command](#)

Modifying the properties of resources

Add or change the properties for individual resources or for multiple resources. You can use the properties to filter or sort the resources in the GUI or in an external application if the data is shared or exported.

Before you begin

To add or modify the properties of resources, you must have Administrator privileges.

About this task

For Servers, storage systems, hypervisors, switches, and fabrics, you can modify the properties of a single resource or multiple resources. You can modify the properties of a single pool, but not the properties of multiple pools.

Modifying the properties of multiple resources

1. From the menu, click the type of resource that you want to edit. For example, if you want to edit the properties for servers, click **Resources > Servers**.
2. To select the resources, click Ctrl + click or Shift + click.
3. Right-click the selected resources and click **View Properties**.
The properties can have the following values:
 - If the property is blank, it means that the values were never assigned or the resources that were selected have different values assigned to that property. For example, the selected servers have different locations.
 - If the selected resources have the same value for a property, the value is shown.
4. In the Properties notebook, click **Edit**.
5. Modify the properties and click **Save**.

Modifying the properties of a single resource

1. From the menu, click the type of resource that you want to edit. For example, if you want to edit the properties for servers, click **Resources > Servers**.
 2. Right-click the resource that you want to modify and click **View Properties**.
 3. In the Properties notebook, click **Edit**.
 4. Modify the properties and click **Save**.
- **Properties of resources that can be modified**
You can modify the properties, such as the name or location, of the resources that are monitored by IBM Spectrum Control.

Properties of resources that can be modified

You can modify the properties, such as the name or location, of the resources that are monitored by IBM Spectrum® Control.

The following table lists the properties that you can modify for each type of resource:

Resource	Properties that can be modified
Storage systems	<ul style="list-style-type: none">• Name (label)• Location• Custom tags (3)
Pools	<ul style="list-style-type: none">• Tier• Back-end storage system type• Back-end storage RAID level• Back-end storage disk type• Back-end storage disks <p>Tip: You can edit the back-end values if the back-end storage system for the related storage virtualizer was not probed and the values for the pool are unknown. If you manually enter values for these properties, IBM Spectrum Control uses the values to help calculate the approximate read I/O capability of the pool.</p>
Servers	<p>Servers with Storage Resource agents</p> <ul style="list-style-type: none">• Location• Custom tags (3)• Agent trace• Trace level• Number of trace files• Trace file size• Run scripts on agent <p>Servers without Storage Resource agents (agentless)</p> <p>You can modify the following properties for agentless servers:</p> <ul style="list-style-type: none">• Name (label)• OS type• IP address• Location• Custom tags (3)
Hypervisors	<ul style="list-style-type: none">• Location• Custom tags (3)
Switches	<ul style="list-style-type: none">• Name (label)• Location• Custom tags (3)

Resource	Properties that can be modified
Fabrics	<ul style="list-style-type: none"> Name (label) Location Custom tags (3)

Opening the management GUI for a resource

Resources such as storage systems and switches can have their own management GUIs or element managers. In IBM Spectrum® Control, you can open the start page in these GUIs from resource list pages, such as the Storage Systems page and Switches page.

About this task

The action for opening a management GUI is available for storage systems and switches under the following conditions:

- The resource is monitored by IBM Spectrum Control.
- The resource has a management GUI that is web-based.

Procedure

- In the menu bar in the GUI, go to a type of top-level resource.
For example, if you want open the GUI for a block storage system, go to Storage > Block Storage Systems. If you want open the GUI for a switch, go to Network > Switches.
- Right-click the resource and select the action to open the GUI. For storage systems, select Launch Storage System GUI. For a switch, select Open Switch GUI.
The start page for the management GUI is opened in a separate web browser window.

Opening the DS Storage Manager GUI for a DS8000

About this task

If the firmware level for a DS8000® is earlier than R6.2, you must complete extra configuration steps before you can open its management GUI. To determine the firmware version of a DS8000 and enable the ability to open its management GUI, complete the following steps:

Procedure

- Start IBM Spectrum Control.
- In the menu bar, go to Storage > Block Storage Systems.
- Right-click the DS8000 and select View Properties.
- Check the version in the Firmware field. If the firmware version is earlier than R6.2, continue to the next step. If the version is R6.2 or later, you do not need to complete this procedure.
- Download and start the PuTTY utility. PuTTY is a free implementation of Telnet and SSH for Windows and UNIX. You can download PuTTY from <http://www.chiark.greenend.org.uk/~sgtatham/putty/download.html>.
- On the Session page in the PuTTY tool, complete the following actions:
 - In the Host Name (or IP address field), enter the IP address of the Hardware Management Console (HMC) for the DS8000. You can determine this IP address by viewing the properties of the DS8000 in the IBM Spectrum Control GUI.
 - Select SSH for a Connection type.
 - Click Open.
- Enter the user name and password for logging in to the HMC.
- Run the following command: `touch /opt/esshmc/data/config/ntvbrsen`
- In the GUI, right-click the DS8000 and select Launch Storage System GUI.

Exporting information to a file

You can save information about resources, tasks, or alerts to a PDF, CSV, or HTML file. Information that you can export from the GUI includes all the values that are being shown in the columns for a list of resources, tasks, or alerts.

Before you begin

The information that you export to a file is organized according to the sorting, filtering, and column order that is defined for a list. Before you export information, complete the following tasks to configure a list:

- Change the order of columns in the list as you want them to appear in the generated file.
- Hide columns in the list that you do not want to include in the generated file. Information in hidden columns is not exported.
- Sort the rows in the list as you want them to appear in the generated file. Each list in the GUI has a column or set of columns that determine the order of its rows.
- Filter the list to show only the resources, tasks, or alerts that you want to export. Use filtering to limit the rows that are shown in a list based on value in a specific column or set of default columns.

About this task

You can export information that is shown on the following pages:

Resource list and resource details pages

You can export information about the top-level resources, internal resources, or related resources that are shown on resource list pages and resource details pages. For top-level resources, you can also export information about related tasks or alerts. For example, you can export information about monitored switches on the Switches page. When you select the export action, the generated file includes the column values for each monitored switch in the list. In the Alerts tab on the Switches page, you can export information about all the alerts that are related to switches.

Alerts page

On the Home > Alerts page, you can export information about all the alerts that were detected for monitored resources. Information that you can export includes all the values that are being shown in the columns for the list of alerts.

Tasks page

On the Home > Tasks page, you can export information about all the tasks that are used to optimize resources and provision storage. Information that you can export includes all the values that are being shown in the columns for the list of tasks.

Procedure

1. In the GUI, go to a list of resources, tasks, or alerts for which you want to export information.
2. Right click any row in the table and select Export > `<file_format>`, where `<file_format>` represents the format that you want to use for a file. The following formats are available:

CSV (comma-separated values)

A CSV file is a file that contains comma-delimited values and can be viewed with a text editor or imported into a spreadsheet application. The information in a CSV file has the following format:

```
"Column_name", "Column_name", "Column_name", "Column_name", "Column_name", "Column_name"
"data", "data", "data", "data", "data", "data"
```

where `Column_name` represents the name of a column in a table and `data` represents the data that is associated with a column.

PDF

You can view a PDF file with Acrobat reader. The information that you export to a PDF file is formatted into a table.

Tip: When you export a table of data that contains many columns, the rows in that table might span multiple pages in the resulting PDF. For example, if a table contains 20 columns, then the row for a specific resource might be shown on more than one page (10 columns on the first page and 10 columns on the second page).

To reduce the number of pages that a table spans, before you select the export action, hide the columns that you do not want to include in the PDF. Continue hiding columns until the table no longer spans multiple pages.

HTML

You can view an HTML file with a web browser. The information that you export to an HTML file is formatted into a table.

3. Optional: Depending on how your web browser is configured, you can specify the name and location of the generated file.
4. Click the save option to export the information to a file.

Related concepts

- [Viewing information about resources](#)
- [Customizing lists of resources, tasks, and alerts](#)

Customizing lists

Customize lists to focus on the information that is important to you. You can filter information, sort rows, and show, hide, and reorder columns in the table views for resources, tasks, alerts, and other objects.

Filtering lists

You can filter the items that are shown in a list. Use filtering when you want to limit the rows that are shown in a list based on values in a specific column or set of columns. For example, when viewing alerts, you can filter the list so that only alerts with a value of Warning in the Severity column are shown.

Sorting lists

Each list of resources, tasks, alerts, or other objects in the GUI has a column or set of columns that determines the order of its rows. You can sort the columns in a list to organize the rows according to your requirements.

Showing, hiding, and reordering columns in lists

Each list in the GUI has a set of columns that contain information about resources, tasks, alerts, or other objects. You can change the order of columns, show columns that are hidden, and hide columns that are shown in these lists.

Filtering lists

You can filter the items that are shown in a list. Use filtering when you want to limit the rows that are shown in a list based on values in a specific column or set of columns. For example, when viewing alerts, you can filter the list so that only alerts with a value of Warning in the Severity column are shown.

Procedure

1. In the web-based GUI, go to a list of resources, jobs, or alerts that you want to filter.
2. Click the Filter icon  to determine how to filter the list. The following options are available:

Filter by Default Columns

Select this option to apply the filter to the set of the default columns in a list. Each list contains a set of default columns on which you can filter.

For example, in the lists of alerts on the Home > Alerts page, select this option to apply filter text to the following columns at the same time: **Condition**, **Severity**, **Alert Category**, **Resource**,

Internal Resource, Total Occurrences, Alert Name.

Filter by a Specific Column

Select this option to apply filter text to a specific column in a list. For example, on the Home_>Alerts page, select the Condition column if you want to apply filter text to values in that column only.

Restriction: Some columns in lists cannot be used for filtering and are not shown under the **Filter by a Specific Column** option.

3. In Filter text box , type the text for filtering a list.

You can type letters, whole words, partial words, and numbers. When filtering on certain columns, you can select from a list of values rather than typing in filter text. For example, when filtering on the Status column, you can select one of the following values as the filter text: **Error**, **Unreachable**, **Warning**, **Normal**, **Unknown**.

4. Press Enter to apply the filter to the list.

Only rows with values that match or partially match the filter text are shown.

For example, on the Home_>Alerts page, if you select to filter on the Severity column and type `critical` as the filter text, only alerts that have a severity of `critical` and `critical - acknowledged` are shown in the list.

Tip: The name of a column to which a filter applies is shown next to the Filter icon .

5. Optional: To remove the filtering for a list, click Reset.

Sorting lists

Each list of resources, tasks, alerts, or other objects in the GUI has a column or set of columns that determines the order of its rows. You can sort the columns in a list to organize the rows according to your requirements.

About this task

For example, the list of ports on a fabric is ordered by switch name, blade slot, and port number, in that order. You can change the sort order of these columns to organize a list of resources according to your requirements.

Tip: A visual indicator  is shown next to the primary column that determines the sort order of a list.

Procedure

1. In the GUI, go to a list of resources, tasks, alerts, or other objects that you want to sort.
2. Complete the following tasks to sort the rows in the list:
 - To change whether the rows in a list are sorted by ascending or descending order, click the name of the primary column in the heading row. Click the name of the column again to reverse the sort order.
 - To change the column that determines the sort order of the list, click the name of that column. For example, click the Name column to sort the list of items alphabetically, or click the Status column to sort the list according to the status of items.

Tip: When you click a column other than the primary sort column, that column becomes the new primary sort column. However, the previous primary column maintains its sort order (ascending or descending).

For example, if a list of resources is ordered by the Name column in ascending order and you click the Status column, the rows are sorted according to the statuses of resources. At the same time, the resources for each type of status are still sorted in ascending order by the Name column. There is a maximum of three columns that can be sorted upon at the same time.
3. Optional: To reset the order of the rows for a column to the default setting, right-click the heading row in the list and select Restore Default View.

Example

On the Switches page, you can use the sorting function to group virtual or logical switches with their physical switch. First, show the Virtual and IP Address columns. Click the Virtual column to sort it in ascending alphabetical order. Then, click the IP Address column.

Showing, hiding, and reordering columns in lists

Each list in the GUI has a set of columns that contain information about resources, tasks, alerts, or other objects. You can change the order of columns, show columns that are hidden, and hide columns that are shown in these lists.

Procedure

1. In the GUI, go to a list of resources, task, alerts, or other objects that you want to customize.
2. Complete the following tasks to customize the columns in the list:
 - To show or hide the columns in a list, right-click any of the column headings and select or clear the check box next to a column name.
 - To change the order of columns, click a column heading and drag it to a new position in the list.

Tip: The changes that you make to column settings are saved from session to session.
3. Optional: To reset the order and display of columns to the default setting, right-click any of the column headings and select Restore Default View.

Managing tasks

Tasks are used to provision storage and optimize resources in your storage environment. Use the Tasks page to manage all the tasks that are used by IBM Spectrum® Control to provision storage and optimize resources. Use resource list and resource details pages to manage the tasks for specific resources and resource types.

Discontinued support: Cloud configuration, provisioning, and optimization are no longer supported in IBM Spectrum Control. While these features might still work in this release, it's recommended that you use another tool for your provisioning, optimization, and volume transformation needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

Tasks are created when you take any of the following actions in the GUI:

- You can provision storage to assign storage to servers or hypervisors.
- You can analyze tiering to move volumes to higher or lower tiers.
- You can transform storage to move or convert volumes.
- You can balance pools to distribute the workload of volumes across pools on the same tier.

Use the following actions to manage tasks:

- View the status of tasks in a central location.
- Identify all the tasks that are related to a specific resource or a type of resource.
- Identify all the tasks that are encountering problems when the tasks are running.
- Administer the tasks. The actions that are available depend on the type of task that you select. For example, you can run or rename a tiering-analysis task, or export provisioning task details to a text file.
- Change the number of task runs that are displayed.

Tip: A *task run* is a single invocation of a task.

- **[Viewing tasks](#)**
Use the Tasks page to view all the tasks that are used by IBM Spectrum Control to provision storage and optimize resources. Use resource list and resource details pages to view the tasks for specific resources and resource types.
- **[Managing tasks for provisioning](#)**
Provisioning tasks are used to create storage volumes and assign the volumes to servers or hypervisors. Provisioning tasks are also used to create network-attached storage (NAS) file shares. Use the Tasks page in the GUI to manage all the tasks that are used by IBM Spectrum Control to provision storage. Use resource list and resource details pages to manage the provisioning tasks for specific resources and resource types.
- **[Managing tasks for tiering storage, balancing pools, and transforming storage](#)**
To optimize the resources in your storage environment, use tiering storage, balancing pools, and transforming-storage tasks. Use the Tasks page to manage all the tasks that are used to optimize storage. Use resource list and resource detail pages to manage the optimization tasks for resource types and for specific resources.
- **[Renaming tasks](#)**
You can change the name of a task by using the task detail page. For example, use the Provisioning page to change the name of a provisioning task. A task name is automatically generated when the task is created. If the original name is ambiguous or is not clear enough, you can change the task name to a unique task name that you provide.
- **[Deleting tasks](#)**
Use the Tasks page to delete tasks, such as provisioning, tiering analysis, balance analysis, transform plan, and analysis-execution tasks.

Viewing tasks

Use the Tasks page to view all the tasks that are used by IBM Spectrum® Control to provision storage and optimize resources. Use resource list and resource details pages to view the tasks for specific resources and resource types.

- **[Viewing all tasks](#)**
Use the Tasks page as a central location to view the tasks that IBM Spectrum Control is using to provision storage and optimize resources. You can view all the tasks for resources that are monitored by IBM Spectrum Control.
- **[Viewing pending tasks](#)**
Some tasks might be pending because they can be run or scheduled only by an administrator. If tasks are pending, the number of pending tasks is displayed in the title bar of the GUI.
- **[Viewing tasks for a type of resource](#)**
Use resource list pages to view only the tasks for a specific type of top-level resource. Each resource list page has a Tasks tab that lists only the tasks for that type of resource. For example, you can use the list page for storage systems to view only the tasks that are associated with storage systems.
- **[Viewing tasks for a specific resource](#)**
Use resource detail pages to view only the tasks for a specific monitored resource. Each resource detail page has a Tasks link that lists only the tasks for the associated storage system, server, hypervisor, switch, or fabric.
- **[Viewing task details](#)**
Use task detail pages to view detailed information about the tasks that IBM Spectrum Control uses to optimize resources and provision storage. You can use this information to troubleshoot the reason why a task failed, analyze details of a task before you implement task recommendations, or schedule future task runs.
- **[Viewing task logs](#)**
Task logs include detailed information about the status, actions, and progress of a task. Status information includes informational, warning, and error messages that are related to each action in a task that is taken during processing. You can use this information to troubleshoot any errors that might occur when a task is run.
- **[Setting the number of task runs that are displayed](#)**
You can change the number of task runs that are shown in the GUI by configuring the settings on the History Retention page. By default, the information for the last five runs of a task is shown.

Viewing all tasks

Use the Tasks page as a central location to view the tasks that IBM Spectrum® Control is using to provision storage and optimize resources. You can view all the tasks for resources that are monitored by IBM Spectrum Control.

Procedure

1. In the menu bar in the web-based GUI, go to Home > Tasks.
The information about tasks is organized into columns. These columns include information about the status of tasks, the date and time of the last run for tasks, and the schedule for tasks.

2. Optional: View the status icons at the top of the page to view a summary of task statuses.
This summary includes the number of tasks that have a Failed, Warning, Successful, or Running status.
Tip: To view descriptions of the icons and columns on the Tasks page, click the Help icon  in the upper-right corner of the page.

Viewing pending tasks

Some tasks might be pending because they can be run or scheduled only by an administrator. If tasks are pending, the number of pending tasks is displayed in the title bar of the GUI.

Before you begin

You must be assigned to the Administrator role to view the number of pending tasks.

About this task

Pending tasks are tasks that were not run and are not scheduled to run. Pending tasks might be created by a user who is not authorized to run or schedule the task. For example, users who are assigned to the Monitor or External Application role can have permission to create provisioning tasks by using a service class. However, if the service class specifies that administrator approval is required, these users can only create the provisioning task. The provisioning task is pending until an administrator runs or schedules it.

Procedure

To view pending tasks, complete the following steps:

1. In the title bar of the GUI, look for the pending task count. If no number appears in the title bar, there are no pending tasks.
2. To open a Tasks page that shows only the pending tasks, click the number of pending tasks in the title bar.

Viewing tasks for a type of resource

Use resource list pages to view only the tasks for a specific type of top-level resource. Each resource list page has a Tasks tab that lists only the tasks for that type of resource. For example, you can use the list page for storage systems to view only the tasks that are associated with storage systems.

About this task

Procedure

1. In the menu bar, select a type of top-level resource.
For example, to view the tasks that are related to storage systems, go to Storage and select the type of storage system you want to monitor.
Exception: Provisioning tasks that provision network-attached storage (NAS) file shares to servers or hypervisors are not shown on the resource list pages for servers or hypervisors. You must use the Tasks page to view these tasks.
2. Click the Tasks tab to view a list of all the tasks for the monitored resources of that type.
The information about tasks is organized into columns. These columns include information about the status of tasks, the most recent date and time when tasks ran, and the schedule for tasks.
Tip: The status icon on the Tasks tab represents the most critical status of the tasks that are associated with the monitored resources. For example, if one of the tasks for storage systems failed, the following icon is shown on the tab:
 Tasks
3. Optional: View the status icons on the Tasks page for a summary of task statuses.
This summary includes the number of tasks that have a Failed, Warning, Successful, or Running status.
Tip: To view descriptions of the icons and columns on the Tasks page, click the Help icon .

Viewing tasks for a specific resource

Use resource detail pages to view only the tasks for a specific monitored resource. Each resource detail page has a Tasks link that lists only the tasks for the associated storage system, server, hypervisor, switch, or fabric.

Procedure

1. In the menu bar, select a type of top-level resource.
For example, if you want to view the tasks for a storage system, go to Storage and select the type of storage system you want to monitor.
2. Right-click a resource in the list and select View Details.
The resource detail page is displayed. In the General section, the number next to Tasks represents the number of tasks that are associated with the resource. For example, Tasks (3) indicates that you can view three tasks.
The icon next to the Tasks link represents the most critical status of the tasks that are associated with the resource. For example, if a task failed, the following icon is shown:

Tasks (3) 

3. Click Tasks in the General section to view the tasks for the resource.
The information about tasks is organized into columns. These columns include information about the status of tasks, the most recent date and time when tasks ran, and the schedule for tasks.
4. Optional: View the status icons on the Tasks pane to view a summary of task statuses.
This summary includes the number of tasks that have a Failed, Warning, Successful, or Running status.
Tip: To view descriptions of the icons and columns on the Tasks pane, click the Help icon .

Viewing task details

Use task detail pages to view detailed information about the tasks that IBM Spectrum® Control uses to optimize resources and provision storage. You can use this information to troubleshoot the reason why a task failed, analyze details of a task before you implement task recommendations, or schedule future task runs.

About this task

On all the task detail pages, you can view information such as the task status, the duration and completion date of task runs, and the actions that you can take to manage the task. For tasks such as tiering analysis, balance analysis, and transform plan, you can view information about the recommendations that are generated by the most recent or earlier task runs. For provisioning tasks, you can view the status of the actions that the provisioning task completes for each of the resources that are configured in the task.

Procedure

1. From the menu bar, go to the Tasks page, a resource list page for a resource type, or a resource detail page for a specific resource.
For example, to view the tasks that are related to storage systems, go to Storage and select the type of storage system you want to monitor, and click the Tasks tab.
2. Locate the task that you want to view in more detail.
3. Right-click the task row and select View Details.
The task details page opens in a separate window. For example, the Tiering Analysis page opens if you select a tiering-analysis task row.
4. Optional: To view task logs, click Open Logs. You can use the information in the log file to troubleshoot any errors that might occur when a task is run.
5. Optional: For provisioning tasks, you can export information about the provisioning task to a text file for offline viewing. To export information, click the  icon at the top of the Provisioning page.

Viewing task logs

Task logs include detailed information about the status, actions, and progress of a task. Status information includes informational, warning, and error messages that are related to each action in a task that is taken during processing. You can use this information to troubleshoot any errors that might occur when a task is run.

About this task

The following examples show the type of information that you can view in the task logs:

- View the number of recommendations that are generated by tiering-analysis, balance-analysis, or transform-plan task runs.
- View the options that you have when you transform storage, analyze tiering, or balancing pools. For example, when you create a tiering-analysis task and the options that you choose are recorded in the task log.
- View error messages that are related to task processing.

Procedure

1. From the menu bar, go to the Tasks page, a resource list page for a resource type, or a resource detail page for a specific resource.
For example, to view the tasks that are related to storage systems, go to Storage and select the type of storage system you want to monitor, and click the Tasks tab.
2. Locate the task that has a log file that you want to view.
3. Right-click the task row and select Open Logs.
The Logs page shows log entries for the most recent task run.
4. Optional: On the Logs page, to view the log for a previous task run, select a task run from the Select a log list.
5. Optional: To view only the actions in a task run that have a Warning or Error status, select an option from the Show all list.
You can choose to view only actions that have the following statuses:
 -  Only error entries
 -  Only warning entries
 -  Error and warning entries
6. Optional: To view an explanation of the message that is associated with an action, click the link in the ID column.

Results

The information on the Logs page is automatically updated every 30 seconds. New entries are added to the end of a log. You can view the following information on the Logs page:

- The overall status of a task. The icon that is shown in the Select a log list represents the most critical status that was generated by an action in the task run.
- The status for each action in a task.
- The date and time when an action was completed. The date, time, and time zone of the action is shown in the Date and Time column.
- The ID of the message that is associated with an action. You can click the value in the ID column to view more information about a message.
- The description of an action.

Setting the number of task runs that are displayed

You can change the number of task runs that are shown in the GUI by configuring the settings on the History Retention page. By default, the information for the last five runs of a task is shown.

Procedure

1. In the menu bar, go to Settings > History Retention.
2. Click Edit.
3. In the Job logs field, enter the number of runs that you want to retain for display.
4. Click Save to save your changes.

Results

After you update the value for job logs, the list of task runs is automatically updated within a few minutes. For more information about retention settings, see [Configuring history and data retention](#).

Managing tasks for provisioning

Provisioning tasks are used to create storage volumes and assign the volumes to servers or hypervisors. Provisioning tasks are also used to create network-attached storage (NAS) file shares. Use the Tasks page in the GUI to manage all the tasks that are used by IBM Spectrum® Control to provision storage. Use resource list and resource details pages to manage the provisioning tasks for specific resources and resource types.

Before you begin

Discontinued support: Provisioning is no longer supported in IBM Spectrum Control. While the feature might still work in this release, it's recommended that you use another tool for your provisioning needs, when possible. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

About this task

Use the GUI to complete the following provisioning actions:

- Create provisioning tasks
- Run provisioning tasks immediately
- Schedule provisioning tasks to run at a specified date and time
- Export information about provisioning tasks to text files
- Delete provisioning tasks
- [Creating provisioning tasks](#)
You can create provisioning tasks with the GUI and assign storage volumes or NAS file shares to servers or hypervisors.
- [Running provisioning tasks](#)
Use the Tasks page to run provisioning tasks. You can run provisioning tasks immediately or you can schedule tasks to run at a date and time that you specify. When you run a provisioning task, the configuration changes that are contained in the task are implemented. For example, storage volumes are created and assigned to servers.
- [Exporting provisioning task information](#)
Use the Provisioning detail page to export details of a provisioning task to a text file. The task details that are shown on the Provisioning page are saved to the generated text file.

Related concepts

Creating provisioning tasks

You can create provisioning tasks with the GUI and assign storage volumes or NAS file shares to servers or hypervisors.

Before you begin

You must have Administrator privileges to create provision tasks.

Related tasks

- [Provisioning storage with the IBM Spectrum Control GUI](#)
- [Collecting information about shares on storage systems](#)

Running provisioning tasks

Use the Tasks page to run provisioning tasks. You can run provisioning tasks immediately or you can schedule tasks to run at a date and time that you specify. When you run a provisioning task, the configuration changes that are contained in the task are implemented. For example, storage volumes are created and assigned to servers.

Before you begin

To run provisioning tasks, you must be the owner of the task or have Administrator privileges.

About this task

Provisioning tasks can run only once. You can run the task when you complete the steps for storage provisioning or you can save the provisioning task and run the task later.

The Run Now and Schedule actions are available for a provisioning task when the task is not running, and was not previously run.

Procedure

1. From the menu bar, go to the Tasks page, a resource list page for a resource type, or a resource detail page for a specific resource.
For example, to view the provisioning tasks that are related to servers, go to Servers_>Servers, and click the Tasks tab.
 2. Locate the provisioning task that you want to run.
 3. Depending on when you want the provisioning task to run, choose one of the following options:
 - To run the provisioning task immediately, right-click the task row and select Run Now. The task status changes to Running and the provisioning task runs immediately.
 - To schedule the provisioning task to run at a specific date and time, complete the following steps:
 - Right-click the task row and select Schedule.
 - From the Schedule page, select a future date and time from the Provision lists, and click Save.
- You can also run or schedule the provisioning task from the Provisioning detail page. On the Provisioning detail page, click Execute to run the task immediately or click Schedule to schedule the task to run at a specific date and time.

Results

The provisioning task runs immediately or on the scheduled date and time. To check the progress of the task, you can take the following actions:

- View the task status on the Tasks page.
- View detailed information about the progress of the task on the Provisioning detail page. You can view the task duration and the status of the actions that the provisioning task completes for each of the resources that are configured in the task.
- View the task logs from the Tasks page or from the Provisioning detail page. You can view detailed informational, warning, and error messages that are related to the task. You can use this information to troubleshoot any errors that might occur when a task is run.

Exporting provisioning task information

Use the Provisioning detail page to export details of a provisioning task to a text file. The task details that are shown on the Provisioning page are saved to the generated text file.

About this task

If you do not have authority to provision storage, you can export the provisioning task details to a file and email the file to a user with Administrator privileges. The administrator can run or schedule the provisioning task if they approve the task details.

Procedure

1. From the menu bar, go to the Tasks page, a resource list page for a resource type, or a resource detail page for a specific resource.
For example, to view the provisioning tasks that are related to servers, go to Servers_>Servers, and click the Tasks tab.
2. Locate the provisioning task that you want to export.
3. Right-click the task row and select View Details.
4. From the Provisioning page, to start the export, click the  icon in the upper-right corner of the page.
5. Save the generated text file.
Depending on how your web browser is configured, you can specify the file name and the location where the file is saved.

Results

The provisioning task information is exported to a text file. The generated file includes all the provisioning task details that are listed on the Provisioning page. Columns that are hidden on the Provisioning page are included in the generated file. The information in the file is organized according to a default order and is not affected by the column order that is defined on the Provisioning page.

Managing tasks for tiering storage, balancing pools, and transforming storage

To optimize the resources in your storage environment, use tiering storage, balancing pools, and transforming-storage tasks. Use the Tasks page to manage all the tasks that are used to optimize storage. Use resource list and resource detail pages to manage the optimization tasks for resource types and for specific resources.

Before you begin

Discontinued support: Storage optimization is no longer supported in IBM Spectrum® Control. While the feature might still work in this release, it's recommended that you use another tool for your balancing and tiering needs, when possible. The storage transformation feature is still available. For a complete list of discontinued features, see [Discontinued features in IBM Spectrum Control](#).

To schedule, run, edit, or delete tiering storage, balancing pools, and transforming-storage tasks, you must have Administrator privileges.

About this task

To complete any of the optimization tasks, such as balancing pools, you must complete the following steps:

1. Create the analysis task with the GUI. For example, to balance pools create a balance-analysis task.
2. Run the analysis task to generate the optimization recommendations. For example, run the balance-analysis task to generate the recommendations to move volumes.
3. Edit analyze tiering and balancing pool tasks by modifying the thresholds.
4. Implement the recommendations to optimize storage. For example, implement the recommendations to balance pools by running the analysis-execution task.

Use the Tasks, resource list, and resource detail pages to take the following actions for optimization tasks:

- Run the optimization analysis immediately to generate optimization recommendations.
- Schedule the optimization analysis to run at a specified date and time.
- Implement optimization recommendations immediately.
- Schedule the implementation of optimization recommendations for a specified date and time.
- Pause, cancel, and resume the implementation of optimization recommendations.
- Delete optimization tasks.
- View task logs.
- [Creating analysis tasks](#)
To create tasks for optimizing resources in your storage environment, use IBM Spectrum Control GUI.
- [Running analysis tasks](#)
To run tiering analysis, balance analysis, and transform-plan tasks, use the Tasks page. When you run the analysis for any of these optimization tasks, recommendations are generated to optimize the storage resources that are configured in the task. For example, when you run a tiering-analysis task, recommendations are generated to tier volumes based on the criteria that you set in tiering policies.
- [Implementing recommendations to optimize storage](#)
Use the Tasks page and task detail pages to implement optimization recommendations to tier storage, balance pools, and transform storage. You can implement recommendations immediately or you can schedule the implementation of the recommendations for a future date and time.

- [Modifying the criteria for balancing pools](#)

Creating analysis tasks

To create tasks for optimizing resources in your storage environment, use IBM Spectrum® Control GUI.

Before you begin

You must have Administrator privileges to create tasks for optimizing resources in your storage environment.

About this task

Storage optimization tasks are created when you take any of the following actions in the GUI:

Tier storage

You can analyze tiering to move volumes to higher or lower tiers; a tiering-analysis task is created.

Balance pools

You can balance pools to distribute the workload of volumes across pools on the same tier; a balance-analysis task is created.

Transform storage

You can transform storage to move or convert volumes; a transform-plan task is created.

Related tasks

- [Tiering volumes by I/O density and I/O rate](#)
- [Transforming and migrating volumes](#)

Running analysis tasks

To run tiering analysis, balance analysis, and transform-plan tasks, use the Tasks page. When you run the analysis for any of these optimization tasks, recommendations are generated to optimize the storage resources that are configured in the task. For example, when you run a tiering-analysis task, recommendations are generated to tier volumes based on the criteria that you set in tiering policies.

Before you begin

To run tiering analysis, balance analysis, and transform-plan tasks, you must have Administrator privileges.

About this task

You can run tasks immediately or schedule tasks to run at a future date and time.

Tip: The Run Now action is available when the task is enabled and the task is not running.

Procedure

1. From the menu bar, go to the Tasks page, a resource list page for a resource type, or a resource detail page for a specific resource.
For example, to view the tiering-analysis tasks that are related to servers, go to Servers > Servers, and click the Tasks tab.
2. Locate the tiering analysis, balance analysis, or transform-plan task that you want to run.
3. Right-click the task row and select Run Now.
The task status changes to Running.
4. Optional: To schedule future task runs for tiering analysis or balance-analysis tasks, right-click the task row and select Schedule Analysis. On the Schedule Analysis page, select the time that the task is run and how often the task is run.
Restriction: You cannot schedule future task runs for transform-plan tasks.
5. Optional: To enable or disable a tiering analysis or balance-analysis task, select Enabled or Disabled on the Schedule Analysis page.
When the task is enabled, the task runs according to the defined schedule. If the task is disabled, you can modify the task schedule but the task cannot run at the scheduled time.

Results

When the task run completes, you can view the recommendations that are generated on the task detail page. For example, you can view the recommendations that are generated for a tiering-analysis task on the Tiering Analysis page. To check the progress of the task run, you can take the following actions:

- View the task status on the Tasks page.
- View information about the progress of the task on the task detail page. You can view the duration of the task run, and the date and time that the task run completed.
- View the task logs from the Tasks page or from the task detail page. You can view detailed informational, warning, and error messages that are related to the task. You can use this information to troubleshoot any errors that might occur when a task is run.

Related tasks

- [Modifying the criteria for analyzing tiering](#)

Implementing recommendations to optimize storage

Use the Tasks page and task detail pages to implement optimization recommendations to tier storage, balance pools, and transform storage. You can implement recommendations immediately or you can schedule the implementation of the recommendations for a future date and time.

- **[Implementing recommendations immediately](#)**
To implement optimization recommendations to tier storage, balance pools, and transform storage, use the task detail pages. For example, use the Balance Analysis page to implement the recommendations to balance pools.
- **[Scheduling the implementation of recommendations](#)**
To schedule the implementation of optimization recommendations to tier storage, balance pools, and transform storage, use the Tasks page.

Related tasks

- [Modifying the criteria for analyzing tiering](#)

Implementing recommendations immediately

To implement optimization recommendations to tier storage, balance pools, and transform storage, use the task detail pages. For example, use the Balance Analysis page to implement the recommendations to balance pools.

Before you begin

To implement storage optimization recommendations, you must have Administrator privileges.

About this task

IBM Spectrum® Control uses analysis-execution tasks to implement optimization recommendations. When you implement recommendations for a tiering analysis, balance analysis, or transform-plan task, the following process takes place:

- An analysis-execution task is automatically created so that the recommendations can be implemented.
- The analysis-execution task runs immediately and the optimization recommendations are implemented. For example, volumes are moved to higher or lower tiers when storage-tiering recommendations are implemented.

Tip: In certain instances, running several optimization recommendations at the same time can cause one or more of the individual recommendation executions to encounter a Pool Exhaustion Exception. In these instances, the executions error out, rather than waiting for resources in the thread pool to become free. You might need to manually finish the execution of some recommendations, in particular, the old VDisk copy might not be removed, and you must remove it manually. To reduce the likelihood of encountering the issue again, contact IBM® Support for assistance in decreasing the total number of concurrent executions allowed.

You can view analysis-execution tasks on the Tasks page. The Related Task column shows the related tiering analysis, balance analysis, or transform-plan task.

The Execute action is available under the following conditions:

- Recommendations were generated by the latest run of the tiering analysis, balance analysis, or transform-plan task.
- An analysis-execution task was not already run for the latest set of recommendations.
- An analysis-execution task is not running or paused.

Procedure

1. From the menu bar, go to the Tasks page, a resource list page for a resource type, or a resource detail page for a specific resource.
For example, to view the analysis-execution tasks that are related to servers, go to Servers > Servers, and click the Tasks tab.
2. Locate the tiering analysis, balance analysis, or transform-plan task that you want to implement.
3. Right-click the task row and select View Details.
For example, the Balance Analysis page opens if you select a balance-analysis task.
4. Click Execute.
An analysis-execution task is created and immediately implemented.

Results

The analysis-execution task runs immediately. To check the progress of the task, you can take the following actions:

- View the task status on the Tasks page.
- View the status of individual task recommendations on the Analysis Execution page.
- View the task logs from the Tasks page or from the Analysis Execution page. You can view detailed informational, warning, and error messages that are related to the task. You can use this information to troubleshoot any errors that might occur when a task is run.

Scheduling the implementation of recommendations

To schedule the implementation of optimization recommendations to tier storage, balance pools, and transform storage, use the Tasks page.

Before you begin

To schedule the implementation of storage optimization recommendations, you must have Administrator privileges.

The Schedule Execution action is available under the following conditions:

- Recommendations were generated by the latest run of the tiering analysis, balance analysis, or transform-plan task.
- An analysis-execution task is not running or paused.
- An analysis-execution task was not already run for the latest set of analysis recommendations. For each run of the tiering analysis, balance analysis, or transform-plan task, you can complete only one run of the analysis-execution task.

About this task

When you define the schedule, an analysis-execution task is created for the implementation of the optimization recommendations.

Tip: The analysis-execution task implements the recommendations that were current when the analysis-execution task was defined. For example, you define a tiering-analysis task that runs daily. You review the recommendations every day and, on a Tuesday, you schedule an analysis-execution task to run on the following Friday. When the analysis-execution task runs on Friday, the recommendations that were current on Tuesday are implemented, even if more recent recommendations are available.

Procedure

1. From the menu bar, go to the Tasks page, a resource list page for a resource type, or a resource detail page for a specific resource.
For example, to view the tiering analysis tasks that are related to servers, go to Servers > Servers, and click the Tasks tab.
2. Locate the tiering analysis, balance analysis, or transform-plan task that you want to schedule.
3. Right-click the task row and select Schedule Execution.
4. On the Schedule Execution page, select the date and time that the recommendations are implemented and click Save.

Results

An analysis-execution task is created that you can monitor on the Tasks page. The name of the analysis-execution task is based on the name of the related tiering analysis, balance analysis, or transform-plan task. The Related Task column shows the related tiering analysis, balance analysis, or transform-plan task.

When the analysis-execution task runs on the scheduled date, the optimization recommendations are implemented. For example, volumes are moved to higher or lower tiers when storage-tiering recommendations are implemented.

Tip: In certain instances, running several optimization recommendations at the same time can cause one or more of the individual recommendation executions to encounter a Pool Exhaustion Exception. In these instances, the executions error out, rather than waiting for resources in the thread pool to become free. You might need to manually finish the execution of some recommendations, in particular, the old VDisk copy might not be removed, and you must remove it manually. To reduce the likelihood of encountering the issue again, contact IBM® Support for assistance in decreasing the total number of concurrent executions allowed.

Pausing, resuming, and canceling the implementation of recommendations

IBM Spectrum® Control uses analysis-execution tasks to implement optimization recommendations to tier storage, balance pools, and transform storage. To pause, resume, and cancel analysis-execution tasks, use the Tasks page.

Before you begin

To pause, resume, or cancel analysis-execution tasks, you must have Administrator privileges.

About this task

Procedure

1. From the menu bar, go to the Tasks page, a resource list page for a resource type, or a resource detail page for a specific resource.
For example, to view the analysis-execution tasks that are related to servers, click Servers > Servers, and click the Tasks tab.
2. Locate the analysis-execution task that you want to pause, resume, or cancel.
3. Right-click the task row and select Pause, Resume, or Cancel.

The Pause action is only available when the analysis-execution task is running.

The Resume action is only available when the analysis-execution task is paused.

The Cancel action is available when the task is running or paused.

Results

When you pause, resume, or cancel analysis-execution tasks, the following processing occurs:

Pause

The status of the analysis-execution task changes to Paused and the recommendations that are being implemented are suspended.

Resume

The status of the analysis-execution task changes to Running and the recommendations are resumed.

Cancel

The status of the analysis-execution task changes to Canceled and the recommendations that are being implemented are stopped. Any recommendations that are already implemented for this analysis-execution task are not rolled back. For example, a recommendation is generated to move a volume from **pool_a** to **pool_b**. If this recommendation is already implemented before the task is canceled, the volume remains in **pool_b**. Use the Analysis Execution page to determine which recommendations were implemented for the task before the task was canceled.

You cannot restart an analysis-execution task that is canceled. If you want to implement the same set of recommendations again, you must complete the following steps:

1. Delete the analysis-execution task that you canceled.
2. Use the Schedule Execution action for the tiering analysis, balance analysis, or transform-plan task to create an analysis-execution task.

952

Renaming tasks

You can change the name of a task by using the task detail page. For example, use the Provisioning page to change the name of a provisioning task. A task name is automatically generated when the task is created. If the original name is ambiguous or is not clear enough, you can change the task name to a unique task name that you provide.

Before you begin

You must have the following privileges to rename the different task types:

Provisioning

To rename provisioning tasks, you must be the owner of the task or have Administrator privileges.

Other task types

To rename all other tasks, such as tiering analysis, balance analysis, transform plan, and analysis-execution tasks, you must have Administrator privileges.

Procedure

1. From the menu bar, go to the Tasks page, a resource list page for a resource type, or a resource detail page for a specific resource.
For example, to view the tasks that are related to servers, go to Servers > Servers, and click the Tasks tab.

2. Locate the task that you want to rename.
3. Right-click the task row and select View Details.
The task detail page opens in a separate window. For example, the Provisioning page opens if you select a provisioning task.
4. Type the new name in the task name field.
The naming conventions for task names are:
 - The maximum length is 64 characters.
 - Uppercase and lowercase letters are allowed.
 - Spaces and numbers are allowed.
 - The following special characters are allowed:
! # % & * + - / = ? ^ _ { } ()
5. Click Rename.

Results

The task is renamed. You can view the renamed task on the Tasks page.

Deleting tasks

Use the Tasks page to delete tasks, such as provisioning, tiering analysis, balance analysis, transform plan, and analysis-execution tasks.

Before you begin

You must have the following privileges to delete the different task types:

Provisioning

To delete provisioning tasks, you must be the owner of the task or have Administrator privileges.

Other task types

To delete all other tasks, such as tiering analysis, balance analysis, transform plan, and analysis-execution tasks, you must have Administrator privileges.

About this task

The following conditions apply for the different task types:

Analysis-execution

You can delete analysis-execution tasks that were canceled, already run, or scheduled to run in the future. You cannot delete tasks that are running or paused.

Other task types

You can delete all other tasks if the tasks were already run or if the tasks are scheduled to run in the future. For example, you can delete provisioning, tiering analysis, balance analysis, and transform-plan tasks that were already run. You cannot delete tasks that are running.

Procedure

1. From the menu bar, go to the Tasks page, a resource list page for a resource type, or a resource detail page for a specific resource.
For example, to view tasks that are related to servers, go to Servers, Servers, and click the Tasks tab.
2. Locate the task that you want to delete.
3. Right-click the task row and select Delete. Alternatively, you can delete the task by clicking Delete on the task detail page.
The Delete page opens in a separate window.
4. If you are deleting a provisioning task that was not yet run, enter the reason that you are deleting the task.
5. Click Delete.
To exit the window without deleting the task, click Cancel.

Planning copy data resources

To plan for your block storage requirements, you need to be able to see how you currently use block storage in your storage environment.

You can use the Copy Data view the following aspects of your block storage environment:

- You can see how much of your current allocated capacity is taken up by both the primary and backup data.
- You can see the ratio of allocated capacity that is taken up by primary data and plan for backup data according to your security policies.
- You can analyze storage device relationships to identify how redundancy is affecting available capacity.
- You can view how each type of storage you use is deployed in your environment.
- You can identify the volumes that are not backed up.
- **[Monitoring copy data resources](#)**
You can monitor the use and type of block storage resources in Copy Data.

Monitoring copy data resources

You can monitor the use and type of block storage resources in Copy Data.

You can get a complete breakdown of how each type of storage is used across the block storage environment.

Remote Relationships

Detailed information on remote relationships includes the type of relationship that exists between the source and target storage systems.

Synchronous relationship

Host writes are delayed until the source receives confirmation that the data is written to the target volume.

Asynchronous relationship

Host writes can continue while data is being written to the target volume.

Where the type of volume is known, one of the following icons appears next to the volume in question.

Standard volume

A volume that is not thin-provisioned, compressed, encrypted, or encrypt-able.

Thin provisioned volume

The volume is only allocated the required amount of server space as required.

Compressed VDisk volume

Data is compressed as it is written to the VDisk.

Consistency Group

Details the status and type of the consistency group, and the number of relationships that exist in the group.

FlashCopy

Details the information on the last FlashCopy® operation between each source and target storage system.

VDisk Mirrors

Details the information on the volumes, pools, tiers, and synchronization status of the VDisk mirrors.

- Identify target and source mirror disks at a glance.
- Easily see the disks that are compressed, thin, or normal.

Safeguarded Copy

For DS8000®, you can view the volumes that are backed up, the pool that the copies of a volume are written to, and the amount of capacity that is used to store the volume copies.

HyperSwap

Details the information on the status of the master and auxiliary volumes, pools, and tiers of the HyperSwap® relationships.

- Quickly identify the master and auxiliary volumes and pools.
- Drill down to see the amount of allocated disk for each volume.

Unprotected Volumes

Details the information on the volumes that are not backed up.

IBM Spectrum Control REST API

You can use the Representational State Transfer (REST) API for IBM Spectrum® Control to access information about resources and to generate custom capacity, configuration, and performance reports.

To get the information that you need about your resources, you can use a REST command line utility or you can use a web browser.

- [Retrieving data about resources by using a REST API command line utility](#)
You can connect to the REST API for IBM Spectrum Control and retrieve data by using a REST command line utility.
- [Retrieving data by using REST API with a web browser](#)
A convenient way to use the IBM Spectrum Control REST API is within the interface itself. You can quickly access resource information for your reporting capabilities by using a web browser.

Retrieving data about resources by using a REST API command line utility

You can connect to the REST API for IBM Spectrum® Control and retrieve data by using a REST command line utility.

You can use any REST command line utility, for example, GNU Wget. To access information about the GNU Wget utility, go to <https://www.gnu.org/software/wget/>. The IBM Spectrum Control REST API is hosted here: `https://<hostname>:9569/srm/REST/api/v1/`.

You can enter a command to authenticate with the REST API and store a security token in a file to use in your later queries, for example, `cookies.txt`.

You can use the utility, by entering the following command:

```
wget --post-data "j_username=<user name>&j_password=<password>"
--no-check-certificate --keep-session-cookies --save-cookies cookies.txt
https://<hostname>:9569/srm/j_security_check
```

You can use the security token in all subsequent commands that are issued against the REST API, by entering the following command:

```
wget --no-check-certificate --load-cookies cookies.txt
https://<hostname>:9569/srm/REST/api/v1/
```

Example (partial listing)

```
},
{
  "Description": "Provides a list of ports belonging to a parent storage system.
Format: \StorageSystems\<id>\Ports For a list of ports associated with a
port owner, specify the owner type and id in the URL.
```

To see a list of all storage systems, you can append the URL:

```
https://<hostname>:9569/srm/REST/api/v1/StorageSystems
```

To see more information about a resource type, you can further append the URL (where `<Name>` is the resource type, such as `StorageSystems`, `Switches`, `Servers`, etc.)

```
https://<hostname>:9569/srm/REST/api/v1/<Name>
```

To see more information about a specific resource, add the ID to the URL (where `<id>` is available from `https://<hostname>:9569/srm/REST/api/v1/<Name>`):

```
https://<hostname>:9569/srm/REST/api/v1/<Name>/<id>
```

To query for volumes that belong to a specific storage system, enter:

```
https://<hostname>:9569/srm/REST/api/v1/StorageSystems/57909/Volumes
```

Example (partial listing)

```
[
  {
    "Acknowledged": "No",
    "Allocated Space": "1.00",
    "Capacity": "1.00",
    "Controller": "Node 0",
    "Copy Relationship": "",
    "Easy Tier": "Tiered Pools\No",
    "Encryption": "",
    "Enterprise HDD Capacity": "1.00",
    "Format": "FB",
    "Hosts": "18",
    "LSS or LCU": "00",
    "Last Data Collection": "Apr 10, 2016, 15:03:57",
    "Name": "CET_RA_vol",
    "Nearline HDD Capacity": "",
    "Physical Allocation": "Fully Allocated",
    "Pool": "General Use 1",
    "RAID Level": "RAID 5",
    "SSD Capacity": "",
    "Service Class": "",
    "Shortfall": "",
    "Status": "Normal",
    "Storage System": "DS8000-2107-75BLG91-IBM",
    "Storage Virtualizer": "None",
    "Thin Provisioned": "No",
    "Ticket": "",
    "Tier Distribution": "0",
    "Unallocated Space": "0.00",
    "Unused Space": "",
    "Used Allocated Space": "",
    "Used Space": "1.00",
    "Virtualizer Disk": "None",
    "Volume ID": "0000",
    "Volume Number": "0",
    "Volume Unique ID": "75blg91\0000",
    "id": "79852"
  },

```

The information that is provided in the `Format` field in the example shows what combinations are possible. For example,

```
https://<hostname>:9569/srm/REST/api/v1/StorageSystems/<id>/Ports
```

Tips:

- If the `Format` field is omitted, you can add the ID of one resource to the URL.
- The name elements in the URL are case-sensitive.
- The names of resource types are plural.
- If the URL is not used correctly, you might receive the following error message:

```
{ "result": { "type": "E", "msgId": "BPCUI0099E", "time": "Apr 4, 2016 16:25:07", "text": "The storage resource is not available." }}
```

- If the URL returns a blank page, it means that no data is available for the resource. For example, if you query an application for file shares and there are no file shares in the application, the resulting page is blank.

Table 1. IBM Spectrum Control REST API URL examples

IBM Spectrum Control REST API	Description
<code>https://<hostname>:9569/srm/REST/api/v1/StorageSystems</code>	A list of all monitored storage systems.
<code>https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002</code>	Specific information for one storage system (ID is available from this URL: <code>https://<hostname>:9569/srm/REST/api/v1/StorageSystems</code>).
<code>https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes</code>	A list of all volumes for one storage system.
<code>https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance</code>	The available performance metrics for a volume.
<code>https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/RemoteReplication</code>	The remote mirror replication relationships for storage systems.
<code>https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance/824?granularity=sample&startTime=1455818400000&endTime=1455904800000</code>	Sample performance granularity information and a start and end time for the performance data.

Note: IBM® Storage is changing the capacity terminology that is used in IBM Storage products to make it more consistent. The new capacity terminology is used in IBM Spectrum Control 5.3.6 or later. The new terminology is used in the GUI, but the names used in the REST API have not changed. The output from the REST API continues to use Allocated Space instead of Used Capacity, Physical Allocation instead of Used Capacity %, and so on.

Retrieving data by using REST API with a web browser

A convenient way to use the IBM Spectrum® Control REST API is within the interface itself. You can quickly access resource information for your reporting capabilities by using a web browser.

To use the REST API with a web browser, use these steps:

1. Log on to the IBM Spectrum Control GUI. To start IBM Spectrum Control, see [Starting IBM Spectrum Control](#).
2. Open a new tab in your web browser.
3. Enter `https://<hostname>:9569/srm/REST/api/v1/`.

For example, to see a list of fabrics, enter `https://<hostname>:9569/srm/REST/api/v1/Fabrics` in a new tab of your web browser (partial listing).

```
[
{
  "Acknowledged": "No",
  "Active Zone Set": "",
  "Connected Switch Ports": "0",
  "Custom Tag 1": "",
  "Custom Tag 2": "",
  "Custom Tag 3": "",
  "Data Source Count": "1",
  "Fabric Type": "Cisco",
  "Last Successful Probe": "N/A",
  "Links": "0",
  "Location": "",
  "NPV Switches": "0",
  "Name": "VSAN0002",
  "Parent Fabric": "san_director",
  "Principal Switch of Fabric": "tpc-70swt-csc",
  "Probe Schedule": "N/A",
  "Probe Status": "N/A",
  "Status": "Error",
  "Switch Ports": "0",
  "Switches": "1",
  "Virtual": "Yes",
  "WWN": "2002000DECAC5081",
  "id": "2663"
}
```

To see the information for a specific fabric in your environment, append the URL with the ID:

`https://<hostname>:9569/srm/REST/api/v1/Fabrics/2017`

Example (partial listing)

```
{
  "Acknowledged": "No",
  "Active Zone Set": "",
  "Connected Switch Ports": "18",
  "Custom Tag 1": "",
  "Custom Tag 2": "",
  "Custom Tag 3": "",
  "Data Source Count": "2",
  "Fabric Type": "Cisco",
  "Last Successful Probe": "N/A",
  "Links": "4",
  "Location": "",
  "NPV Switches": "0",
  "Name": "san_director",
  "Parent Fabric": "",
  "Principal Switch of Fabric": "",

```

```

"Probe Schedule": "N\\A",
"Probe Status": "N\\A",
"Status": "Error",
"Switch Ports": "104",
"Switches": "2",
"Virtual": "No",
"WWN": "",
"id": "2017"

```

To see the switches that belong to the fabric "id": "2017", enter:

<https://<hostname>:9569/srm/REST/api/v1/Fabrics/2017/Switches>

Example (partial listing)

```

[
{
  "Acknowledged": "No",
  "Connected Fabrics": "",
  "Custom Tag 1": "",
  "Custom Tag 2": "",
  "Custom Tag 3": "",
  "Data Source Count": "1",
  "Domain ID": "10",
  "Fabric": "unstable BRCD_1-11",
  "Firmware": "v6.4.3g",
  "IP Address": "9.11.91.241",
  "Last Successful Monitor": "None",
  "Last Successful Probe": "None",
  "Links": "",
  "Location": "",
  "Mode": "Native",
  "Model": "Brocade 4100",
  "Name": "mdm-y76-swt",
  "Parent Switch": "",
  "Performance Monitor Interval (min)": "",
  "Performance Monitor Status": "Disabled",
  "Ports": "",
  "Principal Switch of Fabric": "cjswitch4",
  "Probe Status": "Never Probed",
  "Serial Number": "1070029",
  "Status": "Normal",
  "Vendor": "IBM",
  "Virtual": "No",
  "WWN": "100000051E347790",
  "id": "60989"
}
]

```

Note: IBM Spectrum Control can connect to Brocade switches and fabrics either directly or by using Brocade Network Advisor. For Brocade switches and fabrics that IBM Spectrum Control connects to directly, the Data Source Count value is 0.

Table 1. IBM Spectrum Control REST API URL examples

IBM Spectrum Control REST API	Description
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems">https://<hostname>:9569/srm/REST/api/v1/StorageSystems	A list of all monitored storage systems.
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002">https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002	Specific information for one storage system (ID is available from this URL: <a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems">https://<hostname>:9569/srm/REST/api/v1/StorageSystems).
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes">https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes	A list of all volumes for one storage system.
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance">https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance	The available performance metrics for a volume.
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/RemoteReplication">https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/RemoteReplication	The remote mirror replication relationships for storage systems.
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance/824?granularity=sample&startTime=1455818400000&endTime=1455904800000">https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance/824?granularity=sample&startTime=1455818400000&endTime=1455904800000	Sample performance granularity information and a start and end time for the performance data.

Note: IBM® Storage is changing the capacity terminology that is used in IBM Storage products to make it more consistent. The new capacity terminology is used in IBM Spectrum Control 5.3.6 or later. The new terminology is used in the GUI, but the names used in the REST API have not changed. The output from the REST API continues to use Allocated Space instead of Used Capacity, Physical Allocation instead of Used Capacity %, and so on.

Reporting

Keep your colleagues and management up-to-date by sending inventory, capacity, performance, and storage consumption reports by email or by exporting information about your storage environment.

Reports overview

Share the information that is collected about your storage environment by sending reports by email or by exporting the information to create your own reports.

In IBM Spectrum® Control, you can share information with your colleagues and management:

- [By creating predefined inventory and capacity reports that you can save to your file system and send by email](#)
- [By creating custom reports that you can save to your file system or send by email](#)
- [By creating chargeback and consumer reports that you can send by email](#)
- [By using the Representational State Transfer \(REST\) API to get information about storage resources and to generate configuration and performance reports](#)
- [By exporting information about the configuration, capacity, and performance of storage resources to HTML, PDF, or CSV files](#)

More about exporting information to files:
You can use the export feature as follows:

- To export capacity and performance information about your storage resources from IBM Spectrum Control into spreadsheets and the reports that you create for your organization
- To share information with your colleagues about the storage resources in your environment
- To make your colleagues aware of issues and to help them investigate and resolve capacity and performance issues

You can use an external reporting tool, Cognos® Analytics reporting interface, to view predefined reports and create custom reports about IBM Spectrum Control. For more information, see [Reporting with Cognos Analytics](#).

Predefined, custom, and storage consumption reports

Reports

Predefined inventory and capacity reports

Leverage and share the insights that IBM Spectrum Control gains from the metadata that it collects and analyzes to generate information about your storage assets and to monitor capacity usage and plan capacity purchases.

➔ [Create predefined capacity reports](#)

➔ [Create predefined inventory reports](#)

Custom reports

From any table view for a resource, leverage and share the insights that IBM Spectrum Controls gains into the capacity, configuration, performance, and health status of the storage resources that you monitor.

➔ [Create custom reports](#)

Chargeback and consumer reports

Create, schedule, and send chargeback and consumer reports by email to make your organization aware of the cost and the amount of capacity that is used by storage consumers such as applications.

➔ [More information about chargeback and consumer reports](#)

➔ [Create chargeback reports](#)

➔ [Create consumer reports](#)

In the IBM Spectrum Control you can create the following types of reports, which you can configure, schedule, and send by email:

Predefined reports

You can use predefined reports:

- To notify colleagues about the capacity issues that affect them, and to monitor the capacity usage of resources, such as storage systems, pools, and hosts, to ensure that you have sufficient capacity to meet current usage and to help plan capacity purchases
- To generate inventory reports about your storage assets, such as storage systems, hypervisors, servers, IBM Spectrum Virtualize nodes, and IBM Spectrum Scale nodes

Custom reports

You use custom reports to create a variety of reports such as reports that provide information about your storage assets, and capacity and performance reports that provide information about the storage usage and performance of your resources.

Tip: You can open the table view for any resource, such as storage systems, volumes, pools, general groups, applications, and departments and click Create Report to create a custom report that you can save or send in a few simple steps. To create performance reports, open the Performance page for the resource and click Create Report.

Storage consumption reports

Chargeback reports make the owners of resources, such as applications, departments, hypervisors, or physical servers, aware of the amount and cost of the block and file storage that is consumed.

Consumer reports make the owner of a specific resource, such as an application, department, hypervisor, or physical server, aware of the amount and cost of the block and file storage that is consumed.

How to create reports

Watch a short video about how to create and customize a capacity report, attach a file to the report, and schedule when to run it in IBM® Storage Insights Pro.

- [Creating predefined capacity reports](#)
To share information about capacity availability, usage, and growth, create capacity reports. You can configure and refine the information that is included in the report so that your colleagues get the information that they need to monitor the resources that they manage and make capacity planning decisions.
- [Creating predefined inventory reports](#)
To share information with your colleagues about the configuration and properties of your storage assets, create inventory reports.
- [Creating custom reports](#)
Create, configure, and save or send custom reports by email that include asset, capacity, configuration, health status, or performance information about your storage resources.
- [Creating chargeback and consumer reports](#)
To help plan capacity purchases and make your organization aware of the cost and the amount of the storage that is used by storage consumers, create chargeback and consumer reports.
- [Running reports](#)
You can run reports that you created without defining a schedule or changing the schedule that was created for the report.
- [Editing reports](#)
Change the configuration and scheduling for reports.
- [Deleting reports](#)
Remove the reports that you don't need.
- [Configuring the email server](#)
To send reports, you must configure the email server.
- [Investigating issues with reports](#)
You can access log and trace files to investigate the issues that you might have when reports are generated and sent by email or saved to the file system.
- [Types of predefined capacity and inventory reports](#)
The predefined capacity and inventory reports that you can create for your storage resources are listed.
- [Reports FAQ](#)
Find answers to questions about the reports that you can create in IBM Spectrum Control.
- [Capacity metrics for reports](#)
To gain insights into storage usage, review the capacity metrics that are collected, analyzed, and shown in reports.
- [Using the REST API to generate reports](#)
Use the REST command line utility or a web browser to generate capacity, configuration, and performance reports.
- [Exporting information about resources](#)
Notify your colleagues about the current state and potential issues with your storage environment by exporting the capacity and performance information that is shown in the GUI.
- [Reporting with Cognos Analytics](#)
Use the Cognos Analytics reporting tool to view predefined reports and create custom reports about the resources that are monitored by IBM Spectrum Control.

Creating predefined capacity reports

To share information about capacity availability, usage, and growth, create capacity reports. You can configure and refine the information that is included in the report so that your colleagues get the information that they need to monitor the resources that they manage and make capacity planning decisions.

Before you start

If you want to send reports by email, you must set up the mail server. If you already set up the mail server to send alerts or reports, or if you want to only save reports to your file system, you don't have to set up the mail server.

If you want the reports that you will create to be saved to your file system to be stored in a folder other than the default reports folder, you must create the folder before you create the reports.

Saving reports to file systems on remote servers: The machine on which the Web server component was installed and runs must be able to access the remote or shared file system that is specified for saving reports. To make file systems on a server available to remote clients, they must be mounted as a CIFS export on Windows operating systems or as an NFS export on UNIX or Linux® operating systems. On Windows operating systems, the file system must be mounted as the local system user or from a service that is running under the local system account so that it is visible to all logon sessions. One way of mapping a drive as the local system user is to map the drive from a psexec command window. The psexec command window is available as part of the Sysinternals command-line tools for Windows operating systems.

Step 1: Pick your predefined report

Click Reports, and then click Create Report and pick the capacity report that you want to create.

Step 2: Name the report

Provide a unique name for your report. You can use alphabetical and numerical characters, hyphens, dashes, and blank spaces.

Step 3: Specify the scope of the report

Choose one of these options:

- Option 1: Generate capacity information about all of the resources of a specific type.
- Option 2: Generate capacity information about a selection of resources of a specific type.
- Option 3: Generate capacity information about the resources of a specific type in a group.

Option 1: All	Option 2: Selection	Option 3: In a Group
		
Include information in the report about all of the storage systems.	Include information in the report about a selection of the storage systems.	Include information in the report about the storage systems that are assigned to a general group, such as the production platform.

Option 1: All of the resources

Choose this option to generate a report about all of the resources, such as all storage systems, pools, volumes, managed disks, or NAS file systems.

Option 2: One or more of the resources

Choose this option to generate capacity information about a selection of resources such as a selection of storage systems, pools, volumes, managed disks, or NAS file systems.

When you create capacity reports about managed disks, pools, server , or volumes, you can group the types of resources, such as managed disks by storage systems, pools by storage systems, server by applications, and volumes by server .

Try it out: Click Reports, click Create Report, and choose the Pools capacity report. Choose capacity information for one or more resources, and select pools by storage systems or pools by tiers. To refine the list of the resources that are shown, you can enter a matching pattern for the names of the storage systems, or you can select the storage systems that contain the pools that you want to include in the report.

Predefined Capacity Reports: Selecting the resources that you're interested in

Pools capacity reports

Pools by storage systems

Pools by tiers

Volumes capacity reports

Volumes by storage systems

Volumes by pools

Volumes by hosts

Volumes by applications

Managed disks capacity reports

Managed disks by storage systems

Hosts capacity reports

Hosts by applications

Option 3: Resources assigned to groups

You can also generate capacity information about the storage systems that belong to a group that you created, such as a general group that consists of the storage systems that are assigned to your production platform, or the storage resources that are assigned to an application or department.

Tip: The report you pick, determines the level of information that is shown about applications in reports. For example, if you want to see the capacity information about the set of volumes that you added to an application, create a Volumes capacity report and select the application. Or, if you want to see the capacity information about the filesets that you added to an application, create a Filesets capacity report and select the application.

Step 4: Select columns

To ensure that the report's recipients get the information that they need, you can add more information, such as the location of the resources or custom tags. You can also remove the information that your colleagues don't need.

Step 5: Add filters

To refine the information in the report, you can add up to four filters.

Sample filters for block storage systems capacity reports

Sample 1: Filter by storage system name	Sample 2: Filter by Used Capacity %
Column Storage System	Column Used Capacity %
Comparison Contains	Comparison > =
Value storwize	Value 80
Only include capacity information about IBM Storwize family storage systems.	Only include capacity information for IBM Storwize family storage systems with used capacity values of 80% or higher.

For example, if you want to notify resource administrators or owners about capacity shortfalls, you can set threshold values for capacity information. Or if you want to exclude information that is not of interest to the report's recipients, you can add a filter.

Don't forget to check the table when you apply filters to make sure that the recipients of the report will get the information that they need.

Step 6: Schedule and deliver the report

To notify your colleagues of capacity or configuration anomalies, create one-off capacity and inventory reports or create a schedule to provide regular updates about the capacity or state of your storage assets.

Tip: Instead of sending the report by email, you can save the report to the default reports folder or to a folder on your file system. Alternatively, when you send the report by email, you can also attach the report as a CSV, PDF, or HTML file.

Review, edit, and delete reports

To review the report that you created, click Reports, expand the relevant section, such as Capacity Report for predefined capacity reports and Inventory Report for predefined inventory reports, and then select the report.

You can edit the report, such as change the name and scope of the report or schedule of the report. To delete the report, click Actions,⌵Delete Report.

Tip: You want to save a scheduled report to your file system or send it by email report now, but you don't want to change the original schedule? Click Reports. Select the report, and click Actions,⌵Run Now. The report is sent without changing the schedule that you saved.

- [Tutorial: Creating a predefined capacity report about storage systems](#)
Create, schedule, and send predefined capacity reports about your storage systems by email, to keep your colleagues informed about capacity usage and to help them plan capacity and prevent capacity shortages.

- [Adding resources to applications to generate large reports](#)
To generate capacity reports about a large number of resources, add the resources to an application and then generate the report.

Tutorial: Creating a predefined capacity report about storage systems

Create, schedule, and send predefined capacity reports about your storage systems by email, to keep your colleagues informed about capacity usage and to help them plan capacity and prevent capacity shortages.

About this task

You can create a predefined report about the capacity usage of all of the storage systems in your storage environment, a selection of storage systems in your storage environment, or the storage systems that are assigned to a group such as a general group.

Procedure

1. Click Reports, and then click Create Report.
2. In the Capacity Reports section, click Block Storage Systems.
3. Enter the unique name of the report.
4. To specify the range of the report, choose one of the following options:

Specify the range of the report, choose one of the following options:

<div>Option 1: All</div> <div></div> <div>Include information in the report about all of the storage systems.</div>	<div>Option 2: Selection</div> <div></div> <div>Include information in the report about a selection of the storage systems.</div>	<div>Option 3: In a Group</div> <div></div> <div>Include information in the report about the storage systems that are assigned to a general group, such as the production platform.</div>
--	---	--

Option	Description
Capacity information about all of the storage systems	Generate capacity information about all of the block, file, and object storage systems in your storage environment.
Capacity information about one or more storage systems	Generate information about a set of storage systems.
Capacity information about the storage systems that are assigned to a group	Generate information about the storage systems that were assigned to a group such as the production, preproduction, or test platforms general group.

5. Add and remove columns to choose the capacity and any other information that you want to include in the report.
6. Add up to four filters to deliver the capacity information that the report's recipients need.

Sample 1: Filter by storage system name

Column
Storage System

Comparison
Contains

Value
storwize

Only include capacity information about IBM Storwize family storage systems.

Sample 2: Filter by Used Capacity %

Column
Used Capacity %

Comparison
> =

Value
80

Only include capacity information for IBM Storwize family storage systems with used capacity values of 80% or higher.

Tip: To make sure that the report's recipients get the information that you want them to get, use the report preview feature. Each time you apply a filter, or make a configuration change to the report, such as add or remove a column or filter, the table view of the report is refreshed.

7. Choose one of the following options:

Option	Description
Email	Save and send the email now or attach the report to the email as a CSV, PDF, or HTML file.
Save to File System	Schedule and save the report to the default reports folder or to the folder that you created for saving reports.
Email and Save to File System	Schedule the report, send it by email or attach the report to the email as a CSV, PDF, or HTML file, and save the report to the default reports folder or to the folder that you created for saving reports.

Results

The Reports page opens where you can preview and edit the report that you created.

Tutorial: Creating a predefined capacity report about pools

Create, schedule, and send predefined capacity reports about your pools by email, to keep your colleagues informed about capacity usage and to help them plan capacity purchases and prevent capacity shortages.

About this task

You want to send a regular report to the owners of block storage resources so that they'll know:

- Which pools are depleted
- When the pools will run out of capacity

To do this, you include the Zero Capacity column and create a filter.

What's zero capacity: The capacity information that is collected over 180 days is analyzed to determine, based on historical storage consumption, when the pools will run out of capacity. The pools that have already run out of capacity are marked as depleted. For the other pools, a date is provided so that you know when the pools are projected to run out of capacity. If sufficient information isn't collected to analyze the storage usage of the pool, *None* is shown as the value for zero capacity. If a capacity limit is set for the pool, the date shown in the Zero Capacity column is the date when the available capacity based on the capacity limit will be depleted. For example, if the capacity limit for a 100 GiB pool is 80%, it is the date when the available capacity of the pool is less than 20 GiB. *Depleted* is shown in the column when the capacity limit is reached.

Procedure

1. Click Reports, and then click Create Report.
2. In the Capacity Reports section, click Pools.
3. Enter the unique name of the report.
4. To specify the range of the report, choose one of the following options:

Option 1: All

Include information in the report about all of the pools in your storage environment.

Option 2: Selection

Include information in the report about a selection of pools.

Option 3: In a Group

Include information in the report about the pools that are assigned to a group, such as an application.

Option	Description
Capacity information about all of the pools	Generate capacity information about all of the pools in your storage environment.
Capacity information about one or more pools	Generate information about a set of pools. You can select the pools by the storage systems that they belong to or by the tiers that the pools are assigned to.
Capacity information about the pools that are assigned to a group	Generate information about the pools that were assigned to a general group such as an application.

5. Add and remove columns to choose the capacity and any other information that you want to include in the report.
6. Add up to four filters to deliver the capacity information that the report's recipients need.

Sample: Filter by Zero Capacity

Only include capacity information about the pools that are depleted or that could be analyzed to determine when the pools are projected to run out of capacity.

Tip: To make sure that the report's recipients get the information that you want them to get, use the report preview feature. Each time you apply a filter, or make a configuration change to the report, such as add or remove a column or filter, the table view of the report is refreshed.

7. Choose one of the following scheduling options:

Option	Description
Email	Save and send the email now. You can also attach the report to the email as a CSV, or HTML file, or both.
Save to File System	Schedule and save the report to the default reports folder or to the folder that you created for saving reports.
Email and Save to File System	Schedule the report, send it by email or attach the report to the email as a CSV file, PDF file, or HTML file, and save the report to the default reports folder or to the folder that you created for saving reports.

Results

The Reports page opens where you can preview and edit the report that you created.

Tutorial: Creating a predefined capacity report about tiered pools

Create a pools by tier report to share information about the capacity of the pools that are assigned to your production platform.

Before you begin

The pools that are used on your production platform are assigned to one or more tiers.

Assign pools to tiers: Click **Storage > Pools**. To add the Tier column to the table, right-click any column heading, and select **Tier**. Select and then right-click the pools on your production platform, and click **Set Tier**. If you used a naming pattern for the pools or storage systems that are assigned to your production platform, you can filter the pools by pool or storage system name. Just click . Then select **Name** or **Storage System** and enter the pattern that matches the names of the pools or storage systems in the filter.

About this task

You want to create a scheduled report that shows the key capacity values of the pools on your production platform.

Procedure

1. Click **Reports**, and then click **Create Report**.
 2. Pick the **Pools capacity** report.
 3. Enter the name of the report, and click **Capacity information** about one or more pools.
 4. Select **Tiers** from the **Pools** drop-down list.
A list of the tiers that were created is shown.
 5. Select the tiers that you created for your production platform.
When you click **Next**, capacity information about the pools assigned to the tiers that you selected is shown.
 6. Select the capacity information that you want to include in the report.
Tip: Include the name of the tier in the report. In the **General** section, click **Tier**. Drag the **Tier** column and drop it before the **Name** column. To sort the pools by the tiers they are assigned to, click the **Tier** column.
 7. To refine the information that you want to include in the report, add filters.
 8. Schedule the delivery of the report.
- [Optimizing storage tiering](#)
 - [Setting the tier level of storage pools](#)

Tutorial: Creating a predefined capacity report about the volumes assigned to servers

Create, schedule, and send predefined reports about the capacity of the volumes that are assigned to servers .

About this task

When you create reports about the capacity of volumes, you can select volumes:

- By the storage systems that they belong to.
- By the pools that they belong to.

- By the servers that they are assigned to.
- By the applications that they are assigned to.

In this tutorial, you create a capacity report about the volumes that are assigned to the servers in your storage environment.

Procedure

1. Click Reports, and then click Create Report.
2. Click the Volumes capacity report.
3. Enter the name of the report.
4. Select Capacity information about one or more volumes.
5. On the Select Volumes page, select Servers from the Volumes list.
6. On the Select Volumes by Servers page, you can:
 - a. Choose all of the servers.
 - b. Choose one or more of the servers.
 - c. Select Name from the Filter  list. Then, enter a pattern that matches the names of the servers that you want to select.
7. Choose the columns that you want to include in the report.
You can rearrange the columns by dropping the columns where you want them to appear in the report.
8. Add a filter and then click Apply Filter.
For example, you can create a weekly report that lists the volumes with a used capacity greater than 80%.
9. Schedule the report.

Tutorial: Creating a predefined capacity report about managed disks by storage systems

Share information with your colleagues about the capacity of your managed disks grouped by the storage systems that they belong to.

Procedure

1. Click Reports, and then click Create Report.
2. Pick the Managed Disks capacity report.
3. Enter the name of the report and choose Capacity information about one or more managed disks.
4. On the Select Managed Disks page, change the selection from Managed Disks to Block Storage Systems.
5. On the Select Managed Disks by Block Storage Systems page, you can:
 - a. Choose all of the storage systems that have managed disks.
 - b. Choose one or more of the storage systems that have managed disks.
 - c. Select Name from the  the column filter. Then, enter a pattern that matches the names of the storage systems that you want to select.
6. Choose the columns that you want to include in the report.
You can rearrange the order of the columns by dropping the columns where you want them to appear in the report.
7. Add and apply filters.
8. Schedule the report.

Adding resources to applications to generate large reports

To generate capacity reports about a large number of resources, add the resources to an application and then generate the report.

About this task

For example, you want to generate a capacity report about all of the file sets, hosts, or volumes in your production environment. To do this, you can add the resources to an application and then generate a report about the application.

You can also add resources to general groups to generate large reports. However, when you add or remove resources, you'll have to add or remove the resources from the general group that you created. Whereas, when you use naming patterns to match the resources that you associate with applications, the applications are automatically updated when resources are added or removed.

Procedure

1. To add file sets or volumes to an application, complete these steps:

Option	Description
File sets and volumes	<ol style="list-style-type: none"> a. Click Groups > Applications. b. Click Create Application, enter the name of the application, and then click Create. c. Click Assign Storage Resources to the Application. d. Choose a selection of volumes or file sets that match a pattern. e. To add all the file sets or volumes to the filter, type an asterisk (*) . f. Save the filter.

Option	Description
Hosts	<ol style="list-style-type: none"> Click Groups > Applications. Click Create Application, enter the name of the application, and then click Create. Click Assign Storage Resources to the Application. Choose all storage that belongs to set of servers or hypervisors. Enter a pattern that matches the names of you servers. Save the filter.

- Click Reports, and then click Create Report.
- Pick the capacity report that you want to create.
- Enter the name of the report, choose the option for groups and select the group that you created.
- Complete the steps for creating the report.

Creating predefined inventory reports

To share information with your colleagues about the configuration and properties of your storage assets, create inventory reports.

Before you start

If you want to send reports by email, you must set up the mail server. If you already set up the mail server to send alerts or reports, or if you want to only save reports to your file system, you don't have to set up the mail server.

If you want the reports that you will create to be saved to your file system to be stored in a folder other than the default reports folder, you must create the folder before you create the reports.

Saving reports to file systems on remote servers: The machine on which the Web server component was installed and runs must be able to access the remote or shared file system that is specified for saving reports. To make file systems on a server available to remote clients, they must be mounted as a CIFS export on Windows operating systems or as an NFS export on UNIX or Linux® operating systems. On Windows operating systems, the file system must be mounted as the local system user or from a service that is running under the local system account so that it is visible to all logon sessions. One way of mapping a drive as the local system user is to map the drive from a psexec command window. The psexec command window is available as part of the Sysinternals command-line tools for Windows operating systems.

Step 1: Pick your predefined report

Click Reports, and then click Create Report and pick the inventory report that you want to create.

Step 2: Name the report

Provide a unique name for your report. You can use alphabetical and numerical characters, hyphens, dashes, and blank spaces.

Step 3: Specify the scope of the report

Generate information about all of the resources of a specific type, such as an inventory report for block storage systems, or IBM Spectrum Virtualize nodes, or IBM Spectrum Scale nodes.

Step 4: Select columns

To ensure that the report's recipients get the information that they need, you can add more information, such as the location of the resources or custom tags. You can also remove the information that your colleagues don't need.

Step 5: Add filters

To refine the information in the report, you can add up to four filters.

Sample filters for block storage systems inventory reports

Sample 1: Filter by type of storage system			Sample 2: Filter by Firmware version		
					
Column Type		Comparison Contains	Column Firmware	Comparison Not Contains	Value 7.8.1.5
Only include inventory information for IBM Storwize family storage systems.			Only include information for IBM Storwize family storage systems with firmware versions that don't match the value that you enter.		

For example, if you want to check whether your IBM® Storwize® family block storage systems have the correct firmware version, you can add filters to list the storage systems with firmware versions that don't match the value that you enter.

Don't forget to check the table when you apply filters to make sure that the recipients of the report will get the information that they need.

Step 6: Schedule and deliver the report

To notify your colleagues of inventory issues, create one-off inventory reports or create a schedule to provide regular updates about the state of your storage environment.

Tip: Instead of sending the report by email, you can save the report to the default reports folder or to a folder on your file system. Alternatively, when you send the report by email, you can also attach the report as a CSV, PDF, or HTML file.

Review, edit, and delete reports

To review the report that you created, click Reports, expand the relevant section, such as Inventory Report, and then select the report.

You can edit the report, such as change the name and scope of the report or schedule of the report. To delete the report, click Actions...Delete Report.

Tip: You want to save a scheduled report to your file system or send it by email report now, but you don't want to change the original schedule? Click Reports. Select the report, and click Actions...Run Now. The report is sent without changing the schedule that you saved.

- **Tutorial: Creating an inventory report about block storage systems**

Create a predefined report that includes information such as the name, type, model, vendor, and location of your block storage systems.

Tutorial: Creating an inventory report about block storage systems

Create a predefined report that includes information such as the name, type, model, vendor, and location of your block storage systems.

Procedure

1. Click Reports, and then click Create Report.
2. In the Inventory Reports pane, choose Block Storage Systems.
3. Enter the unique name of the report.
4. Choose the inventory information that you want to include in the report.
5. Add up to four filters.

Tip: Don't forget to click Apply Filter when you add each filter, and check the report preview to ensure that the report's recipients will get the information that they need.

6. Choose one of the following scheduling options:

Option	Description
Email	Save and send the email now. You can also attach the report to the email as a CSV, PDF, or HTML file.
Save to File System	Schedule and save the report to the default reports folder or to the folder that you created for saving reports.
Email and Save to File System	Schedule the report, send it by email or attach the report to the email as a CSV, PDF, or HTML file, and save the report to the default reports folder or to the folder that you created for saving reports.

Results

The Reports page opens where you can preview and edit the report that you created.

Creating custom reports

Create, configure, and save or send custom reports by email that include asset, capacity, configuration, health status, or performance information about your storage resources.

Before you begin

If you want to send custom reports by email, you must set up the mail server. If you already set up the mail server to send alerts, or chargeback and consumer reports, or if you want to only save reports to your file system, you don't have to set up the mail server.

If you want the reports that you will create to be saved to your file system to be stored in a folder other than the default reports folder, you must create the folder before you create the reports.

Saving custom reports to file systems on remote servers: The machine on which the Web server component was installed and runs must be able to access the remote or shared file system that is specified for saving custom reports. To make file systems on a server available to remote clients, they must be mounted as a CIFS export on Windows operating systems or as an NFS export on UNIX or Linux® operating systems. On Windows operating systems, the file system must be mounted as the local system user or from a service that is running under the local system account so that it is visible to all logon sessions. One way of mapping a drive as the local system user is to map the drive from a psexec command window. The psexec command window is available as part of the Sysinternals command-line tools for Windows operating systems.

About this task

Use custom reports to quickly create reports to alert members of your organization about performance anomalies, health issues, capacity shortfalls, or capacity depletion. You can also schedule custom reports to keep a close watch on critical resources such as applications, or the storage resources that you use in your production environment.

From any table view that shows information about your storage systems or their related resources, you can create, configure, schedule, and save or send reports by email.

For example, you can create custom reports for top-level storage resources such as:

- Storage systems
- Hypervisors
- Servers
- Fabrics
- Switches

- Back-end storage systems

You can create custom reports for internal resources such as:

- Disks
- Pools
- Volumes
- Filesets
- File systems
- Network Shared Disks

And, if you added groups, you can create custom reports for general groups, applications, and departments.

File names for reports: The format for the name of reports that are saved to the file system is: <report name>.<epoch time>.<HTML|PDF|CSV>, where epoch time reflects the time of the server where IBM Spectrum® Control is installed. For example, the name of your report is *MyReport*, and you save it as a CSV file on 16 October, 2018 at 08:15pm (UTC) server time. The name of the file for the report is *MyReport_1539720900000.CSV*.

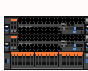

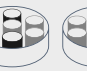

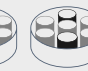

Tip: Monitor the default reports folder or the custom folders that you use to save reports to ensure that you have enough space for saving reports. For example, if you schedule and save a daily report to your file system, each version of the report is saved to the folder you choose. The factors that determine space usage are:

- The number of rows in the report.
- The frequency of the report.
- The format of the report.

Try it out: Open any page that shows information about your storage resources, such as the Block Storage Systems page, click Create Report, and create a custom report. Or, go to the Performance page and click Create Report, to create a performance report.

Procedure

1. Open any page that shows capacity or performance information about your storage systems, and then click Create Report.
2. Provide a unique name for your report. You can use alphabetical and numerical characters, hyphens, dashes, and blank spaces.
Remember: When you create your report, you can also use the table view features to customize your report, such as:
 - Drag the column headings to reorder the information that you want to show in the report.
 - Click the column heading in the table view to sort the values in the column.
3. To ensure that the report's recipients get the information that they need, you can add other information, such as the location of the resources or custom tags and remove the information they don't need.
4. To refine the capacity or asset information that you want to share, you can add up to four filters.

Sample 1: Filter by storage system name			Sample 2: Filter by Used Capacity %		
					
Column Storage System		Comparison Contains	Column Used Capacity %	Comparison > =	Value 80
Only include capacity information about IBM Storwize family storage systems.			Only include capacity information for IBM Storwize family storage systems with used capacity values of 80% or higher.		

For example, if you want to notify resource administrators or owners about capacity shortfalls, you can set threshold values for capacity information. Or if you want to exclude information that is not of interest to the report's recipients, you can add a filter. Check the report preview when you apply filters to make sure that the recipients of the report will get the information that they need.

Tip: You can add advanced filters to refine information about capacity and information about the assets in your storage environment. If advanced filters aren't available for a resource, you can use the filter feature that is available in the table. For example, in reports about volumes, you can filter by volume, pool, or storage system name, or by Easy Tier® attributes.

5. Choose one of the following scheduling options:

Option	Description
Email	Save and send the email now. You can also attach the report to the email as a CSV, PDF, or HTML file.
Save to File System	Schedule and save the report to the default reports folder or to the folder that you created for saving reports.
Email and Save to File System	Schedule the report, send it by email or attach the report to the email as a CSV, PDF, or HTML file, and save the report to the default reports folder or to the folder that you created for saving reports.

Results

To review the report that you created, click Reports, Reports, expand Customs Report, and then select the report.

You can edit the report, such as change the name and the schedule for the report. To delete the report, click Actions, Delete Report.

Tip: You want to save a scheduled report to your file system or send it by email report now, but you don't want to change the original schedule? Click Reports, Reports. Select the report, and click Actions, Run Now. The report is sent without changing the original schedule.

Tutorials: Creating custom capacity and performance reports for applications

In these tutorials, you create an application so that you can create, schedule, and send reports by email about the storage resources that the application consumes.

About this task

You create the application IBM Spectrum® Control, and then create custom capacity and performance reports.

1. [Creating the application for the capacity report](#)
In this scenario, you create the application that you want to use to generate the custom report.
2. [Creating the capacity report for the application](#)
In this scenario, you create a scheduled report about the capacity and storage usage of an application's pools.
3. [Creating the performance report for the application](#)
In this scenario, you create a performance report about the volumes that are assigned to the application.

Creating the application for the capacity report

In this scenario, you create the application that you want to use to generate the custom report.

About this task

Add the storage resources that your application consumes to the application that you create in IBM Spectrum® Control.

Procedure

1. From the Groups menu, click Applications.
2. Click Create Application.
3. Complete these actions:
 - Enter the name.
 - Add a description.
 - Enter the type. For example, to distinguish this application from the other types of application that you create, enter DB or the type of DB, such as db2.
 - Enter the subtype. For example, you can enter preproduction, test, or, production to categorize applications by environment.
4. Click Assign storage resources to the application, and then click A selection of volumes that match a a pattern.
5. In this scenario, you enter an asterisk * as the name pattern for the volumes, then you click Belonging to, and add a name pattern that matches the names of the pools that contain the volumes.
Assigning resources: Enter name patterns instead of adding comma-separated lists of the resources that an application uses. When you add more storage resources that match the name pattern, they are dynamically added to the application.
6. Click Preview to check that you added the storage resources that the application consumes, and then click Save.

Next topic: [Creating the capacity report for the application](#)

Creating the capacity report for the application

In this scenario, you create a scheduled report about the capacity and storage usage of an application's pools.

About this task

You want to create and schedule a report about the capacity of the pools that are assigned to an application.

Procedure

1. From the Groups menu, click Applications.
2. In the Related Resources section, double-click the application, and then click Pools.
3. Click Create Report, enter the unique name of the report, and then click Next.
4. Select the capacity values that you want to include in the report.

In this scenario, the following actions are completed to configure the report output:

- a. In the General section, exclude all of the columns except for the Name and Tier columns.
- b. In the Storage section, add capacity values, and select Zero Capacity from the Other section.

What's zero capacity: The capacity information that is collected over 180 days is analyzed to determine, based on historical storage consumption, when the pools will run out of capacity. The pools that have already run out of capacity are marked as depleted. For the other pools, a date is provided so that you know when the pools are projected to run out of capacity. If sufficient information isn't collected to analyze the storage usage of the pool, `None` is shown as the value for zero capacity. If a capacity limit is set for the pool, the date shown in the Zero Capacity column is the date when the available capacity based on the capacity limit will be depleted. For example, if the capacity limit for a 100 GiB pool is 80%, it is the date when the available capacity of the pool is less than 20 GiB. `Depleted` is shown in the column when the capacity limit is reached.

- c. To reorder the report output, drag the column headings.

5. Add up to four filters.

Sample: Filter by Zero Capacity

Only include capacity information about the pools that are depleted or that could be analyzed to determine when the pools are projected to run out of capacity.

Tip: Don't forget to click Apply Filter when you add each filter, and check the report preview to ensure that the report's recipients will get the information that they need.

6. Choose one of the following scheduling options:

Option	Description
Email	Save and send the email now. You can also attach the report to the email as a CSV, PDF, or HTML file.
Save to File System	Schedule and save the report to the default reports folder or to the folder that you created for saving reports.
Email and Save to File System	Schedule the report, send it by email or attach the report to the email as a CSV, PDF, or HTML file, and save the report to the default reports folder or to the folder that you created for saving reports.

7. Click Save and Schedule.

Results

Depending on the scheduling option that you chose, the report is saved to your file system, sent, or will be sent at the interval that you specified. To preview or edit the report, click Reports>Reports, expand the Custom Report section, and select the report.

Previous topic: [Creating the application for the capacity report](#)

Next topic: [Creating the performance report for the application](#)

Creating the performance report for the application

In this scenario, you create a performance report about the volumes that are assigned to the application.

Procedure

1. Click Groups > Applications.
2. Double-click the application, and then click Volumes in the navigation pane.
3. Select the volumes and click View Performance.
Tip: Before you create the performance report, you can add more or other performance metrics to the table. The average, minimum, and maximum values of the performance metrics that are added to the table are calculated and shown in the report. paneClick Edit Table Metrics and select the additional metrics that you want in the report.
4. Click Create Report.
5. Enter the name of the report and click Next.
6. Select the metrics that you want to include in the report and click Next.
7. Add a filter and then click Apply Filter.
8. Choose one of the following scheduling options:

Option	Description
Email	Save and send the email now. You can also attach the report to the email as a CSV, PDF, or HTML file.
Save to File System	Schedule and save the report to the default reports folder or to the folder that you created for saving reports.
Email and Save to File System	Schedule the report, send it by email or attach the report to the email as a CSV, PDF, or HTML file, and save the report to the default reports folder or to the folder that you created for saving reports.

Results

The report is created. To edit the report, click Reports > Reports, expand the Custom Report section, and click the report.

Previous topic: [Creating the capacity report for the application](#)

Custom capacity and performance view reports

When you create custom capacity or performance view reports, you can specify a relative time range for the information that is shown about the resources in the reports.

To generate custom reports with relative time ranges, you must select one or more resources and click View Capacity, or View Performance. Alternatively, you can open the page for the resource and click the Capacity or Performance tab.

Remember: If you decide to specify your own start date, or end date, or both, you'll get the same information in the report each time it is generated. For example, you change the time range to 2 days, January 1 to January 2, and then generate a weekly report. Each time the report is generated, the information that was collected from January 1 to January 2 is used to generate the report.

Relative time ranges for custom capacity reports

When you create custom capacity reports on Capacity View pages, the default time range for the capacity information that is shown in the report comprises an aggregate of the capacity information that was collected over the previous month.

Choosing relative time ranges in custom capacity reports

Overview

When you create custom reports on the Capacity tab, you choose a relative time range. The time range determines how many daily collections of capacity information are analyzed when the report is generated.

Scenario

On November 18, you select the last week as the relative time range. You create the report and schedule the report to run on the fifth day of each month.

When the report is run on 5 December, the aggregate of the daily capacity information that was collected in the last week of November is shown in the report.

If you navigate to the capacity view for a storage resource, you can specify a relative time range for the capacity information in the report, such as last week, month, 6 months, or year. Depending on the time range that you specify, the aggregated values for the capacity information are shown in the report.

Relative time ranges for custom performance reports

When you create custom performance reports on Performance View pages, the default time range for the performance information that is shown in the report comprises an aggregate of the performance information that was collected over the last 12 hours.

Choosing relative time ranges in custom performance reports

Overview

When you create custom reports on the Performance tab, you choose a relative time range. The time range determines how many hourly or daily collections of performance information are analyzed when the report is generated.

Scenario

On November 18, you select the last week as the relative time range. You create the report and schedule the report to run on the fifth day of each month.

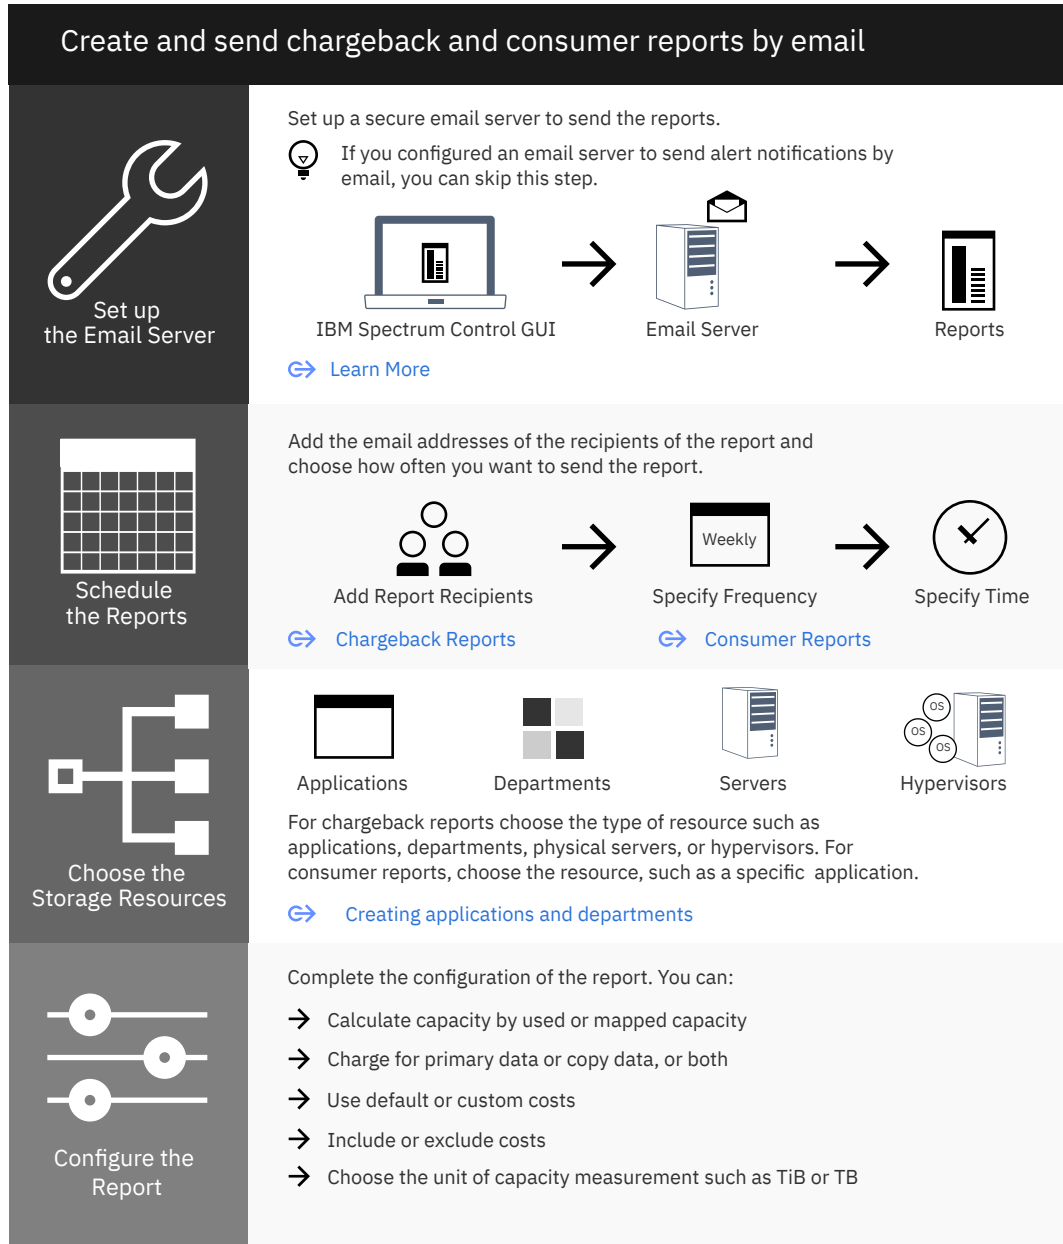

When the report is run on 5 December, the aggregate of the daily performance information that was collected in the last week of November is shown in the report.

If you navigate to the performance view for a storage resource, you can specify a relative time range for the capacity information in the report, such as the last hour, 6 hours, 12 hours, day, week, month, 6 months, or year. Depending on the time range that you specify, the aggregated values for the performance information are shown in the report.

Creating chargeback and consumer reports

To help plan capacity purchases and make your organization aware of the cost and the amount of the storage that is used by storage consumers, create chargeback and consumer reports.

Chargeback and storage consumer reports

In chargeback reports, you create reports that show the capacity and the cost of the block and file storage that is used by the types of storage consumers in your storage environment such as:

- Applications
- Departments
- Hypervisors
- Physical servers

In storage consumer reports, you create reports that show the capacity and cost of the block storage that is used by a single storage consumer, such as the capacity and the cost of the storage that is used by a single application.

To make the owners of the storage consumers aware of the capacity and cost of the storage they use, you schedule and send chargeback and storage consumer reports by email.

Show cost and capacity of tiered storage: If you want to show the block capacity of tiered storage and differentiate between the cost of storing data on tier 1 or on lower tiers of storage, you must assign your block storage pools to tiers. Click **Storage > Pools**. Right-click one or more pools, and then click **Tier** and the tier level from the menu. To view the capacity and charge for the storage that is used by applications and departments, you must create models of the applications and departments in your business organization and map the storage resources to the applications and map the applications that the departments use to the departments. If you organize an application or department in hierarchies, the chargeback and consumer reports show the capacity and cost of the storage resources that the application and its child applications use and the capacity and cost of the storage resources that the department and its child departments use.

Storage capacity

You can choose the unit of measurement that is used to show the amount of storage that is consumed by your storage resources. In consumer and chargeback reports, you can show the storage that is consumed, for example, in PB, PIB, TB, TiB, GB, or GiB.

Storage costs

The cost of the storage that is used by storage consumers is included in all reports even if the storage costs are set to zero. If you want to send reports that show the capacity of the storage, but not the cost of the storage that is used, you can exclude the storage costs from the report.

Before you decide how you want to set the costs for the block storage that is used by the storage consumers, you must choose whether you want to charge for the storage that is allocated to the storage consumer or the storage that is assigned to the storage consumer.

By default, block storage is calculated by the amount of storage that is allocated to the volumes that are being used for storage by the consumer. Whether you choose to calculate by allocated or assigned capacity, it doesn't affect the calculation of capacity for standard-provisioned volumes because standard-provisioned volumes are fully allocated when they are created. However, the calculation of the capacity of thin provisioned and compressed volumes is affected depending on whether you choose to calculate capacity by allocated or assigned capacity.

For example, an application has three volumes, two fully allocated volumes with 1 TiB each and one thin-provisioned volume with an assigned capacity of 3 TiB. The thin-provisioned volume is allocated capacity in increments of 1 TiB. If you generate a report that calculates capacity by allocated capacity, and the thin-provisioned volume is currently allocated 1 TiB, the total amount of capacity for the application is $1 \text{ TiB} + 1 \text{ TiB} + 1 \text{ TiB} = 3 \text{ TiB}$. However, if you choose to calculate by assigned space, the total capacity for the application is $1 \text{ TiB} + 1 \text{ TiB} + 3 \text{ TiB} = 5 \text{ TiB}$. The cost is also affected because the cost is the total capacity of the block storage, which is multiplied by the unit cost or the unit cost per tier.

Restriction: If you choose to calculate block storage by used capacity, the block storage for FlashSystem A9000 and FlashSystem A9000R storage systems is calculated based on the provisioned capacity percentage of the volumes. This restriction occurs because used capacity information for volumes is not available from FlashSystem A9000 and FlashSystem A9000R.

Default or custom storage costs

When you create or update a report, you can choose one of the following options:

Use default cost

Set or use default costs per unit and type of storage.

If you choose to use the default costs option, the changes that you make apply to all of the reports that use the default option to calculate the cost of storage. When you exclude costs from reports that use default costs, you exclude costs from all reports that use default costs to calculate the cost of storage.

Set custom cost

Use custom costs per unit and type of storage.

If you choose to use the custom costs option, the costs that you set are used to calculate the cost of storage only for that report. If you exclude costs from the custom report, the costs are only excluded from the custom report that you create or edit.

The reports that were created in IBM Spectrum® Control 5.2.11 use the unit costs that were specified when the reports were configured.

Tip: If you want to change the configuration of a report, such as how storage costs are calculated, click **Reports > Email Reports**, select the report, and then click **Edit**.

Deleted and unavailable reports

If you delete a storage consumer, such as an application, the entry for that storage consumer is removed from all chargeback reports for applications. If you created a consumer report for a storage consumer that was deleted, the report is automatically deleted.

If you organize your applications or departments in hierarchies, the chargeback and consumer reports show the total capacity and costs for the parent application or department and its child applications and departments. However, if you create a consumer report for a specific application or department and then designate the application or department as a child application of another application, the consumer report is deleted.

For example, you create a consumer report for an application called German Online Sales. You then reorganize your sales applications in a hierarchy and the application for German Online Sales becomes a child application of European Sales. To include the capacity and cost of the storage that is used for German Online sales, you must create a consumer report for the application for European Sales.

Configure reports that make managers aware of the capacity of the storage that is used by their applications, departments, hypervisors, or physical servers. The cost of the storage is not shown in the reports.

Creating chargeback reports

Create chargeback reports that show how much capacity is used and the cost of the capacity that is used by applications, departments, hypervisors, and physical servers.

About this task

Chargeback reports help managers to realize the cost of the storage that they use, plan storage usage more efficiently, and reduce storage costs. For example, a manager gets a chargeback report that shows that the bulk of the storage that is used by a non-critical application is on tier-1. To reduce storage costs and use storage more efficiently, the manager can request the storage administrator to use tier-2 or lower tiers of storage for the application's data.

Procedure

1. Click Reports, and then click Create Report.
2. In the Summary Reports pane, click Chargeback.
3. Type the unique name of the report, and enter the delivery and the scheduling details.
4. Choose the type of storage consumer from the list.
If you choose Hypervisor or Physical Server, the capacity and cost of the hypervisors and physical servers that belong to clusters are listed under the name of the cluster.
5. Choose how you want to calculate the capacity and cost of thin-provisioned storage.
6. Choose the unit of capacity measurement that you want to use in the report.
Tip: To make sure that the recipients of the report get the report that they want, check the report preview.
7. Choose whether you want to use default or customized costs for block and file storage.
To change the default costs for block and file storage, click the lock (🔒) icon.
8. By default, the storage costs are shown in the report. To exclude storage costs from the report, choose one of the following options:

Storage cost option	Steps
Use Default Cost	a. Click the lock (🔒) icon. b. In the Include Storage Cost in Report section, click No. Note: If you exclude costs from a report that uses default costs, the costs are excluded from all of the chargeback and consumer reports that use default costs.
Use Custom Cost	In the Include Storage Cost in Report section, click No.
9. Choose the types of storage that you want to include in the report.
10. Set the unit costs for the storage that is used.
To get a complete picture of the capacity and cost of the block storage, include the cost of the data that is copied.
11. Click Save.
If you set the frequency of the report to Now, you click Save and Send.

Results

The report is saved and, depending on the scheduling option, the report is sent to the recipients or scheduled to be sent later. If you want to change the configuration of the report, click Reports, select the report, and then click Edit.
Tip: You want to send a scheduled report now, but you don't want to change the original schedule? Click Reports, > Reports. Select the report, and click Actions, > Run Now. The report is sent without changing the original schedule.

What to do next

If you want to extract capacity information regularly about your storage resources, you can use the Representational State Transfer (REST) API to automatically export the data that you need to generate custom reports or share with external applications.

- [Chargeback reports](#)
Configure the chargeback reports to include block and file storage and to calculate the cost of the block and file storage that is used by the storage consumers.

Related information

- [REST API](#)

Chargeback reports

Configure the chargeback reports to include block and file storage and to calculate the cost of the block and file storage that is used by the storage consumers.

You configure, schedule, and send chargeback reports so that the owners and managers of storage resources:

- Know the cost of maintaining the block data and file data that they use
- Know the cost of maintaining block data on each tier of storage
- Know the cost of maintaining block copy data

Include total block and file capacity in the report

In the Configure Report section, you choose the types of storage that you want to show in the report. For example, if you click the File Storage check box, the names of the resources and the total file capacity that the resources use are shown in the report.

For block storage, you can show the total storage capacity and, if your storage is tiered, the total capacity by tier. You can also break down the total block capacity into total primary capacity and total copy capacity.

Tip: The recipient of the report, such as the application owner, sees that the capacity for copy data is high for tier-1 storage. To reduce costs and use the block storage more efficiently, the application owner can ask the storage administrator to place the volumes that are used for copy data on lower and less expensive storage tiers. The

storage administrator can also analyze the tiering of the pools to make sure that the application's performance is not affected when the copy data volumes are moved to lower storage tiers.

Include block and file costs in the report

In the Set Storage Cost section, you set the cost per TiB of storage that the resources use. The total cost of the storage that is used is shown in the Cost column in the report.

For block storage, you set the costs as follows:

- If your storage environment is tiered, you set the price per TiB for each tier of storage
- If your storage environment is not tiered, you set the price per TiB for all of your block storage
- If your storage environment contains tiered and non-tiered storage, you can set the price per TiB for the tiered storage, but you can't set a price for the non-tiered storage. Although you can't set the cost for the non-tiered storage, the capacity of the non-tiered storage that is used is calculated.

If you assign your block storage pools to tiers, you can differentiate between the cost of expensive tier-1 storage and the cost of the less expensive storage that is used on the lower tiers of storage.

For file storage, you set a price for all of the file storage that is used by your resources.

When you configure chargeback reports, you can send the report immediately or schedule the report to be sent every day, every week, or every month.

Tip: If your storage environment changes, you should check whether you need to update your scheduled reports. For example, if you add a storage tier, you can edit the report and set the price for the new tier.

Creating consumer reports

Create consumer reports that show how much block capacity is used and the cost of the block capacity that is used by an application, department, hypervisor, or physical server.

About this task

Storage consumer reports help the managers and owners of applications, departments, hypervisors, and physical servers realize the cost of the block storage that they use, plan block storage usage more efficiently, and reduce block storage costs.

Procedure

1. Click Reports, and then click Create Report.
2. In the Summary Reports pane, click Storage Consumer.
3. Type the unique name of the report, and enter the delivery and the scheduling details.
4. From the list, click the type of storage consumer and type or click the name of the storage consumer.
To generate a report about the hypervisors or physical servers that belong to a cluster, you choose Hypervisor or Physical Server, and then choose or type the name of the cluster.
5. Choose whether you want to calculate block capacity by allocated or assigned space.
6. Choose the unit of capacity measurement that you want to use in the report.
Tip: To make sure that the recipients of the report get the report that they want, check the report preview.
7. Choose whether you want to use default or customized costs for block storage.
8. Choose the types of storage that you want to include in the report.
To change the default costs for block storage, click the lock (🔒) icon.
9. By default, the storage costs are shown in the report. To exclude storage costs from the report, choose one of the following options:

Storage cost option	Steps
Use Default Cost	a. Click the lock (🔒) icon. b. In the Include Storage Cost in Report section, click No. Note: If you exclude costs from a report that uses default costs, the costs are excluded from all of the chargeback and consumer reports that use default costs.
Use Custom Cost	In the Include Storage Cost in Report section, click No.

10. Set the unit costs for the block storage that is used.
To get a complete picture of the capacity and cost of the block storage, include the cost of the data that is copied.
11. Click Save.
If you set the frequency of the report to Now, you click Save and Send.

Results

The report is saved and, depending on the scheduling option, the report is sent to the recipients or scheduled to be sent later. If you want to change the configuration of the report, click Reports, select the report, and then click Edit.

Tip: You want to send a scheduled report now, but you don't want to change the original schedule? Click Reports > Reports. Select the report, and click Actions > Run Now. The report is sent without changing the original schedule.

What to do next

If you want to extract capacity information regularly about your storage resources, you can use the Representational State Transfer (REST) API to automatically export the data that you need to generate custom reports or share with external applications.

- [Consumer reports](#)
Configure consumer reports to calculate the cost and capacity of the block storage that is used by a storage consumer such as an application, a department, a

hypervisor, or a physical server.

Related information

- [REST API](#)

Consumer reports

Configure consumer reports to calculate the cost and capacity of the block storage that is used by a storage consumer such as an application, a department, a hypervisor, or a physical server.

You configure, schedule, and send consumer reports so that the owner or manager of the storage consumer knows the cost of maintaining the block storage that the storage consumer uses.

In the Configure Report section, you include the total block storage capacity and, if your storage is tiered, the total capacity by tier in your report. You can also include the total primary capacity and the total copy capacity of the storage that is used, and you can include the total capacity:

- For VDisk mirrors
- For FlashCopy® and Safeguarded Copy volumes
- For remote mirrors such as Global Mirror, Global Copy, and Metro Mirror

In the Set Storage Cost section, you set the cost per TiB of the block storage that the storage consumer uses.

You set the costs as follows:

- If your storage environment is tiered, you set the price per TiB for each tier of storage
- If your storage environment is not tiered, you set the price per TiB for all of your block storage
- If your storage environment contains tiered and non-tiered storage, you can set the price per TiB for the tiered storage, but you can't set a price for the non-tiered storage. Although you can't set the cost for the non-tiered storage, the capacity of the non-tiered storage that is used is calculated.

Creating summary reports of the storage capacity

Configure reports that make managers aware of the capacity of the storage that is used by their applications, departments, hypervisors, or physical servers. The cost of the storage is not shown in the reports.

About this task

You can create reports that show the total capacity of the storage that is used by storage consumers and exclude the storage costs from the reports.

Procedure

1. Click Reports > Reports, and then click Create Report.

2. Choose one of the following options:

Option	Steps
Create chargeback reports	In the Summary Reports pane, click Chargeback.
Create consumer reports	In the Summary Reports pane, click Storage Consumer.

3. Enter the report details and schedule the report.

4. Choose one of the following options:

Option	Steps
Chargeback reports	Choose the type of storage consumer.
Consumer reports	Choose the type of storage consumer and the storage consumer.

5. To calculate the capacity that is assigned to the thin-provisioned volumes, click Assigned space.

By default, the amount of space that is allocated to the thin-provisioned volumes is used to calculate the cost.

6. Choose the unit of capacity measurement that you want to use in the report.

Tip: To make sure that the recipients of the report get the report that they want, check the report preview.

7. In the Configure Report section, choose the capacity values that you want to include in the report.

8. By default, the storage costs are shown in the report. To exclude storage costs from the report, choose one of the following options.

If you exclude costs from a report that uses default costs, the costs are excluded from all of the chargeback and consumer reports that use default costs.

Storage cost option	Steps
Use Default Cost	a. Click the lock (🔒) icon. b. In the Include Storage Cost in Report section, click No.
Use Custom Cost	In the Include Storage Cost in Report section, click No.

9. Click Save.

If you set the frequency of the report to Now, you click Save and Send.

Results

The reports include the capacity values and exclude the costs of the capacity that is used.

Running reports

You can run reports that you created without defining a schedule or changing the schedule that was created for the report.

About this task

If you created a report, but didn't schedule it, you can run the report again. You can also run reports that you scheduled without changing the schedule for the report.

Procedure

1. Click Reports.
2. Click the report.
To run two or more reports, press Ctrl or press Shift and click the reports.
3. Click Actions > Run Now.

Results

The reports are generated and sent to the reports' recipients.

Editing reports

Change the configuration and scheduling for reports.

About this task

You can edit and reschedule custom, predefined capacity and inventory, and consumer and chargeback reports.

Procedure

1. From the Reports menu, click Reports.
2. Expand the section that contains the report.
3. Click the report, and then click Edit.
Tip: For custom and predefined capacity and inventory reports, click one of the links in the task pane. By default, the first page that is shown is the Schedule Delivery page. For example, to add, change, or remove filters, click Edit Filter.
4. Make your changes.

Results

If you schedule the report, the changes are saved and included in the next scheduled report. If you chose send now when you scheduled the report, the changes are saved and the report is sent to the recipients.

What to do next

Don't forget when you send the report that you will need to reconfigure the schedule if you want to send or save the report at regular intervals.

Deleting reports

Remove the reports that you don't need.

Procedure

1. Click Reports.
2. Click the report.
To select two or more reports, press Ctrl or press Shift and click the reports.
3. Click Actions > Delete Report.

Configuring the email server

To send reports, you must configure the email server.

About this task

The email server that is used to send alert notifications is also used to send reports. If you didn't configure the email server for alert notifications, you must configure the email server before you create reports.

IBM Spectrum® Control ensures, when it sends alert notifications and reports by email to your email server, that it complies with the security standards that you configure on your email server. For example, if your email server requires authentication and TLS to send emails, then IBM Spectrum Control uses the authentication credentials that you provide when you set up the email server, and uses TLS to establish the connection with your email server. Because the email server that you set up is automatically trusted, you don't have any additional management tasks such as importing the server certificate into the keystores that are used by IBM Spectrum Control.

Tip: To change the configuration of the mail server, you click [Settings](#) > [Notification Settings](#).

Procedure

1. Type the host name, or IPv4, or IPv6 address of the email server.
2. Type the port number that is used by the email server to send alert notifications and reports.
3. Provide the user's credentials for authenticating with your email server.
If your email server requires authentication to establish the connection, you must enter the user name and password.
4. Optional: Type the email address, such as the email address of the administrator, that you want to use for receiving replies to alert notifications and reports.
If you don't enter a value, and you entered an email address in the User Name field, then replies are sent to that address. Otherwise, replies are sent to **no-reply@<Spectrum_Control_server_host_name>**.
5. Test the connection and then click Save.

Results

You can create reports and send the reports by email.

Investigating issues with reports

You can access log and trace files to investigate the issues that you might have when reports are generated and sent by email or saved to the file system.

In IBM Spectrum® Control, you can create, schedule, and send chargeback and storage consumption reports by email, and you can create, schedule, and save custom reports to your file system or send them by email.

To create reports, the following IBM Spectrum Control components and services are used. (The Export server service is used only for custom reports.)

Table 1. Components used in reporting

Actions	Web server component	Data server component	Device server component	Export server service	SMTP transmission service
Create, update, and delete reports	Yes	Yes	Yes	No	No
Generate and deliver reports	Yes	Yes	No	Yes	Yes

Export server is a new service that converts the data for the report that it gets from the Web server into HTML.

The SMTP transmission service handles all communications, such as the delivery of alert notifications by email, and the sending of chargeback, storage consumption, and custom reports from IBM Spectrum Control to the customers' external SMTP servers.

Setting the trace level for investigating reporting issues

Go to the folder where you installed IBM Spectrum Control and complete these steps:

Tip: For Windows operating systems the default installation directory is C:\Program Files\IBM\TPC. For AIX® and Linux® operating systems the default installation directory is opt/IBM/TPC.

1. On Windows OS, go to installation_dir\IBM\TPC\web\conf. On AIX or Linux OS, go to installation_dir/IBM/TPC/web/conf.
2. In a text editor, open the logging.properties file.
3. Set the value of the **trace.reportdata.level** property to **trace.reportdata.level=debug**.
4. Save the logging.properties file.

You have set the trace level for the traceReportData_<number>.log to debug.

Access log, trace, and other information about reports

Table 2. Location of log, trace, and other files

File name	Description and location
ReportData.log	High-level information about the creation and distribution of reports. Windows: installation_dir\web\log AIX and Linux: installation_dir/web/log
traceReportData_<number>.log	Detailed information about the creation and distribution of custom reports, and SMTP transmission of custom reports. For example, you can check why a custom report isn't saved to the file system, or sent, or received by email. Windows: installation_dir\web\log AIX and Linux: installation_dir/web/log
traceWebServer_<number>.log	Information relating to creating, editing, and scheduling custom reports. Windows: installation_dir\web\log AIX and Linux: installation_dir/web/log
Console.log	Information about whether the report data service, which runs on the Web server, was started or stopped, errors generated when creating and retrieving custom reports, handshake errors that were generated when custom reports are sent by email. Windows: installation_dir\wlp\usr\servers\webServer\logs AIX and Linux: installation_dir/wlp/usr/servers/webServer/logs

File name	Description and location
Messages.log	See the description for the Console.log. Both log files report the same types of errors. Windows: installation_dir\wlp\usr\servers\webServer\logs AIX and Linux: installation_dir/wlp/usr/servers/webServer/logs
traceDeviceServer_<number>.log	Detailed information about the SMTP transmission of the chargeback and storage consumption reports sent by email. For example, you can check why a chargeback or storage consumption report wasn't sent. Windows: installation_dir\device\log AIX and Linux: installation_dir/device/log
Messages.log	Information about whether the Device server was started or stopped, handshake errors that are generated when alert notifications, chargeback, or storage consumption reports are sent. Windows: installation_dir\device\log AIX and Linux: installation_dir/device/log
traceScheduler_<number>.log	Information about when the report creation process began and completed for each report. Windows: installation_dir\data\log AIX and Linux: installation_dir/data/log

Stopping and starting the Export server service

On Windows, the Export server runs as a service called IBM Spectrum Control - Export Server, which can be stopped and restarted.

1. Click the Start menu, type `services.msc`, and then press Enter.
2. Click IBM Spectrum Control - Export Server, and stop or start it.

Alternatively, you can run the following batch files or scripts to stop or start the Export server service on Windows or AIX and Linux operating systems:

Operating system	Location	File
Windows	By default, it's C:\Program Files\IBM\TPC\scripts	Start: startTPCExport.bat Stop: stopTPCExport.bat
AIX and Linux	By default it's /Opt/IBM/TPC/scripts	Start: startTPCExport.sh Stop: stopTPCExport.sh

Types of predefined capacity and inventory reports

The predefined capacity and inventory reports that you can create for your storage resources are listed.

Check the table to see the predefined reports that you can create for the storage resources in your environment.

Table 1. Predefined capacity and inventory reports

Resource	Capacity	Inventory
Block Storage Systems	Yes	Yes
File Storage Systems	Yes	Yes
Object Storage Systems	Yes	Yes
Switches	No	Yes
Chassis	No	Yes
Servers	Yes	Yes
Hypervisors	Yes	Yes
Applications	Yes	No
Departments	Yes	No
Managed Disks	Yes	Yes
Controllers	No	Yes
Enclosures	No	Yes
Filesets	Yes	No
NAS File Systems	Yes	No
Modules	No	Yes
Network Shared Disks	Yes	No
Pools	Yes	No
Spectrum Scale Nodes	No	Yes
Spectrum Virtualize Nodes	No	Yes
Storage System FC Ports	No	Yes
Storage System IP Ports	No	Yes
Server Ports	No	Yes
Switch Ports	No	Yes
Volumes	Yes	No

Reports FAQ

Troubleshooting reports

Why can't I send the report as an attachment?

You're notified that a report can't be sent by email because the report's attachments exceed the maximum size limit. The maximum size limit for attachments is set on your email server.

If you can't change the maximum size limit for attachments, you can edit the report and choose Save to File System as the delivery method on the Schedule Delivery page.

Alternatively, you can reduce the scope of the report to create smaller and more focused reports. For example, when you create reports about volumes, you can select volumes by the storage systems, pools, or applications that they belong to, or the servers that they are assigned to. You can also refine the report by removing columns and adding filters. And, to reduce the size of attachments, choose CSV as the file type.

[Learn more](#)

Why can't I save the report to a custom folder on my file system?

You must have read and write access to the folder and you must create the custom folder before you create the report. Don't forget to enter the full path to the folder, such as C:\Program files\IBM\TPC\myreports or /opt/IBM/TPC/myreports on the Schedule Delivery page.

Why can't I see all of the rows in the report in my email?

If the report is very large, the report's recipients might not see all of the rows in the report in the email.

Click Reports. Select the report and click Edit. On the Schedule Delivery page, add the report as a CSV or HTML attachment. To see all of the rows in the report, the reports' recipients can open the attachment.

Creating and sending

Why can't I create a new custom report on the Reports page?

Unlike chargeback, consumer, and predefined reports, you can't create new custom reports on the Reports page. To create new custom reports, open any page that shows asset, capacity, configuration, or performance information, such as the Block Storage Systems page, and click Create Report. On the Reports page, you can edit or delete the custom reports that you created.

[Learn more](#)

How do I create a custom report about performance?

Go to a page that shows information about block storage resources. Select one or more of the resources, click View Performance, and then click Create Report.

[Learn more](#)

What types of reports can I create?

IBM® Storage Insights Pro users can create chargeback, consumer, predefined capacity, predefined inventory, and custom reports. IBM Storage Insights users can create predefined capacity reports for storage systems and pools and predefined inventory reports for storage systems. To create new predefined reports, click Reports, and then click Create Report.

[Learn more](#)

How can I send the reports that I created now?

You want to send a report now although the report, for example, is scheduled to run next week. Or, you created a report that you didn't schedule and want to send again.

Click Reports. To select the reports, press Ctrl or press Ctrl + Shift and click the reports. From the Actions menu, click Run Now. The report is generated without changing the schedule that you created for the report.

Capacity metrics for reports

To gain insights into storage usage, review the capacity metrics that are collected, analyzed, and shown in reports.

- [Capacity metrics for chargeback and consumer reports](#)
Learn more about how the capacity and costs for block and file storage is calculated in chargeback and consumer reports.

Capacity metrics for chargeback and consumer reports

Learn more about how the capacity and costs for block and file storage is calculated in chargeback and consumer reports.

Chargeback and storage consumer reports

The same block capacity metrics are shown in chargeback and consumer reports. In chargeback reports, the block capacity and costs are shown for all applications, departments, hypervisors, and physical servers. In consumer reports, the block capacity and costs are shown for a specific application, department, hypervisor, or physical server. The capacity and cost of file storage is not included in consumer reports.

If you create reports about physical servers, servers that are virtual machines are excluded from the report.

Tip: To find out which servers are virtual machines, click Servers > Servers, right-click any column heading and click Virtual Machine.

Virtual machine capacity

If you assign the storage resources on a virtual machine to an application or department, the capacity of those storage resources is included in the calculation of capacity and cost for the application or department.

For example, three virtual machines are allocated capacity from a data store, which has a total capacity of 3 TiB. The capacity for the data store comprises:

- One volume on tier 1 with a capacity of 2 TiB
- One volume on tier 2 with a capacity of 1 TiB

The ratio of tier-1 storage to tier-2 storage is 2:1 or 66.66% to 33.33%.

The total capacity of the data store is split across 3 by 1,024 GiB disks and one of the disks is allocated to `Virtual_Machine_1`. The used capacity on `Virtual_Machine_1` is allocated to a database application. So, the total amount of capacity that is allocated to the database application is 1,024 GiB, which comprises 66.66% of tier-1 storage and 33.33% of tier-2 storage. When the report is generated for the database application, the block capacity for tier-1 storage is **1024 GiB*66.66%**, which is 682.67 GiB or 0.67 TiB. The block capacity for the tier-2 storage is **1024 GiB*33.33%**, which is 341.33 GiB or 0.33 TiB.

If you calculate the capacity and cost of storage by used capacity, the capacity and cost of the storage that is used by the application or department is shown in the chargeback and consumer reports.

Restriction: You might get unexpected results in chargeback and consumer reports if the volumes that are used to provide the capacity on the disks for the virtual machine are thin-provisioned and shared by two or more applications.

Hypervisor and physical server clusters

In chargeback and storage consumer reports, the capacity and cost of storage for hypervisors and physical servers that are members of clusters are included in the capacity and cost of the cluster that they belong to. For example, `hypervisor_1` and `hypervisor_2` belong to `cluster_1`. To create the chargeback report about the hypervisors cluster, you choose Hypervisors as the consumer, and the capacity and the cost of the two hypervisors are included in the report entry for `cluster_1`. To create a report for `cluster_1` in a storage consumer report, you choose Hypervisor as the type of consumer, and `cluster_1` as the name of the consumer.

Block storage

The following information is provided about how block capacity is calculated:

Block or Used Capacity

In chargeback reports, the total block capacity for all of the storage resources is called `Block capacity`, whereas in consumer reports the total block capacity that the storage consumer uses is called `Used Capacity`.

The total capacity of these volumes is included in the calculation of block capacity:

- The provisioned capacity of the volumes without copies that are allocated to the consumer
- The provisioned capacity of the volumes with copies that are allocated to the consumer such as:
 - The total capacity of VDisk mirror volumes and their copies
 - The total capacity of FlashCopy® volumes and their target volumes
 - The total capacity of Safeguarded Copy source volumes and their volume backups
 - The total capacity of Global Mirror, Global Copy, and Metro Mirror volumes and their target volumes

For example, an application is assigned all of the block storage volumes on a physical server. In this scenario, the block capacity value includes the capacity of all of the block volumes that are assigned to the physical server. If the assigned volume on the physical server has a VDisk mirror copy or the volume is a FlashCopy source volume, the capacity of the VDisk mirror copy or the capacity of the FlashCopy target volume is also included in the calculation.

Primary capacity

The total capacity of the following types of volumes is included in the calculation of primary capacity:

- The provisioned capacity of the volumes without copies that are allocated to the consumer
- The provisioned capacity of primary VDisk mirror copies that are allocated to the consumer
- The provisioned capacity of the source volumes in FlashCopy relationships that are allocated to the consumer
- The provisioned capacity of the Safeguarded Copy source volumes that are allocated to the consumer
- The provisioned capacity of the Global Mirror, Global Copy, and Metro Mirror source volumes that are allocated to the consumer

VDisk Mirrors

The total capacity of the VDisk mirror copies for the volumes that are allocated to the consumer.

FlashCopy

The total capacity of the following types of volumes is included in the calculation of FlashCopy:

- The capacity of the FlashCopy target volumes for the source volumes that are allocated to the consumer
- The capacity of the volume backups for the Safeguarded Copy source volumes that are allocated to the consumer

Remote Mirrors

The total capacity of the Global Mirror, Global Copy, and Metro Mirror target volumes for the source volumes that are allocated to the consumer.

Primary capacity by tier

The primary capacity that is allocated to the consumer for the specified tier.

Copy capacity by tier

The copy capacity that is allocated to the consumer for the specified tier, which is calculated as follows:

- The total capacity of the non-primary VDisk mirror copies
- The total capacity of the target volumes for volumes in FlashCopy relationships
- The total capacity of target volumes for Global Mirror, Global Copy, and Metro Mirror

In tiered environments, the source volume might be on tier 1 and the target volume on tier 3. In this case, the capacity of the source volume is included in the calculation for the total primary capacity for Tier 1 and the capacity of the target volume is included in the calculation for the total copy capacity for tier 3.

Figure 1. Calculating copy capacity

Restriction: For volumes that have multiple volume copies, only the capacity of the first copy and the capacity of the second copy of the volume are included in the calculation of copy capacity.

File storage

File capacity is the total amount of file storage space that is allocated to the consumer.

For example, if a server mounts a fileset export from a file storage system and a quota is defined for the fileset, the file capacity is the hard limit capacity that is defined for the quota.

If a quota is not defined for the fileset, the file capacity is the capacity of the file system that contains the fileset. If multiple fileset exports from the same file system are mounted and the hard limits that are defined for the quota exceed the total file system capacity, then the file capacity is the total capacity of the file system.

If a hypervisor data store is a mounted NFS export, file capacity is the capacity of the file system on which the export is based.

Using the REST API to generate reports

Use the REST command line utility or a web browser to generate capacity, configuration, and performance reports.

- [Retrieving data about resources by using a REST API command line utility](#)
You can connect to the REST API for IBM Spectrum® Control and retrieve data by using a REST command line utility.
- [Retrieving data by using REST API with a web browser](#)
A convenient way to use the IBM Spectrum Control REST API is within the interface itself. You can quickly access resource information for your reporting capabilities by using a web browser.

Retrieving data about resources by using a REST API command line utility

You can connect to the REST API for IBM Spectrum® Control and retrieve data by using a REST command line utility.

You can use any REST command line utility, for example, GNU Wget. To access information about the GNU Wget utility, go to <https://www.gnu.org/software/wget/>. The IBM Spectrum Control REST API is hosted here: `https://<hostname>:9569/srm/REST/api/v1/`.

You can enter a command to authenticate with the REST API and store a security token in a file to use in your later queries, for example, `cookies.txt`.

You can use the utility, by entering the following command:

```
wget --post-data "j_username=<user name>&j_password=<password>"  
--no-check-certificate --keep-session-cookies --save-cookies cookies.txt  
https://<hostname>:9569/srm/j_security_check
```

You can use the security token in all subsequent commands that are issued against the REST API, by entering the following command:

```
wget --no-check-certificate --load-cookies cookies.txt  
https://<hostname>:9569/srm/REST/api/v1/
```

Example (partial listing)

```
},  
{  
  "Description": "Provides a list of ports belonging to a parent storage system.  
Format: \StorageSystems\<id>\Ports For a list of ports associated with a  
port owner, specify the owner type and id in the URL.
```

To see a list of all storage systems, you can append the URL:

```
https://<hostname>:9569/srm/REST/api/v1/StorageSystems
```

To see more information about a resource type, you can further append the URL (where `<Name>` is the resource type, such as `StorageSystems`, `Switches`, `Servers`, etc.)

```
https://<hostname>:9569/srm/REST/api/v1/<Name>
```

To see more information about a specific resource, add the ID to the URL (where `<id>` is available from `https://<hostname>:9569/srm/REST/api/v1/<Name>`):

```
https://<hostname>:9569/srm/REST/api/v1/<Name>/<id>
```

To query for volumes that belong to a specific storage system, enter:

```
https://<hostname>:9569/srm/REST/api/v1/StorageSystems/57909/Volumes
```

Example (partial listing)

```
[  
  {  
    "Acknowledged": "No",  
    "Allocated Space": "1.00",  
    "Capacity": "1.00",  
    "Controller": "Node 0",  
    "Copy Relationship": "",  
    "Easy Tier": "Tiered Pools\No",  
    "Encryption": "",  
    "Enterprise HDD Capacity": "1.00",  
    "Format": "FB",  
    "Hosts": "18",  
    "LSS or LCU": "00",
```

```

    "Last Data Collection": "Apr 10, 2016, 15:03:57",
    "Name": "CET_RA_vol",
    "Nearline HDD Capacity": "",
    "Physical Allocation": "Fully Allocated",
    "Pool": "General Use 1",
    "RAID Level": "RAID 5",
    "SSD Capacity": "",
    "Service Class": "",
    "Shortfall": "",
    "Status": "Normal",
    "Storage System": "DS8000-2107-75BLG91-IBM",
    "Storage Virtualizer": "None",
    "Thin Provisioned": "No",
    "Ticket": "",
    "Tier Distribution": "0",
    "Unallocated Space": "0.00",
    "Unused Space": "",
    "Used Allocated Space": "",
    "Used Space": "1.00",
    "Virtualizer Disk": "None",
    "Volume ID": "0000",
    "Volume Number": "0",
    "Volume Unique ID": "75blg91\0000",
    "id": "79852"
  },

```

The information that is provided in the **Format** field in the example shows what combinations are possible. For example,

https://<hostname>:9569/srm/REST/api/v1/StorageSystems/<id>/Ports

Tips:

- If the **Format** field is omitted, you can add the ID of one resource to the URL.
- The name elements in the URL are case-sensitive.
- The names of resource types are plural.
- If the URL is not used correctly, you might receive the following error message:

```

{ "result": { "type": "E", "msgId": "BPCUI0099E", "time": "Apr 4, 2016 16:25:07", "text":
"The storage resource is not available." } }

```

- If the URL returns a blank page, it means that no data is available for the resource. For example, if you query an application for file shares and there are no file shares in the application, the resulting page is blank.

Table 1. IBM Spectrum Control REST API URL examples

IBM Spectrum Control REST API	Description
https://<hostname>:9569/srm/REST/api/v1/StorageSystems	A list of all monitored storage systems.
https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002	Specific information for one storage system (ID is available from this URL: https://<hostname>:9569/srm/REST/api/v1/StorageSystems/<id>).
https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes	A list of all volumes for one storage system.
https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance	The available performance metrics for a volume.
https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/RemoteReplication	The remote mirror replication relationships for storage systems.
https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance/824?granularity=sample&startTime=1455818400000&endTime=1455904800000	Sample performance granularity information and a start and end time for the performance data.

Note: IBM® Storage is changing the capacity terminology that is used in IBM Storage products to make it more consistent. The new capacity terminology is used in IBM Spectrum Control 5.3.6 or later. The new terminology is used in the GUI, but the names used in the REST API have not changed. The output from the REST API continues to use Allocated Space instead of Used Capacity, Physical Allocation instead of Used Capacity %, and so on.

Retrieving data by using REST API with a web browser

A convenient way to use the IBM Spectrum® Control REST API is within the interface itself. You can quickly access resource information for your reporting capabilities by using a web browser.

To use the REST API with a web browser, use these steps:

1. Log on to the IBM Spectrum Control GUI. To start IBM Spectrum Control, see [Starting IBM Spectrum Control](#).
2. Open a new tab in your web browser.
3. Enter **https://<hostname>:9569/srm/REST/api/v1/**.

For example, to see a list of fabrics, enter **https://<hostname>:9569/srm/REST/api/v1/Fabrics** in a new tab of your web browser (partial listing).

```

{
  {
    "Acknowledged": "No",
    "Active Zone Set": "",
    "Connected Switch Ports": "0",
    "Custom Tag 1": "",
    "Custom Tag 2": "",
    "Custom Tag 3": "",
    "Data Source Count": "1",
    "Fabric Type": "Cisco",

```

```

    "Last Successful Probe": "N/A",
    "Links": "0",
    "Location": "",
    "NPV Switches": "0",
    "Name": "VSAN0002",
    "Parent Fabric": "san_director",
    "Principal Switch of Fabric": "tpc-70swt-csc",
    "Probe Schedule": "N/A",
    "Probe Status": "N/A",
    "Status": "Error",
    "Switch Ports": "0",
    "Switches": "1",
    "Virtual": "Yes",
    "WWN": "2002000DECAC5081",
    "id": "2663"
}

```

To see the information for a specific fabric in your environment, append the URL with the ID:

<https://<hostname>:9569/srm/REST/api/v1/Fabrics/2017>

Example (partial listing)

```

{
  "Acknowledged": "No",
  "Active Zone Set": "",
  "Connected Switch Ports": "18",
  "Custom Tag 1": "",
  "Custom Tag 2": "",
  "Custom Tag 3": "",
  "Data Source Count": "2",
  "Fabric Type": "Cisco",
  "Last Successful Probe": "N/A",
  "Links": "4",
  "Location": "",
  "NPV Switches": "0",
  "Name": "san_director",
  "Parent Fabric": "",
  "Principal Switch of Fabric": "",
  "Probe Schedule": "N/A",
  "Probe Status": "N/A",
  "Status": "Error",
  "Switch Ports": "104",
  "Switches": "2",
  "Virtual": "No",
  "WWN": "",
  "id": "2017"
}

```

To see the switches that belong to the fabric `"id": "2017"`, enter:

<https://<hostname>:9569/srm/REST/api/v1/Fabrics/2017/Switches>

Example (partial listing)

```

[
  {
    "Acknowledged": "No",
    "Connected Fabrics": "",
    "Custom Tag 1": "",
    "Custom Tag 2": "",
    "Custom Tag 3": "",
    "Data Source Count": "1",
    "Domain ID": "10",
    "Fabric": "unstable_BRCD_1-11",
    "Firmware": "v6.4.3g",
    "IP Address": "9.11.91.241",
    "Last Successful Monitor": "None",
    "Last Successful Probe": "None",
    "Links": "",
    "Location": "",
    "Mode": "Native",
    "Model": "Brocade 4100",
    "Name": "mdm-y76-swt",
    "Parent Switch": "",
    "Performance Monitor Interval (min)": "",
    "Performance Monitor Status": "Disabled",
    "Ports": "",
    "Principal Switch of Fabric": "cjswitch4",
    "Probe Status": "Never Probed",
    "Serial Number": "1070029",
    "Status": "Normal",
    "Vendor": "IBM",
    "Virtual": "No",
    "WWN": "100000051E347790",
    "id": "60989"
  }
]

```

Note: IBM Spectrum Control can connect to Brocade switches and fabrics either directly or by using Brocade Network Advisor. For Brocade switches and fabrics that IBM Spectrum Control connects to directly, the Data Source Count value is 0.

Table 1. IBM Spectrum Control REST API URL examples

IBM Spectrum Control REST API	Description
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems">https://<hostname>:9569/srm/REST/api/v1/StorageSystems	A list of all monitored storage systems.

IBM Spectrum Control REST API	Description
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002">https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002	Specific information for one storage system (ID is available from this URL: <a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems">https://<hostname>:9569/srm/REST/api/v1/StorageSystems).
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes">https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes	A list of all volumes for one storage system.
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance">https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance	The available performance metrics for a volume.
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/RemoteReplication">https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/RemoteReplication	The remote mirror replication relationships for storage systems.
<a href="https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance/824?granularity=sample&startTime=1455818400000&endTime=1455904800000">https://<hostname>:9569/srm/REST/api/v1/StorageSystems/2002/Volumes/2465/Performance/824?granularity=sample&startTime=1455818400000&endTime=1455904800000	Sample performance granularity information and a start and end time for the performance data.

Note: IBM® Storage is changing the capacity terminology that is used in IBM Storage products to make it more consistent. The new capacity terminology is used in IBM Spectrum Control 5.3.6 or later. The new terminology is used in the GUI, but the names used in the REST API have not changed. The output from the REST API continues to use Allocated Space instead of Used Capacity, Physical Allocation instead of Used Capacity %, and so on.

Exporting information about resources

Notify your colleagues about the current state and potential issues with your storage environment by exporting the capacity and performance information that is shown in the GUI.

You can use the information that is shown about your storage resources and their related resources to create reports in HTML or PDF file formats that you can send to your colleagues. Alternatively, you can export the information about your resources to a CSV file, which you can include in a report that you want to create about your storage resources.

You can go to the resource or internal resource page and create reports that contain the following types of information:

Table 1. Types of information in resource reports

Location	Types of information
Resource or internal resource page	Status, configuration, and capacity data
Performance tab for resource or internal resource	Key performance metrics
Capacity tab for resource or internal resource	Key capacity metrics

Restriction: You might not be able to view capacity and performance metrics for all of the resources.

For example, you monitor the pools for a SAN Volume Controller and you see that some of the pools are running out of capacity. To notify your colleagues, you export the information about the pools to an HTML file and send it to your colleagues. You want to include information about the input/output performance of the volumes for your storage systems in a report. To create the report, you export the information that is shown in the performance chart to a CSV file.

If you want to extract configuration, capacity, or performance information regularly about your storage resources, you can use the Representational State Transfer (REST) API to automatically export the data that you need to create your reports.

- [Exporting information about capacity shortages in pools](#)
To include information about the capacity of your resources in reports, use the reporting feature in IBM Spectrum® Control.
- [Exporting information about the input/output performance of volumes](#)
To include information about the performance of your resources in reports, use the reporting feature in IBM Spectrum Control.

Related tasks

- [Exporting information to a file](#)

Related information

- [REST API](#)

Exporting information about capacity shortages in pools

To include information about the capacity of your resources in reports, use the reporting feature in IBM Spectrum® Control.

About this task

You check the capacity of pools on your SAN Volume Controller storage system and see that the capacity of some of the pools is nearly depleted. So, you decide to notify your colleagues by including information about the pools in a report.

Procedure

1. Click **Storage > Block Storage Systems**.
2. Double-click the storage system and click **Pools** in the navigation pane.
3. On the Pools page, right-click one of the column headings and click **Zero Capacity**.

Tip: If you want to export information only about the pools that are depleted, click , select **Zero Capacity**, and type **Depleted** in the filter field. When a capacity limit is set, the pool is considered to be **Depleted** when the capacity limit is reached.

4. Click **Actions** and choose one of the options.

Results

You can get information about the capacity of the pools, whether the pools are depleted, and when the pools will become depleted.

Exporting information about the input/output performance of volumes

To include information about the performance of your resources in reports, use the reporting feature in IBM Spectrum® Control.

About this task

You want to include information about the input/output performance of the volumes in a report.

Procedure

1. Click **Storage > Volumes**.
2. Select all of the volumes in the list and click **View Performance**.
By default, the top 10 volumes are ordered by total input/output rate and the reporting period is set to 24 hours.
3. Click **Actions > Export > Export as CSV**.

Results

Information about the performance of the volumes with the highest input/output rates are exported to a CSV file, which you can download and include in a report.

Reporting with Cognos Analytics

Use the Cognos® Analytics reporting tool to view predefined reports and create custom reports about the resources that are monitored by IBM Spectrum® Control.

Charts are automatically generated for most of the predefined reports. Depending on the type of resource, the charts show statistics for space usage, workload activity, bandwidth percentage, and other statistics. You can schedule reports and specify to create the report output in HTML, PDF, and other formats. You can also configure reports to save the report output to your local file system, and to send reports as email attachments.

You must collect information about your environment before you can use reports to view details about the storage resources in it. You can use IBM Spectrum Control monitoring jobs, such as probes and performance monitors, to gather that information.

- [Getting started](#)
You can view predefined reports and create custom reports about IBM Spectrum Control in the optional Cognos Analytics reporting tool. You work with the reports in the Cognos Analytics reporting tool.
- [Scenarios](#)
Use these scenarios to learn how to use IBM Spectrum Control reports to analyze the most active volumes on hypervisors and to monitor the performance of a critical application. You can learn how to investigate a degradation in the performance of a storage pool. You can also learn how to identify the relationships between a storage system and other resources.
- [Configuring](#)
You can configure the optional Cognos Analytics reporting tool according to your requirements.
- [Predefined reports about resource relationships](#)
You can run predefined reports about the end-to-end relationship from a server to back-end storage. You can also run reports about the end-to-end relationship from file systems on servers to volumes on storage pools.
- [Predefined reports about switches and switch ports](#)
You can run predefined reports to analyze and compare the performance of switches and switch ports.
- [Predefined reports about groups](#)
You can run predefined reports to analyze the capacity of groups. A group is a set of logically related volumes, file systems, and shares. For example, a group that represents a business critical application might include the volumes, file systems, and shares that provide storage to the application.
- [Predefined reports about hypervisors](#)
You can run predefined reports to analyze the capacity and performance of hypervisors.
- [Predefined reports about servers and file systems on servers](#)
You can run predefined reports to analyze the capacity and performance of servers, file systems, and volumes.
- [Predefined reports about storage systems and components](#)
You can run predefined reports to view capacity details and performance metrics for storage systems and their components. The components include controllers, modules, nodes, disks, I/O groups, managed disks, storage pools, ports, RAID arrays, and volumes.
- [Predefined reports about storage tiering](#)
Use storage tier reports to help you determine the best storage-tier configuration for your environment.
- [Custom reports about performance](#)
You can use the optional Cognos Analytics reporting tool to create custom performance reports. Performance reports can contain detailed information about the performance of monitored resources, and some of the properties of those resources.
- [Custom reports about capacity and relationships](#)
You can use Cognos Analytics to create custom reports about capacity and relationships. Capacity and relationship reports can contain detailed information about the properties of monitored resources, and the available space and capacity of those resources.
- [Troubleshooting Cognos Analytics reports](#)
Find answers to questions about resolving issues with reports in the optional Cognos Analytics reporting tool.
- [Showing the package version number and build ID](#)
Access information about the packages for custom reports and predefined reports, such as the version number and the build ID.

Getting started

You can view predefined reports and create custom reports about IBM Spectrum® Control in the optional Cognos Analytics reporting tool. You work with the reports in the Cognos Analytics reporting tool.

The following storage systems run IBM Spectrum Virtualize to virtualize their storage: SAN Volume Controller, IBM Spectrum Virtualize for Public Cloud, IBM Spectrum Virtualize as Software Only, IBM® Storwize® family, FlashSystem 5000, FlashSystem 5100, FlashSystem 7200, FlashSystem 9100, FlashSystem 9200, and FlashSystem V9000. In this documentation, IBM Spectrum Virtualize is used to refer collectively to IBM SAN Volume Controller, IBM Spectrum Virtualize for Public Cloud, IBM Spectrum Virtualize as Software Only, and IBM Storwize storage systems, and to IBM FlashSystem® devices that run IBM Spectrum Virtualize.

- [Predefined reports](#)
You can use the optional Cognos Analytics reporting tool to view predefined reports about IBM Spectrum Control. Predefined reports provide information about the capacity and performance of your resources.
- [Predefined reports listed by package](#)
The data that the predefined reports use is organized into four packages: Capacity and Relationships, Historical Capacity, Performance, and Storage Tiering. Each report uses data from only one package.
- [Custom reports](#)
You can use the optional Cognos Analytics reporting tool to create custom reports about IBM Spectrum Control. Use custom reports to analyze the capacity and performance of your resources.
- [Viewing predefined reports](#)
Use the Cognos Analytics reporting tool to view predefined reports about IBM Spectrum Control.
- [Creating custom reports](#)
Use the Cognos Analytics reporting tool to view custom reports about IBM Spectrum Control. You can create basic reports with limited formatting, or design custom reports to add advanced formatting features to reports.
- [Viewing and creating reports in the Cognos Analytics reporting tool](#)
You access reports from IBM Spectrum Control, and work with the reports in the Cognos Analytics reporting tool.
- [Searching in your report data](#)
Search through your report data in the Cognos Analytics reporting tool.

Predefined reports

You can use the optional Cognos Analytics reporting tool to view predefined reports about IBM Spectrum® Control. Predefined reports provide information about the capacity and performance of your resources.

Predefined reports

You can view the following types of predefined reports:

Reports about the capacity and relationships of your resources

Reports about the capacity and relationships of servers, hypervisors, network-attached storage systems, storage virtualizers, storage systems, storage resource groups, groups, fabrics, and switches. Use these reports to analyze the capacity and relationships of resources. For example, to show the current space statistics for a pool on a storage system, run the Pools Capacity report. To show the pools that are related to a storage system, run the Storage Resource Relationships Summary report.

Reports about performance

Reports about the performance of your monitored resources. You can view reports about storage systems, components of storage systems, switches, and switch ports. Use these reports to analyze the performance of resources. For example, to find out which are the most active volumes on a storage system over a specified period, run the Most Active Volumes report. To view details about the performance of a volume over a specified period, run a report such as the Performance of One Volume report.

Restrictions:

- Performance data is collected at intervals. An interval represents the number of minutes over which samples of performance data are averaged. Data that is collected at certain intervals is automatically consolidated, or rolled up, to higher intervals. For example, data collected at 1-minute intervals is consolidated into 5-minute data. When you create a performance report in the Cognos Analytics reporting tool, the smallest interval for the sample data is 5 minutes. The data collected at 1-minute intervals is not available in the Cognos Analytics reporting tool to avoid performance problems.
- Performance reports are not available for the following storage systems:
 - FlashSystem 900
 - IBM Spectrum Scale
 - Dell EMC Unity
 - Hitachi VSP
 - NetApp storage systems running ONTAP 9
 - Pure FlashArray//M and FlashArray//X storage systems

To view performance metrics for those storage systems, use the IBM Spectrum Control GUI. For more information, see [Monitoring the performance of resources](#).

Reports about historical capacity

Reports that include the historical information about the capacity of your storage systems, pools, and volumes. Use these reports to determine whether more storage resources are required. For example, to show how space is used over a specified period on volumes on storage systems, run the Volumes Historical Capacity report. You can also use these reports to analyze future storage requirements for your environment.

Reports about storage tiering

Reports that include information about the workload activity of these resources: managed disk (MDisk) groups, virtual disks (VDisks) in MDisk groups, VDisks in storage resource groups, and VDisks in storage virtualizers. Use these reports to determine the best storage-tier configuration for your environment.

Charts are automatically generated for most of the predefined reports. Depending on the type of resource, the charts show statistics for space usage, workload activity, bandwidth percentage, and other statistics.

Tip: When you view a predefined report, click Help to find out more about the report.

Related reference

- [Predefined reports listed by package](#)

Predefined reports listed by package

The data that the predefined reports use is organized into four packages: Capacity and Relationships, Historical Capacity, Performance, and Storage Tiering. Each report uses data from only one package.

Tip: When you view a predefined report, click Help to find out more about the report.

Capacity and Relationships package

You can view the following predefined reports about capacity and relationships:

Availability of Switch Ports

Shows a chart of the 20 switches with the most ports and connected ports, and a table with the properties of the switches.

Capacity of One Group

Shows charts and tables of the capacity, available space, and used space statistics for each type of resource in a group. The report shows separate charts and tables for block-level and file-level resources.

Disks Capacity

Shows a chart of the disk classes with the most allocated space, and a table with space statistics for all disks by class. Use the report to review space allocation in your disks.

File System to Volume Relationships

Shows the end-to-end relationship from file systems on servers to volumes on storage pools. The report shows the usage of space on file systems over a specified period. Use the report to analyze changes in your file system requirements.

File Systems Capacity

Shows the available and used capacity of file systems, which are grouped by server. You can use this report to identify file systems that might be running out of space.

Groups Capacity

Shows a chart of the 20 groups with the most capacity, available space, or used space, and a table with details of all groups. Use the report to review the space allocation in your groups.

Hypervisor Data Stores Capacity

Shows a chart of the 20 hypervisor data stores with the most allocated space. This report also shows a table with space statistics for all hypervisor data stores. Use the report to review space allocation in your hypervisor data stores.

Hypervisor Disks Capacity

Shows a chart of the 20 hypervisor disks with the most allocated space, and a table with space statistics for all hypervisor disks. Use the report to review space allocation in your hypervisor disks.

Hypervisors Capacity

Shows a chart of the 20 hypervisors with the most allocated space, and a table with space statistics for all hypervisors. Use the report to review space allocation in your hypervisors.

Managed Disks Capacity

Shows a chart of the 20 managed disks with the most available space, and a table with space statistics for all managed disks. Use the report to review space availability in your managed disks.

Pools Capacity

Shows a chart of the 20 pools with the most allocated space, and a table with space statistics for all pools. Use the report to review space allocation in your pools.

Server Disks Capacity

Shows the available and used disk space for all disks, which are grouped by server. You can use the report to identify disks that have no allocated space.

Servers Capacity

Shows a summary of the available and used disk space, and the available and used file systems, for servers. Use the report to identify servers that are running out of space.

Storage Resource Relationships Summary

Shows the end-to-end relationship from a server to back-end storage. The report shows servers, hypervisors, NAS, storage systems, storage virtualizers, pools, and volumes.

Storage Resource Relationships Summary (Configurable)

Shows the end-to-end relationship from a server to back-end storage. You can configure which resources to show in the report.

Storage Systems Capacity

Shows a chart of the 20 storage systems with the most used space, and a table with details of all storage systems. Use the report to review the space allocation in your storage systems.

Volumes Capacity

Shows a chart of the 20 volumes with the most used space, and a table with details of all volumes. Use the report to review the space allocation in your volumes.

Historical Capacity package

You can view the following predefined reports about historical capacity:

Pools Historical Capacity

Shows the usage of space on storage pools over a specified period. Use the report to analyze changes in your storage pool requirements.

Storage Systems Historical Capacity

Shows the usage of space on storage systems over a specified period. Use the report to analyze changes in your storage system requirements.

Volumes Historical Capacity

Shows the usage of space on volumes over a specified period. Use the report to analyze changes in your volume requirements, particularly the increasing usage of space on thin-provisioned volumes.

Performance package

Performance data is collected at intervals. An interval represents the number of minutes over which samples of performance data are averaged. Data that is collected at certain intervals is automatically consolidated, or rolled up, to higher intervals. For example, data collected at 1-minute intervals is consolidated into 5-minute data. When you create a performance report in the Cognos® Analytics reporting tool, the smallest interval for the sample data is 5 minutes. The data collected at 1-minute intervals is not available in the Cognos Analytics reporting tool to avoid performance problems.

You can view the following predefined reports about performance:

- Compare Performance of Multiple Controllers and Modules
 - Shows up to four performance metrics for multiple controllers or modules over time. Use the report to compare the performance metrics for controllers or modules that are on storage systems.
- Compare Performance of Multiple Disks
 - Shows up to four performance metrics for multiple local disks over time. Use the report to compare the performance metrics for local disks that are on storage systems.
- Compare Performance of Multiple IO Groups
 - Shows up to four performance metrics for multiple I/O groups over time. Use the report to compare the performance metrics for I/O groups that are on storage systems.
- Compare Performance of Multiple Managed Disks
 - Shows up to four performance metrics for multiple managed disks over time. Use the report to compare the performance metrics for managed disks that are on storage systems.
- Compare Performance of Multiple Nodes
 - Shows up to four performance metrics for multiple nodes over time. Use the report to compare the performance metrics for nodes that are on storage systems.
- Compare Performance of Multiple Pools
 - Shows up to four performance metrics for multiple storage pools over time. Use the report to compare the performance metrics for storage pools that are on storage systems.
- Compare Performance of Multiple Ports
 - Shows up to four performance metrics for multiple ports over time. Use the report to compare the performance metrics for ports that are on storage systems.
- Compare Performance of Multiple Storage Systems
 - Shows up to four performance metrics for multiple storage systems over time. Use the report to compare the performance metrics for storage systems.
- Compare Performance of Multiple RAID Arrays
 - Shows up to four performance metrics for multiple arrays over time. Use the report to compare the performance metrics for arrays that are on storage systems.
- Compare Performance of Multiple Switch Ports
 - Shows up to four performance metrics for multiple switch ports over time. Use the report to compare the performance metrics for switch ports.
- Compare Performance of Multiple Switches
 - Shows up to four performance metrics for multiple switches over time. Use the report to compare the performance metrics for switches.
- Compare Performance of Multiple Volumes
 - Shows up to four performance metrics for multiple volumes over time. Use the report to compare the performance metrics for volumes that are on storage systems.
- Compare Performance of One Pool over Time Ranges
 - Shows one performance metric on one pool over two time periods. For example, you can use this report to compare the I/O rate for this week and last week.
- Compare Performance of One Storage System over Time Ranges
 - Shows one performance metric on one storage system over two time periods. For example, you can use this report to compare the I/O rate for this week and last week.
- Compare Performance of One Switch over Time Ranges
 - Shows one performance metric on one switch over two time periods. For example, you can use the report to compare the I/O rate for this week and last week.
- Compare Performance of One Switch Port over Time Ranges
 - Shows one performance metric on one switch port over two time periods. For example, you can use this report to compare the I/O rate for this week and last week.
- Most Active Controllers or Modules
 - Shows a chart of the 20 controllers or modules that are most active, and details for all storage systems, for a time period that you specify. Use the report to analyze the performance of controllers or modules.
- Most Active Disks
 - Shows a chart of the 20 local disks that are most active, and details for all local disks, for a time period that you specify. Use the report to analyze the performance of local disks.
- Most Active Host Connections
 - Shows a chart of the 20 host connections that have the most active volumes. The most active volumes have the greatest aggregate load.
- Most Active Hypervisors
 - Shows a chart of the 20 hypervisors that have the most active volumes. The most active volumes have the greatest aggregate load.
- Most Active IO Groups
 - Shows a chart of the 20 I/O groups that are most active, and details for all I/O groups, for a time period that you specify. Use the report to analyze the performance of I/O groups.
- Most Active Managed Disks
 - Shows a chart of the 20 managed disks that are most active, and details for all managed disks, for a time period that you specify. Use the report to analyze the performance of managed disks.
- Most Active Nodes
 - Shows a chart of the 20 nodes that are most active, and details for all nodes, for a time period that you specify. Use the report to analyze the performance of nodes.
- Most Active Pools
 - Shows a chart of the 20 storage pools that are most active, and details for all pools, for a time period that you specify. Use the report to analyze the performance of pools.
- Most Active Ports
 - Shows a chart of the 20 ports that are most active, and details for all ports, for a time period that you specify. Use the report to analyze the performance of ports.
- Most Active RAID Arrays
 - Shows up to four performance metrics for multiple arrays over time. Use the report to compare the performance metrics for arrays that are on storage systems.
- Most Active Servers
 - Shows a chart of the 20 servers that have the most active volumes. The most active volumes have the greatest aggregate load.
- Most Active Storage Systems
 - Shows a chart of the 20 storage systems that are most active, and details for all storage systems, for a time period that you specify. Use the report to analyze the performance of storage systems.
- Most Active Switch Ports
 - Shows a chart of the 20 switches that are most active, and details for all switches, for a time period that you specify. Use the report to analyze the performance of switches.
- Most Active Volumes

Shows a chart of the 20 volumes that are most active, and details for all volumes, for a time period that you specify. Use the report to analyze the performance of volumes.

Performance Data Export

Exports the performance metrics for one or more resources on a storage system to a spreadsheet file in Microsoft Excel file format. Use the report if you want to analyze performance data in Excel or to send performance data to IBM®.

Performance of One Controller or Module

Shows four charts, and a table of performance metrics for a controller or module over a time period. Use the report to analyze the performance of a controller or module.

Performance of One Disk

Shows four charts, and a table of performance metrics for a local disk over a time period. Use the report to analyze the performance of a local disk.

Performance of One IO Group

Shows four charts, and a table of performance metrics for an I/O group over a time period. Use the report to analyze the performance of an I/O group.

Performance of One Managed Disk

Shows four charts, and a table of performance metrics for a managed disk over a time period. Use the report to analyze the performance of a managed disk.

Performance of One Node

Shows four charts, and a table of performance metrics for a node over a time period. Use the report to analyze the performance of a node.

Performance of One Pool

Shows four charts, and a table of performance metrics for a storage pool over a time period that you specify. Use the report to analyze the performance of a storage pool.

Performance of One Port

Shows four charts, and a table of performance metrics for a port over a time period that you specify. Use the report to analyze the performance of a port.

Performance of One RAID Array

Shows four charts, and a table of performance metrics for a RAID array over a time period. Use the report to analyze the performance of a RAID array.

Performance of One Storage System

Shows four charts, and a table of performance metrics for a storage system over a time period that you specify. Use the report to analyze the performance of a storage system.

Performance of One Switch

Shows three charts, and a table of performance metrics for a switch over a time period that you specify. Use the report to analyze the performance of a switch.

Performance of One Switch Port

Shows four charts, and a table of performance metrics for a switch port. Use this report to view multiple performance metric types on the same chart. For example, you can view I/O rate and response time metrics on the same chart.

Performance of One Volume

Shows four charts, and a table of performance metrics for a volume over a time period that you specify. Use the report to analyze the performance of a volume.

Performance of Volumes by Host Connection

Shows the performance metrics for volumes on a host connection. Use the report to identify the contribution of individual volumes to the load of a particular server in your storage environment.

Performance of Volumes by Hypervisor

Shows the performance metrics for volumes on a hypervisor. Use the report to identify the contribution of individual volumes to the load of a particular hypervisor in your storage environment.

Performance of Volumes by Server

Shows the performance metrics for volumes on a server. Use the report to identify the contribution of individual volumes to the load of a particular server in your storage environment.

Summarized Performance of Volumes by Host Connection

Shows summarized performance metrics for volumes on a host connection. Use the report to identify the aggregate load and the average response time of a particular server.

Summarized Performance of Volumes by Hypervisor

Shows summarized performance metrics for volumes on a hypervisor. Use the report to identify the aggregate load and the average response time of a particular hypervisor.

Summarized Performance of Volumes by Server

Shows summarized performance metrics for volumes on a server. Use the report to identify the aggregate load and the average response time of a particular server.

Storage Tiering package

You can view the following predefined reports about storage tiering:

MDisk Group - VDisk Workload Activity Details

Shows the workload activity of virtual disks (VDisks) in a managed disk (MDisk) group. The workload activity is determined by calculating the average and maximum peak utilization of each VDisk.

MDisk Group Details

Shows the workload activity of a managed disk (MDisk) group. Use the report to analyze storage services for an MDisk group.

MDisk Groups - VDisk Workload Activity

Use this report to monitor the performance of virtual disks (VDisks) in managed disk (MDisk) groups. The workload activity of each MDisk group is determined by calculating the average and the maximum peak utilization of the VDisks in the MDisk group.

MDisk Groups - Workload Activity

Shows the workload activity of managed disk (MDisk) groups. You can use the information that the report provides to investigate which MDisk groups are being underused or overused.

Storage Resource Group - VDisk Workload Activity

Shows the workload activity of virtual disks (VDisks) in storage resource groups. The workload activity is determined by calculating the average and maximum peak utilization of the VDisks in the group.

Storage Resource Group - VDisk Workload Activity Details

Shows the workload activity of virtual disks (VDisks) in storage resource groups. The workload activity is determined by calculating the average and maximum peak utilization of the VDisks in the group.

Storage Virtualizer - VDisk Workload Activity

Shows the workload activity of virtual disks (VDisks) in a storage virtualizer. The workload activity is determined by calculating the average and maximum peak utilization of each VDisk.

VDisk Details

Shows the workload activity of a virtual disk (VDisk) in a managed disk group. Use the report to analyze the performance of a VDisk in a managed disk (MDisk) group.

Custom reports

You can use the optional Cognos Analytics reporting tool to create custom reports about IBM Spectrum® Control. Use custom reports to analyze the capacity and performance of your resources.

Custom reports

Unlike predefined reports, you can select the information that you want to include in custom reports. Custom reports can contain detailed information about the relationships between monitored resources, the properties of monitored resources, and detailed information about the performance of monitored resources.

To create a report, browse the list of monitored resources in your storage environment, and drag items that are associated with the resources into a report. For example, drag items that show capacity data for storage systems into a report.

If you create custom reports, you can also do the following tasks:

- Copy a predefined report and modify the copy to create a custom report.
- Create custom charts. You can create charts with data that is in the combinations that you want to see. Use these custom charts to troubleshoot and to report on the status of resources.
- Create reports with multiple charts. You can create multiple charts with different scales, and display those charts side-by-side. You can use these charts to compare performance metrics. For example, you can review read I/O rates and the number of bytes transferred in the same report.
- Create a custom folder structure to organize your custom reports.
- Run a report from a URL. You can include options for the report in the URL. For options that are not included in the URL, you can specify default values, or prompt the user to specify a value.
- Share a custom report with your organization, or keep it for only your own use. You can also distribute different sections of a report to different teams.

Tip: Custom reports are stored in the Content Manager (cm) database. Back up this database regularly to prevent the loss of your custom reports if a problem occurs with the cm database.

Advanced formatting for custom reports

You can create reports with basic formatting, or design more complex reports with advanced formatting.

Access related reports

You can configure custom reports so that you can click a resource in the report output to access other related reports. If you identify a problem in a report, you can open another report from within that report that might provide specific information about the problem.

For example, the Most Active Servers predefined report shows data for servers. Click the name of a server in the report to view the Summarized Performance of Volumes by Server report for the server. This report shows the aggregated data for all of the volumes on the server. Click the name of a volume in the report to view the Performance of Volumes by Server report for the volume.

Use GUI controls in reports

You can configure custom reports to include GUI controls to enable users to select options for the reports. You can specify default values for these options. In addition, you can create copies of reports with different default values.

The GUI controls that you can add to your reports enable users to select dates, type values, and select from lists. You can also create GUI controls whose values depend on what is selected in another GUI control. You can include GUI controls on the report output in HTML format so that users can change options and run the report again. For example, you can include a drop-down list in the HTML report output so that users can change the sort order of the data.

Schedule reports

You can schedule when to run the report. You can specify the following formats for the report: CSV, Excel, HTML, PDF, and XML. You can specify to email the report output and to save the report output to a location on your file system or on a web server. For example, you might require a monthly report that shows the usage of space on storage systems. Management staff might use this report to analyze changes in your storage system requirements. You can create this report and schedule it to run every month. You can specify that the report output is emailed to management staff, or saved to a location from which management staff can access it.

Viewing predefined reports

Use the Cognos® Analytics reporting tool to view predefined reports about IBM Spectrum® Control.

Before you begin

If you use Internet Explorer 10 or 11, you must set the browser to compatibility mode. For information about compatibility mode, see <http://windows.microsoft.com/en-us/internet-explorer/use-compatibility-view>.

Procedure

1. Go to the URL for your Cognos Analytics server. The format of the URL is similar to this URL: `http://myhostname:9300/bi`
2. In the Welcome portal, click Team Content.
3. Click IBM Spectrum Control Predefined Reports.
4. Navigate to the report that you want to see, and then click the name of the report.

To view a description of a report or folder, right-click the report or folder, then click Properties. The description is in the General tab.

Tip: When you run some predefined reports, you can select the configuration of the storage systems. You can select to run the report on systems that are configured as storage systems or as storage virtualizers. If you select one of these configurations, you must also select one or more storage systems from the list of available storage systems. If you do not specify storage systems, the report shows data for both configurations.

Creating custom reports

Use the Cognos® Analytics reporting tool to view custom reports about IBM Spectrum® Control. You can create basic reports with limited formatting, or design custom reports to add advanced formatting features to reports.

About this task

Restriction:

You cannot create custom reports from the following packages:

- Historical Capacity
- Storage Tiering

Note: If you use Microsoft Internet Explorer 10 or 11, you must set the browser to compatibility mode. For information about compatibility mode, go to the following link:

➔ <http://windows.microsoft.com/en-us/internet-explorer/use-compatibility-view>

Procedure

1. Go to the URL for your Cognos Analytics server. The format of the URL is similar to this URL: `http://myhostname:9300/bi`
2. Depending on the type of report that you want to see, open the appropriate report tool:
 - To create a basic report with limited formatting about the capacity and relationships of resources, complete the following steps:
 - Click New  in the Welcome portal.
 - Click Other, then click Query Studio.
 - Click IBM Spectrum Control Packages, then click the Capacity and Relationships package.
 - To create a basic report with limited formatting about the performance of resources, complete the following steps:
 - Click New  in the Welcome portal.
 - Click Other, then click Query Studio.
 - Click IBM Spectrum Control Packages, then click the Performance package.
3. Optional: To create a report with advanced formatting features, complete the following steps:
 - a. Click Team Content in the Welcome portal.
 - b. Click IBM Spectrum Control Packages.
 - c. Right-click Capacity and Relationships or Performance, then click Create report.
 - d. Click a template for the report.

Related tasks

Viewing and creating reports in the Cognos Analytics reporting tool

You access reports from IBM Spectrum® Control, and work with the reports in the Cognos® Analytics reporting tool.

About this task

When you view and create reports, you can navigate from predefined reports to custom reports and from custom reports to predefined reports within the Cognos Analytics reporting tool.

Procedure

1. In the Cognos Analytics reporting tool, click Team Content in the Welcome portal.
2. Depending on the type of report that you want to work with, complete one of the following actions:
 - To view predefined reports, click IBM Spectrum Control Predefined Reports.
 - To create a basic custom report with limited formatting, complete the following steps:
 - Click the New icon  in the Welcome portal.
 - Click Other, then click Query Studio.
 - Click IBM Spectrum Control Packages, then click the Capacity and Relationships or Performance package.
 - To create a report and apply advanced formatting features to the report, complete the following steps:
 - Click IBM Spectrum Control Packages.
 - Right-click the Capacity and Relationships or Performance package, then click Create report.
 - Click a template for the report.

Searching in your report data

Search through your report data in the Cognos® Analytics reporting tool.

Procedure

1. In the Welcome portal, click Search.
2. Type the search terms in the Search field, then press Enter.
Tip: You can filter and save searches.
3. Optional: Alternatively, you can search the online help for properties or metrics.
 - a. In the Cognos Analytics reporting tool, click any predefined report.
 - b. Click Help, which is in the upper-right corner of the page.
 - c. In the Search IBM Documentation field, type the name of the property or metric in quotation marks followed by the word `report`. Press Enter to search for the term.
For example, type one of the following:
 - "Storage Pool Name" report
 - "Port Receive I/O Rate" reportThe list of help topics that contain the property or metric is displayed in the search results.

Scenarios

Use these scenarios to learn how to use IBM Spectrum Control reports to analyze the most active volumes on hypervisors and to monitor the performance of a critical application. You can learn how to investigate a degradation in the performance of a storage pool. You can also learn how to identify the relationships between a storage system and other resources.

- [Analyzing the volumes on the most active hypervisors](#)
In this scenario, you use the predefined reports for hypervisors to analyze the volumes on hypervisors. You can view the most active volumes. Then, you can view summary information for a hypervisor and details for individual volumes. You can also use this scenario to analyze the volumes on servers, agentless servers, and cluster resource groups.
- [Monitoring daily the performance of volumes](#)
In this scenario, you create a report view from a predefined report to run a daily report about the performance of volumes. You can also use this scenario to monitor any other resources and performance metrics.
- [Investigating a degradation in the performance of a storage pool](#)
You can use the Compare Performance of One Pool over Time Ranges report to analyze a change in the performance of a storage pool. You can also use this scenario to compare the performance metrics of storage systems, switches, and switch ports over two periods of time.
- [Identifying the relationships between a storage system and other resources](#)
In this scenario, you use a predefined relationships report to identify the relationships between a storage system and other servers or hypervisors. You can also use this scenario to identify the relationships between storage systems and NAS, pools, and volumes. Use this scenario to identify the relationships between storage virtualizers and servers, hypervisors, NAS, pools, and volumes.

Analyzing the volumes on the most active hypervisors

In this scenario, you use the predefined reports for hypervisors to analyze the volumes on hypervisors. You can view the most active volumes. Then, you can view summary information for a hypervisor and details for individual volumes. You can also use this scenario to analyze the volumes on servers, agentless servers, and cluster resource groups.

About this task

You have 10-20 volumes on the hypervisors in your storage environment. You receive reports that the performance of some volumes is slow. You want to analyze the performance of these volumes as a group, and the performance of individual volumes.

Procedure

1. Run the Most Active Hypervisors report.
Use the chart in the report output to see the 20 hypervisors that have the most active volumes. The most active volumes have the greatest aggregate load. You see that the volumes on one hypervisor are considerably more active than the volumes on other hypervisors. You want to investigate that hypervisor.
2. To analyze the activity on this hypervisor, click the name of the hypervisor in the report table.
The Summarized Performance of Volumes by Hypervisor report runs for the hypervisor. Use the report to see summarized performance metrics for the volumes on the hypervisor. You can also use the report to see the aggregate load and the average response time of the volumes on the hypervisor.
In the charts and the table on the report, you see that the I/O response times for the hypervisor are slower than normal.
3. To investigate the individual volumes on the hypervisor, click the name of the hypervisor in the report table.
The Performance of Volumes by Hypervisor report runs for the hypervisor. Use the report to see the performance metrics for individual volumes on the hypervisor. Use the report to identify the contribution of individual volumes to the load of a particular hypervisor in your storage environment.
In the charts and the table on the report, you see that the I/O response times for one volume are slow.

What to do next

You identified the volume with the slow I/O response times. You can now copy data to the other volumes to more evenly distribute the load of the volumes.

Monitoring daily the performance of volumes

In this scenario, you create a report view from a predefined report to run a daily report about the performance of volumes. You can also use this scenario to monitor any other resources and performance metrics.

About this task

You have applications that are critical to your business. The applications access volumes in your storage environment. You want to monitor daily the performance of the volumes to confirm that they are functioning correctly. To monitor the volumes, you must create a report view to run a daily report about the performance of volumes.

Procedure

1. Go to the URL for your Cognos® Analytics server. The format of the URL is similar to this URL: `http://myhostname:9300/bi`
2. In the Welcome portal, click Team Content.
3. Click IBM Spectrum Control Predefined Reports.
4. Click Storage Systems > Volumes.
5. Right-click the Compare Performance of Multiple Volumes report, then click Create report view.
6. Type a name for the report view, then click Save.
7. Right-click the new report view, then click Properties.
8. Click the Schedule tab.
9. Click New to create new schedule.
10. Schedule the report view to run daily.
11. In the Options area, click Format, then select HTML and PDF formats.
12. In the Prompts area, click Set values, and then click Set.
13. Specify the storage systems and the volumes that you want to monitor, and then click Next.
14. Select the following performance metrics:
 - Total Overall I/O Rate (ops/s)
 - Overall Response Time (ms/op)
 - Total Data Rate (MiB/s)
 - Total Overall Cache Hit Percentage
15. Specify an interval and a reporting period for the report view, and then click Finish.
16. Click Create to save the schedule, format, and prompt value settings.

What to do next

View the output of this report every day to confirm that these volumes are functioning correctly. Click the report view to view the latest output for the report. If the report output is not displayed, make sure that the Default action for report view in the properties of the report view is set to View most recent report.

Investigating a degradation in the performance of a storage pool

You can use the Compare Performance of One Pool over Time Ranges report to analyze a change in the performance of a storage pool. You can also use this scenario to compare the performance metrics of storage systems, switches, and switch ports over two periods of time.

About this task

In the previous three days, the performance of a storage pool has significantly degraded. You want to investigate the reasons for the degradation. To do this, use the Compare Performance of One Pool over Time Ranges report to compare the recent poor performance of the pool with a period when the performance was normal.

Procedure

1. Go to the URL for your Cognos® Analytics server. The format of the URL is similar to this URL: `http://myhostname:9300/bi`
2. In the Welcome portal, click Team Content.
3. Click IBM Spectrum Control Predefined Reports.
4. Click Storage Systems, and then click Pools.
5. Click Compare Performance of One Pool over Time Ranges.
6. Specify the storage system and the pool whose performance has degraded.
7. Specify the performance metric that you want to analyze, for example Overall Response Time (ms/op).
8. Specify an interval.
9. Specify two custom date ranges for the two reporting periods. Specify the previous three days as one reporting period. For the other reporting period, specify a period when the performance of the pool was normal.
10. Click Finish.

What to do next

To investigate other possible reasons for the degradation, run the report again, and select another metric.

Identifying the relationships between a storage system and other resources

In this scenario, you use a predefined relationships report to identify the relationships between a storage system and other servers or hypervisors. You can also use this scenario to identify the relationships between storage systems and NAS, pools, and volumes. Use this scenario to identify the relationships between storage virtualizers and servers, hypervisors, NAS, pools, and volumes.

About this task

You want to take a storage system offline and migrate the volumes to another storage system. To prepare for the migration, you first identify which servers or hypervisors are affected when the storage system goes offline.

Procedure

1. Go to the URL for your Cognos® Analytics server. The format of the URL is similar to this URL: `http://myhostname:9300/bi`
2. In the Welcome portal, click Team Content.
3. Click IBM Spectrum Control Predefined Reports.
4. Click Storage Resource Relationships Summary.
5. From the Storage systems list, select the storage system that you plan to take offline.
6. Click Finish.

What to do next

View the output of the report to see which servers or hypervisors are affected when the storage system goes offline. You can now migrate the volumes.

Configuring

You can configure the optional Cognos Analytics reporting tool according to your requirements.

- [Setting options for reports](#)
When you schedule or run a report, you can specify the output format and how the report is delivered.
- [Scheduling a report to run with predefined options](#)
You can schedule a report to run on different systems and with different options that you define. To monitor the performance of different sets of volumes, you can schedule a Compare Performance of Multiple Volumes report for each of the sets.
- [Creating a copy of a predefined report](#)
Create a copy of a predefined report if you want to modify report. You might want to modify the queries that the report uses, or to add or remove a column. Changes to the predefined report do not affect copies of the report.
- [Starting the Cognos Configuration GUI](#)
You can use the IBM® Cognos Configuration GUI to configure Cognos Analytics reporting tool components. For example, you can configure an archive location for the output of reports, and configure a connection between the Cognos Analytics reporting tool and an SMTP server.
- [Sending reports by email](#)
To send reports as attachments in email messages, configure a connection between the Cognos Analytics reporting tool and an SMTP server.
- [Specifying locations for saving reports](#)
You can configure reports to save the report output to your local file system. You specify a root directory in the file system in which the output of reports can be saved in the IBM Cognos Configuration GUI. You specify the locations in which you want to save the output of reports. Then, you can configure individual reports to save the report output to a location in the file system. For example, you can schedule a report and configure the report output to be saved to a location like C:\marketing_team\sales or /usr/marketing_team/sales.
- [Setting up multiple connections to the database repository](#)
In Cognos Analytics, you can add multiple connections to the IBM Spectrum Control data source so that you can run reports against multiple IBM Spectrum Control databases (TPCDBs).
- [Customizing the logo and title of reports](#)
You can change the logo that is displayed in all IBM Spectrum Control reports and the title of individual reports. Before you modify predefined reports, create backup copies of them.

Setting options for reports

When you schedule or run a report, you can specify the output format and how the report is delivered.

About this task

You can select output formats for the report. For example, you can select PDF, HTML, and other formats. If you choose PDF as the format for your report, you can set options such as the orientation and paper size for reports.

You can also specify to print the report, to send the report by email, and other delivery options.

Procedure

1. Navigate to a report in the Cognos® Analytics reporting tool.
2. Depending on whether you want to schedule a report or run a report, do one of the following steps:
 - To schedule a report and select format and delivery options, right-click the report that you want to schedule, then click Properties. Click the Schedule tab, then click New.
 - To run a report and select format and delivery options, right-click the report, then click Run as. Click Run in background, then click Advanced to select format and delivery options.

- [Advanced Report Options](#)

Scheduling a report to run with predefined options

You can schedule a report to run on different systems and with different options that you define. To monitor the performance of different sets of volumes, you can schedule a Compare Performance of Multiple Volumes report for each of the sets.

About this task

You can specify schedules and output formats for the reports, and different ways to share the reports.

To schedule a report to run with parameters that you specify, you first create a report view from the report. Then, you schedule the report and set the parameters and options in the report view.

If the report from which a report view was created is updated, the report view is also updated.

Procedure

1. Go to the URL for your Cognos® Analytics server. The format of the URL is similar to this URL: **http://myhostname:9300/bi**
2. In the Welcome portal, click Team Content.
3. Click IBM Spectrum Control Predefined Reports.
4. Right-click the report, then click Create report view.
5. Type a name for the report view, then click Save.
6. To set predefined options for the report view, right-click the report view, complete one or more of the following steps:
 - To set a schedule for the report view, right-click the report view, and then click the Properties tab. Add a new schedule for the report view in the Schedule tab.
 - To set formats for the report view, right-click the report view, and then click the Properties tab. Set the format for the report view in the Report tab. Click Report options to set the format options.
 - You can specify parameters such as the resources, the interval, and the reporting period for the report view. To set parameters for the report view, right-click the report view, and then click the Properties tab. In the Report tab, click Set values. Click Set on the Current values panel. Select the values for the parameters, then click Finish.

Creating a copy of a predefined report

Create a copy of a predefined report if you want to modify report. You might want to modify the queries that the report uses, or to add or remove a column. Changes to the predefined report do not affect copies of the report.

About this task

When you create a copy of a report, the links to related reports in the report output do not work correctly.

If the predefined report is changed during an upgrade, the copy of the report is not affected. If you modify a predefined report instead of creating a copy and then you upgrade your reports software, your modifications might be overwritten.

Procedure

1. In the Welcome portal, click Team Content.
2. Click IBM Spectrum Control Predefined Reports.
3. Navigate to the report that you want to copy, right-click the report, then click Copy or move.
4. Navigate to the location where you want to copy the report, then click Copy to.

Starting the Cognos Configuration GUI

You can use the IBM® Cognos® Configuration GUI to configure Cognos Analytics reporting tool components. For example, you can configure an archive location for the output of reports, and configure a connection between the Cognos Analytics reporting tool and an SMTP server.

Procedure

To start Cognos Configuration GUI, follow the instructions for your operating system:

Windows

- Click Start, IBM Cognos Configuration.
- Alternatively, run the `cogconfig.bat` file in the `cognos_analytics_install_directory\bin64` directory.

AIX® or Linux®

Log on to a graphical session, and then run the following commands:

```
cd cognos_analytics_install_directory/bin64/  
./home/db2inst1/sqllib/db2profile  
./cogconfig.sh
```

Note the space between the `.` and the `/` in the second command.

Sending reports by email

To send reports as attachments in email messages, configure a connection between the Cognos® Analytics reporting tool and an SMTP server.

About this task

You use the IBM® Cognos Configuration GUI to configure a connection between the Cognos Analytics reporting tool and an SMTP server. When you configure the connection to the SMTP server, you can send the custom and predefined reports that you create as email attachments.

Procedure

1. Open the IBM Cognos Configuration GUI.
2. On the Explorer pane, click Data Access.
3. Click Notification, and then enter values in the following fields:
 - SMTP Mail Server
 - Enter the host name and port number of the mail server.
 - Account and password
 - Leave the field blank if authentication is not required to log on to the mail server. If authentication is required to log on to the mail server, click the Edit icon.
 - Enter a valid user ID and password, and then click OK.
 - Default sender
 - Enter the email address of the sender.
4. To ensure that the connection to the mail server is correctly configured, right-click Notification, and then click Test.
5. Click Save.
6. Click File, Exit.
7. To restart the IBM Cognos server, click Yes in the IBM Cognos Configuration message.

Specifying locations for saving reports

You can configure reports to save the report output to your local file system. You specify a root directory in the file system in which the output of reports can be saved in the IBM® Cognos® Configuration GUI. You specify the locations in which you want to save the output of reports. Then, you can configure individual reports to save the

report output to a location in the file system. For example, you can schedule a report and configure the report output to be saved to a location like C:\marketing_team\sales or /usr/marketing_team/sales.

- [Specifying a root directory for saving reports](#)
You can specify a root directory in the file system in which the output of reports can be saved. To do this, you configure an archive location in IBM Cognos Configuration.
- [Specifying file system locations for reports](#)

You can configure a report to save the report output to a location in a file system. You can also specify the file name for the report output, and whether to append a date and time to the file name.

Specifying a root directory for saving reports

You can specify a root directory in the file system in which the output of reports can be saved. To do this, you configure an archive location in IBM® Cognos® Configuration.

Procedure

1. Create a directory in your file system to use as the root directory for the output of reports.
Tip: Ensure that the directory is accessible to users and separate from the Cognos Analytics installation directory. For example, in a distributed installation on Microsoft Windows, you can use an archive folder such as \\server_name\directory.
2. Open the IBM Cognos Configuration GUI.
3. Click Actions > Edit Global Configuration.
4. Click the General tab.
5. In the Archive Location File System Root field, enter a URI using the format file:///directory where *directory* is the directory you created in step 1.
The file:/// part of the URI is required. You can use Windows Universal Naming Convention (UNC) names, such as \\server_name\directory. If you use a Windows UNC name, format the URI as follows:

file:///\\server_name\directory
Tip: Don't use a mapped drive when you run Cognos Analytics as a Microsoft Windows service.
6. Click Test to confirm that the correct location will be used.
7. Click OK.
8. Click File > Save.
9. Click Actions > Restart or Actions > Start to restart the Cognos Analytics server.

Related tasks

- [Starting the Cognos Configuration GUI](#)

Specifying file system locations for reports

You can specify the locations in which you want to save the output of reports in the Cognos® Analytics reporting tool.

Before you begin

You must configure the root directory of the locations that you specify in the Cognos Analytics reporting tool. You must stop and restart the Cognos Analytics server after you specify the locations.

About this task

Specify the locations for report output if you want to share reports with an external application, such as a web site. The reports are saved to this location every time they are updated so that current content is always available. You can also save reports on a local network for users who do not have access to Cognos Analytics software. You can specify multiple locations for the report output.

Procedure

1. Go to the URL for your Cognos Analytics server. The format of the URL is similar to this URL: `http://myhostname:9300/bi`
2. Click Manage in the Welcome portal, then click Administration console.
3. Click the Configuration tab.
4. Click Dispatchers and Services.
5. Click the Define File System Locations icon .
6. On the Define file system locations page, click New.
7. Specify a name and the directory for the location on the file system, and then click Finish.
For example, enter `sales`.
The directory is created the first time that the output of a report for the directory is created.
Repeat this step to configure more file system locations.

Results

The location that you specified is appended to the file system root location that is specified in the IBM® Cognos Configuration GUI. In the IBM Cognos Configuration GUI, the file system root location is referred to as the Archive Location File System Root.

When users select Save report as an external file as the report delivery method when they run or schedule a report, the report output files are saved to this location each time the report runs.

Related tasks

- [Starting the Cognos Configuration GUI](#)

Specifying a report to save the report output to a file system

You can configure a report to save the report output to a location in a file system. You can also specify the file name for the report output, and whether to append a date and time to the file name.

Before you begin

You must configure the locations in which you want to save the output of reports in the Cognos® Analytics reporting tool.

Procedure

1. In the Cognos Analytics reporting tool, right-click the report, then click Properties.
2. Click the Schedule tab.
3. Click New to create a new schedule.
4. In the Options area, click Delivery, then click Save report as an external file.
5. Optional: Specify the name to use for the report, the location of the report output on the file system, and what to do if there is a file name conflict.
6. Click Done.
7. Click Create to save the schedule for the report.

Setting up multiple connections to the database repository

In Cognos® Analytics, you can add multiple connections to the IBM Spectrum® Control data source so that you can run reports against multiple IBM Spectrum Control databases (TPCDBs).

Before you begin

If your IBM Spectrum Control database is on a different computer than the computer where you installed Cognos Analytics, you must catalog the node and database for the remote IBM Spectrum Control database before you create the Cognos Analytics data source for the IBM Spectrum Control database.

About this task

If you create multiple connections, you can run reports for multiple IBM Spectrum Control servers from one Cognos Analytics server. You can also develop and test reports on multiple TPCDB databases in your storage environment.

After you add multiple connections to the TPCDB data source, when you run a report you select the TPCDB database to connect to.

Procedure

1. Go to the URL for your Cognos Analytics server. The format of the URL is similar to this URL: `http://myhostname:9300/bi`
2. In the Welcome portal, click **Manage > Administration** console.
3. In the Configuration tab, click Data Source Connections.
4. Click the TPCDB data source.
5. On the toolbar, click the New Connection icon .
6. On the Specify a name and description page, type a name for the new connection in the Name field and then click Next.
Do not use TPCDB as the name for the new connection because that conflicts with the existing TPCDB connection.
7. On the Specify the connection page, select IBM DB2 from the Type list.
8. Verify that Use the default object gateway is selected.
9. Clear Configure JDBC connection then click Next.
10. On the Specify the IBM DB2 connection string page, in the DB2 database name property, enter the alias value that you used when you cataloged the remote database.
For example, enter the value `remDB`.
11. In the Signon section, do the following:
 - a. Verify that Signons is selected.
 - b. Click Password.
 - c. In the User ID property, enter the user name of the owner of the DB2® instance where the IBM Spectrum Control database is located.
On Windows operating systems, this user name is typically `db2admin`. On Linux® or AIX® operating systems, this user name is typically `db2inst1`.
 - d. In the Password and Confirm password properties, enter the password that is associated with the User ID property in [11.c](#).
12. In the Testing section, click Test the connection.
13. On the Test the connection page, click Test.
14. When the test is successful, click Close on the View the results page.
15. On the Test the connection page, click Close.
16. On the Specify the IBM DB2 connection string page, click Next.
17. On the Specify the commands page, click Finish.

18. If you scheduled reports, modify the parameters of all scheduled reports to specify the database against which to run the report.

Creating a folder in the Cognos Analytics reporting tool

You can create a folder to store backup copies of the predefined reports that you want to modify or for custom reports that you create.

Procedure

1. In the Cognos® Analytics reporting tool, click Team Content in the Welcome portal.
2. Navigate to the location where you want to create the folder. For example, click IBM Spectrum Control Predefined Reports.
3. Click the New folder icon .
4. Type a name for the folder.
For example, type `Backups` as the name of the folder.

Creating a backup copy of a report

Before you modify a predefined report, create a backup copy of the report.

Procedure

1. In the optional Cognos® Analytics reporting tool, create a folder in which to store the backup copy.
2. Navigate to the report of which you want to create a backup copy.
3. Right-click on the report, then click Copy or move.
4. In the Copy or move window, navigate to the folder that you created in step [1](#).
5. Click Copy to.

Changing the logo for all reports

You can change the logo that is displayed in the output of all reports. You can change the default logo to your company logo or to another image.

Before you begin

Make sure that your logo is approximately the same size as the default logo that is in all predefined reports.

Procedure

1. To store images for your company, create a directory, for example, `/myCompany/images`, at the following location:
`Cognos_installation_directory/webcontent/bi/samples`
2. Copy the logo image to the new directory, for example, `../samples/myCompany/images/myLogo.jpg`.
3. In the Welcome portal of the Cognos® Analytics reporting tool, click Team Content > IBM Spectrum Control Report Layouts.

4. Create a backup copy of the report_page_template file.
5. Right-click the report_page_template file, then click Edit report.
6. Click the default image that is displayed underneath the "Double-click to edit text" of the workspace.
7. Click the More icon  for the report, then click Edit Image URL.
8. Modify the image URL to refer to your logo image.
For example, you can specify the following image URL:

`../samples/myCompany/images/myLogo.jpg`

9. Click Save.

- [File System to Volume Relationships report](#)
Shows the end-to-end relationship from file systems on servers to volumes on storage pools. The report shows the usage of space on file systems over a specified period. Use the report to analyze changes in your file system requirements.

Running the Storage Resource Relationships Summary report

To show the relationships between storage resources, run the Storage Resource Relationships Summary report.

Before you begin

To run the report with the default settings, click Finish.

Tip: To select a resource, click the resource. To select multiple resources, press Ctrl and click the resources. To select a series of resources, select the first resource, and then press Shift and click the last resource.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Resource Relationships Summary.
3. Optional: Select one or more of the following:
 - a. Servers
 - b. Hypervisors
 - c. NAS resources

- d. Storage virtualizers
 - e. Storage systems
4. Click Finish.

Results

If the resources that you selected are not related, or if no data is available, a message is displayed in the report.
Restriction: To create a report when you select a single resource, the selected resource must be connected to other resources.

- [Storage Resource Relationships Summary report](#)

Storage Resource Relationships Summary report

Shows the end-to-end relationship from a server to back-end storage. The report shows servers, hypervisors, NAS, storage systems, storage virtualizers, pools, and volumes.

Report output

Information is provided about related resources and the devices, such as managed disks (MDisks), that are related to resources.

Server Name

The fully qualified domain name of the server. For example, the name of a server might be `server.example.com`.

Hypervisor Name

The fully qualified domain name of the hypervisor. For example, the name of a hypervisor might be `hypervisor.example.com`.

NAS Name

The fully qualified domain name of the NAS device. For example, the name of a NAS device might be `nas.example.com`.

Storage Virtualizer Name

A user-defined name of the storage virtualizer. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage virtualizer was added for monitoring.

Storage Virtualizer Volume Name

The name that was assigned to the storage virtualizer volume when it was added to the system.

Storage Virtualizer Volume Assigned Host Connection

The host connection to which the storage virtualizer volume is assigned. The host connection is a definition in the storage virtualizer that contains the WWPN for the server. The storage virtualizer uses the WWPN to assign volumes to servers.

Storage Virtualizer Pool Name

The name that was assigned to the pool when it was added to the system.

Storage Virtualizer MDisk Name

The name that was assigned to the managed disk on a storage virtualizer when it was added to the system.

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum Control shows the name that was defined when the storage system was added for monitoring.

Storage Volume Assigned Host Connection

The host connection to which the storage volume is assigned. The host connection is a definition in the storage system that contains the WWPN for the server. The storage system uses the WWPN to assign volumes to servers.

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

- [Storage Resource Relationships Summary \(Configurable\) report](#)

Storage Resource Relationships Summary (Configurable) report

Shows the end-to-end relationship from a server to back-end storage. You can configure which resources to show in the report.

Report output

Information is provided about related resources and the devices, such as managed disks (MDisks), that are related to resources.

Server Name

The fully qualified domain name of the server. For example, the name of a server might be `server.example.com`.

Server Disk Name

The identifier that specifies a path to a server disk, for example `/dev/hdisk0`.

Logical Volume Path

The path to a logical volume on a resource, for example `/dev/hd1`.

File System Mount Point

The name or mount point of the file system for the resource. For example, on Microsoft Windows systems, the value in this property might be `c:\` or `d:\`. On operating systems such as AIX®, Linux®, Solaris, or HP-UX, the mount point might be `/opt` or `/export/home`.

Hypervisor Name

The fully qualified domain name of the hypervisor. For example, the name of a hypervisor might be `hypervisor.example.com`.

Hypervisor Disk Name

The path that the operating system uses for the server disk.

NAS Name

The fully qualified domain name of the NAS device. For example, the name of a NAS device might be `nas.example.com`.

NAS Export Name

The name of the exported file system.

Storage Virtualizer Name

A user-defined name of the storage virtualizer. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage virtualizer was added for monitoring.

Storage Virtualizer Volume Assigned Host Connection

The host connection to which the storage virtualizer volume is assigned. The host connection is a definition in the storage virtualizer that contains the WWPN for the server. The storage virtualizer uses the WWPN to assign volumes to servers.

Storage Virtualizer Volume Name

The name that was assigned to the storage virtualizer volume when it was added to the system.

Storage Virtualizer Pool Name

The name that was assigned to the pool when it was added to the system.

Storage Virtualizer MDisk Name

The name that was assigned to the managed disk on a storage virtualizer when it was added to the system.

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage Volume Assigned Host Connection

The host connection to which the storage volume is assigned. The host connection is a definition in the storage system that contains the WWPN for the server. The storage system uses the WWPN to assign volumes to servers.

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Related reference

- [File System to Volume Relationships report](#)

File System to Volume Relationships report

Shows the end-to-end relationship from file systems on servers to volumes on storage pools. The report shows the usage of space on file systems over a specified period. Use the report to analyze changes in your file system requirements.

Report output

The information that is provided about the servers, storage virtualizers, storage systems, pools, and volumes is as follows:

Server Name

The fully qualified domain name of the server. For example, the name of a server might be **server.example.com**.

File System Mount Point

The name or mount point of the file system for the resource. For example, on Microsoft Windows systems, the value in this property might be c:\ or d:\. On operating systems such as AIX®, Linux®, Solaris, or HP-UX, the mount point might be /opt or /export/home.

Server Disk Name

The identifier that specifies a path to a server disk, for example `/dev/hdisk0`.

File System Capacity (GiB)
The amount of storage space on the file system of the resource.

File System Available Space (GiB)
The amount of unused storage space in the file system of the resource.

File System Available Space Percentage
The percentage of space in the file system that is unused.

Storage Virtualizer Name
A user-defined name of the storage virtualizer. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage virtualizer was added for monitoring.

Storage Virtualizer Volume Name
The name that was assigned to the storage virtualizer volume when it was added to the system.

Storage Virtualizer Volume Is Thin Provisioned
Shows whether a volume or volume copy is thin-provisioned. If this value is **yes**, the resource is thin-provisioned.

Storage Virtualizer Volume Allocated Space Percentage
The percentage of space on a volume that is reserved.
This property applies only to volumes on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Volume Used Space Percentage
The percentage of reserved space that is being used on a volume.
This property applies only to volumes on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Pool Name
The name that was assigned to the pool when the pool was added to the system.

Storage Virtualizer Pool Available Space (GiB)
The amount of space in a pool that is not reserved for volumes.

Storage System Name
A user-defined name of the storage system. If a name was not defined, IBM Spectrum Control shows the name that was defined when the storage system was added for monitoring.

Storage Volume Name
The name that was assigned to the storage volume when it was added to the system.

Storage Volume Is Thin Provisioned
Shows whether a volume or volume copy is thin-provisioned. If this value is **yes**, the resource is thin-provisioned.

Storage Volume Allocated Space Percentage
The percentage of space on a volume that is reserved.
This property applies only to volumes on SAN Volume Controller and Storwize® V7000 systems.

Storage Volume Used Space Percentage
The percentage of reserved space that is being used on a volume.
This property applies only to volumes on SAN Volume Controller and Storwize V7000 systems.

Storage Pool Name
The name that was assigned to the pool when it was added to the system.

Storage Pool Available Space (GiB)
The amount of unused space that is not reserved for volumes in pools that are on the storage system.
IBM Spectrum Control uses the following formula to determine this value:

pool capacity - used space

For XIV® systems, this value represents the unallocated physical space in the pool, not the unallocated virtual space. For some storage systems, this value usually includes only the usable capacity, but might also include overhead space if the pool is unformatted.

- [Running the Compare Performance of Multiple Switches report](#)
Use the Compare Performance of Multiple Switches report to compare up to four performance metrics for multiple switches. For example, you can compare

bandwidth percentages, data rates, and frame rates.

- [Compare Performance of Multiple Switches report](#)

Shows up to four performance metrics for multiple switches over time. Use the report to compare the performance metrics for switches.

- [Running the Compare Performance of One Switch over Time Ranges report](#)

To compare a performance metric for one switch in two date ranges, run the Compare Performance of One Switch over Time Ranges report.

- [Compare Performance of One Switch over Time Ranges report](#)

Shows one performance metric on one switch over two time periods. For example, you can use the report to compare the I/O rate for this week and last week.

Running the Availability of Switch Ports report

To see information about the ports and connected ports that are available from switches, run the Availability of Switch Ports report.

Before you begin

Tip: To select a resource, click the resource. To select multiple resources, press Ctrl and click the resources. To select a series of resources, select the first resource, and then press Shift and click the last resource.

Procedure

1. In the Welcome portal, click Team Content, IBM Spectrum Control Predefined Reports.
2. Click Fabrics and Switches.
3. Click Switches.
4. Click Availability of Switch Ports.
5. Select the switches, and then select a sort order.
6. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Availability of Switch Ports report](#)

Availability of Switch Ports report

Shows a chart of the 20 switches with the most ports and connected ports, and a table with the properties of the switches.

Charts

The chart shows the number of ports for each switch that are not online, and the number of ports that are online and connected to other ports.

Tip: To change the sort order, select a value from the Sort Order list.

Report output

For each switch, the following information is provided:

Switch Name

The logical name of the switch where a Fibre Channel port is located, or the name that was defined when the switch was added for monitoring. If neither name is available, IBM Spectrum® Control uses the WWN of the switch.

Switch Location

The physical location of the switch. The location is defined when a switch is added to IBM Spectrum Control. You can add or edit the location of the switch on the General tab of the properties notebook.

Switch WWN

The World Wide Name (WWN) of the switch. A WWN is the unique 64-bit identifier for the switch.

Switch Is Virtual

Shows whether a switch is a logical switch. If this value is **Yes**, the switch is a logical switch.

Switch IP Address

The IP address of the resource.

Switch Vendor

The vendor who supplied the resource.

Switch Model

The model name or model number of the resource.

Switch Ports

The total number of ports on the switch that are not online, and ports that are online and connected to other ports.

Switch Connected Ports

The number of ports that are connected to a storage resource, where the storage resource can be a storage system, server, or hypervisor. This value is only available when a switch is viewed as a related resource of a storage system, server, or hypervisor.

Switch Last Data Collection

The date and time when storage statistics were last collected from the resource.
Switch Last Data Collection Status
The condition of the last data collection. The status can show if the collection was a success, a failure, or if data was collected from the resource.

- [Performance of One Switch report](#)

Performance of One Switch report

Shows three charts, and a table of performance metrics for a switch over a time period that you specify. Use the report to analyze the performance of a switch.

Charts

The charts show the following performance metrics for the ports on the switch:

- The send frame rates, the receive frame rates, and the total frame rates
- The send data rates, the receive data rates, and the total data rates
- The send bandwidth percentages, the receive bandwidth percentages, and the overall bandwidth percentages

Report output

The following information is provided in the report for the period that you specified:

Switch Name

The logical name of the switch or the name that was defined when the switch was added to IBM Spectrum® Control. If neither name is available, the WWN of the switch is displayed.

Switch Location

The physical location of the switch. The location is defined when a switch is added to IBM Spectrum Control. You can add or edit the location of the switch on the General tab of the properties notebook.

Port Send Frame Rate (frames/s)

The average number of frames per second that are sent by the port.

Port Receive Frame Rate (frames/s)

The average number of frames per second that are received by the port.

Total Port Frame Rate (frames/s)

The average number of frames per second that are transferred. This value includes frames that are sent and received by the port.

Port Send Data Rate (MiB/s)

The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)

The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)

The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port Send Bandwidth Percentage

The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Port Receive Bandwidth Percentage

The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Overall Port Bandwidth Percentage

The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

- [Compare Performance of One Switch over Time Ranges report](#)

Compare Performance of One Switch over Time Ranges report

Shows one performance metric on one switch over two time periods. For example, you can use the report to compare the I/O rate for this week and last week.

Charts

The chart shows the performance data of the switch on the performance metric you selected, over the time periods that you selected.

Report output

The following information is provided in the report:

Switch Name

The logical name of the switch or the name that was defined when the switch was added to IBM Spectrum® Control. If neither name is available, the WWN of the switch is displayed.

Day in Range

The number of the day in the date range at which the performance metric data was collected, relative to the date range that you specified. The number of days that are shown is determined by the reporting period that was selected for the report. If Last 30 Days was selected, then entries for days 1 - 30 are shown on the report.

Hour in Range

The number of the hour in the day at which the performance metric data was collected. For example, 0 is between 12:00:00 a.m. and 12:59:59 a.m., 1 is between 01:00:00 a.m. and 01:59:59 a.m.

Minute in Range

The interval of minutes during which the performance metric data was collected. For example, 0 shows that performance data was collected 0 - 5 minutes after the hour. Similarly, 5 shows that the performance data that was collected 5 - 10 minutes after the hour.

First Date Range

The details of the performance metric data in the first date range. The details are displayed in two columns in the First Date Range column. Depending on the interval that you selected, the Time, Day, or Hour column shows the time at which the performance metric data was collected. The column with the performance metric name shows the data for the performance metric for the first date range.

Second Date Range

The details of the performance metric data in the second date range. The details are displayed in two columns in the Second Date Range column. Depending on the interval that you selected, the Time, Day, or Hour column shows the time at which the performance metric data was collected. The column with the performance metric name shows the data for the performance metric for the second date range.

Most Active Switch Ports report

Shows a chart of the 20 switches that are most active, and details for all switches, for a time period that you specify. Use the report to analyze the performance of switches.

Charts

The bar chart shows the most active ports on the switch. By default, ports are sorted by the total frame rate.
Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided about the most active ports on switches is as follows:

Switch Name

The logical name of the switch or the name that was defined when the switch was added to IBM Spectrum® Control. If neither name is available, the WWN of the switch is displayed.

Switch Blade Slot Number

The number of the slot on the switch to which the blade is attached. This property applies to ports on blades.

Switch Port Number

The number of the port on the switch.

Switch Port WWPN

The worldwide port name of the port on the switch.

Total Port Frame Rate (frames/s)
The average number of frames per second that are transferred. This value includes frames that are sent and received by the port.

Total Port Data Rate (MiB/s)
The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Overall Port Bandwidth Percentage
The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

- [Performance of One Switch Port report](#)

Performance of One Switch Port report

Shows four charts, and a table of performance metrics for a switch port. Use this report to view multiple performance metric types on the same chart. For example, you can view I/O rate and response time metrics on the same chart.

Charts

The charts show the following performance statistics for the port:

- The send frame rate, the receive frame rate, and the total frame rate
- The send data rate, the receive data rate, and the total data rate
- The send bandwidth percentage, the receive bandwidth percentage, and the overall bandwidth percentage
- The error rates

Report output

The following information is provided in the report for the period that you specified:

Switch Name

The logical name of the switch or the name that was defined when the switch was added to IBM Spectrum® Control. If neither name is available, the WWN of the switch is displayed.

Switch Blade Slot Number

The number of the slot on the switch to which the blade is attached. This property applies to ports on blades.

Switch Port Number

The number of the port on the switch.

Switch Port WWPN

The worldwide port name of the port on the switch.

Port Send Frame Rate (frames/s)

The average number of frames per second that are sent by the port.

Port Receive Frame Rate (frames/s)

The average number of frames per second that are received by the port.

Total Port Frame Rate (frames/s)

The average number of frames per second that are transferred. This value includes frames that are sent and received by the port.

Port Send Data Rate (MiB/s)

The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)

The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)

The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port Send Bandwidth Percentage

The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Port Receive Bandwidth Percentage

The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Overall Port Bandwidth Percentage

The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Error Frame Rate (count/s)

The average number of error frames per second that are received. An error frame is a frame that violates the Fibre Channel Protocol.

Discarded Frame Rate (count/s)

The average number of frames per second that are discarded because host buffers are unavailable for the port.

Link Failure Rate (count/s)

The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.

CRC Error Rate (count/s)

The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.

Discarded Class 3 Frame Rate (count/s)

The average number of class 3 frames per second that are discarded.

Invalid Transmission Word Rate (count/s)

The average number of bit errors per second that are detected.

Running the Compare Performance of Multiple Switch Ports report

Use the Compare Performance of Multiple Switch Ports report to compare up to four performance metrics for multiple switch ports. For example, you can compare bandwidth percentages, data rates, and I/O rates.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Fabrics and Switches.
3. Click Switch Ports.
4. Click Compare Performance of Multiple Switch Ports.
5. Select the switches.
6. Select switch ports. To select switch ports, complete the following steps:
 - a. Type a keyword.
For example, type `example1` to find the names of switch ports that start with `example1`.
To change the default search option, click Options.
Use the percent sign as a wildcard.

- For example, type a% to find switch ports with names begin with 'a' or 'A'. Type %a to find switch ports with names that begin with or contain the letter 'a' or 'A'. You can type % to retrieve all of the switch ports on a resource.
- b. Click Search.
If the search is successful, the switch ports are displayed in the Results list.
 - c. Select the switch ports that you require from the list, and then click Insert.
7. Click Next.
 8. Select the category of performance metric that you want to include in the report, and then select the performance metric.
 9. Optional: To add more metrics to the report, complete the following steps:
 - a. Click Add Metric.
 - b. Select the category of performance metric, and then select the performance metric.
 - c. If you want to remove the last metric that you added, click Remove Metric.
 10. Optional: Select an interval.
 11. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
 12. Click Finish.

Results

If the resources that you selected are not related, or if no data is available, a message is displayed in the report.

If information is not available for any of the resources that you selected, those resources are not included in the report.

Predefined reports about groups

You can run predefined reports to analyze the capacity of groups. A group is a set of logically related volumes, file systems, and shares. For example, a group that represents a business critical application might include the volumes, file systems, and shares that provide storage to the application.

- [Running the Capacity of One Group report](#)
To see information about the block-level and file-level capacity and space of a group, run the Capacity of One Group report.
- [Capacity of One Group report](#)
Shows charts and tables of the capacity, available space, and used space statistics for each type of resource in a group. The report shows separate charts and tables for block-level and file-level resources.
- [Running the Groups Capacity report](#)
To see information about the capacity and space of groups, run the Groups Capacity report.
- [Groups Capacity report](#)
Shows a chart of the 20 groups with the most capacity, available space, or used space, and a table with details of all groups. Use the report to review the space allocation in your groups.

Running the Capacity of One Group report

To see information about the block-level and file-level capacity and space of a group, run the Capacity of One Group report.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Groups.
3. Click Capacity of One Group.
4. Select a group.
5. Optional: Select a sort order.
6. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Capacity of One Group report](#)

Capacity of One Group report

Shows charts and tables of the capacity, available space, and used space statistics for each type of resource in a group. The report shows separate charts and tables for block-level and file-level resources.

Charts

The charts show the following block-level and file-level capacity statistics for a group:

- Total capacity
- Total available space
- Total used space

If there are any block-level storage devices in the group, the chart also shows the total allocated space for those devices.

Tip: To change the sort order, select a value from the Sort Order list.

Report output

The report provides the following information about the group:

Group Name

The name that was assigned to the group by the user when the group was created.

Resource Name

For a server or NAS file server, this property shows the fully qualified domain name of the server or NAS file server.

For a block-level storage resource, this property shows the user-defined name of the resource.

Resource Type

For a server or NAS file server, this property shows the operating system that is running on the server or NAS file server.

For a block-level storage resource, this property shows the type of resource. For example, the property can be IBM System Storage DS8800 or another type of resource.

Total File Capacity (GiB)

The total amount of file-level storage space that is on the file systems in the group. The space is exported space, that is, the space is on file systems that are made available to remote clients over a network.

Total File Used Space (GiB)

The total amount of file-level storage space that is used by the file systems in the group. The space is exported space, that is, the space is on file systems that are made available to remote clients over a network.

Total File Available Space (GiB)

The total amount of file-level unused space that is on the file systems in the group. The space is exported space, that is, the space is on file systems that are made available to remote clients over a network.

Total Block Capacity (GiB)

The total amount of block-level storage space that is committed to storage system volumes or storage virtualizer volumes in a group.

Total Block Used Space (GiB)

The total amount of block-level allocated space that is used by storage system volumes or storage virtualizer volumes in a group.

Total Block Available Space (GiB)

The total amount of block-level unused space that is available on storage system volumes or storage virtualizer volumes in a group.

Total Block Allocated Space (GiB)

The total amount of block-level space that is reserved for the storage system volumes or storage virtualizer volumes in a group. The allocated space includes both thin-provisioned and standard volumes.

Related tasks

- [Running the Capacity of One Group report](#)

Running the Groups Capacity report

To see information about the capacity and space of groups, run the Groups Capacity report.

Before you begin

Tip: To select a resource, click the resource. To select multiple resources, press Ctrl and click the resources. To select a series of resources, select the first resource, and then press Shift and click the last resource.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Groups.
3. Click Groups Capacity.
4. Optional: Select one or more groups.
5. Optional: Select a sort order.
6. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Groups Capacity report](#)

Groups Capacity report

Shows a chart of the 20 groups with the most capacity, available space, or used space, and a table with details of all groups. Use the report to review the space allocation in your groups.

Charts

The bar chart shows the following block-level and file-level capacity statistics for groups:

- Total available space
- Total used space

Tip: To change the sort order, select a value from the Sort Order list.

Report output

For each group, the following information is provided:

Group Custom Tag 1

User-defined text that is associated with a group.

Group Name

The name that was assigned to the group by the user when the group was created.

Total Capacity (GiB)

The total amount of block-level and file-level storage space that is committed to volumes, file systems, and shares.

Total Used Space (GiB)

The total amount of block-level and file-level space that is used by volumes, file systems, and shares.

Total Available Space (GiB)

The total amount of block-level and file-level space that is available on volumes, file systems, and shares.

Total Block Capacity (GiB)

The total amount of block-level storage space that is committed to storage system volumes or storage virtualizer volumes in a group.

Total Block Used Space (GiB)

The total amount of block-level allocated space that is used by storage system volumes or storage virtualizer volumes in a group.

Total Block Available Space (GiB)

The total amount of block-level unused space that is available on storage system volumes or storage virtualizer volumes in a group.

Total Block Allocated Space (GiB)

The total amount of block-level space that is reserved for the storage system volumes or storage virtualizer volumes in a group. The allocated space includes both thin-provisioned and standard volumes.

Total File Capacity (GiB)

The total amount of file-level storage space that is on the file systems in the group. The space is exported space, that is, the space is on file systems that are made available to remote clients over a network.

Total File Used Space (GiB)

The total amount of file-level storage space that is used by the file systems in the group. The space is exported space, that is, the space is on file systems that are made available to remote clients over a network.

Total File Available Space (GiB)

The total amount of file-level unused space that is on the file systems in the group. The space is exported space, that is, the space is on file systems that are made available to remote clients over a network.

Hypervisors Capacity report

Shows a chart of the 20 hypervisors with the most allocated space, and a table with space statistics for all hypervisors. Use the report to review space allocation in your hypervisors.

Charts

The bar chart shows the used space and available space on hypervisors.

Report output

For each hypervisor, the following information is provided:

Hypervisor Name

The fully qualified domain name of the hypervisor. For example, the name of a hypervisor might be `hypervisor.example.com`.

Hypervisor Location

The physical location of a hypervisor. The location is defined when a hypervisor is added to IBM Spectrum® Control. You can add or edit the location of the hypervisor in the Properties pane of the hypervisor.

Hypervisor Cluster Name

The name of a cluster that is monitored in your storage environment. A cluster is a group of hypervisors that collaborate for the purposes of workload balancing and failover.

Hypervisor Total Disk Capacity (GiB)

The amount of storage space that is on a hypervisor.

Hypervisor Total Disk Available Space (GiB)

The amount of unused storage space on all disks on a hypervisor.

Hypervisor Total Disk Used Space (GiB)

The amount of storage space that is used on all disks on a hypervisor.

Hypervisor Total Disk Used Space (%)

The amount of storage space that is used on a hypervisor.

Hypervisor Data Store Capacity (GiB)

The amount of storage space that is on the hypervisor data store.

Hypervisor Data Store Available Space (GiB)

The amount of unused storage space on a hypervisor data store.

Hypervisor Data Store Used Space (GiB)

The amount of storage space that is used on a hypervisor data store.

Hypervisor Data Store Used Space (%)

The percentage of storage space that is used on all disks on a hypervisor.

Running the Most Active Hypervisors report

To see which hypervisors are the most active, run the Most Active Hypervisors report.

Before you begin

To run the report with the default settings, click Finish. The report shows information about all of the resources in the list.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Hypervisors.
3. Click Most Active Hypervisors.
4. Select the hypervisors, and then select a sort order.
5. To set the time frame of the report, specify a reporting period.
If the report does not include a particular resource that you want to see, select a reporting period for which data is available for the resource.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
6. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Most Active Hypervisors report](#)

Most Active Hypervisors report

Shows a chart of the 20 hypervisors that have the most active volumes. The most active volumes have the greatest aggregate load.

Charts

The bar chart shows the most active hypervisors. By default, hypervisors are sorted by the total I/O rate.

Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided about the most active hypervisors is as follows:

Hypervisor Name

The fully qualified domain name of the hypervisor. For example, the name of a hypervisor might be **hypervisor.example.com**.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Volume Utilization

The average percentage of time that the volume is busy.

2. Click Hypervisors.
3. Click Summarized Performance of Volumes by Hypervisor.
4. Select one or more hypervisors.
5. Select the volumes.
6. Optional: Select an interval.
7. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
8. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Summarized Performance of Volumes by Hypervisor report](#)

Summarized Performance of Volumes by Hypervisor report

Shows summarized performance metrics for volumes on a hypervisor. Use the report to identify the aggregate load and the average response time of a particular hypervisor.

Charts

The charts show the following performance metrics for the volumes on a hypervisor:

- The total I/O rates and the total response times
- The read I/O rates, the write I/O rates, the read response times, and the write response times
- The read data rates, the write data rates, and the total data rates
- The read cache percentages and the write cache percentages

Report output

The following information is provided in the report for the period that you specified:

Hypervisor Name

The fully qualified domain name of the hypervisor. For example, the name of a hypervisor might be **hypervisor.example.com**.

Day, hour, or time

The day, hour, or time at which the information about the specified resource or device was collected. Whether the day, hour, or time is displayed depends on the interval that you select for the report.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation, across all volumes on the hypervisor. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second, across all volumes on the hypervisor. This value includes both sequential and nonsequential operations. The average value for each volume is added to give a total I/O rate for all volumes on the hypervisor.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations, across all volumes on the hypervisor. The average value for each volume is added to give a total data rate for all volumes on the hypervisor.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation, across all volumes on the hypervisor.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation, across all volumes on the hypervisor.

Read Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations, across all volumes on the hypervisor. The average value for each volume is added to give a read data rate for all volumes on the hypervisor.

Write Data Rate (MiB/s)

The average number of MiB per second that are transferred for write operations, across all volumes on the hypervisor. The average value for each volume is added to give a write data rate for all volumes on the hypervisor.

Overall Read I/O Rate (ops/s)

The average number of read operations per second, which is totaled for all volumes on the hypervisor. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second, which is totaled for all volumes on the hypervisor. This value includes both sequential and nonsequential write operations.

Overall Read Cache Hit Percentage

The average percentage of all read operations that find data in the cache, across all volumes on the hypervisor. This value includes both sequential and nonsequential read operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Overall Write Cache Hit Percentage

The average percentage of all write operations that are handled in the cache, across all volumes on the hypervisor. This value includes both sequential and nonsequential write operations.

- [Performance of Volumes by Hypervisor report](#)

Performance of Volumes by Hypervisor report

Shows the performance metrics for volumes on a hypervisor. Use the report to identify the contribution of individual volumes to the load of a particular hypervisor in your storage environment.

Charts

The charts show the following performance metrics for the volumes:

- The total overall I/O rates. The chart shows the contribution of each volume to the overall load on the hypervisor.
- The total data rates. The chart shows the contribution of each volume to the overall load on the hypervisor.
- The volume utilization percentages. The utilization percentage of each volume is displayed relative to the utilization percentage of the other volumes.
- The total response times. The response time of each volume is displayed relative to the response time of the other volumes.

Report output

The following information is provided in the report for the period that you specified:

Hypervisor Name

The fully qualified domain name of the hypervisor. For example, the name of a hypervisor might be `hypervisor.example.com`.

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Day, hour, or time

The day, hour, or time at which the information about the specified resource or device was collected. Whether the day, hour, or time is displayed depends on the interval that you select for the report.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Volume Utilization

The average percentage of time that the volume is busy.

Hypervisor Data Stores Capacity report

Shows a chart of the 20 hypervisor data stores with the most allocated space. This report also shows a table with space statistics for all hypervisor data stores. Use the report to review space allocation in your hypervisor data stores.

Charts

The bar chart shows the used space and available space for data stores on hypervisors.

Report output

For each hypervisor, the following information is provided:

Hypervisor Cluster Name

The name of a cluster that is monitored in your storage environment. A cluster is a group of hypervisors that collaborate for the purposes of workload balancing and failover.

Hypervisor Data Store

The path to the VMware ESX data store on the hypervisor, for example datastore_svc3c.

Hypervisor Data Store Cluster Name

The name of the cluster, if the data store is a member of a data store cluster. If the data store is not a member of a data store cluster, no information is displayed.

Hypervisor Data Store Type

The type of file system that the hypervisor data store uses. For example, the type can be NFS or VMFS.

Hypervisor System Mount Point

The name or mount point of the file system for the resource. For example, on Microsoft Windows systems, the value in this property might be c:\ or d:\. On operating systems such as AIX®, Linux®, Solaris, or HP-UX, the mount point might be /opt or /export/home.

Hypervisor Data Store Capacity (GiB)

The amount of storage space that is on the hypervisor data store.

Hypervisor Data Store Used Space (GiB)

The amount of storage space that is used on a hypervisor data store.

Hypervisor Data Store Available Space (GiB)

The amount of unused storage space on a hypervisor data store.

Hypervisor Data Store Used Space (%)

The percentage of storage space that is used on all disks on a hypervisor.

Hypervisor File System Capacity (GiB)

The amount of storage space on the file system of the hypervisor.

Hypervisor File System Available Space (GiB)

The amount of unused storage space in the file system of the hypervisor.

Hypervisor Disks Capacity report

Shows a chart of the 20 hypervisor disks with the most allocated space, and a table with space statistics for all hypervisor disks. Use the report to review space allocation in your hypervisor disks.

Charts

The bar chart shows the used space and available space on hypervisors.

Report output

For each hypervisor, the following information is provided:

Hypervisor Cluster Name

The name of a cluster that is monitored in your storage environment. A cluster is a group of hypervisors that collaborate for the purposes of workload balancing and failover.

Hypervisor Disk Name

The path that the operating system uses for the server disk.

Hypervisor Disk Capacity (GiB)

The amount of storage space that is on a hypervisor disk.

Hypervisor Disk Available Space (GiB)

The amount of unused storage space that is on a hypervisor disk.

Hypervisor Disk Used Space (GiB)

The amount of storage space that is used on a hypervisor disk.

Hypervisor Disk Used Space (%)

The amount of storage space that is used on a hypervisor disk.

Hypervisor Disk Status

The status of a disk on the hypervisor. Use the status to determine the condition of the disk, and if any actions must be taken. For example, if a disk has an Error status, take immediate action to correct the problem. If the disk has an Operational status, then it is operating normally and no further action is required.

Hypervisor Disk Vendor

The vendor who supplied the hypervisor disk.

Hypervisor Disk Model

The model name or model number of the hypervisor disk.

Hypervisor Disk Serial Number

The serial number of the hypervisor disk.

Hypervisor Disk Firmware Version

The version number of the firmware that is running on the hypervisor disk.

To see the load that a particular server adds to your storage environment, use the Summarized Performance of Volumes by Server report.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Servers.
3. Click Summarized Performance of Volumes by Server.
4. Select one or more servers.
5. Select the volumes.
6. Optional: Select an interval.
7. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
8. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Summarized Performance of Volumes by Server report

Shows summarized performance metrics for volumes on a server. Use the report to identify the aggregate load and the average response time of a particular server.

Charts

The charts show the following performance metrics for the volumes on a server:

- The total I/O rates and the total response times
- The read I/O rates, the write I/O rates, the read response times, and the write response times
- The read data rates, the write data rates, and the total data rates

- The read cache percentages and the write cache percentages

Report output

The following information is provided in the report for the period that you specified:

Server Name

The fully qualified domain name of the server. For example, the name of a server might be `server.example.com`.

Day, hour, or time

The day, hour, or time at which the information about the specified resource or device was collected. Whether the day, hour, or time is displayed depends on the interval that you select for the report.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation, across all volumes on the server. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second, across all volumes on the server. This value includes both sequential and nonsequential operations. The average value for each volume is added to give a total I/O rate for all volumes on the server.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations, across all volumes on the server. The average value for each volume is added to give a total data rate for all volumes on the server.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation, across all volumes on the server.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation, across all volumes on the server.

Read Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations, across all volumes on the server. The average value for each volume is added to give a read data rate for all volumes on the server.

Write Data Rate (MiB/s)

The average number of MiB per second that are transferred for write operations, across all volumes on the server. The average value for each volume is added to give a write data rate for all volumes on the server.

Overall Read I/O Rate (ops/s)

The average number of read operations per second, which is totaled for all volumes on the server. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second, which is totaled for all volumes on the server. This value includes both sequential and nonsequential write operations.

Overall Read Cache Hit Percentage

The average percentage of all read operations that find data in the cache, across all volumes on the server. This value includes both sequential and nonsequential read operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Overall Write Cache Hit Percentage

The average percentage of all write operations that are handled in the cache, across all volumes on the server. This value includes both sequential and nonsequential write operations.

Performance of Volumes by Server report

Shows the performance metrics for volumes on a server. Use the report to identify the contribution of individual volumes to the load of a particular server in your storage environment.

Charts

The charts show the following performance metrics for the volumes:

- The total overall I/O rates. The chart shows the contribution of each volume to the overall load on the server.
- The total data rates. The chart shows the contribution of each volume to the overall load on the server.
- The volume utilization percentages. The utilization percentage of each volume is displayed relative to the utilization percentage of the other volumes.
- The total response times. The response time of each volume is displayed relative to the response time of the other volumes.

Report output

The following information is provided in the report for the period that you specified:

Server Name

The fully qualified domain name of the server. For example, the name of a server might be `server.example.com`.

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Day, hour, or time

The day, hour, or time at which the information about the specified resource or device was collected. Whether the day, hour, or time is displayed depends on the interval that you select for the report.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Volume Utilization

The average percentage of time that the volume is busy.

Server Disks Capacity report

Shows the available and used disk space for all disks, which are grouped by server. You can use the report to identify disks that have no allocated space.

Charts

The bar chart shows the capacity, used space, available space, and percentage of used space for disks on servers.

Tip: To change the sort order, select a value from the Sort Order list.

Report output

For each server, the following information is provided:

- Server Disk Name
The identifier that specifies a path to a server disk, for example /dev/hdisk0.
- Server Disk Capacity (GiB)
The amount of storage space that is on a server disk.
- Server Disk Available Space (GiB)
The amount of unused storage space that is on a server disk.
- Server Disk Used Space (GiB)
The amount of storage space that is used on a server disk.
- Server Disk Used Space (%)
The percentage of used storage space on the disk.
- Server Disk Status
The condition of the resource, for example normal, warning, or error.
- Server Disk Firmware Version
The version number of the firmware that is running on the disk.
- Server Disk Model
The model name or model number of the resource.
- Server Disk Vendor
The vendor who supplied the resource.

File Systems Capacity report

Shows the available and used capacity of file systems, which are grouped by server. You can use this report to identify file systems that might be running out of space.

Charts

The bar chart shows the capacity, used space, available space, and percentage of used space for file systems on servers.
Tip: To change the sort order, select a value from the Sort Order list.

Report output

For each server, the following information is provided:

File System Mount Point

The name or mount point of the file system for the resource. For example, on Microsoft Windows systems, the value in this property might be c:\ or d:\. On operating systems such as AIX®, Linux®, Solaris, or HP-UX, the mount point might be /opt or /export/home.

File System Type

The type of file system that the resource uses.

File System Used Space (GiB)

The amount of used storage space in the file system of the resource.

File System Available Space (GiB)

The amount of unused storage space in the file system of the resource.

File System Capacity (GiB)

The amount of storage space on the file system of the resource.

File System Used Space (%)

The percentage of used space in the file system on the server.

File System Available Inodes

The number of unused inodes in file systems on the operating system.

File System Used Inodes

The number of used inodes in file systems on the operating system.

Tip: For Microsoft Windows systems, this property is blank.

Shows one performance metric on one storage system over two time periods. For example, you can use this report to compare the I/O rate for this week and last week.
- [Running the Performance Data Export report](#)
To get a spreadsheet of the performance metrics for one or more resources on a storage system, run the Performance Data Export report.
- [Performance Data Export report](#)
Exports the performance metrics for one or more resources on a storage system to a spreadsheet file in Microsoft Excel file format. Use the report if you want to analyze performance data in Excel or to send performance data to IBM®.

Running the Storage Systems Capacity report

To see information about the capacity of disks, pools, and volumes on storage systems, run the Storage Systems Capacity report.

Before you begin

To run the report with the default settings, click Finish. The report shows information about all of the resources in the list.

Procedure

1. In the Welcome portal, click Team Content  IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Storage Systems Capacity.
4. Optional: Select the configuration of the storage systems.
5. Select one or more storage systems.
6. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Storage Systems Capacity report](#)

Storage Systems Capacity report

Shows a chart of the 20 storage systems with the most used space, and a table with details of all storage systems. Use the report to review the space allocation in your storage systems.

Charts

The bar chart shows the used space and available space for pools on storage systems.

Report output

Note: IBM FlashSystem® A9000 and A9000R storage systems are not supported by IBM Spectrum® Control for this report.
For each storage system, the following information is provided:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage System Type

The type of storage system. For example, the storage system can be an IBM System Storage DS8800 system, an IBM System Storage DS8700 system, an IBM System Storage XIV system, or another type of storage system.

Storage System Location

The physical location of a storage system. The location is defined when a storage system is added to IBM Spectrum Control. You can add or edit the location of the storage system in the Properties pane of the storage system.

Storage System Pool Capacity (GiB)

The amount of storage space in pools that are on the storage system. For an XIV® or IBM Spectrum Accelerate, this value represents the physical capacity of the pool, not the virtual capacity. For other storage systems, this value might also include overhead space if the pool is unformatted.

Storage System Used Pool Space (GiB)

The amount of space that is in use in all pools on a storage system.

Storage System Pool Available Space (GiB)

The amount of unused space that is not reserved for volumes in pools that are on the storage system.

Storage System Physical Allocation Percentage

The percentage of physical space in storage system pools that is reserved for volumes. This value is always less than or equal to 100% because you cannot reserve more physical space than is available in the pools.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{allocated pool space} \div \text{pool capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a 200 GiB storage pool. Therefore, the space that is reserved for volumes is 50 GiB.

Storage System Virtual Allocation Percentage

The percentage of physical space in storage system pools that is committed to the total virtual capacity of the volumes in the pool. In thin-provisioned environments, this percentage exceeds 100% if a pool is overcommitted (over-provisioned).

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{total volume capacity} \div \text{pool capacity}) \times 100$$

For example, for a total pool size of 15 GiB, the allocation percentage might be 200%. Therefore, the virtual capacity that is committed to the volumes in the pools is 30 GiB. This configuration means that twice as much space is committed than is physically contained in the pools. If the allocation percentage is 100% for the same pools, then the virtual capacity that is committed to the pools is 15 GiB. This configuration means that all the physical capacity of the pools is already allocated to volumes.

An allocation percentage that is higher than 100% is considered aggressive. The pools have insufficient physical capacity to satisfy the maximum allocation for all the thin-provisioned volumes in the pools. In such cases, use the Storage System Shortfall Percentage property to estimate how critical the shortage of space is for storage system pools.

Storage System Shortfall Percentage

The percentage of the remaining unallocated volume space in storage system pools that is not available to be allocated. The higher the percentage, the more critical the shortfall of pool space.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{unallocatable space} \div (\text{volume space} - \text{used volume space})) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in pools reaches a critically high level. For example, the physical space in pools might be less than the committed virtual space. In this case, the pools do not have enough space to fulfill the commitment to virtual space for a volume.

This value represents the percentage of the committed virtual space that is not available in pools. As more space is used over time by volumes while the pool capacity remains the same, this percentage increases.

For example, the physical capacity of pools is 70 GiB, but 150 GiB of virtual space is committed to thin-provisioned volumes. If the volumes are using 50 GiB, then there is still 100 GiB committed to those volumes (150 GiB - 50 GiB). There is only 20 GiB of available pool space (70 GiB - 50 GiB). Because only 20 GiB of pool space is available, 80 GiB of the committed space cannot be allocated (100 GiB - 20 GiB). In this case, the percentage of committed space that is unavailable is 80% (80 GiB ÷ 100 GiB × 100).

This value is only available for pools with thin-provisioned volumes.

Storage System Volume Capacity (GiB)

The amount of space on all volumes on the storage system.

Storage System Number of Volumes

The number of volumes on a resource.

Storage System Number of Disks

The number of physical disks on the storage system. For a resource that is running IBM Spectrum Virtualize and is configured as a back-end device, the value is the number of managed disks on the resource.

Storage System Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Storage System Unallocated Disk Space (GiB)

The amount of disk space that can be added to a pool.

Storage System Volume Capacity Assigned to MDisks (GiB)

The amount of space that is on volumes that are assigned to a storage virtualizer to use as managed disks.

Storage System Disk Capacity (GiB)

The total amount of space that is on a physical disk on the storage system.

Storage System Total Disk Capacity (GiB)

The amount of space on physical disks on a storage system, including spare disks.

Storage System Cache (GiB)

The size of the cache on the storage system. This value is not shown for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System Assigned Volume Space (GiB)

The amount of space in the pool that is on volumes that are assigned to a server or storage virtualizer.

Storage System Volume Capacity for z/OS

The amount of space on all volumes on the storage system that the z/OS® operating system can use.

Storage System Real Available Pool Space (GiB)

The amount of unused space in pools that have an associated soft size on an XIV or IBM Spectrum Accelerate. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage System Real Configured Pool Space (GiB)

The amount of storage space that is in pools that have an associated soft size on an XIV or IBM Spectrum Accelerate. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage System MDisk Available Space (GiB)

The amount of storage space that is available on a managed disk. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Systems Historical Capacity report

Shows the usage of space on storage systems over a specified period. Use the report to analyze changes in your storage system requirements.

Charts

The chart shows the following space statistics for the storage systems:

- The capacity of the pools on the storage systems
- The used space in the pools on the storage systems
- The available space in the pools on the storage systems
- The capacity of the volumes on the storage systems
- The available space on the managed disks on the storage systems
- The capacity of the managed disks on the storage systems

Report output

The following information is included in reports for storage systems:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Date

The date that the data was collected for the report.

Storage System Pool Capacity (GiB)

The amount of storage space in pools that are on the storage system. For an XIV® or IBM Spectrum Accelerate, this value represents the physical capacity of the pool, not the virtual capacity. For other storage systems, this value might also include overhead space if the pool is unformatted.

Storage System Used Pool Space (GiB)

The amount of space that is in use in all pools on a storage system.

Storage System Available Pool Space (GiB)

The amount of unused space in pools that are on the storage system.

Storage System Volume Capacity (GiB)

The amount of space on all volumes on the storage system.

Storage System Number of Volumes

The number of volumes on a resource.

Storage System Number of Disks

The number of physical disks on the storage system. For a resource that is running IBM Spectrum Virtualize and is configured as a back-end device, the value is the number of managed disks on the resource.

Storage System Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Storage System Unallocated Disk Space (GiB)

The amount of disk space that can be added to a pool.

Storage System Volume Capacity Assigned to MDisks (GiB)

The amount of space that is on volumes that are assigned to a storage virtualizer to use as managed disks.

Storage System Disk Capacity (GiB)

The amount of storage space on physical disks in a storage system, excluding spare disks. This value is not shown for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System Total Disk Capacity (GiB)

The amount of space on physical disks on a storage system, including spare disks.

Storage System Assigned Volume Space (GiB)

The amount of space in the pool that is on volumes that are assigned to a server or storage virtualizer.

Storage System Volume Capacity for z/OS (GiB)

The amount of space on all volumes on the storage system that the z/OS® operating system can use.

Storage System Real Available Pool Space (GiB)

The amount of unused space in pools that have an associated soft size on an XIV or IBM Spectrum Accelerate. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage System Real Configured Pool Space (GiB)

The amount of storage space that is in pools that have an associated soft size on an XIV or IBM Spectrum Accelerate. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage System MDisk Capacity (GiB)

The amount of storage space on the managed disk.

Storage System MDisk Available Space (GiB)

The amount of storage space that is available on a managed disk. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

To see which storage systems are the most active, run the Most Active Storage Systems report.

Before you begin

To run the report with the default settings, click Finish. The report shows information about all of the resources in the list.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Most Active Storage Systems.
4. Optional: Select the configuration of the storage systems.
5. Select the storage systems, and then select a sort order.
6. To set the time frame of the report, specify a reporting period.
If the report does not include a particular resource that you want to see, select a reporting period for which data is available for the resource.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
7. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Most Active Storage Systems report](#)

Most Active Storage Systems report

Shows a chart of the 20 storage systems that are most active, and details for all storage systems, for a time period that you specify. Use the report to analyze the performance of storage systems.

Charts

The bar chart shows the most active storage systems. By default, storage systems are sorted by the total I/O rate.
Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided about the most active storage systems is as follows:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Location

The physical location of a storage system. The location is defined when a storage system is added to IBM Spectrum Control. You can add or edit the location of the storage system in the Properties pane of the storage system.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

- [Running the Most Active Storage Systems report](#)

Running the Performance of One Storage System report

To see performance metrics for a storage system, run the Performance of One Storage System report.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Performance of One Storage System.
4. Optional: Select the configuration of the storage system.
5. Select a storage system.
6. Optional: Select an interval.
7. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
8. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Performance of One Storage System report](#)

Performance of One Storage System report

Shows four charts, and a table of performance metrics for a storage system over a time period that you specify. Use the report to analyze the performance of a storage system.

Charts

The charts show the following performance metrics for a storage system:

- The total I/O rates, and the total response times
- The read I/O rates, write I/O rates, and response times
- The read data rates, and the write data rates
- The read cache hit percentages, and the write cache hit percentages

Report output

The following information is provided in the report for the period that you specified:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Location

The physical location of a storage system. The location is defined when a storage system is added to IBM Spectrum Control. You can add or edit the location of the storage system in the Properties pane of the storage system.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Running the Compare Performance of Multiple Storage Systems report

Use the Compare Performance of Multiple Storage Systems report to compare up to four performance metrics on multiple storage systems. For example, you can compare cache percentages, data rates, and I/O rates.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Compare Performance of Multiple Storage Systems.
4. Select the storage systems, and then click Next.
5. Select the category of performance metric that you want to include in the report, and then select the performance metric.
6. Optional: To add more metrics to the report, complete the following steps:
 - a. Click Add Metric.
 - b. Select the category of performance metric, and then select the performance metric.
 - c. If you want to remove the last metric that you added, click Remove Metric.
7. Optional: Select an interval.
8. To set the time frame of the report, specify a reporting period.

It is easier to analyze small amounts of information over shorter periods.

Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
9. Click Finish.

Results

If the resources that you selected are not related, or if no data is available, a message is displayed in the report.

If information is not available for any of the resources that you selected, those resources are not included in the report.

Running the Compare Performance of One Storage System over Time Ranges report

To compare a performance metric for one storage system in two date ranges, run the Compare Performance of One Storage System over Time Ranges report.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Compare Performance of One Storage System over Time Ranges.
4. Optional: Select the configuration of the storage systems.
5. Select the storage system.
6. Select the category of performance metric about which you want a report, and then select the performance metric.
7. Select an interval.
8. Specify the two date ranges or reporting periods that you want to compare.
For example, you can compare the performance metric for this week with last week.
Tip: To specify a start date and an end date for a reporting period, select Custom Date Range from the list of reporting periods.
9. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Compare Performance of One Storage System over Time Ranges report](#)

Compare Performance of One Storage System over Time Ranges report

Shows one performance metric on one storage system over two time periods. For example, you can use this report to compare the I/O rate for this week and last week.

Charts

The chart shows the performance data of the storage system on the performance metric you selected, over the time periods that you selected.

Report output

The following information is provided in the report:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Day in Range

The number of the day in the date range at which the performance metric data was collected, relative to the date range that you specified. The number of days that are shown is determined by the reporting period that was selected for the report. If Last 30 Days was selected, then entries for days 1 - 30 are shown on the report.

Hour in Range

The number of the hour in the day at which the performance metric data was collected. For example, 0 is between 12:00:00 a.m. and 12:59:59 a.m., 1 is between 01:00:00 a.m. and 01:59:59 a.m.

Minute in Range

The interval of minutes during which the performance metric data was collected. For example, 0 shows that performance data was collected 0 - 5 minutes after the hour. Similarly, 5 shows that the performance data that was collected 5 - 10 minutes after the hour.

First Date Range

The details of the performance metric data in the first date range. The details are displayed in two columns in the First Date Range column. Depending on the interval that you selected, the Time, Day, or Hour column shows the time at which the performance metric data was collected. The column with the performance metric name shows the data for the performance metric for the first date range.

Second Date Range

The details of the performance metric data in the second date range. The details are displayed in two columns in the Second Date Range column. Depending on the interval that you selected, the Time, Day, or Hour column shows the time at which the performance metric data was collected. The column with the performance metric name shows the data for the performance metric for the second date range.

Running the Performance Data Export report

To get a spreadsheet of the performance metrics for one or more resources on a storage system, run the Performance Data Export report.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Performance Data Export.
4. Optional: Select the configuration of the storage systems.
5. Select one or more storage systems.
6. Optional: Click Next, and then select the devices for which you want performance metrics in the report.
7. Click Finish.

Results

You can open or save the spreadsheet from your browser.

Related reference

- [Performance Data Export report](#)

Performance Data Export report

Exports the performance metrics for one or more resources on a storage system to a spreadsheet file in Microsoft Excel file format. Use the report if you want to analyze performance data in Excel or to send performance data to IBM®.

Report output

The spreadsheet contains a worksheet for each resource on the storage system. The worksheet for a resource contains the performance metric data for that resource.

Running the Most Active Controllers or Modules report

To see which controllers or modules are most active on storage systems, run the Most Active Controllers or Modules report.

Before you begin

To run the report with the default settings, click Finish. The report shows information about all of the resources in the list.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Controllers, Modules, and Nodes.
4. Click Most Active Controllers or Modules.
5. Optional: Select the configuration of the storage systems.
6. Select the storage systems, and then select a sort order.
7. To set the time frame of the report, specify a reporting period.
If the report does not include a particular resource that you want to see, select a reporting period for which data is available for the resource.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
8. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Most Active Controllers or Modules report](#)

Most Active Controllers or Modules report

Shows a chart of the 20 controllers or modules that are most active, and details for all storage systems, for a time period that you specify. Use the report to analyze the performance of controllers or modules.

Restriction: This report applies only to DS8000®, XIV® systems, IBM Spectrum Accelerate, and vendor-acquired systems.

Charts

The bar chart shows the most active controllers or modules on storage systems. By default, controllers or modules are sorted by the overall I/O rate.

Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided about the most active controllers or modules is as follows:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Controller or Module Name

The name that was assigned to the controller or module when it was added to the system.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Performance of One Node report

Shows four charts, and a table of performance metrics for a node over a time period. Use the report to analyze the performance of a node.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Charts

The charts show the following performance statistics for a node on a storage system:

- The total overall I/O rates, and the total response times
- The overall I/O rates for read and write operations, the response times for read and write operations
- The data rates for read and write operations, and the total data rates
- The overall cache hit percentage for read operations, the cache delay percentage for write operations, and the utilization percentage for processors

Report output

The following information is provided in the report for the period that you specified:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage I/O Group Name

The name that was assigned to the I/O group when it was added to the system.

Storage Node Name

The name that was assigned to the storage system node when it was added to the system.

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Processor Utilization Percentage

The average percentage of time that the processors on nodes are busy doing system I/O tasks. This value applies only to resources that are running IBM Spectrum Virtualize.

 - a. Click Add Metric.
 - b. Select the category of performance metric, and then select the performance metric.
 - c. If you want to remove the last metric that you added, click Remove Metric.
9. Optional: Select an interval.
10. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
11. Click Finish.

Results

If the resources that you selected are not related, or if no data is available, a message is displayed in the report.

If information is not available for any of the resources that you selected, those resources are not included in the report.

Compare Performance of Multiple Nodes report

Shows up to four performance metrics for multiple nodes over time. Use the report to compare the performance metrics for nodes that are on storage systems.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Charts

The charts show the performance metrics for the nodes that you selected for the period that you specified.

Report output

The following information is provided in the report:

Performance metrics

Shows the data for each performance metric.

Storage system names

Shows the names of the storage systems, and the performance metric data for each storage system.

Nodes

Shows the names of the nodes, and the performance metric data for each node.

Shows up to four performance metrics for multiple local disks over time. Use the report to compare the performance metrics for local disks that are on storage systems.

Running the Disks Capacity report

Run the Disks Capacity report to see information about the capacity of disks on storage systems.

Before you begin

To run the report with the default settings, click Finish. The report shows information about all of the resources in the list.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Disks.
4. Click Disks Capacity.
5. Optional: Select the configuration of the storage systems.
6. Select one or more storage systems.
7. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

- [Disks Capacity report](#)

Disks Capacity report

Shows a chart of the disk classes with the most allocated space, and a table with space statistics for all disks by class. Use the report to review space allocation in your disks.

Charts

The bar chart shows the capacity of disks, grouped by storage class, on storage systems.

Report output

For each disk on a storage system, the following information is provided:

- Storage Disk Name
The name that was assigned to the storage disk when it was added to the system.
- Storage System Type
The type of storage system. For example, the storage system can be an IBM System Storage DS8800 system, an IBM System Storage DS8700 system, an IBM System Storage XIV system, or another type of storage system.
- Storage System Configuration
Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.
- Storage Pool Name
The name that was assigned to the pool when it was added to the system.
- Storage System Name
A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.
- Storage Disk Tag
A number that identifies the array to which a disk belongs. This property applies only to DS8000® storage systems.
- Storage Disk Vendor
The vendor who supplied the resource.
- Storage Disk Model
The model name or model number of the resource.
- Storage Disk Serial Number

The serial number of the resource.

Storage Disk Firmware Version
The version number of the firmware that is running on the disk.

Storage Disk Capacity (GiB)
The amount of storage space that is on a physical disk on the storage system.

Storage Disk Speed (RPM)
The speed of the disk.

Running the Most Active Disks report

To see which local disks that are on storage systems are the most active, use the Most Active Disks report. This report shows information only for SAN Volume Controller and Storwize® V7000 storage systems.

Before you begin

To run the report with the default settings, click Finish. The report shows information about all of the resources in the list.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Disks.
4. Click Most Active Disks.
5. Optional: Select the configuration of the storage systems.
6. Select the storage systems, and then select a sort order.
7. To set the time frame of the report, specify a reporting period.
If the report does not include a particular resource that you want to see, select a reporting period for which data is available for the resource.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
8. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Most Active Disks report](#)

Most Active Disks report

Shows a chart of the 20 local disks that are most active, and details for all local disks, for a time period that you specify. Use the report to analyze the performance of local disks.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Charts

The bar chart shows the most active local disks that are on storage systems. By default, local disks are sorted by the total I/O rate.
Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided about the most active local disks that are on storage systems is as follows:

Storage System Name
A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage MDisk Name
The name that was assigned to the managed disk when it was added to the system.

Storage Local Disk Name
The name that was assigned to the local disk on the storage system when the local disk was created on the system.

Storage System Configuration
Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage Local Disk Storage Class

The storage technology of the local disk on a storage system. For example, the storage class can be a serial-attached SCSI (SAS) or solid-state drive (SSD).

Storage Local Disk Speed (RPM)

The speed of the local disk on a storage system.

Storage Local Disk Capacity (GiB)

The amount of storage space on the local disk.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Total Back-End Data Rate (MiB/s)

The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

- [Performance of One Disk report](#)

Performance of One Disk report

Shows four charts, and a table of performance metrics for a local disk over a time period. Use the report to analyze the performance of a local disk.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Charts

The charts show the following performance metrics for a local disk on a storage system:

- The total back-end I/O rates and the overall back-end response times
- The read I/O rates, the write I/O rates, the read response times, and the write response times
- The read data rates, the write data rates, and the total data rates

- The read queue times, the write queue times, and the overall queue times

Report output

The following information is provided in the report for the period that you specified:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage MDisk Name

The name that was assigned to the managed disk when it was added to the system.

Storage Local Disk Name

The name that was assigned to the local disk on the storage system when the local disk was created on the system.

Storage Local Disk Storage Class

The storage technology of the local disk on a storage system. For example, the storage class can be a serial-attached SCSI (SAS) or solid-state drive (SSD).

Storage Local Disk Speed (RPM)

The speed of the local disk on a storage system.

Storage Local Disk Capacity (GiB)

The amount of storage space on the local disk.

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Back-End Read Data Rate (MiB/s)

The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)

The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)

The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Queue Time (ms/op)

The average number of milliseconds that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Back-End Write Queue Time (ms/op)

The average number of milliseconds that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Overall Back-End Queue Time (ms/op)

The average number of milliseconds that a read or a write operation spends in the queue before the operation is sent to the back-end storage resources.

You can run predefined reports to analyze and compare the performance of volumes on host connections.

- [Running the Most Active Host Connections report](#)
To see which host connections are the most active, run the Most Active Host Connections report.
- [Most Active Host Connections report](#)
Shows a chart of the 20 host connections that have the most active volumes. The most active volumes have the greatest aggregate load.
- [Running the Summarized Performance of Volumes by Host Connection report](#)
To see the load that a particular server adds to your storage environment, use the Summarized Performance of Volumes by Host Connection report.
- [Summarized Performance of Volumes by Host Connection report](#)
Shows summarized performance metrics for volumes on a host connection. Use the report to identify the aggregate load and the average response time of a particular server.
- [Running the Performance of Volumes by Host Connection report](#)
To see performance metrics for the volumes on a server, use the Performance of Volumes by Host Connection report.
- [Performance of Volumes by Host Connection report](#)
Shows the performance metrics for volumes on a host connection. Use the report to identify the contribution of individual volumes to the load of a particular server in your storage environment.

Running the Most Active Host Connections report

To see which host connections are the most active, run the Most Active Host Connections report.

Before you begin

To run the report with the default settings, click Finish. The report shows information about all of the resources in the list.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Host Connections.
4. Click Most Active Host Connections.
5. Optional: Select the configuration of the storage systems.
6. Select the storage systems, and then select a sort order.
7. To set the time frame of the report, specify a reporting period.
If the report does not include a particular resource that you want to see, select a reporting period for which data is available for the resource.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
8. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Most Active Host Connections report](#)

Most Active Host Connections report

Shows a chart of the 20 host connections that have the most active volumes. The most active volumes have the greatest aggregate load.

Chart

The bar chart shows the most active host connections. By default, host connections are sorted by the total I/O rate.
Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided about the most active host connections is as follows:

Storage Host Connection Name

The user-defined name that describes the server or storage device that is assigned to a volume.

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

XIV® Cluster

The name of the cluster, if any, as defined on the XIV. If no cluster is defined for the host connection, this field is blank.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Related tasks

- [Running the Most Active Host Connections report](#)

Running the Summarized Performance of Volumes by Host Connection report

To see the load that a particular server adds to your storage environment, use the Summarized Performance of Volumes by Host Connection report.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Host Connections.
4. Click Summarized Performance of Volumes by Host Connection.
5. Select a host connection. To select a host connection, complete the following steps:
 - a. Type a keyword.
For example, type `example1` to find the names of host connections that start with `example1`.
To change the default search option, click Options.
Use the percent sign as a wildcard.
For example, type `a%` to find host connections that begin with 'a' or 'A'. Type `%a` to find host connections that begin with or contain the letter 'a' or 'A'. You can type `%` to retrieve all of the host connections on a resource.
 - b. Click Search.
The report searches the user-defined names for the host connections. The report does not search the server names that are defined when a server is probed.
If the search is successful, the host connections are displayed in the Choice list.
 - c. From the list, select a host connection, and then click Refresh.
6. Select the volumes.
7. Optional: Select an interval.
8. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
9. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Summarized Performance of Volumes by Host Connection report](#)

Summarized Performance of Volumes by Host Connection report

Shows summarized performance metrics for volumes on a host connection. Use the report to identify the aggregate load and the average response time of a particular server.

Charts

The charts show the following performance statistics for the volumes on a host connection:

- The total I/O rates and the total response times
- The read I/O rates, the write I/O rates, the read response times, and the write response times
- The read data rates, the write data rates, and the total data rates
- The read cache percentages and the write cache percentages

Report output

The following information is provided in the report for the period that you specified:

Storage Host Connection Name

The user-defined name that describes the server or storage device that is assigned to a volume.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation, across all volumes on the server. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second, across all volumes on the server. This value includes both sequential and nonsequential operations. The average value for each volume is added to give a total I/O rate for all volumes on the server.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations, across all volumes on the server. The average value for each volume is added to give a total data rate for all volumes on the server.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation, across all volumes on the server.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation, across all volumes on the server.

Read Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations, across all volumes on the server. The average value for each volume is added to give a read data rate for all volumes on the server.

Write Data Rate (MiB/s)

The average number of MiB per second that are transferred for write operations, across all volumes on the server. The average value for each volume is added to give a write data rate for all volumes on the server.

Overall Read I/O Rate (ops/s)

The average number of read operations per second, which is totaled for all volumes on the server. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second, which is totaled for all volumes on the server. This value includes both sequential and nonsequential write operations.

Overall Read Cache Hit Percentage

The average percentage of all read operations that find data in the cache, across all volumes on the server. This value includes both sequential and nonsequential read operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Overall Write Cache Hit Percentage

The average percentage of all write operations that are handled in the cache, across all volumes on the server. This value includes both sequential and nonsequential write operations.

Performance of Volumes by Host Connection report

Shows the performance metrics for volumes on a host connection. Use the report to identify the contribution of individual volumes to the load of a particular server in your storage environment.

Charts

The charts show the following performance metrics for the volumes:

- The total overall I/O rates. This is a stacked area chart that shows the contribution of each volume to the overall load on the server.
- The total data rates. This is a stacked area chart that shows the contribution of each volume to the overall load on the server.
- The volume utilization percentages. The utilization percentage of each volume is displayed relative to the utilization percentage of the other volumes.
- The total response times. The response time of each volume is displayed relative to the response time of the other volumes.

Report output

The following information is provided in the report for the period that you specified:

Storage Host Connection Name

The user-defined name that describes the server or storage device that is assigned to a volume.

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Volume Utilization

The average percentage of time that the volume is busy.

- [Most Active IO Groups report](#)

Most Active IO Groups report

Shows a chart of the 20 I/O groups that are most active, and details for all I/O groups, for a time period that you specify. Use the report to analyze the performance of I/O groups.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Charts

The chart shows the most active I/O groups on storage systems. By default, I/O groups are sorted by the total overall I/O rate.

Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided for I/O groups is as follows:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage I/O Group Name

The name that was assigned to the I/O group when it was added to the system.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Processor Utilization Percentage

The average percentage of time that the processors on nodes are busy doing system I/O tasks. This value applies only to resources that are running IBM Spectrum Virtualize.

- [Running the Most Active IO Groups report](#)

Running the Performance of One IO Group report

To see information about the performance of an I/O group on a storage system, run the Performance of One IO Group report.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click IO Groups.
4. Click Performance of One IO Group.
5. Optional: Select the configuration of the storage systems.

6. Select a storage system.
7. Select an I/O group.
8. Optional: Select an interval.
9. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
10. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Performance of One IO Group report](#)

Performance of One IO Group report

Shows four charts, and a table of performance metrics for an I/O group over a time period. Use the report to analyze the performance of an I/O group.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Charts

The charts show the following performance metrics for an I/O group on a storage system:

- The total overall I/O rates, and the total response times
- The overall I/O rates for read and write operations, and the response times for read and write operations
- The data rates for read and write operations, and the total data rates
- The overall cache hit percentage for read operations, the cache delay percentage for write operations, and the utilization percentage for processors

Report output

The following information is provided in the report for the period that you specified:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage I/O Group Name

The name that was assigned to the I/O group when it was added to the system.

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Processor Utilization Percentage

The average percentage of time that the processors on nodes are busy doing system I/O tasks. This value applies only to resources that are running IBM Spectrum Virtualize.

Related reports

To open related reports, click the name of the storage system and then click the name of the report. You can open the following related reports:

Running the Compare Performance of Multiple IO Groups report

Use the Compare Performance of Multiple IO Groups report to compare up to four performance metrics for multiple I/O groups that are on storage systems. For example, you can compare cache percentages, data rates, and I/O rates.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click IO Groups.
4. Click Compare Performance of Multiple IO Groups.
5. Select the storage systems, and then click Refresh.
6. Select the I/O groups, and then click Next.
7. Select the category of performance metric that you want to include in the report, and then select the performance metric.
8. Optional: To add more metrics to the report, complete the following steps:
 - a. Click Add Metric.
 - b. Select the category of performance metric, and then select the performance metric.
 - c. If you want to remove the last metric that you added, click Remove Metric.
9. Optional: Select an interval.
10. To set the time frame of the report, specify a reporting period.

It is easier to analyze small amounts of information over shorter periods.

Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
11. Click Finish.

Results

If the resources that you selected are not related, or if no data is available, a message is displayed in the report.

If information is not available for any of the resources that you selected, those resources are not included in the report.

- [Managed Disks Capacity report](#)

Managed Disks Capacity report

Shows a chart of the 20 managed disks with the most available space, and a table with space statistics for all managed disks. Use the report to review space availability in your managed disks.

Restriction: This report applies only to SAN Volume Controller, Storwize®, and Hitachi Universal Storage Platform V systems.

Charts

The bar chart shows the used space and the available space for managed disk on storage systems.

Report output

For each managed disk on a storage system, the following information is provided:

Storage System MDisk Name

The name that was assigned to the managed disk on a storage system when it was added to the system.

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage System MDisk Capacity (GiB)

The amount of storage space on the managed disk.

Storage System MDisk Used Space (GiB)

The amount of used space on the managed disk.

Storage System MDisk Available Space (GiB)

The amount of storage space that is available on a managed disk. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage MDisk RAID Level

The RAID level of the managed disk, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the managed disk.

Storage System MDisk Type

The type of managed disk on a storage system. For example, the disk on a storage system can be a local managed disk.

Storage System MDisk Mode

The access mode of a managed disk on a storage virtualizer. The access mode describes how extents are provided for virtual disks. Extents can be provided to virtual disks in the following ways:

Array

Extents are provided from local disks.

Managed

Extents are provided from a back-end storage volume.

Unmanaged

The managed disk is not used in the system.

Storage System MDisk Strip Size (KB)

The RAID strip size on a managed disk on a storage system.

Storage System MDisk Is Balanced

Shows whether LUNs are balanced across storage controllers on the managed disk. If this value is **Yes**, the LUNs are balanced.

Storage System MDisk Fast Write State

Shows whether the cache for a volume on a disk that is managed by a storage system is empty, contains data, or is corrupted.

Storage System MDisk Write Verify

Shows whether all write operations on a managed disk on a storage system are verified by an immediate follow-up read operation. The follow-up read operation verifies that the write operation was successful. If this value is **Yes**, all write operations are verified by a follow-up read operation.

Restriction: This report applies only to SAN Volume Controller, Storwize®, and Hitachi Universal Storage Platform V systems.

Charts

The charts show the following performance statistics for a managed disk on a storage system:

- The total I/O rates and the total response times
- The read I/O rates, the write I/O rates, the read response times, and the write response times
- The read data rates and the write data rates
- The read cache percentages, the write cache percentages, and the volume utilization percentages

Report output

The following information is provided in the report for the period that you specified:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage MDisk Name

The name that was assigned to the managed disk when it was added to the system.

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Back-End Read Data Rate (MiB/s)

The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)

The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)

The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Queue Time (ms/op)

The average number of milliseconds that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Back-End Write Queue Time (ms/op)

The average number of milliseconds that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Overall Back-End Queue Time (ms/op)

The average number of milliseconds that a read or a write operation spends in the queue before the operation is sent to the back-end storage resources.

Running the Compare Performance of Multiple Managed Disks report

Use the Compare Performance of Multiple Managed Disks report to compare up to four performance metrics for multiple managed disks that are on storage systems. For example, you can compare data rates, I/O rates, and response times.

Procedure

1. In the Welcome portal, click Team Content, IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Managed Disks.
4. Click Compare Performance of Multiple Managed Disks.
5. Select the storage systems.
6. Select managed disks. To select managed disks, complete the following steps:
 - a. Type a keyword.
For example, type `mdisk1` to find the names of managed disks that start with `mdisk1`.
To change the default search option, click Options.
Use the percent sign as a wildcard.
For example, type `a%` to find managed disks that begin with 'a' or 'A'. Type `%a` to find managed disks that begin with or contain the letter 'a' or 'A'. You can type `%` to retrieve all of the managed disks on a resource.
 - b. Click Search.
If the search is successful, the managed disks are displayed in the Results list.
 - c. Select the managed disks that you require from the list, and then click Insert.
7. Click Next.
8. Select the category of performance metric that you want to include in the report, and then select the performance metric.
9. Optional: To add more metrics to the report, complete the following steps:
 - a. Click Add Metric.
 - b. Select the category of performance metric, and then select the performance metric.
 - c. If you want to remove the last metric that you added, click Remove Metric.
10. Optional: Select an interval.
11. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
12. Click Finish.

Results

If the resources that you selected are not related, or if no data is available, a message is displayed in the report.

If information is not available for any of the resources that you selected, those resources are not included in the report.

Shows one performance metric on one pool over two time periods. For example, you can use this report to compare the I/O rate for this week and last week.

Running the Pools Capacity report

To see information about the used and available space of pools on storage systems, run the Pools Capacity report.

Before you begin

To run the report with the default settings, click Finish. The report shows information about all of the resources in the list.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Pools.
4. Click Pools Capacity.
5. Optional: Select the configuration of the storage systems.
6. Optional: Select one or more storage systems.
7. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Pools Capacity report](#)

Pools Capacity report

Shows a chart of the 20 pools with the most allocated space, and a table with space statistics for all pools. Use the report to review space allocation in your pools.

Charts

The bar chart shows the used space and available space for pools on storage systems.

Report output

For each pool on a storage system, the following information is provided:

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage Pool Capacity (GiB)

The total amount of storage space in a pool.

Storage Pool Used Space (GiB)

The amount of storage space that is used in the pool.

Storage Pool Available Space (GiB)

The amount of unused space that is not reserved for volumes in pools that are on the storage system. IBM Spectrum Control uses the following formula to determine this value:

$$\text{pool capacity} - \text{used space}$$

For XIV® systems and IBM Spectrum Accelerate, this value represents the unallocated physical space in the pool, not the unallocated virtual space. For some storage systems, this value usually includes only the usable capacity, but might also include overhead space if the pool is unformatted.

Storage Pool Physical Allocation Percentage

The percentage of physical space in a pool that is reserved for volumes. This value is always less than or equal to 100% because you cannot reserve more physical space than is available in a pool.

IBM Spectrum Control uses the following formula to determine the allocation percentage:

$$(\text{allocated space} \div \text{pool capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a total pool size of 200 GiB. Therefore, the space that is reserved for volumes is 50 GiB.

Storage Pool Virtual Allocation Percentage

The percentage of physical space in a pool that is committed to the total virtual capacity of the volumes in the pool. In thin-provisioned environments, this percentage exceeds 100% if a pool is overcommitted (over-provisioned).

IBM Spectrum Control uses the following formula to determine the allocation percentage:

$$(\text{total volume capacity} \div \text{pool capacity}) \times 100$$

For example, the allocation percentage is 200% for a total pool size of 15 GiB. Therefore, the virtual capacity that is committed to the volumes in the pool is 30 GiB. This configuration means that twice as much space is committed than is physically contained in the pool. If the allocation percentage is 100% for the same pool, then the virtual capacity that is committed to the pool is 15 GiB. This configuration means that all the physical capacity of the pool is already allocated to volumes. An allocation percentage that is higher than 100% is considered aggressive. The pool has insufficient physical capacity to satisfy the maximum allocation for all the thin-provisioned volumes in the pool. In such cases, you can use the value for Storage Pool Shortfall Percentage to estimate how critical the shortage of space is for a pool.

This value is only available for pools with thin-provisioned volumes.

Storage Pool Shortfall Percentage

The percentage of the remaining unallocated volume space in a pool that is not available to be allocated.

The higher the percentage, the more critical the shortfall of pool space.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{unallocatable space} \div (\text{virtual capacity} - \text{allocated space})) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in a pool reaches a critically high level. For example, the physical space in a pool might be less than the committed virtual space. In this case, the pool does not have enough space to fulfill the commitment to virtual space.

This value represents the percentage of the committed virtual space that is not available in a pool. As more space is used over time by volumes while the pool capacity remains the same, this percentage increases.

For example, the physical capacity of a pool is 70 GiB, however, 150 GiB of virtual space is committed to thin-provisioned volumes. If the volumes are using 50 GiB, then there is still 100 GiB committed to those volumes (150 GiB - 50 GiB). There is only 20 GiB of available pool space (70 GiB - 50 GiB). Because only 20 GiB of pool space is available, 80 GiB of the committed space cannot be allocated (100 GiB - 20 GiB). In this case, the percentage of committed space that cannot be allocated is 80% (80 GiB ÷ 100 GiB × 100).

This value is only available for pools with thin-provisioned volumes.

Storage Pool Assigned Volume Space (GiB)

The amount of space in the pool that is on volumes that are assigned to a server or storage virtualizer.

Storage Pool Unassigned Volume Space (GiB)

The amount of volume space in the pool that is not assigned to a server or storage virtualizer.

Storage Pool Total Volume Capacity (GiB)

The total storage space on all the volumes in a pool, which includes thin-provisioned and standard volumes. For thin-provisioned volumes, this value includes virtual space.

Storage Pool Allocated Space (GiB)

The amount of space that is reserved for all the volumes in a pool, which includes both thin-provisioned and standard volumes. The space that is allocated for thin-provisioned volumes is less than their virtual capacity, which is shown in the Storage Pool Total Volume Capacity (GiB) property. If a pool does not contain thin-provisioned volumes, this value is the same as the value in the Storage Pool Total Volume Capacity (GiB) property. This value is equal to the value in the Storage Pool Used Volume Space (GiB) property for the following resources:

- Resources other than those that are running IBM Spectrum Virtualize and are configured as back-end storage
- Resources that are running IBM Spectrum Virtualize, are configured as back-end storage, and are not thin-provisioned

Storage Pool Used Volume Space (GiB)

The amount of allocated space that is used by the volumes in a pool, which includes thin-provisioned and standard volumes.

For resources that are running IBM Spectrum Virtualize, you can preallocate thin-provisioned volume space when volumes are created. For these resources, the Storage Pool Used Space might be different than the Storage Pool Allocated Space for pools that contain thin-provisioned volumes. In other cases, the values for Storage Pool Used Space and Storage Pool Allocated Space are equal.

This value is accurate as of the most recent time that IBM Spectrum Control collected data about a volume. The value in this property might not be 100% accurate for the current state of volumes. This inaccuracy might occur because data collection is run on a set schedule and the used space on volumes can change rapidly.

Storage Pool Real Configured Space (GiB)

The amount of storage space that is in an XIV or IBM Spectrum Accelerate pool that has an associated soft size. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage Pool Real Available Space (GiB)

The amount of unused space that is in an XIV or IBM Spectrum Accelerate pool that has an associated soft size. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage Pool RAID Level

The RAID level of the resource, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the resource.

Storage Pool Is Thin Provisioned

Shows whether a pool, volume, or volume copy is thin-provisioned. If this value is **Yes**, the resource is thin-provisioned.

Storage Pool Is Solid State

Shows whether there are solid-state drives in the pool. This property can contain the following values:

Mixed

The pool contains both hard disk drives and solid-state drives.

Non solid state

The pool contains no solid-state drives.

Solid state

The pool contains a least one solid-state drive.

Storage Pool Number of MDisks

The number of managed disks in a storage pool.

Storage Pool Extent Size (MiB)

The size of the extent that was specified when a pool was created. Smaller extent sizes limit the maximum size of the volumes that can be created in a pool. Smaller extent sizes minimize the amount of potentially wasted space per volume.

This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Pool Warning Level

The percentage of used capacity of the storage pool at which a warning is generated.

Storage Pool Repository Capacity (GiB)

The amount of space on all extents in the repository of a pool. This space can be used to allocate track space-efficient volumes. This attribute applies only to DS8000® storage systems.

Storage Pool Used Repository Space (GiB)

The amount of space on all extents in the repository of a pool that are allocated. This space can be used to allocate track space-efficient volumes. This attribute applies only to the DS8000 storage systems.

Report links

To open related reports, click the name of the storage pool and then click the name of the report. You can open the following related reports:

- Pools Historical Capacity

Running the Pools Historical Capacity report

To see how space in pools on storage systems is used, run the Pools Historical Capacity report.

Before you begin

You can see how space in a pool on a storage system, or in pools in a storage resource group, are used.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Pools.
4. Click Pools Historical Capacity.
5. Select the type of historical space report that you want to create. You can select either of the following options:
 - Of a Pool in a Storage System
 - Click Next.
 - Optional: Select the configuration of the storage system.
 - Select a storage system, and then select a pool.
 - Of Pools in a Storage Resource Group
 - Click Next.

- Optional: Select the configuration of the storage system.
 - Select a storage resource group.
6. Select an interval.
 7. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
 8. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Pools Historical Capacity report](#)

Pools Historical Capacity report

Shows the usage of space on storage pools over a specified period. Use the report to analyze changes in your storage pool requirements.

Charts

The chart shows the following space statistics for the pool on a storage system:

- The capacity of the pool
- The used space in the pool
- The available space in the pool
- The virtual volume capacity of the pool
- The used volume space in the pool
- The allocated space in the pool

The chart shows the following space statistics for the pool in the storage resource group:

- The capacity of the pools
- The used space in the pools
- The available space in the pools
- The virtual volume capacity of the pools
- The used volume space in the pools
- The allocated space in the pool

Report output

The following information is included in reports for a pool on a storage system or for pools in a storage resource group:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Date

The date that the data was collected for the report.

Storage System Pool Capacity (GiB)

The amount of storage space in pools that are on the storage system. For an XIV® or IBM Spectrum Accelerate, this value represents the physical capacity of the pool, not the virtual capacity. For other storage systems, this value might also include overhead space if the pool is unformatted.

Storage Pool Available Space (GiB)

The amount of unused space that is not reserved for volumes in pools that are on the storage system.

IBM Spectrum Control uses the following formula to determine this value:

pool capacity - used space

For XIV systems and IBM Spectrum Accelerate, this value represents the unallocated physical space in the pool, not the unallocated virtual space. For some storage systems, this value usually includes only the usable capacity, but might also include overhead space if the pool is unformatted.

Storage Pool Allocated Space (GiB)

The amount of space that is reserved for all the volumes in a pool, which includes both thin-provisioned and standard volumes. The space that is allocated for thin-provisioned volumes is less than their virtual capacity, which is shown in the Storage Pool Total Volume Capacity (GiB) property. If a pool does not contain thin-provisioned volumes, this value is the same as the value in the Storage Pool Total Volume Capacity (GiB) property. This value is equal to the value in the Storage Pool Used Volume Space (GiB) property for the following resources:

- Resources other than those that are running IBM Spectrum Virtualize and are configured as back-end storage
- Resources that are running IBM Spectrum Virtualize, are configured as back-end storage, and are not thin-provisioned

Storage Pool Used Space (GiB)

The amount of storage space that is used in the pool.

Storage Pool Total Volume Capacity (GiB)

The total storage space on all the volumes in a pool, which includes thin-provisioned and standard volumes. For thin-provisioned volumes, this value includes virtual space.

Storage Pool Used Volume Space (GiB)

The amount of allocated space that is used by the volumes in a pool, which includes thin-provisioned and standard volumes.

For resources that are running IBM Spectrum Virtualize, you can preallocate thin-provisioned volume space when volumes are created. For these resources, the Storage Pool Used Space might be different than the Storage Pool Allocated Space for pools that contain thin-provisioned volumes. In other cases, the values for Storage Pool Used Space and Storage Pool Allocated Space are equal.

This value is accurate as of the most recent time that IBM Spectrum Control collected data about a volume. The value in this property might not be 100% accurate for the current state of volumes. This inaccuracy might occur because data collection is run on a set schedule and the used space on volumes can change rapidly.

Storage Pool Assigned Volume Space (GiB)

The amount of space in the pool that is on volumes that are assigned to a server or storage virtualizer.

Storage Pool Unassigned Volume Space (GiB)

The amount of volume space in the pool that is not assigned to a server or storage virtualizer.

Storage Pool Real Configured Space (GiB)

The amount of storage space that is in pools that have an associated soft size on an XIV or IBM Spectrum Accelerate. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage System MDisk Available Space (GiB)

The amount of storage space that is available on a managed disk. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Pool Number of MDisk

The number of managed disks in a storage pool.

Storage Pool Number of Storage Volumes

The number of volumes in the storage pool.

Running the Most Active Pools report

To see which pools are most active on storage systems, run the Most Active Pools report.

Before you begin

To run the report with the default settings, click Finish. The report shows information about all of the resources in the list.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Pools.
4. Click Most Active Pools.
5. Optional: Select the configuration of the storage systems.
6. Select the storage systems, and then select a sort order.
7. To set the time frame of the report, specify a reporting period.
If the report does not include a particular resource that you want to see, select a reporting period for which data is available for the resource.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
8. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

- [Most Active Pools report](#)

Most Active Pools report

Shows a chart of the 20 storage pools that are most active, and details for all pools, for a time period that you specify. Use the report to analyze the performance of pools.

Charts

The bar chart shows the most active pools on storage systems. By default, pools are sorted by the I/O rate.

Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided about the most active pools is as follows:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Related reference

- [Performance of One Pool report](#)

Performance of One Pool report

Shows four charts, and a table of performance metrics for a storage pool over a time period that you specify. Use the report to analyze the performance of a storage pool.

Charts

The charts show the following performance metrics for a pool on a storage system:

- The total overall rates for I/O operations, and the total response times
- The overall I/O rates for read and write operations, and the response times for read and write operations
- The total I/O rates for back-end operations, and overall response times for back-end operations

- The I/O rates for back-end read operations and back-end write operations, and the response rates for back-end read and back-end write operations

Report output

The following information is provided in the report for the period that you specified:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Running the Compare Performance of Multiple Pools

Use the Compare Performance of Multiple Pools report to compare up to four performance metrics for multiple pools that are on storage systems. For example, you can compare cache percentages, data rates, and I/O rates.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Pools.
4. Click Compare Performance of Multiple Pools.
5. Select the storage systems, and then click Refresh.
6. Select the pools, and then click Next.
7. Select the category of performance metric that you want to include in the report, and then select the performance metric.
8. Optional: To add more metrics to the report, complete the following steps:
 - a. Click Add Metric.
 - b. Select the category of performance metric, and then select the performance metric.
 - c. If you want to remove the last metric that you added, click Remove Metric.
9. Optional: Select an interval.
10. To set the time frame of the report, specify a reporting period.

It is easier to analyze small amounts of information over shorter periods.

Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
11. Click Finish.

Results

If the resources that you selected are not related, or if no data is available, a message is displayed in the report.

If information is not available for any of the resources that you selected, those resources are not included in the report.

Running the Compare Performance of One Pool over Time Ranges report

To compare a performance metric for one pool in two date ranges, run the Compare Performance of One Pool over Time Ranges report.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Pools.
4. Click Compare Performance of One Pool over Time Ranges.
5. Optional: Select the configuration of the storage systems.
6. Select the storage system.
7. Select the category of performance metric about which you want a report, and then select the performance metric.
8. Select an interval.
9. Specify the two date ranges or reporting periods that you want to compare.
For example, you can compare the performance metric for this week with last week.
Tip: To specify a start date and an end date for a reporting period, select Custom Date Range from the list of reporting periods.
10. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Compare Performance of One Pool over Time Ranges report](#)

Compare Performance of One Pool over Time Ranges report

Shows one performance metric on one pool over two time periods. For example, you can use this report to compare the I/O rate for this week and last week.

Charts

The chart shows the performance data of the pool on the performance metric you selected, over the time periods that you selected.

Report output

The following information is provided in the report:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Day in Range

The number of the day in the date range at which the performance metric data was collected, relative to the date range that you specified. The number of days that are shown is determined by the reporting period that was selected for the report. If Last 30 Days was selected, then entries for days 1 - 30 are shown on the report.

Hour in Range

The number of the hour in the day at which the performance metric data was collected. For example, 0 is between 12:00:00 a.m. and 12:59:59 a.m., 1 is between 01:00:00 a.m. and 01:59:59 a.m.

Minute in Range

The interval of minutes during which the performance metric data was collected. For example, 0 shows that performance data was collected 0 - 5 minutes after the hour. Similarly, 5 shows that the performance data that was collected 5 - 10 minutes after the hour.

First Date Range

The details of the performance metric data in the first date range. The details are displayed in two columns in the First Date Range column. Depending on the interval that you selected, the Time, Day, or Hour column shows the time at which the performance metric data was collected. The column with the performance metric name shows the data for the performance metric for the first date range.

Second Date Range

The details of the performance metric data in the second date range. The details are displayed in two columns in the Second Date Range column. Depending on the interval that you selected, the Time, Day, or Hour column shows the time at which the performance metric data was collected. The column with the performance metric name shows the data for the performance metric for the second date range.

- [Most Active Ports report](#)

Most Active Ports report

Shows a chart of the 20 ports that are most active, and details for all ports, for a time period that you specify. Use the report to analyze the performance of ports.

Charts

The bar chart shows the most active ports on storage systems. By default, ports are sorted by the I/O rate.

Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided about the most active ports is as follows:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Port Name

The name that was assigned to the storage port when the storage system was added to the system.

Storage System Port Location

The physical location of a port on DS8000® storage systems and XIV® systems. For all other systems, this property shows the WWPN of the port.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Overall Port Response Time (ms/op)

The average number of milliseconds to complete a send or receive operation.

Total Port I/O Rate (ops/s)

The average number of send operations and receive operations per second.

Total Port Data Rate (MiB/s)

The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Overall Port Bandwidth Percentage

The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

The name that was assigned to the storage port when the storage system was added to the system.

Storage System Port Location

The physical location of a port on DS8000® storage systems and XIV® systems. For all other systems, this property shows the WWPN of the port.

Port Send I/O Rate (ops/s)

The average number of I/O operations per second for operations in which data is sent from a port. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive I/O Rate (ops/s)

The average number of I/O operations per second for operations in which the port receives data. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port I/O Rate (ops/s)

The average number of send operations and receive operations per second.

Port Send Response Time (ms/op)

The average number of milliseconds to complete a send operation.

Port Receive Response Time (ms/op)

The average number of milliseconds to complete a receive operation.

Overall Port Response Time (ms/op)

The average number of milliseconds to complete a send or receive operation.

Port Send Data Rate (MiB/s)

The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)

The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)

The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port Send Bandwidth Percentage

The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Port Receive Bandwidth Percentage

The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Overall Port Bandwidth Percentage

The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Running the Compare Performance of Multiple Ports report

Use the Compare Performance of Multiple Ports report to compare up to four performance metrics for multiple ports that are on storage systems. For example, you can compare data rates, I/O rates, and bandwidth percentages.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Ports.
4. Click Compare Performance of Multiple Ports.
5. Select the storage systems.
6. Select ports. To select ports, complete the following steps:
 - a. Type a keyword.
For example, type `port1` to find the names of ports that start with `port1`.
To change the default search option, click Options.
Use the percent sign as a wildcard.
For example, type `a%` to find ports that begin with 'a' or 'A'. Type `%a` to find ports that begin with or contain the letter 'a' or 'A'. You can type `*` to retrieve all of the ports on a resource.
 - b. Click Search.
If the search is successful, the ports are displayed in the Results list.
 - c. Select the ports that you require from the list, and then click Insert.
7. Click Next.
8. Select the category of performance metric that you want to include in the report, and then select the performance metric.
9. Optional: Select an interval.
10. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
11. Click Finish.

Results

If the resources that you selected are not related, or if no data is available, a message is displayed in the report.

If information is not available for any of the resources that you selected, those resources are not included in the report.

Compare Performance of Multiple Ports report

Shows up to four performance metrics for multiple ports over time. Use the report to compare the performance metrics for ports that are on storage systems.

Charts

The charts show the performance metrics for the ports that you selected for the period that you specified.

Report output

The following information is provided in the report:

Day, hour, or time

The day, hour, or time at which the information about the specified resource or device was collected. Whether the day, hour, or time is displayed depends on the interval that you select for the report.

Performance metrics

Shows the performance metric data for the resource.

Storage system names

Shows the names of the storage systems, and the performance metric data for each storage system.

Ports

Shows the names of the storage ports, and the performance metric data for each port.

- [Most Active RAID Arrays report](#)

Most Active RAID Arrays report

Shows up to four performance metrics for multiple arrays over time. Use the report to compare the performance metrics for arrays that are on storage systems.

Restriction: This report applies only to DS8000® systems.

Charts

The bar chart shows the most active RAID on DS8000, DS6000™, and TotalStorage™ Enterprise Storage Server® storage systems. By default, arrays are sorted by the I/O rate.

Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided about the most active RAID is as follows:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Controller Name

The name that was assigned to the controller when it was added to the system.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage RAID Array Name

The name that was assigned to the RAID array when it was added to the system.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Total Back-End Data Rate (MiB/s)

The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Disk Utilization Percentage

The average percentage of time that the disks that are associated with an array are busy.

No value is calculated for this property if there are multiple ranks in the extent pool where the thin-provisioned volumes are allocated. In this case, the value **N/A** is displayed. This limitation applies only to DS8000 storage systems.

If there is only a single rank in the extent pool, the value for this property is calculated regardless of the thin-provisioned volumes.

Tip: Some highly sequential workloads such as batch or backup processing might continually exceed the threshold because they drive the arrays to high utilization percentages. For these types of workloads, a high utilization indicates that the work is being performed very efficiently and is not a cause for concern.

Performance of One RAID Array report

Shows four charts, and a table of performance metrics for a RAID array over a time period. Use the report to analyze the performance of a RAID array.

Restriction: This report applies only to DS8000® systems.

Charts

The charts show the following performance statistics for arrays on storage systems:

- The total I/O rates, and the total response times
- The read I/O rates, the write I/O rates, the read response times, and the write response times
- The back-end I/O rates, and the back-end I/O response times
- The back-end read I/O rates, the back-end write I/O rates, the read response times, and the write response times

Report output

The following information is provided in the report for the period that you specified:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Controller Name

The name that was assigned to the controller when it was added to the system.

Storage RAID Array Name

The name that was assigned to the RAID array when it was added to the system.

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Disk Utilization Percentage

The average percentage of time that the disks that are associated with an array are busy.

No value is calculated for this property if there are multiple ranks in the extent pool where the thin-provisioned volumes are allocated. In this case, the value **N/A** is displayed. This limitation applies only to DS8000 storage systems.

If there is only a single rank in the extent pool, the value for this property is calculated regardless of the thin-provisioned volumes.

Tip: Some highly sequential workloads such as batch or backup processing might continually exceed the threshold because they drive the arrays to high utilization percentages. For these types of workloads, a high utilization indicates that the work is being performed very efficiently and is not a cause for concern.

For DS8000 storage systems, this property is available only for 8.5.0 and later. For earlier versions, the value **N/A** is shown.

Running the Volumes Capacity report

To see information about the capacity of volumes on storage systems, run the Volumes Capacity report.

Before you begin

To run the report with the default settings, click Finish. The report shows information about all of the resources in the list.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.

2. Click Storage Systems.

3. Click Volumes.

4. Click Volumes Capacity.

5. Optional: Select the configuration of the storage systems.

6. Select one or more storage systems.

7. Optional: If you selected SAN Volume Controller or Storwize® V7000 storage systems, you can select the type of volume.

Option	Description
All Volumes	Select All, the default, to view information about all of the volumes on the selected storage systems.
Only Primary Volumes	Select Primary to view information about primary volumes on the selected storage systems.
Only Secondary Volumes	Select Secondary to view information about secondary volumes on the selected storage systems.

8. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Volumes Capacity report](#)

Volumes Capacity report

Shows a chart of the 20 volumes with the most used space, and a table with details of all volumes. Use the report to review the space allocation in your volumes.

Charts

The bar chart shows the following statistics for volumes on storage systems:

- Used space.
- Unallocated space.
- Unused allocated space, that is, the value of Storage Volume Allocated Space (GiB) minus the value of Storage Volume Used Space (GiB).

Report output

For each volume on a storage system, the following information is provided:

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage Volume WWN

The worldwide name of the volume.

Storage Volume Capacity (GiB)

The total amount of storage space that is committed to a volume.

For thin-provisioned volumes, this value represents the virtual capacity of the volume.

For XIV® systems and IBM Spectrum Accelerate, this value represents the physical (hard) capacity of the volume, not the virtual (soft) capacity. For other storage systems, this value might also include overhead space if the pool is unformatted.

Storage Volume Allocated Space (GiB)

The amount of space that is reserved for a volume. The space that is allocated for a thin-provisioned volume is less than its virtual capacity, which is shown in the Storage Volume Capacity (GiB) property. This value is equal to the value in the Storage Volume Used Space (GiB) property for the following resources:

- Resources other than those that are running IBM Spectrum Virtualize and are configured as back-end storage
- Resources that are running IBM Spectrum Virtualize, are configured as back-end storage, and are not thin-provisioned

Storage Volume Used Space (GiB)

The amount of allocated space that is used by a volume.

For resources that are running IBM Spectrum Virtualize, you can preallocate thin-provisioned volume space when the volumes are created. In these cases, the Storage Volume Used Space (GiB) might be different than the Storage Volume Allocated Space (GiB). For volumes that are not thin provisioned, the values for Storage Volume Used Space (GiB) and Storage Volume Allocated Space (GiB) are equal.

This value is accurate as of the most recent time that IBM Spectrum Control collected data about a volume. The value in this property might not be 100% accurate for the current state of volumes. This inaccuracy might occur because data collection is run on a set schedule and the used space on volumes can change rapidly.

Storage Volume Unallocated Space (GiB)

The amount of space in a pool that is not reserved for a volume.

IBM Spectrum Control uses the following formula to determine this value:

capacity - allocated space

Available only for thin provisioned volumes.

Storage Volume Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Storage Volume Physical Allocation Percentage

The percentage of physical space that is reserved for a volume. This value is always less than or equal to 100% because you cannot reserve more physical space than is available.

IBM Spectrum Control uses the following formula to determine this value:

(allocated space ÷ capacity) × 100

For example, the physical allocation percentage is 25% for a volume size of 200 GiB. Therefore, the space that is reserved for volumes is 50 GiB.

Storage Volume Shortfall Percentage

The percentage of the remaining unallocated volume space in a pool that is not available to be allocated to a volume.

The higher the percentage, the more critical the shortfall of space.

IBM Spectrum Control uses the following formula to determine this value:

(unallocatable volume space ÷ volume unallocated space) × 100

You can use this percentage to determine when the amount of overcommitted space in pools reaches a critically high level. For example, the physical space in pools might be less than the committed virtual space. In this case, the pools do not have enough space to fulfill the commitment to virtual space for a volume.

This Storage Volume Shortfall Percentage represents the percentage of the committed virtual space that is not available in a pool. As more space is used over time by a volume while the pool capacity remains the same, this percentage increases.

For example, the remaining physical capacity of a pool is 70 GiB, however, 150 GiB of virtual space is committed to a thin-provisioned volume. If the volume is using 50 GiB, then there is still 100 GiB committed to that volume (150 GiB - 50 GiB). There is a shortfall of 30 GiB (70 GiB remaining pool space - 100 GiB remaining commitment of volume space to the volume). The volume is overcommitted by 30 GiB based on the available space in the pool. The shortfall is 30% when you use the following calculation:

**100 GiB unallocated volume space - 70 GiB remaining
pool space ÷ 100 GiB unallocated volume space × 100**

Storage Volume Used Allocated Space Percentage

The percentage of reserved space for a volume that is being used. This value is always less than or equal to 100% because a volume cannot use more space than is allocated.

IBM Spectrum Control uses the following formula to determine this value:

(volume used space ÷ volume allocated space) × 100

This property is available only for volumes on resources that are running IBM Spectrum Virtualize.

Storage Volume RAID Level

The RAID level of the resource, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the resource.

Storage Volume Is Assigned

Shows whether the volume is assigned to a server. If this value is **Yes**, the volume is assigned to a server.

Storage Volume Is Thin Provisioned

Shows whether a pool, volume, or volume copy is thin-provisioned. If this value is **Yes**, the resource is thin-provisioned.

Storage Volume Type

The type of storage volume. For example, the storage volume can be striped or sequential. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Grain Size (KiB)

The grain size with which a thin-provisioned volume was created. This value is typically 32, 64, 128, or 256 KiB. Larger grain sizes maximize performance, whereas smaller grain sizes maximize space efficiency. Grain sizes also limit the maximum virtual space of a volume.

This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Warning Level

The percentage of volume capacity that is used at which a warning is generated. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Logical Subsystem

The logical subsystem (LSS) to which a volume or pool belongs.

Storage Volume Copy ID
The identifier of a volume copy.
Storage Volume Copy Is Primary
Shows whether the volume copy is the primary volume copy.

Running the Volumes Historical Capacity report

To see how space on volumes on storage systems is used, run the Volumes Historical Capacity report.

Before you begin

You can see how space on a volume on a storage system, or on volumes in a storage resource group, are used.

Procedure

1. In the Welcome portal, click Team Content, IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Volumes.
4. Click Volumes Historical Capacity.
5. Select the type of historical capacity report that you want to create. You can select either of the following options:
 - Of a Volume in a Storage System
 - Click Next.
 - Optional: Select the configuration of the storage system.
 - Select a storage system.
 - Type a keyword and click Search. For example, type lun, to find the names of volumes that start with lun. To change the default search option, click Options.
Tip: Use the percent sign (%) as a wildcard. For example, type a% to find volume names that begin with 'a' or 'A'. Type %a to find volume names that begin with or contain the letter 'a' or 'A'. You can type % to retrieve all of the volumes on a resource.
 - Select a volume.
 - Of Volumes in a Storage Resource Group
 - Click Next.
 - Select a storage resource group.
6. Select an interval.
7. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
8. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Volumes Historical Capacity report](#)

Volumes Historical Capacity report

Shows the usage of space on volumes over a specified period. Use the report to analyze changes in your volume requirements, particularly the increasing usage of space on thin-provisioned volumes.

Charts

The chart shows the following space statistics for the volume on a storage system:

- The capacity of the volume
- The used space on the volume
- The space on the volume that is used for system management
- The allocated space on the volume

The chart shows the following space statistics for the volumes in a storage resource group:

- The capacity of the volumes
- The used space on the volumes
- The space on the volumes that is used for system management
- The allocated space on the volume

If the volume is thin provisioned, the chart shows the total amount of virtual space that is allocated to the volume, and the total amount of real space that is used by the volume.

Report output

The following information is included in reports for a volume on a storage system, or for volumes in a storage resource group:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Date

The date that the data was collected for the report.

Storage Volume Capacity (GiB)

The total amount of storage space that is committed to a volume.

For thin-provisioned volumes, this value represents the virtual capacity of the volume.

For XIV® systems and IBM Spectrum Accelerate, this value represents the physical (hard) capacity of the volume, not the virtual (soft) capacity. For other storage systems, this value might also include overhead space if the pool is unformatted.

Storage Volume Used Space (GiB)

The amount of allocated space that is used by a volume.

For resources that are running IBM Spectrum Virtualize, you can preallocate thin-provisioned volume space when the volumes are created. In these cases, the Storage Volume Used Space (GiB) might be different than the Storage Volume Allocated Space (GiB). For volumes that are not thin provisioned, the values for Storage Volume Used Space (GiB) and Storage Volume Allocated Space (GiB) are equal.

This value is accurate as of the most recent time that IBM Spectrum Control collected data about a volume. The value in this property might not be 100% accurate for the current state of volumes. This inaccuracy might occur because data collection is run on a set schedule and the used space on volumes can change rapidly.

Storage Volume Allocated Space (GiB)

The amount of space that is reserved for a volume. The space that is allocated for a thin-provisioned volume is less than its virtual capacity, which is shown in the Storage Volume Capacity (GiB) property. This value is equal to the value in the Storage Volume Used Space (GiB) property for the following resources:

- Resources other than those that are running IBM Spectrum Virtualize and are configured as back-end storage
- Resources that are running IBM Spectrum Virtualize, are configured as back-end storage, and are not thin-provisioned

Storage Volume Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

- [Most Active Volumes report](#)

Most Active Volumes report

Shows a chart of the 20 volumes that are most active, and details for all volumes, for a time period that you specify. Use the report to analyze the performance of volumes.

Charts

The bar chart shows the most active volumes on storage systems. By default, volumes are sorted by the I/O rate.

Tip: To change the sort order, select a value from the Sort Order list.

Report output

The information that is provided about the most active volumes is as follows:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Volume Utilization

The average percentage of time that the volume is busy.

Running the Performance of One Volume report

To see performance metrics for volumes on a storage system, run the Performance of One Volume report.

Procedure

1. In the Welcome portal, click Team Content, IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Volumes.
4. Click Performance of One Volume.
5. Optional: Select the configuration of the storage systems.

6. Select a storage system.
7. Select a volume. To select a volume, complete the following steps:
 - a. Type a keyword.
For example, type `1un`, to find the names of volumes that start with `1un`.
To change the default search option, click Options.
Use the percent sign as a wildcard.
For example, type `a%` to find volume names that begin with 'a' or 'A'. Type `%a` to find volume names that begin with or contain the letter 'a' or 'A'. You can type `%` to retrieve all of the volumes on a resource.
 - b. Click Search.
If the search is successful, the names of the volumes are displayed in the Choice list.
 - c. From the list, select a volume.
8. Optional: Select an interval.
9. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
10. Click Finish.

Results

If information is available for the resources that you selected, a report is created. If no information is available for the selected resources, or data collection was unsuccessful, a message is displayed in the report.

Related reference

- [Performance of One Volume report](#)

Performance of One Volume report

Shows four charts, and a table of performance metrics for a volume over a time period that you specify. Use the report to analyze the performance of a volume.

Charts

The charts show the following performance metrics for a volume on a storage system:

- The total I/O rates, and the total response times
- The read I/O rates, the write I/O rates, the read response times, and the write response times
- The read data rates, and the write data rates
- The read cache percentages, the write cache percentages, and the volume utilization percentages

Report output

The following information is provided in the report for the period that you specified:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Volume Utilization

The average percentage of time that the volume is busy.

Running the Compare Performance of Multiple Volumes report

Use the Compare Performance of Multiple Volumes report to compare up to four performance metrics for multiple volumes that are on storage systems. For example, you can compare cache percentages, data rates, and I/O rates.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Predefined Reports.
2. Click Storage Systems.
3. Click Volumes.
4. Click Compare Performance of Multiple Volumes.
5. Select the storage systems.
6. Select volumes. To select volumes, complete the following steps:
 - a. Type a keyword.
For example, type `example1` to find the names of volumes that start with `example1`.
To change the default search option, click Options.
Use the percent sign as a wildcard.
For example, type `a%` to find volumes that begin with 'a' or 'A'. Type `%a` to find volumes that begin with or contain the letter 'a' or 'A'. You can type `%` to retrieve all of the volumes on a resource.
 - b. Click Search.
If the search is successful, the volumes are displayed in the Results list.
 - c. Select the volumes that you require from the list, and then click Insert.
7. Click Next.
8. Select the category of performance metric that you want to include in the report, and then select the performance metric.
9. Optional: To add more metrics to the report, complete the following steps:
 - a. Click Add Metric.
 - b. Select the category of performance metric, and then select the performance metric.
 - c. If you want to remove the last metric that you added, click Remove Metric.
10. Optional: Select an interval.
11. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
12. Click Finish.

Results

If the resources that you selected are not related, or if no data is available, a message is displayed in the report.

If information is not available for any of the resources that you selected, those resources are not included in the report.

Predefined reports about storage tiering

Use storage tier reports to help you determine the best storage-tier configuration for your environment.

Information collection

IBM Spectrum® Control collects information from:

- SAN Volume Controller
- Storwize® V7000
- Storwize V7000 Unified

IBM Spectrum Control provides reports that show performance and usage data for the SAN Volume Controller, Storwize V7000, and Storwize V7000 Unified systems in your environment.

Workload activity reports

Before you run workload activity reports, you must set the back-end properties of the managed disk (MDisk) groups in your environment.

You can use the IBM Spectrum Control CLI called `tcptool` to set the back-end properties of MDisk groups. Alternatively, you can set the properties in the MDisk Group Details page in the IBM Spectrum Control GUI.

With the information that is collected from IBM Spectrum Control, you can run workload activity reports. The reports provide information about the workload activity of these resources:

- Managed disk (MDisk) groups
- Virtual disks (VDisks) in MDisk groups
- VDisks in storage resource groups
- VDisks in storage virtualizers

By analyzing workload activity reports, you can determine:

- Whether the workload activity of an MDisk group is too low or too high
- Whether a VDisk should be migrated in one of the following ways:
 - To an MDisk group with a faster read I/O capability rate
 - To an MDisk group with a slower read I/O capability rate

Explanation: In the predefined reports about performance, resources, and historical information, MDisk groups are called pools, and VDisks are called volumes.

Running the Storage Resource Group - VDisk Workload Activity Details report

To see which virtual disks (VDisks) are most active in a storage resource group, run the Storage Resource Group - VDisk Workload Activity Details report.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Packages.
2. Click Storage Tiering.
3. Click VDisk Workload Activity Reports.
4. Select Storage Resource Group - VDisk Workload Activity Details, then click Next.
5. Select a storage virtualizer, and then select a storage resource group.
6. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
7. Click Finish.

Related reference

- [Storage Resource Group - VDisk Workload Activity Details report](#)

Storage Resource Group - VDisk Workload Activity Details report

Shows the workload activity of virtual disks (VDisks) in storage resource groups. The workload activity is determined by calculating the average and maximum peak utilization of the VDisks in the group.

In the IBM Spectrum® Control GUI, storage resource groups are available as general groups.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Reporting period

The name of the storage virtualizer, the name of the storage resource group, the date filter such as `Last 7 days`, and the reporting period are displayed in the report.

Retention of report data

If you remove an MDisk group or a VDisk, the daily data that is collected for reports is retained for a configurable period. The default is 90 days. If you run a report after the data retention period expired, the daily data for the MDisk group or the VDisk is unavailable.

VDisk migration

If a VDisk is migrated to another MDisk group during a reporting period, daily VDisk reports are produced only for the target MDisk group. For the target MDisk group, VDisk reports are produced from the day that the VDisk is migrated from the source MDisk group until the last day of the reporting period.

Charts

The maximum length of an MDisk group, VDisk, or storage resource group name in charts is 25 characters. Names that are longer than 25 characters are truncated. To indicate that a name is truncated, an ellipsis (...) is appended to the name. For example, if the name of an MDisk group is `myverylongmanageddiskgroupname123` in a chart, it is truncated and displayed as `myverylongmanageddiskgroupname...`

Two charts are displayed:

Most Active VDIs chart

For each storage resource group, two bars are shown:

- A yellow bar that shows average VDisk utilization
- A red bar that shows maximum VDisk utilization

To calculate average VDisk utilization, the following formula is used:

average(vdisk_peak_utilization)

To calculate maximum VDisk utilization, the following formula is used:

maximum(vdisk_peak_utilization)

In this sample excerpt of report output for VDisk1, the values that are required to calculate average and maximum VDisk utilization are provided.

VDisk Report Date	VDisk Peak Utilization (%)
Dec 6 2011	86.30
Dec 7 2011	50.01
Dec 8 2011	79.41

To calculate the average value of a VDisk:

1. The values for VDisk1 in the VDisk Utilization (%) column are added:

$$86.30 + 50.01 + 79.41 = 215.72$$

2. The total is divided by the number of days that are specified in the date range. For example, if the reporting period spans 3 days, the total is divided by 3.

$$215.72 \div 3 = 71.91$$

In the sample, the average peak VDisk utilization is 71.91.

In this sample excerpt of report output for VDisk1, the values that are required to calculate average and maximum VDisk utilization are provided.

VDisk Report Date	VDisk Peak Utilization (%)
Dec 6 2011	86.30
Dec 7 2011	50.01
Dec 8 2011	79.41

Least Active VDIs chart

For each storage resource group, two bars are shown:

- A yellow bar that shows average VDisk utilization
- A red bar that shows maximum VDisk utilization

The same formulas that are used in the most active VDIs chart are also used in the least active VDIs chart.

The number of VDIs that a storage resource group uses determines how many VDIs are displayed in each chart, as shown in the table.

Number of VDIs that the storage resource group uses	Number of VDIs in the Most Active VDIs chart	Number of VDIs in the Least Active VDIs chart
≥ 10	5	5
9	5	4
8	4	4
7	4	3
6	3	3
5	3	2
4	2	2
3	2	1
2	1	1
1	1	0

Tip: Click the bar that represents a VDisk in a chart to open the VDisk Details Report. Alternatively, click the name of the VDisk in the report. Click the name of the MDisk group in the report to open the MDisk Group Details Report. To monitor the workload activity of VDIs for all storage resource groups in a storage virtualizer, run the Storage Resource Group - VDisk Workload Activity Report.

Threshold values

The names of the threshold values that are used in the report to monitor workload activity for VDIs are as follows:

- VDisk Max Read Response Time Threshold
- VDisk Max Write Response Time Threshold
- Max Read Cache Hits Time Threshold
- Max Read I/O Rate Threshold
- Max Write I/O Rate Threshold

Threshold values are set during installation. If a threshold value is changed during a reporting period, the original value and the new threshold value are displayed as minimum and maximum values. If, for example, the VDisk maximum read response time threshold value is changed during a reporting period from 70% to 80%, the name of the column is changed to VDisk Max Read Response Time Threshold of {70 - 80%} Exceeded By (hr:min.). The convention that is used to represent a threshold value is

a number followed by the percent sign and enclosed in brackets: {%. When the report is run, the variable value is replaced with the threshold value. To calculate whether read or write response time thresholds are exceeded, the following formula is used: $(\text{maximum_response_time_value} \times \text{maximum_response_time_threshold_value})/100$. The result is converted from seconds to hours and minutes, and displayed in the report. Read and write response times are sampled at 5-minute intervals over a 24-hour period.

Report output

The following information is provided about VDIs in the storage resource group:

MDisk Group

The name of the MDisk group.

VDisk

The name of the VDisk.

VDisk Report Date

The date that the data was collected for the report.

VDisk Capacity (GB)

The total storage capacity of the VDisk in GB.

VDisk Thin Provisioning Capacity Status

The warning level threshold is set in the thin provisioning profile for the VDisk. The threshold is exceeded when the capacity of the VDisk that is used exceeds or is equal to the warning level threshold. If the used capacity of the VDisk in GB is \geq the specified warning threshold value, a status value of `Warning` is displayed. If the used capacity of the VDisk in GB is $<$ the specified warning threshold value, a status value of `OK` is displayed. If thin provisioning is not used, a status value of `Not Applicable` is displayed.

VDisk Peak Utilization (%)

The highest value of VDisk utilization over a 24-hour period.

VDisk Read I/O Rate (ops/s)

The read I/O rate of the VDisk in operations per second.

VDisk Max Read I/O Rate (ops/s)

The maximum read I/O rate of the VDisk in operations per second.

VDisk Average Read Response Time (ms/op)

The average read response time in milliseconds per operation.

VDisk Max Read Response Time (ms/op)

The maximum read response time in milliseconds per operation.

VDisk Max Read Response Time Threshold of {%) Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read response time threshold for the VDisk is exceeded over a 24 hour period.

VDisk Write I/O Rate (ops/s)

The write I/O rate in operations per second.

VDisk Average Write Response Time (ms/op)

The average write response time in milliseconds per operation.

VDisk Max Write Response Time (ms/op)

The maximum write response time in milliseconds per operation.

VDisk Max Write Response Time Threshold of {%) Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write response time threshold for the VDisk is exceeded over a 24 hour period.

VDisk Max Read Density Rate (ops/s per GB)

The maximum read density rate in operations per second per GB. This value is calculated by dividing the maximum read I/O rate in operations per second by the number of GB that the VDisk was allocated.

VDisk I/O Rate Share of Total VDisk Read I/O Rate (%)

The maximum read I/O rate of the VDisk as a percentage of the total maximum read I/O rate of all the VDIs in the MDisk group.

VDisk Capacity Share of Total VDisk Capacity (%)

The real capacity of the VDisk as a percentage of the real capacity of all the VDIs in the MDisk group.

VDisk Average Read Cache Hits (%)

The average read cache hits in percent.

VDisk Max Read Cache Hits (%)

The maximum read cache hits in percent.

VDisk Max Read Cache Hits Time Threshold of {%) Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read cache hits time threshold is exceeded over a 24 hour period.

VDisk Max Read I/O Rate Threshold of {%) Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read I/O rate threshold is exceeded over a 24 hour period.

VDisk Max Write I/O Rate Threshold of {%) Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write I/O rate threshold is exceeded over a 24 hour period.

VDisk Max Write Cache Delay I/O Rate (ops/s)

The maximum write cache delay I/O rate of the VDisk in operations per second.

VDisk Details report

Shows the workload activity of a virtual disk (VDisk) in a managed disk group. Use the report to analyze the performance of a VDisk in a managed disk (MDisk) group.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Reporting period

The name of the storage virtualizer, the name of the VDisk, the date filter such as `Last 7 days`, and the reporting period are displayed in the report.

Retention of report data

If you remove an MDisk group or a VDisk, the daily data that is collected for reports is retained for a configurable period. The default is 90 days. If you run a report after the data retention period expired, the daily data for the MDisk group or the VDisk is unavailable.

Threshold values

The names of the threshold values that are used in the report to monitor workload activity for VDisks are as follows:

- VDisk Max Read Response Time Threshold
- VDisk Max Write Response Time Threshold
- Max Read Cache Hits Time Threshold
- Max Read I/O Rate Threshold
- Max Write I/O Rate Threshold

Threshold values are set during installation. If a threshold value is changed during a reporting period, the original value and the new threshold value are displayed as minimum and maximum values. If, for example, the VDisk maximum read response time threshold value is changed during a reporting period from 70% to 80%, the name of the column is changed to VDisk Max Read Response Time Threshold of {70 - 80%} Exceeded By (hr.:min.). The convention that is used to represent a threshold value is a number followed by the percent sign and enclosed in brackets: {%}. When the report is run, the variable value is replaced with the threshold value. To calculate whether read or write response time thresholds are exceeded, the following formula is used: $(\text{maximum_response_time_value} \times \text{maximum_response_time_threshold_value}) / 100$. The result is converted from seconds to hours and minutes, and displayed in the report. Read and write response times are sampled at 5-minute intervals over a 24-hour period.

Report output

The following information is displayed about the VDisk:

MDisk Group

The name of the MDisk group.

VDisk

The name of the VDisk.

VDisk Report Date

The date that the data was collected for the report.

VDisk Capacity (GB)

The total storage capacity of the VDisk in GB.

VDisk Thin Provisioning Capacity Status

The warning level threshold is set in the thin provisioning profile for the VDisk. The threshold is exceeded when the capacity of the VDisk that is used exceeds or is equal to the warning level threshold. If the used capacity of the VDisk in GB is \geq the specified warning threshold value, a status value of `Warning` is displayed. If the used capacity of the VDisk in GB is $<$ the specified warning threshold value, a status value of `OK` is displayed. If thin provisioning is not used, a status value of `Not Applicable` is displayed.

VDisk Peak Utilization (%)

The highest value of VDisk utilization over a 24-hour period.

VDisk Read I/O Rate (ops/s)

The read I/O rate of the VDisk in operations per second.

VDisk Max Read I/O Rate (ops/s)

The maximum read I/O rate of the VDisk in operations per second.

VDisk Average Read Response Time (ms/op)

The average read response time in milliseconds per operation.

VDisk Max Read Response Time (ms/op)

The maximum read response time in milliseconds per operation.

VDisk Max Read Response Time Threshold of {%} Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read response time threshold for the VDisk is exceeded over a 24 hour period.

VDisk Write I/O Rate (ops/s)

The write I/O rate in operations per second.

VDisk Average Write Response Time (ms/op)

The average write response time in milliseconds per operation.

VDisk Max Write Response Time (ms/op)

The maximum write response time in milliseconds per operation.

VDisk Max Write Response Time Threshold of {%} Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write response time threshold for the VDisk is exceeded over a 24 hour period.

VDisk Max Read Density Rate (ops/s per GB)

The maximum read density rate in operations per second per GB. This value is calculated by dividing the maximum read I/O rate in operations per second by the number of GB that the VDisk was allocated.

VDisk I/O Rate Share of Total VDisk Read I/O Rate (%)

The maximum read I/O rate of the VDisk as a percentage of the total maximum read I/O rate of all the VDIs in the MDisk group.

VDisk Capacity Share of Total VDisk Capacity (%)

The real capacity of the VDisk as a percentage of the real capacity of all the VDIs in the MDisk group.

VDisk Average Read Cache Hits (%)

The average read cache hits in percent.

VDisk Max Read Cache Hits (%)

The maximum read cache hits in percent.

VDisk Max Read Cache Hits Time Threshold of {%} Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read cache hits time threshold is exceeded over a 24 hour period.

VDisk Max Read I/O Rate Threshold of {%} Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read I/O rate threshold is exceeded over a 24 hour period.

VDisk Max Write I/O Rate Threshold of {%} Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write I/O rate threshold is exceeded over a 24 hour period.

VDisk Max Write Cache Delay I/O Rate (ops/s)

The maximum write cache delay I/O rate of the VDisk in operations per second.

Running the MDisk Groups - VDisk Workload Activity report

To see which virtual disks (VDIs) are most active in managed disk (MDisk) groups, run the MDisk Groups - VDisk Workload Activity report.

Procedure

1. In the Welcome portal, click Team Content, IBM Spectrum Control Packages.
2. Click Storage Tiering.
3. Click VDisk Workload Activity Reports.
4. Select MDisk Groups - VDisk Workload Activity, then click Next.
5. Select a storage virtualizer.
6. To set the time frame of the report, specify a reporting period.

It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
7. Click Finish.

MDisk Groups - VDisk Workload Activity report

Use this report to monitor the performance of virtual disks (VDisks) in managed disk (MDisk) groups. The workload activity of each MDisk group is determined by calculating the average and the maximum peak utilization of the VDisks in the MDisk group.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Reporting period

The name of the storage virtualizer, the date filter such as `Last 7 days`, and the reporting period are displayed in the report.

Retention of report data

If you remove an MDisk group or a VDisk, the daily data that is collected for reports is retained for a configurable period. The default is 90 days. If you run a report after the data retention period expired, the daily data for the MDisk group or the VDisk is unavailable.

VDisk migration

If a VDisk is migrated to another MDisk group during a reporting period, daily VDisk reports are produced only for the target MDisk group. For the target MDisk group, VDisk reports are produced from the day that the VDisk is migrated from the source MDisk group until the last day of the reporting period.

Charts

The maximum length of an MDisk group, VDisk, or storage resource group name in charts is 25 characters. Names that are longer than 25 characters are truncated. To indicate that a name is truncated, an ellipsis (...) is appended to the name. For example, if the name of an MDisk group is `myverylongmanageddiskgroupname123` in a chart, it is truncated and displayed as `myverylongmanageddiskgroupname...`

Two charts are shown:

Most Active MDisk Groups chart

For each MDisk group two bars are shown:

- A yellow bar that shows average VDisk utilization
- A red bar that shows maximum VDisk utilization

To calculate average VDisk utilization, the following formula is used:

`average(vdisk_peak_utilization)`

To calculate maximum VDisk utilization, the following formula is used:

`maximum(vdisk_peak_utilization)`

In this sample excerpt of report output for VDisk1, the values that are required to calculate average and maximum VDisk utilization are provided.

VDisk Report Date	VDisk Peak Utilization (%)
Dec 6 2011	86.30
Dec 7 2011	50.01
Dec 8 2011	79.41

To calculate the average value of a VDisk:

1. The values for VDisk1 in the VDisk Utilization (%) column are added:

$$86.30 + 50.01 + 79.41 = 215.72$$

2. The total is divided by the number of days that are specified in the date range. For example, if the reporting period spans 3 days, the total is divided by 3.

$$215.72 \div 3 = 71.91$$

In the sample, the average peak VDisk utilization is 71.91.

For each MDisk group, the maximum VDisk utilization is also shown in the chart. The maximum VDisk utilization is the highest value for a VDisk in the `VDisk Utilization (%)` column. In the sample, the highest value for VDisk1 is 86.30.

Least Active MDisk Groups chart

For each MDisk group two bars are shown:

- A yellow bar that shows average VDisk utilization
- A red bar that shows maximum VDisk utilization

The same formulas that are used in the most active MDisk group chart are also used in the least active MDisk group chart.

The number of MDisk groups in the storage virtualizer determines how many MDisk groups are shown in each chart, as shown in the following table.

Number of MDisk groups in the storage virtualizer	Number of MDisk groups in the Most Active MDisk Groups chart	Number of MDisk groups in the Least Active MDisk Groups chart
≥ 10	5	5
9	5	4
8	4	4
7	4	3
6	3	3
5	3	2
4	2	2
3	2	1
2	1	1
1	1	0

Tip: Click the bar that represents an MDisk group in a chart to open the MDisk Group - VDisk Workload Activity Details Report. Alternatively, click the name of the MDisk group in the report. Click the name of the VDisk in the report to open the VDisk Details Report.

Threshold values

The names of the threshold values that are used in the report to monitor workload activity for VDIs are as follows:

- VDisk Max Read Response Time Threshold
- VDisk Max Write Response Time Threshold
- Max Read Cache Hits Time Threshold
- Max Read I/O Rate Threshold
- Max Write I/O Rate Threshold

Threshold values are set during installation. If a threshold value is changed during a reporting period, the original value and the new threshold value are displayed as minimum and maximum values. If, for example, the VDisk maximum read response time threshold value is changed during a reporting period from 70% to 80%, the name of the column is changed to VDisk Max Read Response Time Threshold of {70 - 80%} Exceeded By (hr.:min.). The convention that is used to represent a threshold value is a number followed by the percent sign and enclosed in brackets: {%}. When the report is run, the variable value is replaced with the threshold value. To calculate whether read or write response time thresholds are exceeded, the following formula is used: $(\text{maximum_response_time_value} \times \text{maximum_response_time_threshold_value}) / 100$. The result is converted from seconds to hours and minutes, and displayed in the report. Read and write response times are sampled at 5-minute intervals over a 24-hour period.

Report output

For each VDisk in an MDisk group, the following information is provided:

MDisk Group

The name of the MDisk group.

VDisk

The name of the VDisk.

VDisk Report Date

The date that the data was collected for the report.

VDisk Capacity (GB)

The total storage capacity of the VDisk in GB.

VDisk Thin Provisioning Capacity Status

The warning level threshold is set in the thin provisioning profile for the VDisk. The threshold is exceeded when the capacity of the VDisk that is used exceeds or is equal to the warning level threshold. If the used capacity of the VDisk in GB is ≥ the specified warning threshold value, a status value of `Warning` is displayed. If the used capacity of the VDisk in GB is < the specified warning threshold value, a status value of `OK` is displayed. If thin provisioning is not used, a status value of `Not Applicable` is displayed.

VDisk Peak Utilization (%)

The highest value of VDisk utilization over a 24-hour period.

VDisk Read I/O Rate (ops/s)

The read I/O rate of the VDisk in operations per second.

VDisk Max Read I/O Rate (ops/s)

The maximum read I/O rate of the VDisk in operations per second.

VDisk Average Read Response Time (ms/op)

The average read response time in milliseconds per operation.

VDisk Max Read Response Time (ms/op)

The maximum read response time in milliseconds per operation.

VDisk Max Read Response Time Threshold of {%} Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read response time threshold for the VDisk is exceeded over a 24 hour period.

VDisk Write I/O Rate (ops/s)

The write I/O rate in operations per second.

VDisk Average Write Response Time (ms/op)

The average write response time in milliseconds per operation.

VDisk Max Write Response Time (ms/op)

The maximum write response time in milliseconds per operation.

VDisk Max Write Response Time Threshold of { } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write response time threshold for the VDisk is exceeded over a 24 hour period.

VDisk Max Read Density Rate (ops/s per GB)

The maximum read density rate in operations per second per GB. This value is calculated by dividing the maximum read I/O rate in operations per second by the number of GB that the VDisk was allocated.

VDisk I/O Rate Share of Total VDisk Read I/O Rate (%)

The maximum read I/O rate of the VDisk as a percentage of the total maximum read I/O rate of all the VDIs in the MDisk group.

VDisk Capacity Share of Total VDisk Capacity (%)

The real capacity of the VDisk as a percentage of the real capacity of all the VDIs in the MDisk group.

VDisk Average Read Cache Hits (%)

The average read cache hits in percent.

VDisk Max Read Cache Hits (%)

The maximum read cache hits in percent.

VDisk Max Read Cache Hits Time Threshold of { } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read cache hits time threshold is exceeded over a 24 hour period.

VDisk Max Read I/O Rate Threshold of { } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read I/O rate threshold is exceeded over a 24 hour period.

VDisk Max Write I/O Rate Threshold of { } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write I/O rate threshold is exceeded over a 24 hour period.

VDisk Max Write Cache Delay I/O Rate (ops/s)

The maximum write cache delay I/O rate of the VDisk in operations per second.

Storage Resource Group - VDisk Workload Activity report

Shows the workload activity of virtual disks (VDisks) in storage resource groups. The workload activity is determined by calculating the average and maximum peak utilization of the VDisks in the group.

In the IBM Spectrum® Control GUI, storage resource groups are available as general groups.
Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Reporting period

The name of the storage virtualizer, the date filter such as `Last 7 days`, and the reporting period are shown in the report.

Retention of report data

If you remove an MDisk group or a VDisk, the daily data that is collected for reports is retained for a configurable period. The default is 90 days. If you run a report after the data retention period expired, the daily data for the MDisk group or the VDisk is unavailable.

VDisk migration

If a VDisk is migrated to another MDisk group during a reporting period, daily VDisk reports are produced only for the target MDisk group. For the target MDisk group, VDisk reports are produced from the day that the VDisk is migrated from the source MDisk group until the last day of the reporting period.

Charts

The maximum length of an MDisk group, VDisk, or storage resource group name in charts is 25 characters. Names that are longer than 25 characters are truncated. To indicate that a name is truncated, an ellipsis (...) is appended to the name. For example, if the name of an MDisk group is `myverylongmanageddiskgroupname123` in a chart, it is truncated and displayed as `myverylongmanageddiskgroupname...`

Two charts are shown:

Most Active Storage Resource Groups chart

For each storage resource group, two bars are shown:

- A yellow bar that shows average VDisk utilization
- A red bar that shows maximum VDisk utilization

To calculate average VDisk utilization, the following formula is used:

`average(vdisk_peak_utilization)`

To calculate maximum VDisk utilization, the following formula is used:

`maximum(vdisk_peak_utilization)`

In this sample excerpt of report output for VDisk1, the values that are required to calculate average and maximum VDisk utilization are provided.

VDisk Report Date	VDisk Peak Utilization (%)
Dec 6 2011	86.30
Dec 7 2011	50.01
Dec 8 2011	79.41

To calculate the average value of a VDisk:

1. The values for VDisk1 in the VDisk Utilization (%) column are added:

$$86.30 + 50.01 + 79.41 = 215.72$$

2. The total is divided by the number of days that are specified in the date range. For example, if the reporting period spans 3 days, the total is divided by 3.

$$215.72 \div 3 = 71.91$$

In the sample, the average peak VDisk utilization is 71.91.

In this sample excerpt of report output for VDisk1, the values that are required to calculate average and maximum VDisk utilization are provided.

Threshold values

The names of the threshold values that are used in the report to monitor workload activity for VDIs are as follows:

- VDisk Max Read Response Time Threshold
- VDisk Max Write Response Time Threshold
- Max Read Cache Hits Time Threshold
- Max Read I/O Rate Threshold
- Max Write I/O Rate Threshold

Threshold values are set during installation. If a threshold value is changed during a reporting period, the original value and the new threshold value are displayed as minimum and maximum values. If, for example, the VDisk maximum read response time threshold value is changed during a reporting period from 70% to 80%, the name of the column is changed to VDisk Max Read Response Time Threshold of {70 - 80%} Exceeded By (hr.:min.). The convention that is used to represent a threshold value is a number followed by the percent sign and enclosed in brackets: {%}. When the report is run, the variable value is replaced with the threshold value. To calculate whether read or write response time thresholds are exceeded, the following formula is used: $(\text{maximum_response_time_value} \times \text{maximum_response_time_threshold value})/100$. The result is converted from seconds to hours and minutes, and displayed in the report. Read and write response times are sampled at 5-minute intervals over a 24-hour period.

Report output

For each storage resource group in a storage virtualizer, the following information is provided about VDIs:

Storage Resource Group

The name of the storage resource group.

MDisk Group

The name of the MDisk group.

VDisk

The name of the VDisk.

VDisk Report Date

The date that the data was collected for the report.

VDisk Capacity (GB)

The total storage capacity of the VDisk in GB.

VDisk Thin Provisioning Capacity Status

The warning level threshold is set in the thin provisioning profile for the VDisk. The threshold is exceeded when the capacity of the VDisk that is used exceeds or is equal to the warning level threshold. If the used capacity of the VDisk in GB is \geq the specified warning threshold value, a status value of `Warning` is displayed. If the used capacity of the VDisk in GB is $<$ the specified warning threshold value, a status value of `OK` is displayed. If thin provisioning is not used, a status value of `Not Applicable` is displayed.

VDisk Peak Utilization (%)

The highest value of VDisk utilization over a 24-hour period.

VDisk Read I/O Rate (ops/s)

The read I/O rate of the VDisk in operations per second.

VDisk Max Read I/O Rate (ops/s)

The maximum read I/O rate of the VDisk in operations per second.

VDisk Average Read Response Time (ms/op)

The average read response time in milliseconds per operation.

VDisk Max Read Response Time (ms/op)

The maximum read response time in milliseconds per operation.

VDisk Max Read Response Time Threshold of { % } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read response time threshold for the VDisk is exceeded over a 24 hour period.

VDisk Write I/O Rate (ops/s)

The write I/O rate in operations per second.

VDisk Average Write Response Time (ms/op)

The average write response time in milliseconds per operation.

VDisk Max Write Response Time (ms/op)

The maximum write response time in milliseconds per operation.

VDisk Max Write Response Time Threshold of { % } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write response time threshold for the VDisk is exceeded over a 24 hour period.

VDisk Max Read Density Rate (ops/s per GB)

The maximum read density rate in operations per second per GB. This value is calculated by dividing the maximum read I/O rate in operations per second by the number of GB that the VDisk was allocated.

VDisk I/O Rate Share of Total VDisk Read I/O Rate (%)

The maximum read I/O rate of the VDisk as a percentage of the total maximum read I/O rate of all the VDIs in the MDisk group.

VDisk Capacity Share of Total VDisk Capacity (%)

The real capacity of the VDisk as a percentage of the real capacity of all the VDIs in the MDisk group.

VDisk Average Read Cache Hits (%)

The average read cache hits in percent.

VDisk Max Read Cache Hits (%)

The maximum read cache hits in percent.

VDisk Max Read Cache Hits Time Threshold of { % } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read cache hits time threshold is exceeded over a 24 hour period.

VDisk Max Read I/O Rate Threshold of { % } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read I/O rate threshold is exceeded over a 24 hour period.

VDisk Max Write I/O Rate Threshold of { % } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write I/O rate threshold is exceeded over a 24 hour period.

VDisk Max Write Cache Delay I/O Rate (ops/s)

The maximum write cache delay I/O rate of the VDisk in operations per second.

MDisk Group - VDisk Workload Activity Details report

Shows the workload activity of virtual disks (VDisks) in a managed disk (MDisk) group. The workload activity is determined by calculating the average and maximum peak utilization of each VDisk.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Reporting period

The name of the storage virtualizer, the name of the MDisk group, the date filter such as `Last 7 days`, and the reporting period are displayed on the report.

Retention of report data

If you remove an MDisk group or a VDisk, the daily data that is collected for reports is retained for a configurable period. The default is 90 days. If you run a report after the data retention period expired, the daily data for the MDisk group or the VDisk is unavailable.

VDisk migration

If a VDisk is migrated to another MDisk group during a reporting period, daily VDisk reports are produced only for the target MDisk group. For the target MDisk group, VDisk reports are produced from the day that the VDisk is migrated from the source MDisk group until the last day of the reporting period.

Charts

The maximum length of an MDisk group, VDisk, or storage resource group name in charts is 25 characters. Names that are longer than 25 characters are truncated. To indicate that a name is truncated, an ellipsis (...) is appended to the name. For example, if the name of an MDisk group is `myverylongmanageddiskgroupname123` in a chart, it is truncated and displayed as `myverylongmanageddiskgroupname...`

Two charts are shown:

Most Active VDisks chart

For each MDisk group, two bars are shown:

- A yellow bar that shows average VDisk utilization
- A red bar that shows maximum VDisk utilization

To calculate average VDisk utilization, the following formula is used:

average (vdisk_peak_utilization)

To calculate maximum VDisk utilization, the following formula is used:

maximum (vdisk_peak_utilization)

In this sample excerpt of report output for VDisk1, the values that are required to calculate average and maximum VDisk utilization are provided.

VDisk Report Date	VDisk Peak Utilization (%)
Dec 6 2011	86.30
Dec 7 2011	50.01
Dec 8 2011	79.41

To calculate the average value of a VDisk:

1. The values for VDisk1 in the VDisk Utilization (%) column are added:

$$86.30 + 50.01 + 79.41 = 215.72$$

2. The total is divided by the number of days that are specified in the date range. For example, if the reporting period spans 3 days, the total is divided by 3.

$$215.72 \div 3 = 71.91$$

In the sample, the average peak VDisk utilization is 71.91.

In this sample excerpt of report output for VDisk1, the values that are required to calculate average and maximum VDisk utilization are provided.

VDisk Report Date	VDisk Peak Utilization (%)
Dec 6 2011	86.30
Dec 7 2011	50.01
Dec 8 2011	79.41

Least Active VDisks chart

For each MDisk group, two bars are shown:

- A yellow bar that shows average VDisk utilization

- A red bar that shows maximum VDisk utilization

The same formulas that are used in the most active MDisk group chart are also used in the least active MDisk group chart.

The number of VDIs in an MDisk group determines how many VDIs are shown in each chart, as shown in the following table.

Number of VDIs in the MDisk group	Number of VDIs in the Most Active VDIs chart	Number of VDIs in the Least Active VDIs chart
≥ 10	5	5
9	5	4
8	4	4
7	4	3
6	3	3
5	3	2
4	2	2
3	2	1
2	1	1
1	1	0

Tip: Click the bar that represents a VDisk in a chart to open the VDisk Details Report. Alternatively, click the name of the VDisk in the report. Click the name of the MDisk group in the report to open the MDisk Group Details Report.

Threshold values

The names of the threshold values that are used in the report to monitor workload activity for VDIs are as follows:

- VDisk Max Read Response Time Threshold
- VDisk Max Write Response Time Threshold
- Max Read Cache Hits Time Threshold
- Max Read I/O Rate Threshold
- Max Write I/O Rate Threshold

Threshold values are set during installation. If a threshold value is changed during a reporting period, the original value and the new threshold value are displayed as minimum and maximum values. If, for example, the VDisk maximum read response time threshold value is changed during a reporting period from 70% to 80%, the name of the column is changed to VDisk Max Read Response Time Threshold of {70 - 80%} Exceeded By (hr.:min.). The convention that is used to represent a threshold value is a number followed by the percent sign and enclosed in brackets: {%}. When the report is run, the variable value is replaced with the threshold value. To calculate whether read or write response time thresholds are exceeded, the following formula is used: $(\text{maximum_response_time_value} \times \text{maximum_response_time_threshold_value}) / 100$. The result is converted from seconds to hours and minutes, and displayed in the report. Read and write response times are sampled at 5-minute intervals over a 24-hour period.

Report output

For each VDisk in an MDisk group, the following information is provided:

MDisk Group

The name of the MDisk group.

VDisk

The name of the VDisk.

VDisk Report Date

The date that the data was collected for the report.

VDisk Capacity (GB)

The total storage capacity of the VDisk in GB.

VDisk Thin Provisioning Capacity Status

The warning level threshold is set in the thin provisioning profile for the VDisk. The threshold is exceeded when the capacity of the VDisk that is used exceeds or is equal to the warning level threshold. If the used capacity of the VDisk in GB is ≥ the specified warning threshold value, a status value of `Warning` is displayed. If the used capacity of the VDisk in GB is < the specified warning threshold value, a status value of `OK` is displayed. If thin provisioning is not used, a status value of `Not Applicable` is displayed.

VDisk Peak Utilization (%)

The highest value of VDisk utilization over a 24-hour period.

VDisk Read I/O Rate (ops/s)

The read I/O rate of the VDisk in operations per second.

VDisk Max Read I/O Rate (ops/s)

The maximum read I/O rate of the VDisk in operations per second.

VDisk Average Read Response Time (ms/op)

The average read response time in milliseconds per operation.

VDisk Max Read Response Time (ms/op)

The maximum read response time in milliseconds per operation.

VDisk Max Read Response Time Threshold of {%} Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read response time threshold for the VDisk is exceeded over a 24 hour period.

VDisk Write I/O Rate (ops/s)

The write I/O rate in operations per second.

VDisk Average Write Response Time (ms/op)

The average write response time in milliseconds per operation.

VDisk Max Write Response Time (ms/op)

The maximum write response time in milliseconds per operation.

VDisk Max Write Response Time Threshold of { } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write response time threshold for the VDisk is exceeded over a 24 hour period.

VDisk Max Read Density Rate (ops/s per GB)

The maximum read density rate in operations per second per GB. This value is calculated by dividing the maximum read I/O rate in operations per second by the number of GB that the VDisk was allocated.

VDisk I/O Rate Share of Total VDisk Read I/O Rate (%)

The maximum read I/O rate of the VDisk as a percentage of the total maximum read I/O rate of all the VDIs in the MDisk group.

VDisk Capacity Share of Total VDisk Capacity (%)

The real capacity of the VDisk as a percentage of the real capacity of all the VDIs in the MDisk group.

VDisk Average Read Cache Hits (%)

The average read cache hits in percent.

VDisk Max Read Cache Hits (%)

The maximum read cache hits in percent.

VDisk Max Read Cache Hits Time Threshold of { } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read cache hits time threshold is exceeded over a 24 hour period.

VDisk Max Read I/O Rate Threshold of { } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read I/O rate threshold is exceeded over a 24 hour period.

VDisk Max Write I/O Rate Threshold of { } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write I/O rate threshold is exceeded over a 24 hour period.

VDisk Max Write Cache Delay I/O Rate (ops/s)

The maximum write cache delay I/O rate of the VDisk in operations per second.

Related tasks

- [Running the MDisk Group - VDisk Workload Activity Details report](#)

Running the MDisk Group Details report

To see statistics about the performance of a managed disk (MDisk) group, run the MDisk Group Details report.

Procedure

1. In the Welcome portal, click Team Content > IBM Spectrum Control Packages.
2. Click Storage Tiering.
3. Click MDisk Group Details.
4. Select a storage virtualizer, and then select an MDisk group.
5. To set the time frame of the report, specify a reporting period.
It is easier to analyze small amounts of information over shorter periods.
Tip: To specify a start date and an end date, select Custom date range from the list of reporting periods.
6. Click Finish.

Related reference

- [MDisk Group Details report](#)

MDisk Group Details report

Shows the workload activity of a managed disk (MDisk) group. Use the report to analyze storage services for an MDisk group.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Reporting period

The name of the storage virtualizer, the name of the MDisk group, the date filter such as Last 7 days, and the reporting period are displayed in the report.

Retention of report data

If you remove an MDisk group or a VDisk, the daily data that is collected for reports is retained for a configurable period. The default is 90 days. If you run a report after the data retention period expired, the daily data for the MDisk group or the VDisk is unavailable.

Read I/O rate capability

If you do not set the back-end pool properties of an MDisk group:

- `Not Set` is displayed in the MDisk Group Read I/O Rate Capability column
- `Not Available` is displayed in the MDisk Group Read I/O Rate Availability column

If the read I/O rate capability of an MDisk group is less than the maximum read I/O rate of the MDisk group, negative values are displayed in the report.

Threshold values

The names of the threshold values in the report that are used to monitor workload activity for MDisk groups are:

- Actual Size Threshold
- Read I/O Rate Threshold
- Max Read Response Time Threshold
- Max Write Response Time Threshold

Threshold values are set during installation. If a threshold value is changed during a reporting period, the original value and the new threshold value are displayed as minimum and maximum values. If, for example, the value of the actual size threshold is changed during a reporting period from 50% to 60%, the name of the column is changed to MDisk Group Available Size < Actual Size Threshold of {50 - 60%}. The convention that is used to represent a threshold value is a number followed by the percent sign and enclosed in brackets: {%. When the report is run, the variable value is replaced with the threshold value. To calculate whether read or write response time thresholds are exceeded, the following formula is used:

$$(\text{maximum_response_time_value} \times \text{maximum_response_time_threshold_value}) \div 100.$$

Tip: To monitor the workload activity of all MDisk groups in a storage virtualizer, run the MDisk Groups - Workload Activity report.

Report output

The following information is provided about the MDisk group:

MDisk Group

The name of the MDisk group.

MDisk Group Report Date

The date that the data was collected for the report.

MDisk Group Capacity Status

If the storage capacity that is allocated is less than the actual storage capacity, a status value of `OK` is displayed. If the storage capacity that is allocated is more than the actual storage capacity, a status value of `Warning` is displayed. The actual capacity of the MDisk group is calculated as follows:

$$(\text{mdisk_group_real_capacity_value} \div \text{mdisk_group_capacity_value}) \times 100$$

MDisk Group Capacity (GB)

The total storage capacity in GB of all of the disks in the MDisk group.

MDisk Group Real Capacity (GB)

The total amount in GB of real storage capacity in the MDisk group.

MDisk Group Free Space (GB)

The total amount of remaining capacity in GB that can be allocated to increase the size of an existing VDisk, or allocated to an additional VDisk.

MDisk Group Available Size < Actual Size Threshold of {%

If the amount of storage space that is available for allocation to VDIs is less than the actual size threshold, `Yes` is displayed in the column. If the amount of storage space that is available for allocation to VDIs is more than the actual size threshold, `No` is displayed in the column.

MDisk Group Read I/O Rate (ops/s)

The read I/O rate of the MDisk group in operations per second.

MDisk Group Read I/O Rate Capability (ops/s)

The read I/O capability rate of the MDisk group in operations per second.

Tip: To find out how the read I/O capability rate is calculated, see [Read I/O capability formula](#)

MDisk Group Max Read I/O Rate (ops/s)

The maximum read I/O rate of the MDisk group in operations per second.

MDisk Group Read I/O Rate Availability (ops/s)

The difference between the read I/O capability rate and the maximum read I/O rate in operations per second.

MDisk Group Read I/O Rate Availability < Read I/O Rate Capability Threshold of {%

The availability rate for read I/O operations is compared with the read I/O rate capability threshold. If the availability rate for read I/O operations is less than the read I/O rate capability threshold, `Yes` is displayed in the column. If the availability rate for read I/O operations is more than the read I/O rate capability threshold, `No` is displayed in the column.

MDisk Group Max Read Response Time (ms/op)

The maximum read response time in milliseconds per operation.

MDisk Group Max Read Response Time Threshold of {%} Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read response time threshold is exceeded over a 24 hour period.

MDisk Group Average Read Response Time (ms/op)

The average read response time in milliseconds per operation.

- MDisk Group Max Write I/O Rate (ops/s)
The maximum write I/O rate in operations per second.
- MDisk Group Max Write Response Time (ms/op)
The maximum write response time in milliseconds per operation.
- MDisk Group Max Write Response Time Threshold of { % } Exceeded By (hr.:min.)
The number of hours and minutes that the maximum write response time threshold is exceeded over a 24 hour period.
- MDisk Group Average Write Response Time (ms/op)
The average write response time in milliseconds per operation.
- MDisk Group Average Write I/O Size (KB)
The average size of write I/O operations in KB.

- [Read I/O capability formula](#)

MDisk Groups - Workload Activity report

Shows the workload activity of managed disk (MDisk) groups. You can use the information that the report provides to investigate which MDisk groups are being underused or overused.

Restriction: This report applies only to SAN Volume Controller and Storwize® systems.

Reporting periods

The name of the storage virtualizer, the date filter such as `Last 7 days`, and the reporting period are displayed in the report.

Retention of report data

If you remove an MDisk group or a VDisk, the daily data that is collected for reports is retained for a configurable period. The default is 90 days. If you run a report after the data retention period expired, the daily data for the MDisk group or the VDisk is unavailable.

Read I/O rate capability

To estimate the read I/O rate capability of an MDisk group, you must set the back-end pool properties of MDisk groups.

If you do not set the back-end pool properties of an MDisk group:

- `Not Set` is displayed in the MDisk Group Read I/O Rate Capability column
- `Not Available` is displayed in the MDisk Group Read I/O Rate Availability column

If the read I/O rate capability of an MDisk group is less than the maximum read I/O rate of the MDisk group, negative values are displayed in the report.

Charts

The maximum length of an MDisk group, VDisk, or storage resource group name in charts is 25 characters. Names that are longer than 25 characters are truncated. To indicate that a name is truncated, an ellipsis (...) is appended to the name. For example, if the name of an MDisk group is `myverylongmanageddiskgroupname123` in a chart, it is truncated and displayed as `myverylongmanageddiskgroupname...`

Two charts are displayed:

- Most Active MDisk Groups
- Most Available MDisk Groups

Most Active MDisk Groups

For each MDisk group two bars are used:

- A yellow bar that shows the average activity value
- A red bar that shows the maximum activity value

To calculate the average activity value of an MDisk group, the following formula is used:

average(maximum_read_I/O_rate ÷ read_I/O_rate_capability)

To calculate the maximum activity value, the following formula is used:

maximum(maximum_read_I/O_rate ÷ read_I/O_rate_capability)

In this sample excerpt of report output for mdiskgroup1, the values that are required to calculate average and maximum activity values are provided.

MDisk Group Report Date	MDisk Group Read I/O Rate Capability (ops/s)	MDisk Group Max Read I/O Rate (ops/s)
Dec 6 2011	331	216.77
Dec 7 2011	331	256.40
Dec 8 2011	331	270.87

The average activity value of an MDisk group is calculated as follows:

1. For each report in the MDisk group, the value in the MDisk Group Max Read I/O Rate column is divided by the value in the MDisk Group Read I/O Rate Capability column:

$$\begin{aligned} 216.77 \div 331 &= 0.65 \\ 256.40 \div 331 &= 0.77 \\ 270.87 \div 331 &= 0.81 \end{aligned}$$

2. The result of the operation for each report is added:

$$0.65 + 0.77 + 0.81 = 2.23$$

3. To get the average value, the total is divided by the number of days that are specified in the date range. For example, if the reporting period spans 3 days, the total is divided by 3.

$$2.23 \div 3 = 0.74$$

The maximum value of an MDisk group is calculated as follows. For each report in an MDisk group, the value in the MDisk Group Max Read I/O Rate column is divided by the value in the MDisk Group Read I/O Rate Capability column:

$$\begin{aligned} 216.77 \div 331 &= 0.65 \\ 256.40 \div 331 &= 0.77 \\ 270.87 \div 331 &= 0.81 \end{aligned}$$

In this sample, the maximum value is 0.81.

Most Available MDisk Groups

For each MDisk group two bars are used:

- A blue bar to represent minimum values
- A red bar to represent average values

In this sample excerpt of report output for mdiskgroup2, the values that are required to calculate minimum and average availability values for MDisk Groups are provided.

MDisk Group Report Date	MDisk Group Read I/O Rate Availability (ops/s)
Dec 6 2011	435.41
Dec 7 2011	560.92
Dec 8 2011	480.95

The minimum value of an MDisk group is calculated as follows:

- For all of the reports for an MDisk group, the lowest value in the MDisk Group Read I/O Rate Availability column is used. In this sample, the lowest value for mdiskgroup2 is 435.41.

The average value of an MDisk group is calculated as follows:

1. For each report in an MDisk group, the values in the MDisk Group Read I/O Rate Availability column are added:

$$435.41 + 560.92 + 480.95 = 1477.28$$

2. To get the average value, the total is divided by the number of days that are specified in the date range. (For example, if the reporting period spans 3 days, the total is divided by 3.)

$$1477.28 \div 3 = 492.42$$

In this sample, the average value is 492.42.

The number of MDisk groups in a storage virtualizer determines how many MDisk groups are displayed in each chart, as shown in the following table.

Number of MDisk groups in the storage virtualizer	Number of MDisk groups in the Most Active MDisk Groups chart	Number of MDisk groups in the Least Active MDisk Groups chart
≥ 10	5	5
9	5	4
8	4	4
7	4	3
6	3	3

Number of MDisk groups in the storage virtualizer	Number of MDisk groups in the Most Active MDisk Groups chart	Number of MDisk groups in the Least Active MDisk Groups chart
5	3	2
4	2	2
3	2	1
2	1	1
1	1	0

Tip: Click the bar that represents an MDisk group in a chart to open the MDisk Group - VDisk Workload Activity Details Report. Alternatively, you can click the name of the MDisk group in the report.

Threshold values

The names of the threshold values in the report that are used to monitor workload activity for MDisk groups are:

- Actual Size Threshold
- Read I/O Rate Threshold
- Max Read Response Time Threshold
- Max Write Response Time Threshold

Threshold values are set during installation. If a threshold value is changed during a reporting period, the original value and the new threshold value are displayed as minimum and maximum values. If, for example, the value of the actual size threshold is changed during a reporting period from 50% to 60%, the name of the column is changed to MDisk Group Available Size < Actual Size Threshold of {50 - 60%}. The convention that is used to represent a threshold value is a number followed by the percent sign and enclosed in brackets: {%}. When the report is run, the variable value is replaced with the threshold value. To calculate whether read or write response time thresholds are exceeded, the following formula is used:

$$(\text{maximum_response_time_value} \times \text{maximum_response_time_threshold_value}) \div 100.$$

The result is converted from seconds to hours and minutes, and displayed in the report. Read and write response times are sampled at 5-minute intervals over a 24-hour period.

Report output

For each MDisk group, the following information is provided:

MDisk Group

The name of the MDisk group.

MDisk Group Report Date

The date that the data was collected for the report.

MDisk Group Capacity Status

If the storage capacity that is allocated is less than the actual storage capacity, a status value of **OK** is displayed. If the storage capacity that is allocated is more than the actual storage capacity, a status value of **Warning** is displayed. The actual capacity of the MDisk group is calculated as follows:

$$(\text{mdisk_group_real_capacity_value} \div \text{mdisk_group_capacity_value}) \times 100$$

MDisk Group Capacity (GB)

The total storage capacity in GB of all of the disks in the MDisk group.

MDisk Group Real Capacity (GB)

The total amount in GB of real storage capacity in the MDisk group.

MDisk Group Free Space (GB)

The total amount of remaining capacity in GB that can be allocated to increase the size of an existing VDisk, or allocated to an additional VDisk.

MDisk Group Available Size < Actual Size Threshold of {%}

If the amount of storage space that is available for allocation to VDIs is less than the actual size threshold, **Yes** is displayed in the column. If the amount of storage space that is available for allocation to VDIs is more than the actual size threshold, **No** is displayed in the column.

MDisk Group Read I/O Rate (ops/s)

The read I/O rate of the MDisk group in operations per second.

MDisk Group Read I/O Rate Capability (ops/s)

The read I/O capability rate of the MDisk group in operations per second.

Tip: To find out how the read I/O capability rate is calculated, see [Read I/O capability formula](#)

MDisk Group Max Read I/O Rate (ops/s)

The maximum read I/O rate of the MDisk group in operations per second.

MDisk Group Read I/O Rate Availability (ops/s)

The difference between the read I/O capability rate and the maximum read I/O rate in operations per second.

MDisk Group Read I/O Rate Availability < Read I/O Rate Capability Threshold of {%}

The availability rate for read I/O operations is compared with the read I/O rate capability threshold. If the availability rate for read I/O operations is less than the read I/O rate capability threshold, **Yes** is displayed in the column. If the availability rate for read I/O operations is more than the read I/O rate capability threshold, **No** is displayed in the column.

MDisk Group Max Read Response Time (ms/op)

The maximum read response time in milliseconds per operation.

MDisk Group Max Read Response Time Threshold of {%} Exceeded By (hr.:min.)

The number of hours and minutes that the maximum read response time threshold is exceeded over a 24 hour period.

MDisk Group Average Read Response Time (ms/op)

The average read response time in milliseconds per operation.

MDisk Group Max Write I/O Rate (ops/s)

The maximum write I/O rate in operations per second.

MDisk Group Max Write Response Time (ms/op)

The maximum write response time in milliseconds per operation.

MDisk Group Max Write Response Time Threshold of { } Exceeded By (hr.:min.)

The number of hours and minutes that the maximum write response time threshold is exceeded over a 24 hour period.

MDisk Group Average Write Response Time (ms/op)

The average write response time in milliseconds per operation.

MDisk Group Average Write I/O Size (KB)

The average size of write I/O operations in KB.

Related tasks

- [Running the MDisk Groups - Workload Activity report](#)

Read I/O capability formula

The read I/O capability formula is used by IBM Spectrum® Control to estimate the workload capacity of managed disk (MDisk) groups.

The estimated workload capacity is compared with the actual workload capacity to assess the most active and least active MDisk groups in a storage subsystem. To monitor the workload activity of MDisk groups, you can run customized reports such as the MDisk Groups - Workload Activity Report. This formula is used for MDisk groups in the following storage systems:

- SAN Volume Controller
- Storwize® V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified

The formula that is used by IBM Spectrum Control to estimate the read I/O capability rate is:

$$[\text{Estimated Read I/O Workload} * \text{Type of Disk I/O Capability} * \text{Number of Disks}] / [\text{Estimated Read I/O Workload} * (1 - \text{Cache Hit Ratio}) + \text{Estimated Write I/O Workload} * \text{RAID Type Weighted I/O Ratio}]$$

There are two types of value that are used by the formula:

- Fixed values provided by IBM Spectrum Control
- Variable values that you must specify for each MDisk group

The following fixed values are used by the formula:

Estimated Read I/O Workload

The estimated read I/O workload of an MDisk group. The estimate is set to a fixed value of 0.7 (70%).

Estimated Write I/O Workload

The estimated write I/O workload of an MDisk group. The estimate is set to a fixed value of 0.3 (30%).

You specify the following variable values for each MDisk group:

Type of Disk I/O Capability

When you specify the type of disk that the back-end pool uses:

- You can accept the default I/O capability per second of the disk
- You can enter a new value for the I/O capability per second of the disk

For example, the default value for the I/O capability rate per second of fiber types of disk with 15,000 revolutions per minute (rpm) is 150 I/O operations per second. To change the I/O capability for a type of disk, you issue the **setbackenddisktype** command and you enter a new value for the -iops parameter.

Number of Disks

You specify the number of physical disks that the back-end pool uses.

Cache Hit Ratio

When you specify the type of storage system that the back-end pool uses:

- You can accept the default cache hit ratio for the storage system
- You can enter a new value for the cache hit ratio of the storage system

For example, the default cache hit ratio of the XIV® is 0.7 (70%). To change the cache hit ratio for a type of storage system, you issue the **setbackendtype** command and you enter a new value for the -cachehit parameter.

RAID Type Weighted I/O Ratio

When you specify the type of RAID that the back-end pool uses:

- You can accept the default value for the weighted I/O ratio of the type of RAID
- You can enter a new value for the weighted I/O ratio of the type of RAID

For example the weighted I/O ratio for RAID5 types of RAID is 4:1. To change the weighted I/O ratio for a type of RAID, you issue the **setbackendraidtype** command and you enter a new value for the -weightedio parameter.

Tip: In the IBM Spectrum Control GUI, you can set the values for the back-end properties of an MDisk group. You can also use the IBM Spectrum Control CLI called `tpctool` to set the values for back-end MDisk groups. See the **setarray** command. To change the variable values that are used by the Read I/O capability formula, you must use the IBM Spectrum Control CLI.

Example

The following values have been set for a back-end pool. The type of storage system is the XIV. The type of disk is F15 (Fiber - 15 000 rpm), and the type of RAID is X.

Name of variable	Value
Cache Hit Ratio	0.5 (50%)
Type of Disk I/O Capability	150
RAID Type Weighted I/O Ratio	4
Number of Disks	10

Based on the values that are provided, the read I/O capability per second is:

$[0.7 * 150 * 10] / [0.7 * (1 - 0.5) + 0.3 * 4]$

The read I/O capability per second rate is 677. (The result of the calculation is rounded to the nearest whole number.)

Changing threshold values in storage tier reports

Use the **setdscfg** command to change the threshold values in workload activity reports for managed disk groups and virtual disks.

Before you begin

To change threshold values, you must know the value of the property key that is associated with the name of the threshold in the report.

Procedure

- To start the IBM Spectrum® Control CLI, issue the **tpctool** command.
- Issue the **setdscfg** command, and then set the following values by using the **-property** parameter:
 - Specify the name of the threshold with the *property_key* variable.
 - Specify the new threshold value with the *value* variable.

The following sample code sets the read I/O rate for MDisk groups to 80%:

```
tpctool setdscfg -url localhost:9550 -user ***** -pwd ***** -property  
ManagedDiskGroupAvailIORate 80
```

- Press Enter.

Results

The value of the threshold is changed.

Threshold values in storage tier reports

Threshold values are used to assess the workload activity of managed disk (MDisk) groups and virtual disks (VDisks) in storage tier reports. To change a threshold value, you must know the value of the property key that corresponds with the threshold value that is used in the report.

The following table contains the name of the threshold value and the corresponding value of the property key for the following reports:

- The MDisk Groups - Workload Activity Report
- The MDisk Group Details Report

Threshold name in report	Property key value
Actual Size Threshold	<i>ManagedDiskGroupAvailSize</i>
Read I/O Rate Threshold	<i>ManagedDiskGroupAvailIORate</i>
Max Read Response Time Threshold	<i>ManagedDiskGroupBERResponseExceeds</i>
Max Write Response Time Threshold	<i>ManagedDiskGroupBEWResponseExceeds</i>

The following table contains the name of the threshold value and the corresponding value of the property key for the following reports:

- MDisk Groups - VDisk Workload Activity Report
- MDisk Groups - VDisk Workload Activity Details Report
- VDisk Details Report
- Storage Resource Group - VDisk Workload Activity Report

Threshold name in report	Property key value
VDisk Max Read Response Time Threshold	VDiskFERResponseExceeds
VDisk Max Write Response Time Threshold	VDiskFEWResponseExceeds
Max Read Cache Hits Time Threshold	VDiskFERHitExceeds
Max Read I/O Rate Threshold	VDiskFEIORExceeds
Max Write I/O Rate Threshold	VDiskFEIOWExceeds

Custom reports about performance

You can use the optional Cognos® Analytics reporting tool to create custom performance reports. Performance reports can contain detailed information about the performance of monitored resources, and some of the properties of those resources.

The resources for which you can create performance reports are storage systems and their components, storage virtualizers and their components, and switches and switch ports. You can add statistics for volumes, back-end arrays, caches, ports, port errors, and other statistics to performance reports. For example, you can add key statistics to a report to create and generate a performance chart for a specific volume of a storage system.

Performance data is collected at intervals. An interval represents the number of minutes over which samples of performance data are averaged. Data that is collected at certain intervals is automatically consolidated, or rolled up, to higher intervals. For example, data collected at 1-minute intervals is consolidated into 5-minute data. When you create a performance report in the Cognos Analytics reporting tool, the smallest interval for the sample data is 5 minutes. The data collected at 1-minute intervals is not available in the Cognos Analytics reporting tool to avoid performance problems.

- [Creating custom performance reports](#)
You can create reports that show performance metrics in the Cognos Analytics reporting tool. Performance reports can contain detailed information about the performance of monitored resources and some of the properties of those resources. You access custom performance reports from IBM Spectrum Control, and you create the reports in the Cognos Analytics reporting tool.

You can include capacity data, properties, and other information about storage systems, storage virtualizers, and switches in performance reports.

Creating custom performance reports

You can create reports that show performance metrics in the Cognos® Analytics reporting tool. Performance reports can contain detailed information about the performance of monitored resources and some of the properties of those resources. You access custom performance reports from IBM Spectrum® Control, and you create the reports in the Cognos Analytics reporting tool.

Before you begin

When you create a performance report, include properties and metrics for only one type of device in the report.

The list that you use to create performance reports does not include information about the relationships between storage resources. If you include different types of resources in the report, the report might return incorrect results. For example, if you include storage virtualizers and storage systems in a report, the report might return incorrect results.

Tip: Before you run a report, you can preview the report with no data.

About this task

You must specify the time interval for which you want to view performance information. You can specify the time interval in the following ways:

- Select a time unit, for example, day, day of week, or week of month.
- Select performance metrics from sample data, hourly data, or daily data in the resource for which you want performance information. You can also add the time and the interval length to reports. The time is the time at which the performance data was collected. The interval length is the length of the data interval in seconds for sample data, or in minutes for hourly data or daily data.

Procedure

- Go to the URL for your Cognos Analytics server. The format of the URL is similar to this URL: `http://myhostname:9300/bi`
- Depending on the type of report that you want to see, select one of the following items:
 - To create a basic report with limited formatting about the performance of resources, complete the following steps:
 - Click New  in the Welcome portal.
 - Click Other, then click Query Studio.
 - Click IBM Spectrum Control Packages, then click the Performance package.
 - To create a report about the performance of resources and apply advanced formatting features to the report, complete the following steps:
 - In the Welcome portal, click Team Content.

- Click IBM Spectrum Control Packages.
 - Right-click Performance, then click Create report.
 - Click a template for the report.
3. Expand IBM Spectrum Control in the list of data sources.
 4. Expand Performance.
 5. Optional: Select a time unit from the Time item.
 6. Explore the folders in the list to locate the resources, properties, and metrics that you want to include in the report.
 7. Depending on your browser, add properties and metrics to the report:
 - In Internet Explorer, drag the items that you want to see information about to the work area.
 - In Firefox, select the items that you want to see information about, and then click Insert.
 8. Use filters with your performance reports to ensure that your reports do not include too much data. To use filters with your performance reports, do the following steps:
 - a. Add a resource or resource type to the report.
 - b. Select the column heading for the resource or resource type in the work area, and then filter the name of the resource or resource type if necessary.
 - c. Locate the Sample Data, Hourly Data, or Daily Data folder for the resource or resource type in the list. Add a time stamp from the list to the work area. For example, you can add a day time stamp to the report.
 - d. Select the column heading for the time stamp in the work area, and then filter the time.

If you do not enter a time stamp, the report is run on all the records for this resource or resource type in IBM Spectrum Control.
 9. Click Save.

Data for storage systems in performance reports

You can include general information, capacity data, properties, and other information about storage systems in performance reports.

Information about storage systems

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Capacity and usage data

You can create performance reports that include the following information:

Storage System Pool Capacity (GiB)

The amount of storage space in pools that are on the storage system. For an XIV® or IBM Spectrum Accelerate, this value represents the physical capacity of the pool, not the virtual capacity. For other storage systems, this value might also include overhead space if the pool is unformatted.

Storage System Used Pool Space (GiB)

The amount of space that is in use in all pools on a storage system.

Storage System Available Pool Space (GiB)

The amount of unused space in pools that are on the storage system.

Storage System Volume Capacity (GiB)

The amount of space on all volumes on the storage system.

Storage System Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Storage System Assigned Volume Space (GiB)

The amount of space in the pool that is on volumes that are assigned to a server or storage virtualizer.

Storage System Unallocated Disk Space (GiB)

The amount of disk space that can be added to a pool.

Storage System Number of Disks

The number of physical disks on the storage system. For a resource that is running IBM Spectrum Virtualize and is configured as a back-end device, the value is the number of managed disks on the resource.

Storage System Number of Volumes

The number of volumes on a resource.

Storage System Cache (GiB)

The size of the cache on the storage system. This value is not shown for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System Real Available Pool Space (GiB)

The amount of unused space in pools that have an associated soft size on an XIV or IBM Spectrum Accelerate. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage System Real Configured Pool Space (GiB)

The amount of storage space that is in pools that have an associated soft size on an XIV or IBM Spectrum Accelerate. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage System Volume Capacity for z/OS® (GiB)

The amount of space on all volumes on the storage system that the z/OS operating system can use.

Storage System Volume Capacity Assigned to MDisk (GiB)

The amount of space that is on volumes that are assigned to a storage virtualizer to use as managed disks.

Storage System Disk Capacity (GiB)

The amount of storage space on physical disks in a storage system, excluding spare disks. This value is not shown for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System Total Disk Capacity (GiB)

The amount of space on physical disks on a storage system, including spare disks.

Storage System Physical Allocation Percentage

The percentage of physical space in storage system pools that is reserved for volumes. This value is always less than or equal to 100% because you cannot reserve more physical space than is available in the pools.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{allocated pool space} \div \text{pool capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a 200 GiB storage pool. Therefore, the space that is reserved for volumes is 50 GiB.

Storage System Virtual Allocation Percentage

The percentage of physical space in storage system pools that is committed to the total virtual capacity of the volumes in the pool. In thin-provisioned environments, this percentage exceeds 100% if a pool is overcommitted (over-provisioned).

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{total volume capacity} \div \text{pool capacity}) \times 100$$

For example, for a total pool size of 15 GiB, the allocation percentage might be 200%. Therefore, the virtual capacity that is committed to the volumes in the pools is 30 GiB. This configuration means that twice as much space is committed than is physically contained in the pools. If the allocation percentage is 100% for the same pools, then the virtual capacity that is committed to the pools is 15 GiB. This configuration means that all the physical capacity of the pools is already allocated to volumes.

An allocation percentage that is higher than 100% is considered aggressive. The pools have insufficient physical capacity to satisfy the maximum allocation for all the thin-provisioned volumes in the pools. In such cases, use the Storage System Shortfall Percentage property to estimate how critical the shortage of space is for storage system pools.

Storage System Shortfall Percentage

The percentage of the remaining unallocated volume space in storage system pools that is not available to be allocated. The higher the percentage, the more critical the shortfall of pool space.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{unallocatable space} \div (\text{volume space} - \text{used volume space})) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in pools reaches a critically high level. For example, the physical space in pools might be less than the committed virtual space. In this case, the pools do not have enough space to fulfill the commitment to virtual space for a volume.

This value represents the percentage of the committed virtual space that is not available in pools. As more space is used over time by volumes while the pool capacity remains the same, this percentage increases.

For example, the physical capacity of pools is 70 GiB, but 150 GiB of virtual space is committed to thin-provisioned volumes. If the volumes are using 50 GiB, then there is still 100 GiB committed to those volumes (150 GiB - 50 GiB). There is only 20 GiB of available pool space (70 GiB - 50 GiB). Because only 20 GiB of pool space is available, 80 GiB of the committed space cannot be allocated (100 GiB - 20 GiB). In this case, the percentage of committed space that is unavailable is 80% (80 GiB ÷ 100 GiB × 100).

This value is only available for pools with thin-provisioned volumes.

Storage System MDisk Available Space (GiB)

The amount of storage space that is available on a managed disk. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System MDisk Capacity (GiB)

The amount of storage space on the managed disk.

Component properties

You can create performance reports that include the following information:

Storage System Access Information

The URL from which you can access the storage system or storage virtualizer.

Storage System Alias

An alternative name for a storage system. The user defines this name.

Storage System Code Level

The Shared Ethernet Adapter level of a DS8000® storage system. For other storage systems, this value is the firmware version.

Storage System Time Zone

The time zone in which a resource is located.

Storage System Custom Tag 1, 2, and 3

User-defined text that is associated with a storage system. You can add or edit the custom tags for a storage system in the Properties pane of the storage system.

Storage System Location

The physical location of a storage system. The location is defined when a storage system is added to IBM Spectrum Control. You can add or edit the location of the storage system in the Properties pane of the storage system.

Storage System User Provided Name

The name that was specified for the storage system in the storage environment.

Storage System Is Compression Active

Shows whether the compression feature is enabled on the storage system. If this value is **Yes**, the compression feature is enabled.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Status information

You can create performance reports that include the following information:

Storage System Status

The condition of the resource, for example normal, warning, or error.

Storage System Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Storage System Last Data Collection

The date and time when storage statistics were last collected from the resource.

Storage System Last Data Collection Status

The condition of the last data collection. The status can show if the collection was a success, a failure, or if data was collected from the resource.

Vendor, model, and device information

You can create performance reports that include the following information:

Storage System Type

The type of storage system. For example, the storage system can be an IBM System Storage DS8800 system, an IBM System Storage DS8700 system, an IBM System Storage XIV system, or another type of storage system.

Storage System Vendor

The vendor who supplied the resource.

Storage System Model

The model name or model number of the storage system.

Storage System Machine Type

The machine type of a storage system. For example, the storage system can be DS8800, DS8700, XIV - 2812, or another type of storage system.

Storage System IP Address

The IP address of the resource.

Storage System Serial Number

The serial number of the resource.

- [Performance metrics for SAN Volume Controller and Storwize systems](#)
A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for ports, port errors, volumes, caches, back-end arrays, and other data for these systems in performance reports.
- [Performance metrics for DS8000 storage systems](#)

- [Performance metrics for XIV systems and IBM Spectrum Accelerate](#)
You can include performance data for volumes, caches, and other data for XIV systems and IBM Spectrum Accelerate in performance reports.
- [Performance metrics for block server systems](#)
You can include performance metrics for volumes, and cache data for block server storage systems in performance reports.

Performance metrics for SAN Volume Controller and Storwize systems

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for ports, port errors, volumes, caches, back-end arrays, and other data for these systems in performance reports.

Port data

You can create performance reports that include the following information:

Port Send I/O Rate (ops/s)
The average number of I/O operations per second for operations in which data is sent from a port. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive I/O Rate (ops/s)
The average number of I/O operations per second for operations in which the port receives data. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port I/O Rate (ops/s)
The average number of send operations and receive operations per second.

Port to Host Send I/O Rate (ops/s)
The average number of IOs per second that are sent by the storage system to the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Port to Host Receive I/O Rate (ops/s)
The average number of IOs per second that are received by the storage system from the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Total Port to Host I/O Rate (ops/s)
The average number of IOs per second that are transmitted between the storage system and the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Port to Disk Send I/O Rate (ops/s)
The average number of IOs per second that are sent from the storage system to the back-end storage it is virtualizing. Use this metric to help measure the rate of data that is sent to back-end storage.

Port to Disk Receive I/O Rate (ops/s)
The average number of exchanges per second that are received from back-end storage resources.

Total Port to Disk I/O Rate (ops/s)
The average number of IOs per second that are transmitted between the storage system and the back-end storage it is virtualizing. Use this metric to help measure the rate of data that is sent to back-end storage.

Port to Local Node Send I/O Rate (ops/s)
The average number of IOs per second that are sent to other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Port to Local Node Receive I/O Rate (ops/s)
The average number of IOs per second that are received from other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Total Port to Local Node I/O Rate (ops/s)
The average number of IOs per second that are transmitted between the resource and other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Port to Remote Node Send I/O Rate (ops/s)
The average number of IOs per second that are sent to nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Port to Remote Node Receive I/O Rate (ops/s)
The average number of IOs per second that are received from nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Total Port to Remote Node I/O Rate (ops/s)
The average number of IOs per second that are transmitted between the resource and nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Port Send Data Rate (MiB/s)
The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)
The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)
The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port to Host Send Data Rate (MiB/s)
The average rate at which data is sent to host computers. The rate is measured in MiB per second.

Port to Host Receive Data Rate (MiB/s)
The average rate at which data is received from host computers. The rate is measured in MiB per second.

Total Port to Host Data Rate (MiB/s)
The average rate at which data is transmitted between host computers and the component. The rate is measured in MiB per second and includes both send and receive operations.

Port to Disk Sph_port_send_bandwidth_percentageend Data Rate (MiB/s)
The average rate at which data is sent to back-end storage resources. The rate is measured in MiB per second.

Port to Disk Receive Data Rate (MiB/s)
The average rate at which data is received from back-end storage resources. The rate is measured in MiB per second.

Total Port to Disk Data Rate (MiB/s)
The average rate at which data is transmitted between back-end storage resources and the component. The rate is measured in MiB per second and includes both send and receive operations.

Port to Local Node Send Data Rate (MiB/s)
The average rate at which data is sent to other nodes that are in the local cluster. The rate is measured in MiB per second.

Port to Local Node Receive Data Rate (MiB/s)
The average rate at which data is received from other nodes that are in the local cluster. The rate is measured in MiB per second.

Total Port to Local Node Data Rate (MiB/s)
The average rate at which data is transmitted between the component and other nodes that are in the local cluster. The rate is measured in MiB per second.

Port to Remote Node Send Data Rate (MiB/s)
The average rate at which data is sent to nodes that are in the remote cluster. The rate is measured in MiB per second.

Port to Remote Node Receive Data Rate (MiB/s)
The average rate at which data is received from nodes that are in the remote cluster. The rate is measured in MiB per second.

Total Port to Remote Node Data Rate (MiB/s)
The average rate at which data is transmitted between the component and nodes that are in the remote cluster. The rate is measured in MiB per second.

Port to Local Node Send Response Time (ms/op)
The average number of milliseconds to complete a send operation to another node that is in the local cluster. This value represents the external response time of the transfers.

Port to Local Node Receive Response Time (ms/op)

The average number of milliseconds to complete a receive operation from another node that is in the local cluster. This value represents the external response time of the transfers.

Overall Port to Local Node Response Time (ms/op)

The average number of milliseconds to complete a send or receive operation with another node that is in the local cluster. This value represents the external response time of the transfers.

Port to Local Node Send Queue Time (ms/op)

The average time in milliseconds that a send operation spends in the queue before the operation is processed. This value represents the queue time for send operations that are issued to other nodes that are in the local cluster.

Port to Local Node Receive Queue Time (ms/op)

The average time in milliseconds that a receive operation spends in the queue before the operation is processed. This value represents the queue time for receive operations that are issued from other nodes that are in the local cluster.

Overall Port to Local Node Queue Time (ms/op)

The average number of milliseconds that a send or receive operation spends in the queue before the operation is processed. This value is for send and receive operations that are issued between the component and other nodes that are in the local cluster.

Port to Remote Node Send Response Time (ms/op)

The average number of milliseconds to complete a send operation to a node that is in the remote cluster. This value represents the external response time of the transfers.

Port to Remote Node Receive Response Time (ms/op)

The average number of milliseconds to complete a receive operation from a node that is in the remote cluster. This value represents the external response time of the transfers.

Overall Port to Remote Node Response Time (ms/op)

The average number of milliseconds to complete a send operation to, or a receive operation from a node in the remote cluster. This value represents the external response time of the transfers.

Port to Remote Node Send Queue Time (ms/op)

The average time in milliseconds that a send operation spends in the queue before the operation is processed. This value represents the queue time for send operations that are issued to a node that is in the remote cluster.

Port to Remote Node Receive Queue Time (ms/op)

The average time in milliseconds that a receive operation spends in the queue before the operation is processed. This value represents the queue time for receive operations that are issued from a node that is in the remote cluster.

Overall Port to Remote Node Queue Time (ms/op)

The average number of milliseconds that a send or receive operation spends in the queue before the operation is processed. This value is for send and receive operations that are issued between the component and a node that is in the remote cluster.

Port error data

You can create performance reports that include the following information:

Link Failure Rate (count/s)

The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.

Loss of Sync Rate (count/s)

The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled. Synchronization is assumed lost after a timeout interval expires.

Loss of Signal Rate (count/s)

The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.

CRC Error Rate (count/s)

The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.

Primitive Sequence Protocol Error Rate (count/s)

The average number of primitive sequence protocol errors per second that are detected. This error occurs when there is a link failure for a port.

Invalid Transmission Word Rate (count/s)

The average number of bit errors per second that are detected.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Write Cache Delay I/O Rate (ops/s)

The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Overflow I/O Rate (ops/s)

The average number of tracks per second that are written but are delayed because there is not enough space in the write cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Flush Through I/O Rate (ops/s)

The average number of tracks per second that are written to disk in flush-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Write Through I/O Rate (ops/s)

The average number of tracks per second that are written to disk in write-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Disk to Cache Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer.

Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Read Ahead Percentage of Cache Hits

The percentage of all read cache hits that occur on pre-staged data. This value applies only to the volume copy cache if the resource is running IBM Spectrum Virtualize 7.3 or later.

Dirty Write Percentage of Cache Hits

The percentage of all cache write hits that occur on data in the cache that is marked as modified. This value represents how effectively write operations are coalesced before the data is written to disk. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Overflow Percentage

The percentage of write operations that are delayed because there is not enough space in the write cache.

Write Cache Flush Through Percentage

The percentage of tracks that are written to disk in flush-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Write Through Percentage

The percentage of tracks that are written to disk in write-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Back-end array data

You can create performance reports that include the following information:

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Data Rate (MiB/s)

The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)
The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)
The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Peak Back-End Read Response Time (ms)
The longest time for a back-end storage resource to respond to a read operation.

Peak Back-End Write Response Time (ms)
The longest time for a back-end storage resource to respond to a write operation by a node.

Back-End Read Transfer Size (KiB/op)
The average number of KiB that are transferred per read operation from the back-end storage resources.

Back-End Write Transfer Size (KiB/op)
The average number of KiB that are transferred per write operation to the back-end storage resources.

Overall Back-End Transfer Size (KiB/op)
The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Back-End Read Queue Time (ms/op)
The average number of milliseconds that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Back-End Write Queue Time (ms/op)
The average number of milliseconds that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Overall Back-End Queue Time (ms/op)
The average number of milliseconds that a read or a write operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Read Queue Time (ms)
The longest time that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Write Queue Time (ms)
The longest time that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Other data

You can create performance reports that include the following information:

Global Mirror Write I/O Rate (op/s)
The average number of write operations per second that are issued to the Global Mirror secondary site.

Global Mirror Overlapping Write I/O Rate (op/s)
The average number of overlapping write operations per second that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.
This value applies to resources that are running IBM Spectrum Virtualize.

Peak Read Response Time (ms)
The worst response time measured for a read operation in the sample interval.

Peak Write Response Time (ms)
The worst response time measured for a write operation in the sample interval.

Global Mirror Secondary Write Lag (ms/op)
The average number of additional milliseconds that it takes to service each secondary write operation for Global Mirror. This value does not include the time to service the primary write operations.
You monitor the value of Global Mirror Secondary Write Lag to identify delays that occurred during the process of writing data to the secondary site.
Average number of additional milliseconds it took to service each secondary write operation for Global Mirror, beyond the time needed to service the primary writes

Processor Utilization Percentage
The average percentage of time that the processors on nodes are busy doing system I/O tasks. This value applies only to resources that are running IBM Spectrum Virtualize.

Global Mirror Overlapping Write Percentage
The percentage of overlapping write operations that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.
Applies to resources that are running IBM Spectrum Virtualize.

Overall Host Attributed Response Time Percentage
The percentage of the average response time that can be attributed to delays from host systems. This value includes both read response times and write response times, and can help you diagnose slow hosts and fabrics that are not working efficiently.
For read response time, the value is based on the time that it takes for hosts to respond to transfer-ready notifications from the nodes. For write response time, the value is based on the time that it takes for hosts to send the write data after the node responds to a transfer-ready notification.

Zero Buffer-to-Buffer Credit Timer (microseconds)
The number of microseconds that the port is not able to send frames between ports because there is insufficient buffer-to-buffer credit.
In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports. Buffer-to-buffer credit is measured from the last time that metadata was collected.
If this metric is not available, use the Port Send Delay Time metric instead.

Zero Buffer-to-Buffer Credit Percentage
The amount of time, as a percentage, that the port was not able to send frames between ports because of insufficient buffer-to-buffer credit. The amount of time value is measured from the last time that metadata was collected. In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports.

Performance metrics for DS8000 storage systems

You can include performance metrics for ports, port errors, volumes, caches, back-end arrays, and other data for DS8000* storage systems in performance reports.

Port data

You can create performance reports that include the following information:

Port Send I/O Rate (ops/s)

The average number of I/O operations per second for operations in which data is sent from a port. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive I/O Rate (ops/s)

The average number of I/O operations per second for operations in which the port receives data. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port I/O Rate (ops/s)

The average number of send operations and receive operations per second.

Port PPRC Send I/O Rate (ops/s)

The average number of operations per second that are sent by using the PPRC protocol.

Port PPRC Receive I/O Rate (ops/s)

The average number of operations per second that are received by using the PPRC protocol.

Total Port PPRC I/O Rate (ops/s)

The average number of send operations and receive operations per second using the PPRC protocol.

Port Send Data Rate (MiB/s)

The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)

The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)

The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port PPRC Send Data Rate (MiB/s)

The average number of MiB per second that are sent by using the PPRC protocol.

Port PPRC Receive Data Rate (MiB/s)

The average number of MiB per second that are received by using the Peer-to-Peer Remote Copy (PPRC) protocol.

Total Port PPRC Data Rate (MiB/s)

The average number of MiB per second that are transferred by using the PPRC protocol. This value includes both send and receive PPRC operations.

Port Send Response Time (ms/op)

The average number of milliseconds to complete a send operation.

Port Receive Response Time (ms/op)

The average number of milliseconds to complete a receive operation.

Overall Port Response Time (ms/op)

The average number of milliseconds to complete a send or receive operation.

Port PPRC Send Response Time (ms/op)

The average number of milliseconds to complete a send operation by using the PPRC protocol.

Port PPRC Receive Response Time (ms/op)

The average number of milliseconds to complete a receive operation by using the PPRC protocol.

Overall Port PPRC Response Time (ms/op)

The average number of milliseconds to complete a send or receive operation by using the PPRC protocol.

Port Send Transfer Size (KiB/op)

The average number of KiB that are transferred per send operation. A send operation is a read operation that is processed or a write operation that is initiated by the port.

Port Receive Transfer Size (KiB/op)

The average number of KiB that are transferred per receive operation. A receive operation is a write operation that is processed or a read operation that is initiated by the port.

Overall Port Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

Port error data

You can create performance reports that include the following information:

Link Failure Rate (count/s)

The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.

Loss of Sync Rate (count/s)

The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled. Synchronization is assumed lost after a timeout interval expires.

Loss of Signal Rate (count/s)

The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.

CRC Error Rate (count/s)

The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.

Primitive Sequence Protocol Error Rate (count/s)

The average number of primitive sequence protocol errors per second that are detected. This error occurs when there is a link failure for a port.

Invalid Transmission Word Rate (count/s)

The average number of bit errors per second that are detected.

Error Frame Rate (count/s)
The average number of error frames per second that are received. An error frame is a frame that violates the Fibre Channel Protocol.

Link Reset Transmitted Rate (count/s)
The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR1) state.

Link Reset Received Rate (count/s)
The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR2) state.

Out of Order Data Rate (count/s)
The average number of times per second that an out-of-order frame is detected.

Out of Order ACK Rate (count/s)
The average number of times per second that an out-of-order acknowledge (ACK) frame is detected.
An ACK frame is used for end-to-end flow control and is sent to verify receipt of a frame.

Duplicate Frame Rate (count/s)
The average number of duplicate frames per second that are received. A duplicate frame is a frame that the system previously processed for the port.

Invalid Relative Offset Rate (count/s)
The average number of times per second that frames are received with an invalid relative offset in the frame header.

Sequence Timeout Rate (count/s)
The average number of times per second that the port detects a timeout condition after the port receives a sequence initiative for a Fibre Channel exchange.

Credit Recovery Link Reset Rate
The estimated average number of link resets per second that a switch or port completed to recover buffer credits. This estimate attempts to disregard link resets that were caused by link initialization. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

Volume data

You can create performance reports that include the following information:

Normal Read I/O Rate (ops/s)
The average number of nonsequential read operations per second.

Sequential Read I/O Rate (ops/s)
The average number of sequential read operations per second.

Overall Read I/O Rate (ops/s)
The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Normal Write I/O Rate (ops/s)
The average number of nonsequential write operations per second.

Sequential Write I/O Rate (ops/s)
The average number of sequential write operations per second.

Overall Write I/O Rate (ops/s)
The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Normal I/O Rate (ops/s)
The average number of nonsequential I/O operations per second. This value includes both read and write operations.

Total Sequential I/O Rate (ops/s)
The average number of sequential I/O operations per second. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)
The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Record Mode Read I/O Rate (ops/s)
The average number of I/O operations per second for record-mode read operations.
For record-mode read operations, only the requested data is managed in the cache rather than a full track of data.

Read Data Rate (MiB/s)
The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)
The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)
The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)
The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)
The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)
The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)
The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)
The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)
The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Back-end array data

You can create performance reports that include the following information:

Back-End Read I/O Rate (ops/s)
The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)
The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)
The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Data Rate (MiB/s)

The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)
The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)
The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Back-End Read Transfer Size (KiB/op)
The average number of KiB that are transferred per read operation from the back-end storage resources.

Back-End Write Transfer Size (KiB/op)
The average number of KiB that are transferred per write operation to the back-end storage resources.

Overall Back-End Transfer Size (KiB/op)
The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Cache data

You can create performance reports that include the following information:

Write Cache Delay I/O Rate (ops/s)
The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Normal Read Cache Hit Percentage
The percentage of nonsequential read operations that find data in the cache. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Sequential Read Cache Hit Percentage
The percentage of sequential read operations that find data in the cache. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Overall Read Cache Hit Percentage
The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Normal Write Cache Hit Percentage
The percentage of nonsequential write operations that are handled in the cache.

Sequential Write Cache Hit Percentage
The percentage of sequential write operations that are handled in the cache.

Overall Write Cache Hit Percentage
The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Normal Cache Hit Percentage
The percentage of nonsequential I/O operations that are handled in the cache. This value includes both read and write operations. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Sequential Cache Hit Percentage
The percentage of sequential I/O operations that are handled in the cache. This value includes both read and write operations. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Overall Cache Hit Percentage
The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Disk to Cache Transfer Rate (ops/s)
The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)
The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Delay Percentage
The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Record Mode Read Cache Hit Percentage
The percentage of cache hits for record-mode read operations. For record-mode read operations, only the requested data, rather than a full track of data, is managed in the cache.

Other data

You can create performance reports that include the following information:

HPF Read I/O Rate (ops/s)

The average number of read operations per second that are issued by the High Performance FICON® feature of the storage system.

HPF Write I/O Rate (ops/s)

The average number of write operations per second that are issued by the High Performance FICON feature of the storage system.

Total HPF I/O Rate (ops/s)

The average number of I/O operations per second that are issued by the High Performance FICON feature of the storage system. This value includes both read and write operations.

HPF I/O Percentage

The percentage of all I/O operations that are issued by the High Performance FICON feature of the storage system.

Cache Holding Time (s)

The average number of seconds that I/O data for a storage system node is held in the cache. A short cache-holding time indicates adverse performance.

PPRC Transfer Rate (ops/s)

The average number of tracks per second that are transferred to the secondary device of a Peer-to-Peer Remote Copy (PPRC) pair. This value shows the activity for the source of the PPRC relationship, but shows no activity for the target.

Performance metrics for XIV systems and IBM Spectrum Accelerate

You can include performance data for volumes, caches, and other data for XIV® systems and IBM Spectrum Accelerate in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Read Data Cache Hit Percentage

The percentage of all read data that is read from the cache.

Write Data Cache Hit Percentage

The percentage of all write data that is written to cache slots that are marked as modified.

Overall Data Cache Hit Percentage

The percentage of all data that is handled in the cache. This value includes read data that is read from the cache and write data that is written to cache slots that are marked as modified.

SSD Read Cache Hit Percentage

The percentage of read operations that find data in the cache on a solid-state drive (SSD). The value for this metric is also included in the value for the Overall Read Cache Hit Percentage metric.

This metric is only available for XIV systems that use solid-state drives as drives for caching.

SSD Read Data Cache Hit Percentage

The percentage of all read data that was read from cache memory on a solid-state drive.

This metric is only available for XIV systems that use solid-state drives as drives for caching.

Read Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a read-cache hit operation.

Write Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a write-cache hit operation.

Overall Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a cache hit operation. This value includes the times for both read-cache hit and write-cache hit operations.

Read Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a read-cache miss operation.

Write Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a write-cache miss operation.

Overall Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a cache miss operation. This value includes the times for both read-cache miss and write-cache miss operations.

SSD Read Cache Hit Response Time (ms/op)

The average number of milliseconds that it takes to complete a hit operation on the read cache on a solid-state drive. The value for this metric is also included in the value for the Read Cache Hit Response Time metric.

This metric is only available for XIV systems that use solid-state drives as drives for caching.

Other data

You can create performance reports that include the following information:

Small Transfers I/O Percentage

The percentage of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers I/O Percentage

The percentage of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers I/O Percentage

The percentage of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers I/O Percentage

The percentage of I/O operations with a data transfer size that is greater than 512 KiB.

Small Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a data transfer size that is greater than 512 KiB.

Small Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation with a data transfer size that is greater than 512 KiB.

Performance metrics for block server systems

You can include performance metrics for volumes, and cache data for block server storage systems in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Data for storage system volumes in performance reports

You can include general information, capacity data, properties, and other information about storage system volumes in performance reports.

Information about storage system volumes

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Controller Name

The name that was assigned to the controller when it was added to the system.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage RAID Array Name

The name that was assigned to the RAID array when it was added to the system.

Storage I/O Group Name

The name that was assigned to the I/O group when it was added to the system.

Storage Preferred Node Name

The name of the storage node that is used for I/O operations for a volume.

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Storage Volume Assigned Host Connection

The host connection to which the storage volume is assigned. The host connection is a definition in the storage system that contains the WWPN for the server. The storage system uses the WWPN to assign volumes to servers.

Storage Volume Host Connection OS Type

The operating system type of the server or hypervisor that the volume is assigned to.

Storage System Volume Group ID

The unique identifier for a collection of volumes on DS8000® storage systems. The storage system generates this identifier.

Storage Volume Group Name

The user-defined name for a collection of volumes on DS8000 storage systems.

Server Name

The fully qualified domain name of the server. For example, the name of a server might be `server.example.com`.

Hypervisor Name

The fully qualified domain name of the hypervisor. For example, the name of a hypervisor might be `hypervisor.example.com`.

Hypervisor Cluster Name

The name of a cluster that is monitored in your storage environment. A cluster is a group of hypervisors that collaborate for the purposes of workload balancing and failover.

Capacity and usage data

You can create performance reports that include the following information:

Storage Volume Capacity (GiB)

The total amount of storage space that is committed to a volume.

For thin-provisioned volumes, this value represents the virtual capacity of the volume.

For XIV® systems and IBM Spectrum Accelerate, this value represents the physical (hard) capacity of the volume, not the virtual (soft) capacity. For other storage systems, this value might also include overhead space if the pool is unformatted.

Storage Volume Used Space (GiB)

The amount of allocated space that is used by a volume.

For resources that are running IBM Spectrum Virtualize, you can preallocate thin-provisioned volume space when the volumes are created. In these cases, the Storage Volume Used Space (GiB) might be different than the Storage Volume Allocated Space (GiB). For volumes that are not thin provisioned, the values for Storage Volume Used Space (GiB) and Storage Volume Allocated Space (GiB) are equal.

This value is accurate as of the most recent time that IBM Spectrum Control collected data about a volume. The value in this property might not be 100% accurate for the current state of volumes. This inaccuracy might occur because data collection is run on a set schedule and the used space on volumes can change rapidly.

Storage Volume Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Storage Volume Allocated Space (GiB)

The amount of space that is reserved for a volume. The space that is allocated for a thin-provisioned volume is less than its virtual capacity, which is shown in the Storage Volume Capacity (GiB) property. This value is equal to the value in the Storage Volume Used Space (GiB) property for the following resources:

- Resources other than those that are running IBM Spectrum Virtualize and are configured as back-end storage
- Resources that are running IBM Spectrum Virtualize, are configured as back-end storage, and are not thin-provisioned

Storage Volume Unallocated Space (GiB)

The amount of space in a pool that is not reserved for a volume.

IBM Spectrum Control uses the following formula to determine this value:

capacity - allocated space

Available only for thin provisioned volumes.

Storage Volume Physical Allocation Percentage

The percentage of physical space that is reserved for a volume. This value is always less than or equal to 100% because you cannot reserve more physical space than is available.

IBM Spectrum Control uses the following formula to determine this value:

(allocated space ÷ capacity) × 100

For example, the physical allocation percentage is 25% for a volume size of 200 GiB. Therefore, the space that is reserved for volumes is 50 GiB.

Storage Volume Shortfall Percentage

The percentage of the remaining unallocated volume space in a pool that is not available to be allocated to a volume.

The higher the percentage, the more critical the shortfall of space.

IBM Spectrum Control uses the following formula to determine this value:

(unallocatable volume space ÷ volume unallocated space) × 100

You can use this percentage to determine when the amount of overcommitted space in pools reaches a critically high level. For example, the physical space in pools might be less than the committed virtual space. In this case, the pools do not have enough space to fulfill the commitment to virtual space for a volume.

This Storage Volume Shortfall Percentage represents the percentage of the committed virtual space that is not available in a pool. As more space is used over time by a volume while the pool capacity remains the same, this percentage increases.

For example, the remaining physical capacity of a pool is 70 GiB, however, 150 GiB of virtual space is committed to a thin-provisioned volume. If the volume is using 50 GiB, then there is still 100 GiB committed to that volume (150 GiB - 50 GiB). There is a shortfall of 30 GiB (70 GiB remaining pool space - 100 GiB remaining commitment of volume space to the volume). The volume is overcommitted by 30 GiB based on the available space in the pool. The shortfall is 30% when you use the following calculation:

**100 GiB unallocated volume space - 70 GiB remaining
pool space ÷ 100 GiB unallocated volume space × 100**

Storage Volume Unallocatable Space (GiB)

The unallocatable storage space in GiB of a thin-provisioned volume. Unallocatable space cannot be supplied by the pool to which the volume belongs.

Storage Volume Used Allocated Space Percentage

The percentage of reserved space for a volume that is being used. This value is always less than or equal to 100% because a volume cannot use more space than is allocated.

IBM Spectrum Control uses the following formula to determine this value:

(volume used space ÷ volume allocated space) × 100

This property is available only for volumes on resources that are running IBM Spectrum Virtualize.

Storage Volume Unused Space (GiB)

The amount of space that is allocated to a volume and is not yet used.

IBM Spectrum Control uses the following formula to determine this value:

allocated space - used space

This property is available only for pools on resources that are running IBM Spectrum Virtualize.

Storage Volume Uncompressed Capacity (GiB)

The amount of storage space that is used if the compressed volume space is uncompressed. For example, if 100 GiB of uncompressed data is compressed, and the size of the compressed data is 20 GiB, the value is 100.

Component properties

You can create performance reports that include the following information:

Storage Volume RAID Level

The RAID level of the resource, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the resource.

Storage Volume Is Thin Provisioned

Shows whether a pool, volume, or volume copy is thin-provisioned. If this value is **Yes**, the resource is thin-provisioned.

Storage Volume Is Assigned
Shows whether the volume is assigned to a server. If this value is **Yes**, the volume is assigned to a server.

Storage Volume Is Encrypted
Shows whether the resource is encrypted. If this value is **Yes**, the resource is encrypted.

Storage Volume Is Encryptable
Shows whether the resource can be encrypted. If this value is **Yes**, the resource can be encrypted.

Storage Volume Is Volume Control Manager Database
Shows whether a volume is used as the Volume Control Manager Database. If this value is **Yes**, the volume is used as the Volume Control Manager Database.

Storage Volume Format
Shows the format of the volume or pool. The format can be a Count Key Data (CKD) format, or a fixed block format.

Storage Volume Serial Number
The serial number or volume ID of the volume.

Storage Volume Number
The number of the volume that is assigned by the system.

Storage Volume WWN
The worldwide name of the volume.

Storage Volume FlashCopy® Relationship
Shows whether a volume on a storage system is in a FlashCopy relationship. This property can contain the following values:

- Source Relationship**
The volume is the source of the relationship.
- Target Relationship**
The volume is the target of the relationship.
- Both Source and Target Relationship**
The volume is both the source and target of the relationship.
- Not in a FlashCopy Relationship**
The volume is not in a FlashCopy relationship.

Storage Volume Remote Copy Relationship
Shows whether a volume on a storage system is in a remote copy relationship. This property can contain the following values:

- Not in a Copy Relationship**
The volume is not in a remote copy relationship.
- Source Relationship**
The volume is the source of the relationship.
- Target Relationship**
The volume is the target of the relationship.
- Both Source and Target Relationship**
The volume is both the source and target of the relationship.

Storage Volume Logical Subsystem
The logical subsystem (LSS) to which a volume or pool belongs.

Storage Volume Type
The type of storage volume. For example, the storage volume can be striped or sequential. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Fast Write State
Shows whether the cache for a volume on a disk that is managed by a storage virtualizer is empty, contains data, or is corrupted.

Storage Volume Grain Size (KiB)
The grain size with which a thin-provisioned volume was created. This value is typically 32, 64, 128, or 256 KiB. Larger grain sizes maximize performance, whereas smaller grain sizes maximize space efficiency. Grain sizes also limit the maximum virtual space of a volume.
This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Is Auto Expand Enabled
Shows whether a volume can automatically allocate new extents from a pool. Volumes might allocate new extents to expand the real capacity of the volume. If this value is **Yes**, the volume can automatically allocate new extents from a pool.
This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Metro Mirror Name
The name of the Metro Mirror that keeps the synchronous copy of the storage volume. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Mirror Count
The number of mirrors that keep a synchronous copy of the resource. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Throttle
The maximum number of commands that the volume can queue. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Warning Level
The percentage of volume capacity that is used at which a warning is generated. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Is Compressed
Shows whether the volume is compressed. If this value is **Yes**, the volume is compressed.

Storage System Configuration
Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Status information

You can create performance reports that include the following information:

Storage Volume Status

The condition of the resource, for example normal, warning, or error.

Storage Volume Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Storage Volume Native Status

The condition of the volume. The status can be online, offline, degraded, or excluded.

- [Performance metrics for volumes on SAN Volume Controller and Storwize systems](#)

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for volumes, caches, and other data for volumes on these systems in performance reports.

- [Performance metrics for volumes on DS8000 storage systems](#)

You can include performance data for volumes, caches, and other data for storage system volumes on DS8000 storage systems in performance reports.

- [Performance metrics for storage system volumes on XIV systems and IBM Spectrum Accelerate](#)

You can include performance data for volumes, caches, and other data for storage system volumes on XIV systems and IBM Spectrum Accelerate in performance reports.

- [Performance metrics for storage system volumes on block servers](#)

You can include performance data for volumes and caches for storage system volumes on block servers in performance reports.

Performance metrics for volumes on SAN Volume Controller and Storwize systems

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for volumes, caches, and other data for volumes on these systems in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Maximum Read I/O Rate (ops/s)

The maximum read I/O rate of the volume in operations per second. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Maximum Write I/O Rate (ops/s)

The maximum write I/O rate of the volume in operations per second. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Maximum Write I/O Size (KiB)

The maximum size of write I/O operations in kibibytes. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Maximum Read Response Time (ms/op)

The maximum read response time of the volume in milliseconds per operation. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Maximum Write Response Time (ms/op)

The maximum write response time of the volume in milliseconds per operation. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Volume Utilization

The average percentage of time that the volume is busy.

Maximum Volume Utilization Percentage

The maximum period in percentage that the volume is busy. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Cache data

You can create performance reports that include the following information:

Write Cache Overflow I/O Rate (ops/s)

The average number of tracks per second that are written but are delayed because there is not enough space in the write cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Delay I/O Rate (ops/s)

The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Flush Through I/O Rate (ops/s)

The average number of tracks per second that are written to disk in flush-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Write Through I/O Rate (ops/s)

The average number of tracks per second that are written to disk in write-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Maximum Write Cache Delay I/O Rate (ops/s)

The maximum number of delayed I/O operations per second for the volume, where the delay occurred because of space constraints or other conditions.

This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Disk to Cache Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Read Ahead Percentage of Cache Hits

The percentage of all read cache hits that occur on pre-staged data. This value applies only to the volume copy cache if the resource is running IBM Spectrum Virtualize 7.3 or later.

Dirty Write Percentage of Cache Hits

The percentage of all cache write hits that occur on data in the cache that is marked as modified. This value represents how effectively write operations are coalesced before the data is written to disk. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Overflow Percentage

The percentage of write operations that are delayed because there is not enough space in the write cache.

Write Cache Flush Through Percentage

The percentage of tracks that are written to disk in flush-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Write Through Percentage

The percentage of tracks that are written to disk in write-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Maximum Read Cache Hit Percentage

The maximum number of cache hits in percentage for sequential and nonsequential read operations for the volume over a specified interval. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Other data

You can create performance reports that include the following information:

Global Mirror Write I/O Rate (op/s)

The average number of write operations per second that are issued to the Global Mirror secondary site.

Global Mirror Overlapping Write Percentage

The percentage of overlapping write operations that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.

Applies to resources that are running IBM Spectrum Virtualize.

Global Mirror Overlapping Write I/O Rate (op/s)

The average number of overlapping write operations per second that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.

This value applies to resources that are running IBM Spectrum Virtualize.

Peak Read Response Time (ms)

The worst response time measured for a read operation in the sample interval.

Peak Write Response Time (ms)

The worst response time measured for a write operation in the sample interval.

Global Mirror Secondary Write Lag (ms/op)

The average number of additional milliseconds that it takes to service each secondary write operation for Global Mirror. This value does not include the time to service the primary write operations.

You monitor the value of Global Mirror Secondary Write Lag to identify delays that occurred during the process of writing data to the secondary site.

Average number of additional milliseconds it took to service each secondary write operation for Global Mirror, beyond the time needed to service the primary writes

Overall Host Attributed Response Time Percentage

The percentage of the average response time that can be attributed to delays from host systems. This value includes both read response times and write response times, and can help you diagnose slow hosts and fabrics that are not working efficiently.

For read response time, the value is based on the time that it takes for hosts to respond to transfer-ready notifications from the nodes. For write response time, the value is based on the time that it takes for hosts to send the write data after the node responds to a transfer-ready notification.

Nonpreferred Node Usage Percentage

The overall percentage of I/O operations that are not directed against the preferred node for each volume in an I/O Group. There is a small performance penalty when I/O does not go to the preferred node for each volume.

Performance metrics for volumes on DS8000 storage systems

You can include performance data for volumes, caches, and other data for storage system volumes on DS8000® storage systems in performance reports.

Volume data

You can create performance reports that include the following information:

Normal Read I/O Rate (ops/s)

The average number of nonsequential read operations per second.

Sequential Read I/O Rate (ops/s)

The average number of sequential read operations per second.

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Normal Write I/O Rate (ops/s)

The average number of nonsequential write operations per second.

Sequential Write I/O Rate (ops/s)

The average number of sequential write operations per second.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Normal I/O Rate (ops/s)

The average number of nonsequential I/O operations per second. This value includes both read and write operations.

Total Sequential I/O Rate (ops/s)

The average number of sequential I/O operations per second. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Record Mode Read I/O Rate (ops/s)

The average number of I/O operations per second for record-mode read operations.

For record-mode read operations, only the requested data is managed in the cache rather than a full track of data.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Volume Utilization

The average percentage of time that the volume is busy.

Cache data

You can create performance reports that include the following information:

Write Cache Delay I/O Rate (ops/s)

The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Normal Read Cache Hit Percentage

The percentage of nonsequential read operations that find data in the cache.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Sequential Read Cache Hit Percentage

The percentage of sequential read operations that find data in the cache.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Normal Write Cache Hit Percentage

The percentage of nonsequential write operations that are handled in the cache.

Sequential Write Cache Hit Percentage

The percentage of sequential write operations that are handled in the cache.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Normal Cache Hit Percentage

The percentage of nonsequential I/O operations that are handled in the cache. This value includes both read and write operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Sequential Cache Hit Percentage

The percentage of sequential I/O operations that are handled in the cache. This value includes both read and write operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Disk to Cache Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Record Mode Read Cache Hit Percentage

The percentage of cache hits for record-mode read operations.

For record-mode read operations, only the requested data, rather than a full track of data, is managed in the cache.

Other data

You can create performance reports that include the following information:

HPF Read I/O Rate (ops/s)

The average number of read operations per second that are issued by the High Performance FICON® feature of the storage system.

HPF Write I/O Rate (ops/s)

The average number of write operations per second that are issued by the High Performance FICON feature of the storage system.

Total HPF I/O Rate (ops/s)

The average number of I/O operations per second that are issued by the High Performance FICON feature of the storage system. This value includes both read and write operations.

HPF I/O Percentage

The percentage of all I/O operations that are issued by the High Performance FICON feature of the storage system.

PPRC Transfer Rate (ops/s)

The average number of tracks per second that are transferred to the secondary device of a Peer-to-Peer Remote Copy (PPRC) pair. This value shows the activity for the source of the PPRC relationship, but shows no activity for the target.

Performance metrics for storage system volumes on XIV systems and IBM Spectrum Accelerate

You can include performance data for volumes, caches, and other data for storage system volumes on XIV® systems and IBM Spectrum Accelerate in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)
The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)
The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)
The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)
The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)
The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)
The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)
The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)
The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)
The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)
The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Volume Utilization
The average percentage of time that the volume is busy.

Cache data

You can create performance reports that include the following information:

Overall Read Cache Hit Percentage
The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.
You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage
The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage
The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.
You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Read Data Cache Hit Percentage
The percentage of all read data that is read from the cache.

Write Data Cache Hit Percentage
The percentage of all write data that is written to cache slots that are marked as modified.

Overall Data Cache Hit Percentage
The percentage of all data that is handled in the cache. This value includes read data that is read from the cache and write data that is written to cache slots that are marked as modified.

Read Cache Miss Response Time (ms/op)
The average number of milliseconds to complete a read-cache miss operation.

Write Cache Miss Response Time (ms/op)
The average number of milliseconds to complete a write-cache miss operation.

Overall Cache Miss Response Time (ms/op)
The average number of milliseconds to complete a cache miss operation. This value includes the times for both read-cache miss and write-cache miss operations.

Read Cache Hit Response Time (ms/op)
The average number of milliseconds to complete a read-cache hit operation.

Write Cache Hit Response Time (ms/op)
The average number of milliseconds to complete a write-cache hit operation.

Overall Cache Hit Response Time (ms/op)
The average number of milliseconds to complete a cache hit operation. This value includes the times for both read-cache hit and write-cache hit operations.

SSD Read Cache Hit Percentage
The percentage of read operations that find data in the cache on a solid-state drive (SSD). The value for this metric is also included in the value for the Overall Read Cache Hit Percentage metric.
This metric is only available for XIV systems that use solid-state drives as drives for caching.

SSD Read Data Cache Hit Percentage
The percentage of all read data that was read from cache memory on a solid-state drive.
This metric is only available for XIV systems that use solid-state drives as drives for caching.

SSD Read Cache Hit Response Time (ms/op)
The average number of milliseconds that it takes to complete a hit operation on the read cache on a solid-state drive. The value for this metric is also included in the value for the Read Cache Hit Response Time metric.
This metric is only available for XIV systems that use solid-state drives as drives for caching.

Other data

You can create performance reports that include the following information:

Small Transfers I/O Percentage
The percentage of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers I/O Percentage
The percentage of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers I/O Percentage

The percentage of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers I/O Percentage

The percentage of I/O operations with a data transfer size that is greater than 512 KiB.

Small Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a data transfer size that is greater than 512 KiB.

Small Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation with a data transfer size that is greater than 512 KiB.

Performance metrics for storage system volumes on block servers

You can include performance data for volumes and caches for storage system volumes on block servers in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Volume Utilization

The average percentage of time that the volume is busy.

Cache data

You can create performance reports that include the following information:

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Data for storage system ports in performance reports

You can include general information, properties, and other information about storage system ports in performance reports.

Information about storage system ports

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Module Name

The name that was assigned to the module when it was added to the system.

Storage Port Name

The name that was assigned to the storage port when the storage system was added to the system.

Component properties

You can create performance reports that include the following information:

Storage System Port Number

The port number on the resource.

Storage System Port Type

The type of port on the storage system, storage virtualizer, or switch. For example, the port type can be N_Port, F_Port, or another type of port.

Storage System Port Speed (GiB/s)

The speed of a port, which is measured in GiB per second.

Storage System Port Location

The physical location of a port on DS8000® storage systems and XIV® systems. For all other systems, this property shows the WWPN of the port.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Status information

You can create performance reports that include the following information:

Storage System Port Status

The condition of the resource, for example normal, warning, or error.

Storage System Port Enabled State

Shows whether a port is enabled, disabled, or is enabled but offline.

Storage System Port Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

- [Performance metrics for ports on SAN Volume Controller and Storwize systems](#)

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for ports and port errors on these systems in performance reports.

- [Performance metrics for ports on DS8000 and DS6000 storage systems](#)

You can include performance data for storage system port and port errors on DS8000 and DS6000™ storage systems in performance reports.

- [Performance metrics for ports on an XIV](#)

You can include performance metrics for storage system ports on an XIV in performance reports.

- [Performance metrics for storage system ports on block servers](#)

You can include performance metrics for storage system ports on block servers in performance reports.

Performance metrics for ports on SAN Volume Controller and Storwize systems

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for ports and port errors on these systems in performance reports.

Port data

You can create performance reports that include the following information:

Port Send I/O Rate (ops/s)

The average number of I/O operations per second for operations in which data is sent from a port. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive I/O Rate (ops/s)

The average number of I/O operations per second for operations in which the port receives data. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port I/O Rate (ops/s)

The average number of send operations and receive operations per second.

Port to Host Send I/O Rate (ops/s)

The average number of IOs per second that are sent by the storage system to the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Port to Host Receive I/O Rate (ops/s)

The average number of IOs per second that are received by the storage system from the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Total Port to Host I/O Rate (ops/s)

The average number of IOs per second that are transmitted between the storage system and the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Port to Disk Send I/O Rate (ops/s)

The average number of IOs per second that are sent from the storage system to the back-end storage it is virtualizing. Use this metric to help measure the rate of data that is sent to back-end storage.

Port to Disk Receive I/O Rate (ops/s)

The average number of exchanges per second that are received from back-end storage resources.

Total Port to Disk I/O Rate (ops/s)

The average number of IOs per second that are transmitted between the storage system and the back-end storage it is virtualizing. Use this metric to help measure the rate of data that is sent to back-end storage.

Port to Local Node Send I/O Rate (ops/s)

The average number of IOs per second that are sent to other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Port to Local Node Receive I/O Rate (ops/s)

The average number of IOs per second that are received from other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Total Port to Local Node I/O Rate (ops/s)

The average number of IOs per second that are transmitted between the resource and other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Port to Remote Node Send I/O Rate (ops/s)

The average number of IOs per second that are sent to nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Port to Remote Node Receive I/O Rate (ops/s)

The average number of IOs per second that are received from nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Total Port to Remote Node I/O Rate (ops/s)

The average number of IOs per second that are transmitted between the resource and nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Port Send Data Rate (MiB/s)

The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)

The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)

The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port to Host Send Data Rate (MiB/s)

The average rate at which data is sent to host computers. The rate is measured in MiB per second.

Port to Host Receive Data Rate (MiB/s)

The average rate at which data is received from host computers. The rate is measured in MiB per second.

Total Port to Host Data Rate (MiB/s)

The average rate at which data is transmitted between host computers and the component. The rate is measured in MiB per second and includes both send and receive operations.

Port to Disk Sph_port_send_bandwidth_percentageend Data Rate (MiB/s)

The average rate at which data is sent to back-end storage resources. The rate is measured in MiB per second.

Port to Disk Receive Data Rate (MiB/s)

The average rate at which data is received from back-end storage resources. The rate is measured in MiB per second.

Total Port to Disk Data Rate (MiB/s)

The average rate at which data is transmitted between back-end storage resources and the component. The rate is measured in MiB per second and includes both send and receive operations.

Port to Local Node Send Data Rate (MiB/s)

The average rate at which data is sent to other nodes that are in the local cluster. The rate is measured in MiB per second.

Port to Local Node Receive Data Rate (MiB/s)

The average rate at which data is received from other nodes that are in the local cluster. The rate is measured in MiB per second.

Total Port to Local Node Data Rate (MiB/s)

The average rate at which data is transmitted between the component and other nodes that are in the local cluster. The rate is measured in MiB per second.

Port to Remote Node Send Data Rate (MiB/s)

The average rate at which data is sent to nodes that are in the remote cluster. The rate is measured in MiB per second.

Port to Remote Node Receive Data Rate (MiB/s)

The average rate at which data is received from nodes that are in the remote cluster. The rate is measured in MiB per second.

Total Port to Remote Node Data Rate (MiB/s)

The average rate at which data is transmitted between the component and nodes that are in the remote cluster. The rate is measured in MiB per second.

Port Send Bandwidth Percentage

The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Port Receive Bandwidth Percentage

The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Overall Port Bandwidth Percentage

The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Port error data

You can create performance reports that include the following information:

Link Failure Rate (count/s)

The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.

Loss of Sync Rate (count/s)

The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled. Synchronization is assumed lost after a timeout interval expires.

Loss of Signal Rate (count/s)

The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.

CRC Error Rate (count/s)

The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.

Primitive Sequence Protocol Error Rate (count/s)

The average number of primitive sequence protocol errors per second that are detected. This error occurs when there is a link failure for a port.

Invalid Transmission Word Rate (count/s)

The average number of bit errors per second that are detected.

Zero Buffer-to-Buffer Credit Timer (microseconds)

The number of microseconds that the port is not able to send frames between ports because there is insufficient buffer-to-buffer credit.

In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports. Buffer-to-buffer credit is measured from the last time that metadata was collected.

If this metric is not available, use the Port Send Delay Time metric instead.

Zero Buffer-to-Buffer Credit Percentage

The amount of time, as a percentage, that the port was not able to send frames between ports because of insufficient buffer-to-buffer credit. The amount of time value is measured from the last time that metadata was collected. In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports.

Port Congestion Index

The estimated degree to which frame transmission was delayed due to a lack of buffer credits. This value is generally 0 - 100. The value 0 means there was no congestion. The value can exceed 100 if the buffer credit exhaustion persisted for an extended amount of time. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

Performance metrics for ports on DS8000 and DS6000 storage systems

You can include performance data for storage system port and port errors on DS8000® and DS6000™ storage systems in performance reports.

Port data

You can create performance reports that include the following information:

Port Send I/O Rate (ops/s)

The average number of I/O operations per second for operations in which data is sent from a port. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive I/O Rate (ops/s)

The average number of I/O operations per second for operations in which the port receives data. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port I/O Rate (ops/s)

The average number of send operations and receive operations per second.

Port FICON Send I/O Rate (ops/s)

The average number of send operations per second for Fibre Channel connection (FICON®) usage.

Port FICON Receive I/O Rate (ops/s)

The average number of receive operations per second for FICON usage.

Total Port FICON I/O Rate (ops/s)

The average number of send and receive operations per second for FICON usage.

Port FCP Send I/O Rate (ops/s)

The average number of send operations per second for Fibre Channel Protocol (FCP) usage.

Port FCP Receive I/O Rate (ops/s)

The average number of receive operations per second for FCP usage.

Total Port FCP I/O Rate (ops/s)

The average number of send operations and receive operations per second for FCP usage.

Port PPRC Send I/O Rate (ops/s)

The average number of operations per second that are sent by using the PPRC protocol.

Port PPRC Receive I/O Rate (ops/s)

The average number of operations per second that are received by using the PPRC protocol.

Total Port PPRC I/O Rate (ops/s)

The average number of send operations and receive operations per second using the PPRC protocol.

Port Send Data Rate (MiB/s)

The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)
The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)
The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port FICON Send Data Rate (MiB/s)
The average number of MiB per second that is sent for FICON usage.

Port FICON Receive Data Rate (MiB/s)
The average number of MiB per second that is received for FICON usage.

Total Port FICON Data Rate (MiB/s)
The average number of MiB per second that is transferred for FICON usage. This value includes both send and receive FICON operations.

Port FCP Send Data Rate (MiB/s)
The average number of MiB per second that are sent for FCP usage.

Port FCP Receive Data Rate (MiB/s)
The average number of MiB per second that are received for FCP usage.

Total Port FCP Data Rate (MiB/s)
The average number of MiB per second that are transferred for FCP usage. This value includes both send and receive FCP operations.

Port PPRC Send Data Rate (MiB/s)
The average number of MiB per second that are sent by using the PPRC protocol.

Port PPRC Receive Data Rate (MiB/s)
The average number of MiB per second that are received by using the Peer-to-Peer Remote Copy (PPRC) protocol.

Total Port PPRC Data Rate (MiB/s)
The average number of MiB per second that are transferred by using the PPRC protocol. This value includes both send and receive PPRC operations.

Port Send Response Time (ms/op)
The average number of milliseconds to complete a send operation.

Port Receive Response Time (ms/op)
The average number of milliseconds to complete a receive operation.

Overall Port Response Time (ms/op)
The average number of milliseconds to complete a send or receive operation.

Port FCP Send Response Time (ms/op)
The average number of milliseconds to complete a send operation for FCP usage.

Port FCP Receive Response Time (ms/op)
The average number of milliseconds to complete a receive operation for FCP usage.

Overall Port FCP Response Time (ms/op)
The average number of milliseconds to complete a send or receive operation for FCP usage.

Port FICON Send Response Time (ms/op)
The average number of milliseconds to complete a send operation for FICON usage.

Port FICON Receive Response Time (ms/op)
The average number of milliseconds to complete a receive operation for FICON usage.

Overall Port FICON Response Time (ms/op)
The average number of milliseconds to complete a send or receive operation for FICON usage. This value includes both send and receive FICON operations.

Port PPRC Send Response Time (ms/op)
The average number of milliseconds to complete a send operation by using the PPRC protocol.

Port PPRC Receive Response Time (ms/op)
The average number of milliseconds to complete a receive operation by using the PPRC protocol.

Overall Port PPRC Response Time (ms/op)
The average number of milliseconds to complete a send or receive operation by using the PPRC protocol.

Port Send Transfer Size (KiB/op)
The average number of KiB that are transferred per send operation. A send operation is a read operation that is processed or a write operation that is initiated by the port.

Port Receive Transfer Size (KiB/op)
The average number of KiB that are transferred per receive operation. A receive operation is a write operation that is processed or a read operation that is initiated by the port.

Overall Port Transfer Size (KiB/op)
The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

Port Send Utilization Percentage
The average percentage of time that the port is busy sending data.

Port Receive Utilization Percentage
The average percentage of time that the port is busy receiving data.

Overall Port Utilization Percentage
The average percentage of time that the port is busy sending or receiving data.

Port Send Bandwidth Percentage
The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Port Receive Bandwidth Percentage
The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Overall Port Bandwidth Percentage
The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Port error data

You can create performance reports that include the following information:

Error Frame Rate (count/s)

The average number of error frames per second that are received. An error frame is a frame that violates the Fibre Channel Protocol.

Link Failure Rate (count/s)

The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.

Loss of Sync Rate (count/s)

The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled.

Synchronization is assumed lost after a timeout interval expires.

Loss of Signal Rate (count/s)

The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.

CRC Error Rate (count/s)

The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.

Primitive Sequence Protocol Error Rate (count/s)

The average number of primitive sequence protocol errors per second that are detected.

This error occurs when there is a link failure for a port.

Invalid Transmission Word Rate (count/s)

The average number of bit errors per second that are detected.

Out of Order Data Rate (count/s)

The average number of times per second that an out-of-order frame is detected.

Out of Order ACK Rate (count/s)

The average number of times per second that an out-of-order acknowledge (ACK) frame is detected.

An ACK frame is used for end-to-end flow control and is sent to verify receipt of a frame.

Duplicate Frame Rate (count/s)

The average number of duplicate frames per second that are received. A duplicate frame is a frame that the system previously processed for the port.

Invalid Relative Offset Rate (count/s)

The average number of times per second that frames are received with an invalid relative offset in the frame header.

Sequence Timeout Rate (count/s)

The average number of times per second that the port detects a timeout condition after the port receives a sequence initiative for a Fibre Channel exchange.

Link Reset Transmitted Rate (count/s)

The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR1) state.

Link Reset Received Rate (count/s)

The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR2) state.

Credit Recovery Link Reset Rate

The estimated average number of link resets per second that a switch or port completed to recover buffer credits. This estimate attempts to disregard link resets that were caused by link initialization. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

Performance metrics for ports on an XIV

You can include performance metrics for storage system ports on an XIV® in performance reports.

Port data

You can create performance reports that include the following information:

Port Send I/O Rate (ops/s)

The average number of I/O operations per second for operations in which data is sent from a port. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive I/O Rate (ops/s)

The average number of I/O operations per second for operations in which the port receives data. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port I/O Rate (ops/s)

The average number of send operations and receive operations per second.

Port Send Data Rate (MiB/s)

The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)

The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)

The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port Send Response Time (ms/op)

The average number of milliseconds to complete a send operation.

Port Receive Response Time (ms/op)

The average number of milliseconds to complete a receive operation.

Overall Port Response Time (ms/op)

The average number of milliseconds to complete a send or receive operation.

Port Send Bandwidth Percentage

The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Port Receive Bandwidth Percentage

The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Overall Port Bandwidth Percentage

The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Performance metrics for storage system ports on block servers

You can include performance metrics for storage system ports on block servers in performance reports.

Port data

You can create performance reports that include the following information:

Port Send I/O Rate (ops/s)

The average number of I/O operations per second for operations in which data is sent from a port. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive I/O Rate (ops/s)

The average number of I/O operations per second for operations in which the port receives data. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port I/O Rate (ops/s)

The average number of send operations and receive operations per second.

Port Send Data Rate (MiB/s)

The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)

The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)

The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port Send Response Time (ms/op)

The average number of milliseconds to complete a send operation.

Port Receive Response Time (ms/op)

The average number of milliseconds to complete a receive operation.

Overall Port Response Time (ms/op)

The average number of milliseconds to complete a send or receive operation.

Port Send Transfer Size (KiB/op)

The average number of KiB that are transferred per send operation. A send operation is a read operation that is processed or a write operation that is initiated by the port.

Port Receive Transfer Size (KiB/op)

The average number of KiB that are transferred per receive operation. A receive operation is a write operation that is processed or a read operation that is initiated by the port.

Overall Port Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both send and receive operations.

Data for storage system RAID arrays in performance reports

You can include general information, capacity data, and properties of storage system RAID arrays in performance reports.

Information about storage system RAID arrays

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Controller Name

The name that was assigned to the controller when it was added to the system.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage RAID Array Name

The name that was assigned to the RAID array when it was added to the system.

Capacity and usage data

You can create performance reports that include the following information:

Storage RAID Array DDM Capacity (GiB)

The amount of storage space on the disk drive modules in an array.

Component properties

You can create performance reports that include the following information:

Storage RAID Array RAID Level

The RAID level of the resource, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the resource.

Storage RAID Array Width

The number of disks that are in the storage array.

- Storage RAID Array DDM Speed (RPM)
The speed of the disk drive module in the array.
- Storage RAID Array Description
Shows the array site that the array is associated with.
- Storage RAID Array Tag
A number that identifies an array.
- Storage System Configuration
Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.
- [Performance metrics for storage system arrays](#)
You can include front end data, cache data, back-end data, and other data for storage system arrays in performance reports.

Performance metrics for storage system arrays

You can include front end data, cache data, back-end data, and other data for storage system arrays in performance reports.

Front end data

You can create performance reports that include the following information:

- Normal Read I/O Rate (ops/s)
The average number of nonsequential read operations per second.
- Sequential Read I/O Rate (ops/s)
The average number of sequential read operations per second.
- Overall Read I/O Rate (ops/s)
The average number of read operations per second. This value includes both sequential and nonsequential read operations.
- Normal Write I/O Rate (ops/s)
The average number of nonsequential write operations per second.
- Sequential Write I/O Rate (ops/s)
The average number of sequential write operations per second.
- Overall Write I/O Rate (ops/s)
The average number of write operations per second. This value includes both sequential and nonsequential write operations.
- Total Normal I/O Rate (ops/s)
The average number of nonsequential I/O operations per second. This value includes both read and write operations.
- Total Sequential I/O Rate (ops/s)
The average number of sequential I/O operations per second. This value includes both read and write operations.
- Total Overall I/O Rate (ops/s)
The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.
- Record Mode Read I/O Rate (ops/s)
The average number of I/O operations per second for record-mode read operations.
For record-mode read operations, only the requested data is managed in the cache rather than a full track of data.
- Read Data Rate (MiB/s)
The average number of MiBs per second that are transferred for read operations.
- Write Data Rate (MiB/s)
The average number of MiBs per second that are transferred for write operations.
- Total Data Rate (MiB/s)
The average number of MiB per second that are transferred for read operations and write operations.
- Read Response Time (ms/op)
The average number of milliseconds to complete a read operation.
- Write Response Time (ms/op)
The average number of milliseconds to complete a write operation.
- Overall Response Time (ms/op)
The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.
- Read Transfer Size (KiB/op)
The average number of KiB that are transferred per read operation.
- Write Transfer Size (KiB/op)
The average number of KiB that are transferred per write operation.
- Overall Transfer Size (KiB/op)
The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

- Write Cache Delay I/O Rate (ops/s)
The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.
This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.
- Normal Read Cache Hit Percentage
The percentage of nonsequential read operations that find data in the cache.
You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.
- Sequential Read Cache Hit Percentage
The percentage of sequential read operations that find data in the cache.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Normal Write Cache Hit Percentage

The percentage of nonsequential write operations that are handled in the cache.

Sequential Write Cache Hit Percentage

The percentage of sequential write operations that are handled in the cache.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Normal Cache Hit Percentage

The percentage of nonsequential I/O operations that are handled in the cache. This value includes both read and write operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Sequential Cache Hit Percentage

The percentage of sequential I/O operations that are handled in the cache. This value includes both read and write operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Record Mode Read Cache Hit Percentage

The percentage of cache hits for record-mode read operations.

For record-mode read operations, only the requested data, rather than a full track of data, is managed in the cache.

Disk to Cache Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer.

Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Back-end data

You can create performance reports that include the following information:

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Sequential Back-End I/O Percentage

The percentage of all I/O operations that are issued to the back-end storage resources. The operations are for the array and are sequential operations.

Back-End Read Data Rate (MiB/s)

The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)

The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)

The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Back-End Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation from the back-end storage resources.

Back-End Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation to the back-end storage resources.

Overall Back-End Transfer Size (KiB/op)

The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Other data

You can create performance reports that include the following information:

HPF Read I/O Rate (ops/s)

The average number of read operations per second that are issued by the High Performance FICON® feature of the storage system.

HPF Write I/O Rate (ops/s)

The average number of write operations per second that are issued by the High Performance FICON feature of the storage system.

Total HPF I/O Rate (ops/s)

The average number of I/O operations per second that are issued by the High Performance FICON feature of the storage system. This value includes both read and write operations.

HPF I/O Percentage

The percentage of all I/O operations that are issued by the High Performance FICON feature of the storage system.

PPRC Transfer Rate (ops/s)

The average number of tracks per second that are transferred to the secondary device of a Peer-to-Peer Remote Copy (PPRC) pair. This value shows the activity for the source of the PPRC relationship, but shows no activity for the target.

Disk Utilization Percentage

The average percentage of time that the disks that are associated with an array are busy.

No value is calculated for this property if there are multiple ranks in the extent pool where the thin-provisioned volumes are allocated. In this case, the value **N/A** is displayed. This limitation applies only to DS8000® storage systems.

If there is only a single rank in the extent pool, the value for this property is calculated regardless of the thin-provisioned volumes.

Tip: Some highly sequential workloads such as batch or backup processing might continually exceed the threshold because they drive the arrays to high utilization percentages. For these types of workloads, a high utilization indicates that the work is being performed very efficiently and is not a cause for concern.

For DS8000 storage systems, this property is available only for 8.5.0 and later. For earlier versions, the value **N/A** is shown.

Data for storage system controllers in performance reports

You can include general information about storage system controllers in performance reports.

Information about storage system controllers

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Controller Name

The name that was assigned to the controller when it was added to the system.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

- [Performance metrics for storage system controllers on DS8000 storage systems](#)

You can include front end data, cache data, back-end data, and other data for storage system controllers on DS8000® series systems in performance reports.

- [Performance metrics for storage system controllers on block servers](#)

You can include performance data for volumes and caches for storage system controllers on block servers in performance reports.

Performance metrics for storage system controllers on DS8000 storage systems

You can include front end data, cache data, back-end data, and other data for storage system controllers on DS8000® series systems in performance reports.

Front end data

You can create performance reports that include the following information:

Normal Read I/O Rate (ops/s)

The average number of nonsequential read operations per second.

Sequential Read I/O Rate (ops/s)

The average number of sequential read operations per second.

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Normal Write I/O Rate (ops/s)

The average number of nonsequential write operations per second.

Sequential Write I/O Rate (ops/s)

The average number of sequential write operations per second.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Normal I/O Rate (ops/s)

The average number of nonsequential I/O operations per second. This value includes both read and write operations.

Total Sequential I/O Rate (ops/s)

The average number of sequential I/O operations per second. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Record Mode Read I/O Rate (ops/s)

The average number of I/O operations per second for record-mode read operations.

For record-mode read operations, only the requested data is managed in the cache rather than a full track of data.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Write Cache Delay I/O Rate (ops/s)

The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Normal Read Cache Hit Percentage

The percentage of nonsequential read operations that find data in the cache.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Sequential Read Cache Hit Percentage

The percentage of sequential read operations that find data in the cache.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Normal Write Cache Hit Percentage

The percentage of nonsequential write operations that are handled in the cache.

Sequential Write Cache Hit Percentage

The percentage of sequential write operations that are handled in the cache.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Normal Cache Hit Percentage

The percentage of nonsequential I/O operations that are handled in the cache. This value includes both read and write operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Sequential Cache Hit Percentage

The percentage of sequential I/O operations that are handled in the cache. This value includes both read and write operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Record Mode Read Cache Hit Percentage

The percentage of cache hits for record-mode read operations.

For record-mode read operations, only the requested data, rather than a full track of data, is managed in the cache.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Disk to Cache Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer.

Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Back-end data

You can create performance reports that include the following information:

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Data Rate (MiB/s)

The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)

The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)

The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Back-End Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation from the back-end storage resources.

Back-End Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation to the back-end storage resources.

Overall Back-End Transfer Size (KiB/op)

The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Other data

You can create performance reports that include the following information:

HPF Read I/O Rate (ops/s)

The average number of read operations per second that are issued by the High Performance FICON® feature of the storage system.

HPF Write I/O Rate (ops/s)

The average number of write operations per second that are issued by the High Performance FICON feature of the storage system.

Total HPF I/O Rate (ops/s)

The average number of I/O operations per second that are issued by the High Performance FICON feature of the storage system. This value includes both read and write operations.

HPF I/O Percentage

The percentage of all I/O operations that are issued by the High Performance FICON feature of the storage system.

PPRC Transfer Rate (ops/s)

The average number of tracks per second that are transferred to the secondary device of a Peer-to-Peer Remote Copy (PPRC) pair. This value shows the activity for the source of the PPRC relationship, but shows no activity for the target.

Cache Holding Time (s)

The average number of seconds that I/O data for a storage system node is held in the cache. A short cache-holding time indicates adverse performance.

Performance metrics for storage system controllers on block servers

You can include performance data for volumes and caches for storage system controllers on block servers in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Data for storage system modules in performance reports

You can include properties of storage system modules, and other information about storage system modules in performance reports.

Information about storage system modules

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Module Name

The name that was assigned to the module when it was added to the system.

Component properties

You can create performance reports that include the following information:

Storage Module IP Address

The IP address of the resource.

Storage Module WWN

The worldwide name of the module.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Status information

You can create performance reports that include the following information:

Storage Module Status

The condition of the resource, for example normal, warning, or error.

Storage Module Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

- [Performance metrics for storage system modules on XIV systems and IBM Spectrum Accelerate](#)

You can include performance metrics for volumes, caches, and other data for storage system modules on XIV® systems and IBM Spectrum Accelerate in performance reports.

Performance metrics for storage system modules on XIV systems and IBM Spectrum Accelerate

You can include performance metrics for volumes, caches, and other data for storage system modules on XIV® systems and IBM Spectrum Accelerate in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Read Data Cache Hit Percentage

The percentage of all read data that is read from the cache.

Write Data Cache Hit Percentage

The percentage of all write data that is written to cache slots that are marked as modified.

Overall Data Cache Hit Percentage

The percentage of all data that is handled in the cache. This value includes read data that is read from the cache and write data that is written to cache slots that are marked as modified.

Read Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a read-cache hit operation.

Write Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a write-cache hit operation.

Overall Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a cache hit operation. This value includes the times for both read-cache hit and write-cache hit operations.

Read Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a read-cache miss operation.

Write Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a write-cache miss operation.

Overall Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a cache miss operation. This value includes the times for both read-cache miss and write-cache miss operations.

SSD Read Cache Hit Percentage

The percentage of read operations that find data in the cache on a solid-state drive (SSD). The value for this metric is also included in the value for the Overall Read Cache Hit Percentage metric.

This metric is only available for XIV systems that use solid-state drives as drives for caching.

SSD Read Data Cache Hit Percentage

The percentage of all read data that was read from cache memory on a solid-state drive.

This metric is only available for XIV systems that use solid-state drives as drives for caching.

SSD Read Cache Hit Response Time (ms/op)

The average number of milliseconds that it takes to complete a hit operation on the read cache on a solid-state drive. The value for this metric is also included in the value for the Read Cache Hit Response Time metric.

This metric is only available for XIV systems that use solid-state drives as drives for caching.

Other data

You can create performance reports that include the following information:

Small Transfers I/O Percentage

The percentage of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers I/O Percentage

The percentage of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers I/O Percentage

The percentage of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers I/O Percentage

The percentage of I/O operations with a data transfer size that is greater than 512 KiB.

Small Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a data transfer size that is greater than 512 KiB.

Small Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation with a data transfer size that is greater than 512 KiB.

Data for storage system pools in performance reports

You can include general information, capacity data, properties, and other information about storage system pools in performance reports.

Information about storage system pools

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Capacity and usage data

You can create performance reports that include the following information:

Storage Pool Capacity (GiB)

The total amount of storage space in a pool.

Storage Pool Available Space (GiB)

The amount of unused space that is not reserved for volumes in pools that are on the storage system.

IBM Spectrum Control uses the following formula to determine this value:

pool capacity - used space

For XIV® systems and IBM Spectrum Accelerate, this value represents the unallocated physical space in the pool, not the unallocated virtual space. For some storage systems, this value usually includes only the usable capacity, but might also include overhead space if the pool is unformatted.

Storage Pool Total Volume Capacity (GiB)

The total storage space on all the volumes in a pool, which includes thin-provisioned and standard volumes. For thin-provisioned volumes, this value includes virtual space.

Storage Pool Allocated Space (GiB)

The amount of space that is reserved for all the volumes in a pool, which includes both thin-provisioned and standard volumes. The space that is allocated for thin-provisioned volumes is less than their virtual capacity, which is shown in the Storage Pool Total Volume Capacity (GiB) property. If a pool does not contain thin-provisioned volumes, this value is the same as the value in the Storage Pool Total Volume Capacity (GiB) property. This value is equal to the value in the Storage Pool Used Volume Space (GiB) property for the following resources:

- Resources other than those that are running IBM Spectrum Virtualize and are configured as back-end storage
- Resources that are running IBM Spectrum Virtualize, are configured as back-end storage, and are not thin-provisioned

Storage Pool Used Volume Space (GiB)

The amount of allocated space that is used by the volumes in a pool, which includes thin-provisioned and standard volumes.

For resources that are running IBM Spectrum Virtualize, you can preallocate thin-provisioned volume space when volumes are created. For these resources, the Storage Pool Used Space might be different than the Storage Pool Allocated Space for pools that contain thin-provisioned volumes. In other cases, the values for Storage Pool Used Space and Storage Pool Allocated Space are equal.

This value is accurate as of the most recent time that IBM Spectrum Control collected data about a volume. The value in this property might not be 100% accurate for the current state of volumes. This inaccuracy might occur because data collection is run on a set schedule and the used space on volumes can change rapidly.

Storage Pool Extent Size (MiB)

The size of the extent that was specified when a pool was created. Smaller extent sizes limit the maximum size of the volumes that can be created in a pool. Smaller extent sizes minimize the amount of potentially wasted space per volume.

This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Pool Assigned Volume Space (GiB)

The amount of space in the pool that is on volumes that are assigned to a server or storage virtualizer.

Storage Pool Unassigned Volume Space (GiB)

The amount of volume space in the pool that is not assigned to a server or storage virtualizer.

Storage Pool Number of Storage Volumes

The number of volumes in the storage pool.

Storage Pool Number of MDisks

The number of managed disks in a storage pool.

Storage Pool Physical Allocation Percentage

The percentage of physical space in a pool that is reserved for volumes. This value is always less than or equal to 100% because you cannot reserve more physical space than is available in a pool.

IBM Spectrum Control uses the following formula to determine the allocation percentage:

$$(\text{allocated space} \div \text{pool capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a total pool size of 200 GiB. Therefore, the space that is reserved for volumes is 50 GiB.

Storage Pool Virtual Allocation Percentage

The percentage of physical space in a pool that is committed to the total virtual capacity of the volumes in the pool. In thin-provisioned environments, this percentage exceeds 100% if a pool is overcommitted (over-provisioned).

IBM Spectrum Control uses the following formula to determine the allocation percentage:

$$(\text{total volume capacity} \div \text{pool capacity}) \times 100$$

For example, the allocation percentage is 200% for a total pool size of 15 GiB. Therefore, the virtual capacity that is committed to the volumes in the pool is 30 GiB. This configuration means that twice as much space is committed than is physically contained in the pool. If the allocation percentage is 100% for the same pool, then the virtual capacity that is committed to the pool is 15 GiB. This configuration means that all the physical capacity of the pool is already allocated to volumes. An allocation percentage that is higher than 100% is considered aggressive. The pool has insufficient physical capacity to satisfy the maximum allocation for all the thin-provisioned volumes in the pool. In such cases, you can use the value for Storage Pool Shortfall Percentage to estimate how critical the shortage of space is for a pool.

This value is only available for pools with thin-provisioned volumes.

Storage Pool Shortfall Percentage

The percentage of the remaining unallocated volume space in a pool that is not available to be allocated.

The higher the percentage, the more critical the shortfall of pool space.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{unallocatable space} \div (\text{virtual capacity} - \text{allocated space})) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in a pool reaches a critically high level. For example, the physical space in a pool might be less than the committed virtual space. In this case, the pool does not have enough space to fulfill the commitment to virtual space.

This value represents the percentage of the committed virtual space that is not available in a pool. As more space is used over time by volumes while the pool capacity remains the same, this percentage increases.

For example, the physical capacity of a pool is 70 GiB, however, 150 GiB of virtual space is committed to thin-provisioned volumes. If the volumes are using 50 GiB, then there is still 100 GiB committed to those volumes (150 GiB - 50 GiB). There is only 20 GiB of available pool space (70 GiB - 50 GiB). Because only 20 GiB of pool space is available, 80 GiB of the committed space cannot be allocated (100 GiB - 20 GiB). In this case, the percentage of committed space that cannot be allocated is 80% (80 GiB ÷ 100 GiB × 100).

This value is only available for pools with thin-provisioned volumes.

Storage Pool Unallocated Volume Space (GiB)

The amount of the Total Volume Capacity in the pool that is not allocated.

IBM Spectrum Control uses the following formula to determine this value:

$$\text{total volume capacity} - \text{allocated space}$$

The space that is allocated for thin-provisioned volumes is typically less than their virtual capacity. Therefore, the unallocated space represents the difference between the virtual capacity and the allocated space for all the volumes in the pool.

Storage Pool Unused Volume Space (GiB)

The amount of space that is allocated to the volumes in a pool and is not yet used.

IBM Spectrum Control uses the following formula to determine this value:

$$\text{allocated space} - \text{used space}$$

Storage Pool Unallocatable Volume Space (GiB)

The amount of space by which the Total Volume Capacity exceeds the physical capacity of a pool.

In thin-provisioned environments, it is possible to over commit (over provision) storage in a pool. If you create volumes with more virtual capacity than can be physically allocated in the pool, you can over commit storage in the pool.

This value represents the amount of volume space that cannot be allocated based on the current capacity of the pool.

Storage Pool Used Space Percentage

The percentage of allocated space that is used by the volumes in a pool, which includes thin-provisioned and standard volumes.

Storage Pool Compressed Virtual Capacity (GiB)

The total virtual capacity of all the volumes that are compressed in a pool.

Storage Pool Compressed Capacity (GiB)

The amount of storage space that is used by compressed volumes in a pool. For example, if 100 GiB of uncompressed data is compressed, and the size of the compressed data is 20 GiB, the value is 20.

Storage Pool Uncompressed Capacity (GiB)

The amount of storage space that is used if the compressed volume space is uncompressed. For example, if 100 GiB of uncompressed data is compressed, and the size of the compressed data is 20 GiB, the value is 100.

Storage Pool Maximum I/O Capability

The projected maximum number of I/O operations per second for a pool. This value is calculated based on the value in the Storage Pool Back-End Storage Disks property, and on the values in following properties:

- Storage Pool Back-End Storage System Type
- Storage Pool Back-End Storage RAID Level
- Storage Pool Back-End Storage Disk Type

This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Pool Back-End Storage Disks

The number of physical disks that contribute to the volumes on the back-end storage system. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Component properties

You can create performance reports that include the following information:

Storage Pool Is Encryptable

Shows whether the storage pool can be encrypted. If this value is **Yes**, the storage pool can be encrypted.

Storage Pool Is Encrypted

Shows whether the resource is encrypted. If this value is **Yes**, the resource is encrypted.

Storage Pool Is Solid State

Shows whether there are solid-state drives in the pool. This property can contain the following values:

Mixed

The pool contains both hard disk drives and solid-state drives.

Non solid state

The pool contains no solid-state drives.

Solid state

The pool contains a least one solid-state drive.

Storage Pool Is Thin Provisioned

Shows whether a pool, volume, or volume copy is thin-provisioned. If this value is **Yes**, the resource is thin-provisioned.

Storage Pool RAID Level

The RAID level of the resource, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the resource.

Storage Pool Warning Level

The percentage of used capacity of the storage pool at which a warning is generated.

Storage Pool Is Compression Active

Shows whether the compression feature is enabled on the storage pool. If this value is **Yes**, the compression feature is enabled.

Storage Pool Custom Tag 1, 2, and 3

User-defined text that is associated with a storage pool. You can add or edit the custom tags for a storage pool on the Properties notebook of the pool.

Storage Pool Back-End Storage System Type

The type of storage system that provides storage space to a pool. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Pool Back-End Storage RAID Level

The RAID level of the volumes on the back-end storage system that provide storage space to a pool. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Pool Back-End Storage Disk Type

The class and speed of the physical disks that contribute to the volumes on the back-end storage system. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Status information

You can create performance reports that include the following information:

Storage Pool Status

The condition of the resource, for example normal, warning, or error.

Storage Pool Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

- [Performance metrics for pools on SAN Volume Controller and Storwize systems](#)

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for volumes and back-end arrays for pools on these systems in performance reports.

- [Performance metrics for pools on DS8000 storage systems](#)

You can include performance metrics for volumes, caches, back-end arrays, and other data for pools that are on DS8000® storage systems in performance reports.

- [Performance metrics for pools on XIV systems and IBM Spectrum Accelerate](#)

You can include performance data for volumes, caches, and other data for pools on XIV systems and IBM Spectrum Accelerate in performance reports.

Performance metrics for pools on SAN Volume Controller and Storwize systems

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for volumes and back-end arrays for pools on these systems in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Maximum Read I/O Rate (ops/s)

The maximum read I/O rate of the volume in operations per second. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Back-end array data

You can create performance reports that include the following information:

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Maximum Back-End Read I/O Rate (ops/s)

The maximum number of read operations per second that are issued to the back-end storage resources. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Maximum Back-End Write I/O Rate (ops/s)

The maximum number of write operations per second that are issued to the back-end storage resources. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Back-End Read Data Rate (MiB/s)

The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)

The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)

The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation from the back-end storage resources.

Back-End Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation to the back-end storage resources.

Overall Back-End Transfer Size (KiB/op)

The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Back-End Read Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Peak Back-End Read Response Time (ms)

The longest time for a back-end storage resource to respond to a read operation.

Peak Back-End Write Response Time (ms)

The longest time for a back-end storage resource to respond to a write operation by a node.

Maximum Back-End Read Response Time (ms/op)

The maximum number of milliseconds for the back-end storage resources to respond to a read operation. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Maximum Back-End Write Response Time (ms/op)

The maximum number of milliseconds for the back-end storage resources to respond to a write operation. This metric is available only for hourly data and daily data for resources that are running IBM Spectrum Virtualize.

Back-End Read Queue Time (ms/op)

The average number of milliseconds that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Back-End Write Queue Time (ms/op)

The average number of milliseconds that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Overall Back-End Queue Time (ms/op)
The average number of milliseconds that a read or a write operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Read Queue Time (ms)
The longest time that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Write Queue Time (ms)
The longest time that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Performance metrics for pools on DS8000 storage systems

You can include performance metrics for volumes, caches, back-end arrays, and other data for pools that are on DS8000® storage systems in performance reports.

Volume data

You can create performance reports that include the following information:

Normal Read I/O Rate (ops/s)
The average number of nonsequential read operations per second.

Sequential Read I/O Rate (ops/s)
The average number of sequential read operations per second.

Overall Read I/O Rate (ops/s)
The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Normal Write I/O Rate (ops/s)
The average number of nonsequential write operations per second.

Sequential Write I/O Rate (ops/s)
The average number of sequential write operations per second.

Overall Write I/O Rate (ops/s)
The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Normal I/O Rate (ops/s)
The average number of nonsequential I/O operations per second. This value includes both read and write operations.

Total Sequential I/O Rate (ops/s)
The average number of sequential I/O operations per second. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)
The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Record Mode Read I/O Rate (ops/s)
The average number of I/O operations per second for record-mode read operations.
For record-mode read operations, only the requested data is managed in the cache rather than a full track of data.

Read Data Rate (MiB/s)
The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)
The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)
The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)
The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)
The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)
The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)
The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)
The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)
The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Back-end array data

You can create performance reports that include the following information:

Back-End Read I/O Rate (ops/s)
The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)
The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)
The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Data Rate (MiB/s)
The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)
The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)
The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Back-End Read Transfer Size (KiB/op)
The average number of KiB that are transferred per read operation from the back-end storage resources.

Back-End Write Transfer Size (KiB/op)
The average number of KiB that are transferred per write operation to the back-end storage resources.

Overall Back-End Transfer Size (KiB/op)
The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Cache data

You can create performance reports that include the following information:

Write Cache Delay I/O Rate (ops/s)
The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.
This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Normal Read Cache Hit Percentage
The percentage of nonsequential read operations that find data in the cache.
You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Sequential Read Cache Hit Percentage
The percentage of sequential read operations that find data in the cache.
You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Overall Read Cache Hit Percentage
The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.
You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Normal Write Cache Hit Percentage
The percentage of nonsequential write operations that are handled in the cache.

Sequential Write Cache Hit Percentage
The percentage of sequential write operations that are handled in the cache.

Overall Write Cache Hit Percentage
The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Normal Cache Hit Percentage
The percentage of nonsequential I/O operations that are handled in the cache. This value includes both read and write operations.
You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Sequential Cache Hit Percentage
The percentage of sequential I/O operations that are handled in the cache. This value includes both read and write operations.
You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Overall Cache Hit Percentage
The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.
You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Disk to Cache Transfer Rate (ops/s)
The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)
The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Delay Percentage
The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.
This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Record Mode Read Cache Hit Percentage
The percentage of cache hits for record-mode read operations.
For record-mode read operations, only the requested data, rather than a full track of data, is managed in the cache.

Other data

You can create performance reports that include the following information:

HPF Read I/O Rate (ops/s)
The average number of read operations per second that are issued by the High Performance FICON® feature of the storage system.

HPF Write I/O Rate (ops/s)
The average number of write operations per second that are issued by the High Performance FICON feature of the storage system.

Total HPF I/O Rate (ops/s)

The average number of I/O operations per second that are issued by the High Performance FICON feature of the storage system. This value includes both read and write operations.

HPF I/O Percentage

The percentage of all I/O operations that are issued by the High Performance FICON feature of the storage system.

PPRC Transfer Rate (ops/s)

The average number of tracks per second that are transferred to the secondary device of a Peer-to-Peer Remote Copy (PPRC) pair. This value shows the activity for the source of the PPRC relationship, but shows no activity for the target.

Performance metrics for pools on XIV systems and IBM Spectrum Accelerate

You can include performance data for volumes, caches, and other data for pools on XIV® systems and IBM Spectrum Accelerate in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Read Data Cache Hit Percentage

The percentage of all read data that is read from the cache.

Write Data Cache Hit Percentage

The percentage of all write data that is written to cache slots that are marked as modified.

Overall Data Cache Hit Percentage

The percentage of all data that is handled in the cache. This value includes read data that is read from the cache and write data that is written to cache slots that are marked as modified.

Read Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a read-cache hit operation.

Write Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a write-cache hit operation.

Overall Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a cache hit operation. This value includes the times for both read-cache hit and write-cache hit operations.

Read Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a read-cache miss operation.

Write Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a write-cache miss operation.

Overall Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a cache miss operation. This value includes the times for both read-cache miss and write-cache miss operations.

Other data

You can create performance reports that include the following information:

Small Transfers I/O Percentage

The percentage of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers I/O Percentage

The percentage of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers I/O Percentage

The percentage of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers I/O Percentage

The percentage of I/O operations with a data transfer size that is greater than 512 KiB.

Small Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a data transfer size that is greater than 512 KiB.

Small Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation with a data transfer size that is greater than 512 KiB.

Data for managed disks on storage systems in performance reports

You can include general information, capacity data, properties, and other information about managed disks on storage systems in performance reports.

Information about managed disks on storage systems

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Storage System MDisk Name

The name that was assigned to the managed disk on a storage system when it was added to the system.

Capacity and usage data

You can create performance reports that include the following information:

Storage System MDisk Capacity (GiB)

The amount of storage space on the managed disk.

Storage MDisk Available Space (GiB)

The amount of unused storage space on the managed disk on a storage system.

Storage System MDisk Strip Size (KB)

The RAID strip size on a managed disk on a storage system.

Component properties

You can create performance reports that include the following information:

Storage MDisk RAID Level

The RAID level of the managed disk, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the managed disk.

Storage MDisk Spare Goal

The number of spare drives that are required to maintain redundancy. Use spare drives to protect the system against drive failures in the array on a managed disk on a storage virtualizer.

Storage System MDisk Type

The type of managed disk on a storage system. For example, the disk on a storage system can be a local managed disk.

Storage System MDisk Mode

The access mode of a managed disk on a storage virtualizer. The access mode describes how extents are provided for virtual disks. Extents can be provided to virtual disks in the following ways:

Array

Extents are provided from local disks.

Managed

Extents are provided from a back-end storage volume.

Unmanaged

The managed disk is not used in the system.

Storage System MDisk Is Balanced

Shows whether LUNs are balanced across storage controllers on the managed disk. If this value is **Yes**, the LUNs are balanced.

Storage System MDisk Fast Write State

Shows whether the cache for a volume on a disk that is managed by a storage system is empty, contains data, or is corrupted.

Storage System MDisk Write Verify

Shows whether all write operations on a managed disk on a storage system are verified by an immediate follow-up read operation. The follow-up read operation verifies that the write operation was successful. If this value is **Yes**, all write operations are verified by a follow-up read operation.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Status information

You can create performance reports that include the following information:

Storage MDisk Status

The condition of the resource, for example normal, warning, or error.

Storage MDisk Native Status

Shows the level of access of nodes in the system to a managed disk or volume on a storage system. The level of access can be online, offline, degraded, or excluded.

- [Performance metrics for managed disks on SAN Volume Controller and Storwize systems](#)

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for back-end arrays on managed disks on these systems in performance reports.

Performance metrics for managed disks on SAN Volume Controller and Storwize systems

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for back-end arrays on managed disks on these systems in performance reports.

Back-end array data

You can create performance reports that include the following information:

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Data Rate (MiB/s)

The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)

The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)

The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Peak Back-End Read Response Time (ms)

The longest time for a back-end storage resource to respond to a read operation.

Peak Back-End Write Response Time (ms)

The longest time for a back-end storage resource to respond to a write operation by a node.

Back-End Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation from the back-end storage resources.

Back-End Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation to the back-end storage resources.

Overall Back-End Transfer Size (KiB/op)

The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Back-End Read Queue Time (ms/op)

The average number of milliseconds that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Back-End Write Queue Time (ms/op)

The average number of milliseconds that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Overall Back-End Queue Time (ms/op)

The average number of milliseconds that a read or a write operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Read Queue Time (ms)

The longest time that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Write Queue Time (ms)

The longest time that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Data for storage system nodes in performance reports

You can include general information, capacity data, properties, and other information about storage system nodes in performance reports.

Information about storage system nodes

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Node Name

The name that was assigned to the storage system node when it was added to the system.

Storage I/O Group Name

The name that was assigned to the I/O group when it was added to the system.

Component properties

You can create performance reports that include the following information:

Storage Node IP Address

The IP address of the resource.

Storage Node WWN

The worldwide name of the node.

Storage Node Configuration

The number of the node for the resource. This value can be either 0 or 1.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Status information

You can create performance reports that include the following information:

Storage Node Status

Shows whether a storage system node is online.

- [Performance metrics for nodes on SAN Volume Controller and Storwize systems](#)

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for ports, front ends, caches, back-end arrays, and other data for nodes on these systems in performance reports.

Performance metrics for nodes on SAN Volume Controller and Storwize systems

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for ports, front ends, caches, back-end arrays, and other data for nodes on these systems in performance reports.

Port data

You can create performance reports that include the following information:

Port Send I/O Rate (ops/s)

The average number of I/O operations per second for operations in which data is sent from a port. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive I/O Rate (ops/s)

The average number of I/O operations per second for operations in which the port receives data. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port I/O Rate (ops/s)

The average number of send operations and receive operations per second.

Port to Host Send I/O Rate (ops/s)

The average number of IOs per second that are sent by the storage system to the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Port to Host Receive I/O Rate (ops/s)
The average number of IOs per second that are received by the storage system from the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Total Port to Host I/O Rate (ops/s)
The average number of IOs per second that are transmitted between the storage system and the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Port to Disk Send I/O Rate (ops/s)
The average number of IOs per second that are sent from the storage system to the back-end storage it is virtualizing. Use this metric to help measure the rate of data that is sent to back-end storage.

Port to Disk Receive I/O Rate (ops/s)
The average number of exchanges per second that are received from back-end storage resources.

Total Port to Disk I/O Rate (ops/s)
The average number of IOs per second that are transmitted between the storage system and the back-end storage it is virtualizing. Use this metric to help measure the rate of data that is sent to back-end storage.

Port to Local Node Send I/O Rate (ops/s)
The average number of IOs per second that are sent to other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Port to Local Node Receive I/O Rate (ops/s)
The average number of IOs per second that are received from other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Total Port to Local Node I/O Rate (ops/s)
The average number of IOs per second that are transmitted between the resource and other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Port to Remote Node Send I/O Rate (ops/s)
The average number of IOs per second that are sent to nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Port to Remote Node Receive I/O Rate (ops/s)
The average number of IOs per second that are received from nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Total Port to Remote Node I/O Rate (ops/s)
The average number of IOs per second that are transmitted between the resource and nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Port Send Data Rate (MiB/s)
The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)
The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)
The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port to Host Send Data Rate (MiB/s)
The average rate at which data is sent to host computers. The rate is measured in MiB per second.

Port to Host Receive Data Rate (MiB/s)
The average rate at which data is received from host computers. The rate is measured in MiB per second.

Total Port to Host Data Rate (MiB/s)
The average rate at which data is transmitted between host computers and the component. The rate is measured in MiB per second and includes both send and receive operations.

Port to Disk Sph_port_send_bandwidth_percentagend Data Rate (MiB/s)
The average rate at which data is sent to back-end storage resources. The rate is measured in MiB per second.

Port to Disk Receive Data Rate (MiB/s)
The average rate at which data is received from back-end storage resources. The rate is measured in MiB per second.

Total Port to Disk Data Rate (MiB/s)
The average rate at which data is transmitted between back-end storage resources and the component. The rate is measured in MiB per second and includes both send and receive operations.

Port to Local Node Send Data Rate (MiB/s)
The average rate at which data is sent to other nodes that are in the local cluster. The rate is measured in MiB per second.

Port to Local Node Receive Data Rate (MiB/s)
The average rate at which data is received from other nodes that are in the local cluster. The rate is measured in MiB per second.

Total Port to Local Node Data Rate (MiB/s)
The average rate at which data is transmitted between the component and other nodes that are in the local cluster. The rate is measured in MiB per second.

Port to Remote Node Send Data Rate (MiB/s)
The average rate at which data is sent to nodes that are in the remote cluster. The rate is measured in MiB per second.

Port to Remote Node Receive Data Rate (MiB/s)
The average rate at which data is received from nodes that are in the remote cluster. The rate is measured in MiB per second.

Total Port to Remote Node Data Rate (MiB/s)
The average rate at which data is transmitted between the component and nodes that are in the remote cluster. The rate is measured in MiB per second.

Port to Local Node Send Response Time (ms/op)
The average number of milliseconds to complete a send operation to another node that is in the local cluster. This value represents the external response time of the transfers.

Port to Local Node Receive Response Time (ms/op)
The average number of milliseconds to complete a receive operation from another node that is in the local cluster. This value represents the external response time of the transfers.

Overall Port to Local Node Response Time (ms/op)
The average number of milliseconds to complete a send or receive operation with another node that is in the local cluster. This value represents the external response time of the transfers.

Port to Remote Node Send Response Time (ms/op)
The average number of milliseconds to complete a send operation to a node that is in the remote cluster. This value represents the external response time of the transfers.

Port to Remote Node Receive Response Time (ms/op)

The average number of milliseconds to complete a receive operation from a node that is in the remote cluster. This value represents the external response time of the transfers.

Overall Port to Remote Node Response Time (ms/op)

The average number of milliseconds to complete a send operation to, or a receive operation from a node in the remote cluster. This value represents the external response time of the transfers.

Port to Local Node Send Queue Time (ms/op)

The average time in milliseconds that a send operation spends in the queue before the operation is processed. This value represents the queue time for send operations that are issued to other nodes that are in the local cluster.

Port to Local Node Receive Queue Time (ms/op)

The average time in milliseconds that a receive operation spends in the queue before the operation is processed. This value represents the queue time for receive operations that are issued from other nodes that are in the local cluster.

Overall Port to Local Node Queue Time (ms/op)

The average number of milliseconds that a send or receive operation spends in the queue before the operation is processed. This value is for send and receive operations that are issued between the component and other nodes that are in the local cluster.

Port to Remote Node Send Queue Time (ms/op)

The average time in milliseconds that a send operation spends in the queue before the operation is processed. This value represents the queue time for send operations that are issued to a node that is in the remote cluster.

Port to Remote Node Receive Queue Time (ms/op)

The average time in milliseconds that a receive operation spends in the queue before the operation is processed. This value represents the queue time for receive operations that are issued from a node that is in the remote cluster.

Overall Port to Remote Node Queue Time (ms/op)

The average number of milliseconds that a send or receive operation spends in the queue before the operation is processed. This value is for send and receive operations that are issued between the component and a node that is in the remote cluster.

Front end data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Write Cache Delay I/O Rate (ops/s)

The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Overflow I/O Rate (ops/s)

The average number of tracks per second that are written but are delayed because there is not enough space in the write cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Flush Through I/O Rate (ops/s)

The average number of tracks per second that are written to disk in flush-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Write Through I/O Rate (ops/s)

The average number of tracks per second that are written to disk in write-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable. You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Read Ahead Percentage of Cache Hits

The percentage of all read cache hits that occur on pre-staged data. This value applies only to the volume copy cache if the resource is running IBM Spectrum Virtualize 7.3 or later.

Dirty Write Percentage of Cache Hits

The percentage of all cache write hits that occur on data in the cache that is marked as modified. This value represents how effectively write operations are coalesced before the data is written to disk. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Overflow Percentage

The percentage of write operations that are delayed because there is not enough space in the write cache.

Write Cache Flush Through Percentage

The percentage of tracks that are written to disk in flush-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Write Through Percentage

The percentage of tracks that are written to disk in write-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Disk to Cache Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Back-end data

You can create performance reports that include the following information:

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Data Rate (MiB/s)

The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)

The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)

The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Peak Back-End Read Response Time (ms)

The longest time for a back-end storage resource to respond to a read operation.

Peak Back-End Write Response Time (ms)

The longest time for a back-end storage resource to respond to a write operation by a node.

Back-End Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation from the back-end storage resources.

Back-End Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation to the back-end storage resources.

Overall Back-End Transfer Size (KiB/op)

The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Back-End Read Queue Time (ms/op)

The average number of milliseconds that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Back-End Write Queue Time (ms/op)

The average number of milliseconds that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Overall Back-End Queue Time (ms/op)

The average number of milliseconds that a read or a write operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Read Queue Time (ms)

The longest time that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Write Queue Time (ms)

The longest time that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Other data

You can create performance reports that include the following information:

Global Mirror Write I/O Rate (op/s)

The average number of write operations per second that are issued to the Global Mirror secondary site.

Global Mirror Overlapping Write Percentage

The percentage of overlapping write operations that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.

Applies to resources that are running IBM Spectrum Virtualize.

Global Mirror Overlapping Write I/O Rate (op/s)

The average number of overlapping write operations per second that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.

This value applies to resources that are running IBM Spectrum Virtualize.

Global Mirror Secondary Write Lag (ms/op)

The average number of additional milliseconds that it takes to service each secondary write operation for Global Mirror. This value does not include the time to service the primary write operations.

You monitor the value of Global Mirror Secondary Write Lag to identify delays that occurred during the process of writing data to the secondary site.

Average number of additional milliseconds it took to service each secondary write operation for Global Mirror, beyond the time needed to service the primary writes

Peak Read Response Time (ms)

The worst response time measured for a read operation in the sample interval.

Peak Write Response Time (ms)

The worst response time measured for a write operation in the sample interval.

Link Failure Rate (count/s)

The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.

Loss of Sync Rate (count/s)

The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled.

Synchronization is assumed lost after a timeout interval expires.

Loss of Signal Rate (count/s)

The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.

CRC Error Rate (count/s)

The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.

Primitive Sequence Protocol Error Rate (count/s)

The average number of primitive sequence protocol errors per second that are detected.

This error occurs when there is a link failure for a port.

Invalid Transmission Word Rate (count/s)

The average number of bit errors per second that are detected.

Processor Utilization Percentage

The average percentage of time that the processors on nodes are busy doing system I/O tasks. This value applies only to resources that are running IBM Spectrum Virtualize.

Overall Host Attributed Response Time Percentage

The percentage of the average response time that can be attributed to delays from host systems. This value includes both read response times and write response times, and can help you diagnose slow hosts and fabrics that are not working efficiently.

For read response time, the value is based on the time that it takes for hosts to respond to transfer-ready notifications from the nodes. For write response time, the value is based on the time that it takes for hosts to send the write data after the node responds to a transfer-ready notification.

Zero Buffer-to-Buffer Credit Timer (microseconds)

The number of microseconds that the port is not able to send frames between ports because there is insufficient buffer-to-buffer credit.

In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports. Buffer-to-buffer credit is measured from the last time that metadata was collected.

If this metric is not available, use the Port Send Delay Time metric instead.

Zero Buffer-to-Buffer Credit Percentage

The amount of time, as a percentage, that the port was not able to send frames between ports because of insufficient buffer-to-buffer credit. The amount of time value is measured from the last time that metadata was collected. In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports.

Data for storage system I/O groups in performance reports

You can include general information, capacity data, properties, and other information about storage system I/O groups in performance reports.

Information about storage system I/O groups

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage I/O Group Name

The name that was assigned to the I/O group when it was added to the system.

Component properties

You can create performance reports that include the following information:

Storage I/O Group Mirroring Total Memory (MiB)

The total amount of memory that is allocated on the nodes in an I/O group to provide volume mirroring functions.

Storage I/O Group Mirroring Free Memory (MiB)

The amount of available memory on the nodes in an I/O group to provide volume mirroring functions.

Storage I/O Group FlashCopy Total Memory (MiB)

The total amount of memory that is allocated on the nodes in an I/O group to provide FlashCopy® mirroring functions.

Storage I/O Group FlashCopy Free Memory (MiB)

The amount of available memory on the nodes in an I/O group to provide FlashCopy mirroring functions.

Storage I/O Group Remote Copy Total Memory (MiB)

The total amount of memory that is allocated on the nodes in an I/O group to provide mirroring functions by using a remote copy.

Storage I/O Group Remote Copy Free Memory (MiB)

The amount of available memory on the nodes in an I/O group to provide mirroring functions by using a remote copy.

Storage I/O Group RAID Total Memory (MiB)

The total amount of memory that is allocated on the nodes in an I/O group to provide RAID mirroring functions.

Storage I/O Group RAID Free Memory (MiB)

The amount of available memory on the nodes in an I/O group to provide RAID mirroring functions.

Status information

You can create performance reports that include the following information:

Storage I/O Group Maintenance

Shows whether the I/O group is in maintenance mode. If this value is **Yes**, the I/O group is in maintenance mode.

Storage I/O Group Is Compression Active

Shows whether the compression feature is enabled on the volumes in the storage I/O group. If this value is **Yes**, the compression feature is enabled.

Storage I/O Group Is Compression Supported

Shows whether the compression feature is available for volumes in the storage I/O group. If this value is **Yes**, the compression feature is available.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

- **Performance metrics for I/O groups on SAN Volume Controller and Storwize systems**

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for ports, volumes, caches, back-end arrays, and other data for I/O groups on these systems in performance reports.

Performance metrics for I/O groups on SAN Volume Controller and Storwize systems

A storage environment can include SAN Volume Controller systems, Storwize® V7000 systems, and a Storwize V7000 Unified systems. You can include performance metrics for ports, volumes, caches, back-end arrays, and other data for I/O groups on these systems in performance reports.

Port data

You can create performance reports that include the following information:

Port Send I/O Rate (ops/s)

The average number of I/O operations per second for operations in which data is sent from a port. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive I/O Rate (ops/s)

The average number of I/O operations per second for operations in which the port receives data. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port I/O Rate (ops/s)

The average number of send operations and receive operations per second.

Port to Host Send I/O Rate (ops/s)

The average number of IOs per second that are sent by the storage system to the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Port to Host Receive I/O Rate (ops/s)

The average number of IOs per second that are received by the storage system from the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Total Port to Host I/O Rate (ops/s)

The average number of IOs per second that are transmitted between the storage system and the hosts that are accessing its storage. Use this metric to help measure host workload against the storage system.

Port to Disk Send I/O Rate (ops/s)

The average number of IOs per second that are sent from the storage system to the back-end storage it is virtualizing. Use this metric to help measure the rate of data that is sent to back-end storage.

Port to Disk Receive I/O Rate (ops/s)

The average number of exchanges per second that are received from back-end storage resources.

Total Port to Disk I/O Rate (ops/s)

The average number of IOs per second that are transmitted between the storage system and the back-end storage it is virtualizing. Use this metric to help measure the rate of data that is sent to back-end storage.

Port to Local Node Send I/O Rate (ops/s)

The average number of IOs per second that are sent to other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Port to Local Node Receive I/O Rate (ops/s)

The average number of IOs per second that are received from other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Total Port to Local Node I/O Rate (ops/s)
The average number of I/Os per second that are transmitted between the resource and other nodes within the local cluster. Use this metric to understand the rate of inter-cluster communication.

Port to Remote Node Send I/O Rate (ops/s)
The average number of I/Os per second that are sent to nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Port to Remote Node Receive I/O Rate (ops/s)
The average number of I/Os per second that are received from nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Total Port to Remote Node I/O Rate (ops/s)
The average number of I/Os per second that are transmitted between the resource and nodes that are in a remote cluster. Use this metric to understand the amount of remote replication workload.

Port Send Data Rate (MiB/s)
The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)
The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)
The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port to Host Send Data Rate (MiB/s)
The average rate at which data is sent to host computers. The rate is measured in MiB per second.

Port to Host Receive Data Rate (MiB/s)
The average rate at which data is received from host computers. The rate is measured in MiB per second.

Total Port to Host Data Rate (MiB/s)
The average rate at which data is transmitted between host computers and the component. The rate is measured in MiB per second and includes both send and receive operations.

Port to Disk Sph_port_send_bandwidth_percentageend Data Rate (MiB/s)
The average rate at which data is sent to back-end storage resources. The rate is measured in MiB per second.

Port to Disk Receive Data Rate (MiB/s)
The average rate at which data is received from back-end storage resources. The rate is measured in MiB per second.

Total Port to Disk Data Rate (MiB/s)
The average rate at which data is transmitted between back-end storage resources and the component. The rate is measured in MiB per second and includes both send and receive operations.

Port to Local Node Send Data Rate (MiB/s)
The average rate at which data is sent to other nodes that are in the local cluster. The rate is measured in MiB per second.

Port to Local Node Receive Data Rate (MiB/s)
The average rate at which data is received from other nodes that are in the local cluster. The rate is measured in MiB per second.

Total Port to Local Node Data Rate (MiB/s)
The average rate at which data is transmitted between the component and other nodes that are in the local cluster. The rate is measured in MiB per second.

Port to Remote Node Send Data Rate (MiB/s)
The average rate at which data is sent to nodes that are in the remote cluster. The rate is measured in MiB per second.

Port to Remote Node Receive Data Rate (MiB/s)
The average rate at which data is received from nodes that are in the remote cluster. The rate is measured in MiB per second.

Total Port to Remote Node Data Rate (MiB/s)
The average rate at which data is transmitted between the component and nodes that are in the remote cluster. The rate is measured in MiB per second.

Port to Local Node Send Response Time (ms/op)
The average number of milliseconds to complete a send operation to another node that is in the local cluster. This value represents the external response time of the transfers.

Port to Local Node Receive Response Time (ms/op)
The average number of milliseconds to complete a receive operation from another node that is in the local cluster. This value represents the external response time of the transfers.

Overall Port to Local Node Response Time (ms/op)
The average number of milliseconds to complete a send or receive operation with another node that is in the local cluster. This value represents the external response time of the transfers.

Port to Remote Node Send Response Time (ms/op)
The average number of milliseconds to complete a send operation to a node that is in the remote cluster. This value represents the external response time of the transfers.

Port to Remote Node Receive Response Time (ms/op)
The average number of milliseconds to complete a receive operation from a node that is in the remote cluster. This value represents the external response time of the transfers.

Overall Port to Remote Node Response Time (ms/op)
The average number of milliseconds to complete a send operation to, or a receive operation from a node in the remote cluster. This value represents the external response time of the transfers.

Port to Local Node Send Queue Time (ms/op)
The average time in milliseconds that a send operation spends in the queue before the operation is processed. This value represents the queue time for send operations that are issued to other nodes that are in the local cluster.

Port to Local Node Receive Queue Time (ms/op)
The average time in milliseconds that a receive operation spends in the queue before the operation is processed. This value represents the queue time for receive operations that are issued from other nodes that are in the local cluster.

Overall Port to Local Node Queue Time (ms/op)
The average number of milliseconds that a send or receive operation spends in the queue before the operation is processed. This value is for send and receive operations that are issued between the component and other nodes that are in the local cluster.

Port to Remote Node Send Queue Time (ms/op)
The average time in milliseconds that a send operation spends in the queue before the operation is processed. This value represents the queue time for send operations that are issued to a node that is in the remote cluster.

Port to Remote Node Receive Queue Time (ms/op)
The average time in milliseconds that a receive operation spends in the queue before the operation is processed. This value represents the queue time for receive operations that are issued from a node that is in the remote cluster.

Overall Port to Remote Node Queue Time (ms/op)

The average number of milliseconds that a send or receive operation spends in the queue before the operation is processed. This value is for send and receive operations that are issued between the component and a node that is in the remote cluster.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Back-end array data

You can create performance reports that include the following information:

Back-End Read I/O Rate (ops/s)

The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)

The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)

The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Data Rate (MiB/s)

The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)

The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)

The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)

The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Peak Back-End Read Response Time (ms)

The longest time for a back-end storage resource to respond to a read operation.

Peak Back-End Write Response Time (ms)

The longest time for a back-end storage resource to respond to a write operation by a node.

Back-End Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation from the back-end storage resources.

Back-End Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation to the back-end storage resources.

Overall Back-End Transfer Size (KiB/op)

The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Back-End Read Queue Time (ms/op)

The average number of milliseconds that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Back-End Write Queue Time (ms/op)

The average number of milliseconds that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Overall Back-End Queue Time (ms/op)

The average number of milliseconds that a read or a write operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Read Queue Time (ms)

The longest time that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Write Queue Time (ms)

The longest time that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Cache data

You can create performance reports that include the following information:

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Flush Through I/O Rate (ops/s)

The average number of tracks per second that are written to disk in flush-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Write Through I/O Rate (ops/s)

The average number of tracks per second that are written to disk in write-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Overflow I/O Rate (ops/s)

The average number of tracks per second that are written but are delayed because there is not enough space in the write cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Delay I/O Rate (ops/s)

The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Disk to Cache Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer.

Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Read Ahead Percentage of Cache Hits

The percentage of all read cache hits that occur on pre-staged data. This value applies only to the volume copy cache if the resource is running IBM Spectrum Virtualize 7.3 or later.

Dirty Write Percentage of Cache Hits

The percentage of all cache write hits that occur on data in the cache that is marked as modified. This value represents how effectively write operations are coalesced before the data is written to disk. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Flush Through Percentage

The percentage of tracks that are written to disk in flush-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Write Through Percentage

The percentage of tracks that are written to disk in write-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Overflow Percentage

The percentage of write operations that are delayed because there is not enough space in the write cache.

Other data

You can create performance reports that include the following information:

Global Mirror Write I/O Rate (op/s)

The average number of write operations per second that are issued to the Global Mirror secondary site.

Global Mirror Overlapping Write Percentage

The percentage of overlapping write operations that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.

Applies to resources that are running IBM Spectrum Virtualize.

Global Mirror Overlapping Write I/O Rate (op/s)

The average number of overlapping write operations per second that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.

This value applies to resources that are running IBM Spectrum Virtualize.

Peak Read Response Time (ms)

The worst response time measured for a read operation in the sample interval.

Peak Write Response Time (ms)

The worst response time measured for a write operation in the sample interval.

Global Mirror Secondary Write Lag (ms/op)

The average number of additional milliseconds that it takes to service each secondary write operation for Global Mirror. This value does not include the time to service the primary write operations.

You monitor the value of Global Mirror Secondary Write Lag to identify delays that occurred during the process of writing data to the secondary site.

Average number of additional milliseconds it took to service each secondary write operation for Global Mirror, beyond the time needed to service the primary writes

Link Failure Rate (count/s)

The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.

Loss of Sync Rate (count/s)

The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled.

Synchronization is assumed lost after a timeout interval expires.

Loss of Signal Rate (count/s)

The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.

CRC Error Rate (count/s)

The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.

Processor Utilization Percentage

The average percentage of time that the processors on nodes are busy doing system I/O tasks. This value applies only to resources that are running IBM Spectrum Virtualize.

Overall Host Attributed Response Time Percentage

The percentage of the average response time that can be attributed to delays from host systems. This value includes both read response times and write response times, and can help you diagnose slow hosts and fabrics that are not working efficiently.

For read response time, the value is based on the time that it takes for hosts to respond to transfer-ready notifications from the nodes. For write response time, the value is based on the time that it takes for hosts to send the write data after the node responds to a transfer-ready notification.

Nonpreferred Node Usage Percentage

The overall percentage of I/O operations that are not directed against the preferred node for each volume in an I/O Group. There is a small performance penalty when I/O does not go to the preferred node for each volume.

Primitive Sequence Protocol Error Rate (count/s)

The average number of primitive sequence protocol errors per second that are detected.

This error occurs when there is a link failure for a port.

Invalid Transmission Word Rate (count/s)

The average number of bit errors per second that are detected.

Zero Buffer-to-Buffer Credit Timer (microseconds)

The number of microseconds that the port is not able to send frames between ports because there is insufficient buffer-to-buffer credit.

In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports. Buffer-to-buffer credit is measured from the last time that metadata was collected.

If this metric is not available, use the Port Send Delay Time metric instead.

Zero Buffer-to-Buffer Credit Percentage

The amount of time, as a percentage, that the port was not able to send frames between ports because of insufficient buffer-to-buffer credit. The amount of time value is measured from the last time that metadata was collected. In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports.

Data for local disks on storage systems in performance reports

You can include general information, capacity data, properties, and other information about local disks that are on storage systems in performance reports.

Information about local disks on storage systems

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage MDisk Name

The name that was assigned to the managed disk when it was added to the system.

Storage Local Disk Name

The name that was assigned to the local disk on the storage system when the local disk was created on the system.

Capacity and usage data

You can create performance reports that include the following information:

Storage Local Disk Capacity (GiB)

The amount of storage space on the local disk.

Component properties

You can create performance reports that include the following information:

Storage Local Disk Is Encryptable

Shows whether the resource can be encrypted. If this value is **Yes**, the resource can be encrypted.

Storage Local Disk Is Encrypted

Shows whether the resource is encrypted. If this value is **Yes**, the resource is encrypted.

Storage Local Disk Storage Class

The storage technology of the local disk on a storage system. For example, the storage class can be a serial-attached SCSI (SAS) or solid-state drive (SSD).

Storage Local Disk Is Solid State

Shows whether the disk is a solid-state drive.

Storage Local Disk Speed (RPM)
The speed of the local disk on a storage system.

Storage System Configuration
Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Status information

You can create performance reports that include the following information:

Storage Local Disk Status
The condition of the resource, for example normal, warning, or error.

Vendor, model, and device information

You can create performance reports that include the following information:

Storage System Local Disk Firmware Version
The version number of the firmware that is running on the disk.

Storage System Local Disk Model
The model name or model number of the resource.

Storage System Local Disk Serial Number
The serial number of the resource.

Storage System Local Disk Vendor
The vendor who supplied the resource.

- [Performance metrics for local disks on storage systems](#)
You can include performance data for back-end arrays on local disks that are on storage systems in performance reports.

Performance metrics for local disks on storage systems

You can include performance data for back-end arrays on local disks that are on storage systems in performance reports.

Back-end array data

You can create performance reports that include the following information:

Back-End Read I/O Rate (ops/s)
The average number of read operations per second that are issued to the back-end storage resources.

Back-End Write I/O Rate (ops/s)
The average number of write operations per second that are issued to the back-end storage resources.

Total Back-End I/O Rate (ops/s)
The average number of I/O operations per second that are transmitted between the back-end storage resources and the component. This value includes both read and write operations.

Back-End Read Data Rate (MiB/s)
The average number of MiB per second that are read from the back-end storage resources.

Back-End Write Data Rate (MiB/s)
The average number of MiB per second that are written to the back-end storage resources.

Total Back-End Data Rate (MiB/s)
The average rate at which data is transmitted between the back-end storage resources and the component. The rate is measured in MiB per second and includes both read and write operations.

Back-End Read Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a read operation.

Back-End Write Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a write operation.

Overall Back-End Response Time (ms/op)
The average number of milliseconds for the back-end storage resources to respond to a read or a write operation.

Peak Back-End Read Response Time (ms)
The longest time for a back-end storage resource to respond to a read operation.

Peak Back-End Write Response Time (ms)
The longest time for a back-end storage resource to respond to a write operation by a node.

Back-End Read Transfer Size (KiB/op)
The average number of KiB that are transferred per read operation from the back-end storage resources.

Back-End Write Transfer Size (KiB/op)
The average number of KiB that are transferred per write operation to the back-end storage resources.

Overall Back-End Transfer Size (KiB/op)
The average transfer size, in KiB, of a read or a write operation to the back-end storage resources.

Back-End Read Queue Time (ms/op)
The average number of milliseconds that a read operation spends in the queue before the operation is sent to the back-end storage resources.

Back-End Write Queue Time (ms/op)
The average number of milliseconds that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Overall Back-End Queue Time (ms/op)
The average number of milliseconds that a read or a write operation spends in the queue before the operation is sent to the back-end storage resources.

Peak Back-End Read Queue Time (ms)

The longest time that a read operation spends in the queue before the operation is sent to the back-end storage resources.
Peak Back-End Write Queue Time (ms)
The longest time that a write operation spends in the queue before the operation is sent to the back-end storage resources.

Data for storage host connections in performance reports

You can include general information, capacity data, properties, and other information about storage host connections in performance reports.

Information about storage host connections

You can create performance reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Storage Host Connection Name

The user-defined name that describes the server or storage device that is assigned to a volume.

XIV® Cluster

The name of the cluster, if any, as defined on the XIV. If no cluster is defined for the host connection, this field is blank.

- [Performance metrics for host connections on SAN Volume Controller, Storwize V7000, or Storwize V7000 Unified systems](#)
You can include performance metrics for volumes, caches, and for other data for host connections in performance reports.
- [Performance metrics for host connections on DS8000 storage systems](#)
You can include performance metrics for volumes, caches, and for other data for storage host connections on DS8000® storage systems in performance reports.
- [Performance metrics for storage host connections on an XIV](#)
You can include performance metrics for volumes, caches, and for other data for storage host connections on an XIV in performance reports.

Performance metrics for host connections on SAN Volume Controller, Storwize® V7000, or Storwize V7000 Unified systems

You can include performance metrics for volumes, caches, and for other data for host connections in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Disk to Cache Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Flush Through I/O Rate (ops/s)

The average number of tracks per second that are written to disk in flush-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Write Through I/O Rate (ops/s)

The average number of tracks per second that are written to disk in write-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Overflow I/O Rate (ops/s)

The average number of tracks per second that are written but are delayed because there is not enough space in the write cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Delay I/O Rate (ops/s)

The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Read Ahead Percentage of Cache Hits

The percentage of all read cache hits that occur on pre-staged data. This value applies only to the volume copy cache if the resource is running IBM Spectrum Virtualize 7.3 or later.

Dirty Write Percentage of Cache Hits

The percentage of all cache write hits that occur on data in the cache that is marked as modified. This value represents how effectively write operations are coalesced before the data is written to disk. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Flush Through Percentage

The percentage of tracks that are written to disk in flush-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Write Through Percentage

The percentage of tracks that are written to disk in write-through mode. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3.

Write Cache Overflow Percentage

The percentage of write operations that are delayed because there is not enough space in the write cache.

Other data

You can create performance reports that include the following information:

Global Mirror Write I/O Rate (op/s)

The average number of write operations per second that are issued to the Global Mirror secondary site.

Global Mirror Overlapping Write I/O Rate (op/s)

The average number of overlapping write operations per second that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.

This value applies to resources that are running IBM Spectrum Virtualize.

Peak Read Response Time (ms)

The worst response time measured for a read operation in the sample interval.

Peak Write Response Time (ms)

The worst response time measured for a write operation in the sample interval.

Global Mirror Secondary Write Lag (ms/op)

The average number of additional milliseconds that it takes to service each secondary write operation for Global Mirror. This value does not include the time to service the primary write operations.

You monitor the value of Global Mirror Secondary Write Lag to identify delays that occurred during the process of writing data to the secondary site.

Average number of additional milliseconds it took to service each secondary write operation for Global Mirror, beyond the time needed to service the primary writes

Overall Host Attributed Response Time Percentage

The percentage of the average response time that can be attributed to delays from host systems. This value includes both read response times and write response times, and can help you diagnose slow hosts and fabrics that are not working efficiently.

For read response time, the value is based on the time that it takes for hosts to respond to transfer-ready notifications from the nodes. For write response time, the value is based on the time that it takes for hosts to send the write data after the node responds to a transfer-ready notification.

Global Mirror Overlapping Write Percentage

The percentage of overlapping write operations that are issued by the Global Mirror primary site. Some overlapping writes are processed in parallel and are excluded from this value.

Applies to resources that are running IBM Spectrum Virtualize.

Nonpreferred Node Usage Percentage

The overall percentage of I/O operations that are not directed against the preferred node for each volume in an I/O Group. There is a small performance penalty when I/O does not go to the preferred node for each volume.

Performance metrics for host connections on DS8000 storage systems

You can include performance metrics for volumes, caches, and for other data for storage host connections on DS8000® storage systems in performance reports.

Volume data

You can create performance reports that include the following information:

Normal Read I/O Rate (ops/s)

The average number of nonsequential read operations per second.

Sequential Read I/O Rate (ops/s)

The average number of sequential read operations per second.

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Normal Write I/O Rate (ops/s)

The average number of nonsequential write operations per second.

Sequential Write I/O Rate (ops/s)

The average number of sequential write operations per second.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Normal I/O Rate (ops/s)

The average number of nonsequential I/O operations per second. This value includes both read and write operations.

Total Sequential I/O Rate (ops/s)

The average number of sequential I/O operations per second. This value includes both read and write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Record Mode Read I/O Rate (ops/s)

The average number of I/O operations per second for record-mode read operations.

For record-mode read operations, only the requested data is managed in the cache rather than a full track of data.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Write Cache Delay I/O Rate (ops/s)

The average number of I/O operations per second that are delayed because of space constraints in the write cache, or because of other conditions.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Normal Read Cache Hit Percentage

The percentage of nonsequential read operations that find data in the cache.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Sequential Read Cache Hit Percentage

The percentage of sequential read operations that find data in the cache.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Normal Write Cache Hit Percentage

The percentage of nonsequential write operations that are handled in the cache.

Sequential Write Cache Hit Percentage

The percentage of sequential write operations that are handled in the cache.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Normal Cache Hit Percentage

The percentage of nonsequential I/O operations that are handled in the cache. This value includes both read and write operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Sequential Cache Hit Percentage

The percentage of sequential I/O operations that are handled in the cache. This value includes both read and write operations.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Record Mode Read Cache Hit Percentage

The percentage of cache hits for record-mode read operations.

For record-mode read operations, only the requested data, rather than a full track of data, is managed in the cache.

Disk to Cache Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred per second from the disks to the cache. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer.

Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Cache to Disk Transfer Rate (ops/s)

The average number of sectors or tracks per second that are transferred from the cache to the disks. This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Write Cache Delay Percentage

The percentage of I/O operations that are delayed because of space constraints in the write cache, or because of other conditions. The value is a percentage of all operations.

This value applies only to resources that are running a version of IBM Spectrum Virtualize earlier than 7.3. The metric is an approximation because actual transfer rates are different for each cache layer. Therefore, you cannot directly compare this metric from resources that are 7.3 or later with earlier versions.

Other data

You can create performance reports that include the following information:

HPF Read I/O Rate (ops/s)

The average number of read operations per second that are issued by the High Performance FICON® feature of the storage system.

HPF Write I/O Rate (ops/s)

The average number of write operations per second that are issued by the High Performance FICON feature of the storage system.

Total HPF I/O Rate (ops/s)

The average number of I/O operations per second that are issued by the High Performance FICON feature of the storage system. This value includes both read and write operations.

HPF I/O Percentage

The percentage of all I/O operations that are issued by the High Performance FICON feature of the storage system.

PPRC Transfer Rate (ops/s)

The average number of tracks per second that are transferred to the secondary device of a Peer-to-Peer Remote Copy (PPRC) pair. This value shows the activity for the source of the PPRC relationship, but shows no activity for the target.

Performance metrics for storage host connections on an XIV

You can include performance metrics for volumes, caches, and for other data for storage host connections on an XIV® in performance reports.

Volume data

You can create performance reports that include the following information:

Overall Read I/O Rate (ops/s)

The average number of read operations per second. This value includes both sequential and nonsequential read operations.

Overall Write I/O Rate (ops/s)

The average number of write operations per second. This value includes both sequential and nonsequential write operations.

Total Overall I/O Rate (ops/s)

The average number of read operations and write operations per second. This value includes both sequential and nonsequential operations.

Read Data Rate (MiB/s)

The average number of MiBs per second that are transferred for read operations.

Write Data Rate (MiB/s)

The average number of MiBs per second that are transferred for write operations.

Total Data Rate (MiB/s)

The average number of MiB per second that are transferred for read operations and write operations.

Read Response Time (ms/op)

The average number of milliseconds to complete a read operation.

Write Response Time (ms/op)

The average number of milliseconds to complete a write operation.

Overall Response Time (ms/op)

The average number of milliseconds to complete an I/O operation. This value includes both read and write operations.

Read Transfer Size (KiB/op)

The average number of KiB that are transferred per read operation.

Write Transfer Size (KiB/op)

The average number of KiB that are transferred per write operation.

Overall Transfer Size (KiB/op)

The average number of KiB that are transferred per I/O operation. This value includes both read and write operations.

Cache data

You can create performance reports that include the following information:

Overall Read Cache Hit Percentage

The percentage of all read operations that find data in the cache. This value includes both sequential and random read operations, and read operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because in the event of a cache miss, the data must be read from the back-end storage resources.

Overall Write Cache Hit Percentage

The percentage of all write operations that are handled in the cache. This value includes both sequential and random write operations, and write operations in the volume cache and volume copy cache where applicable.

Total Overall Cache Hit Percentage

The percentage of all read operations and write operations that are handled in the cache. This value includes both sequential and random read and write operations, and read and write operations in the volume cache and volume copy cache where applicable.

You can use this value to understand throughput or response times. Low cache-hit percentages can increase response times because a cache miss requires access to the back-end storage resources.

Read Data Cache Hit Percentage

The percentage of all read data that is read from the cache.

Write Data Cache Hit Percentage

The percentage of all write data that is written to cache slots that are marked as modified.

Overall Data Cache Hit Percentage

The percentage of all data that is handled in the cache. This value includes read data that is read from the cache and write data that is written to cache slots that are marked as modified.

Read Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a read-cache hit operation.

Write Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a write-cache hit operation.

Overall Cache Hit Response Time (ms/op)

The average number of milliseconds to complete a cache hit operation. This value includes the times for both read-cache hit and write-cache hit operations.

Read Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a read-cache miss operation.

Write Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a write-cache miss operation.

Overall Cache Miss Response Time (ms/op)

The average number of milliseconds to complete a cache miss operation. This value includes the times for both read-cache miss and write-cache miss operations.

Other data

You can create performance reports that include the following information:

Small Transfers I/O Percentage

The percentage of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers I/O Percentage

The percentage of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers I/O Percentage

The percentage of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers I/O Percentage

The percentage of I/O operations with a data transfer size that is greater than 512 KiB.

Small Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers Data Percentage

The percentage of data that is transferred as a result of I/O operations with a data transfer size that is greater than 512 KiB.

Small Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a small data transfer size. A small data transfer has a size that is less than or equal to 8 KiB.

Medium Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a medium data transfer size. A medium data transfer has a size that is greater than 8 KiB and less than or equal to 64 KiB.

Large Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation that has a large data transfer size. A large data transfer has a size that is greater than 64 KiB and less than or equal to 512 KiB.

Very Large Transfers Response Time (ms/op)

The average number of milliseconds to complete an I/O operation with a data transfer size that is greater than 512 KiB.

Data for switches in performance reports

You can include properties and other information about switches in performance reports.

Information about switches

You can create performance reports that include the following information:

Switch Logical Name

The logical name of a switch or switch port.

Component properties

You can create performance reports that include the following information:

Switch WWN

The World Wide Name (WWN) of the switch. A WWN is the unique 64-bit identifier for the switch.

Parent Switch WWN

The worldwide name of the parent switch.

Switch Management Telnet Address

The Telnet address that you access to manage the switch.

Switch Management SNMP Address

The Simple Network Management Protocol (SNMP) address that you access to manage the switch.

Switch Management URL Address

The URL that you access to manage the switch.

Switch Domain

The domain ID of a switch. The ID is an 8-bit identifier with a range of 0-255. This column is blank for physical switches that are parents of virtual switches.

Switch Version

The version number of the operating system that is running on the switch.

Switch Location

The physical location of the switch. The location is defined when a switch is added to IBM Spectrum® Control. You can add or edit the location of the switch on the General tab of the properties notebook.

Switch Custom Tag 1, 2, and 3

User-defined text that is associated with the switch. You can add or edit the custom tags for the switch on the General tab of the properties notebook.

Status information

You can create performance reports that include the following information:

Switch Status

The condition of the resource, for example normal, warning, or error.

Switch Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Vendor, model, and device information

You can create performance reports that include the following information:

Switch IP Address

The IP address of the resource.

Switch Serial Number

The serial number of the resource.

Switch Vendor

The vendor who supplied the resource.

Switch Model

The model name or model number of the resource.

- [Performance metrics for switches](#)

You can include performance data for switches, including switch error data, in performance reports.

Performance metrics for switches

You can include performance data for switches, including switch error data, in performance reports.

Switch data

You can create performance reports that include the following information:

Port Send Frame Rate (frames/s)

The average number of frames per second that are sent by the port.

Port Receive Frame Rate (frames/s)

The average number of frames per second that are received by the port.

Total Port Frame Rate (frames/s)

The average number of frames per second that are transferred. This value includes frames that are sent and received by the port.

Port Send Data Rate (MiB/s)

The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)

The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)

The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port Send Frame Size (KiB/op)

The average size of a frame, in KiB, that is sent through the port.

Port Receive Frame Size (KiB/op)

The average size of a frame, in KiB, that is received by the port.

Overall Port Frame Size (KiB/op)

The average frame transfer size. This value is measured in KiB and includes frames that are sent and frames that are received by the port.

Port Send Bandwidth Percentage

The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Port Receive Bandwidth Percentage

The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Overall Port Bandwidth Percentage

The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Switch error data

You can create performance reports that include the following information:

Error Frame Rate (count/s)

The average number of error frames per second that are received. An error frame is a frame that violates the Fibre Channel Protocol.

Discarded Frame Rate (count/s)

The average number of frames per second that are discarded because host buffers are unavailable for the port.

Link Failure Rate (count/s)

The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.

Loss of Sync Rate (count/s)

The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled.

Synchronization is assumed lost after a timeout interval expires.

Loss of Signal Rate (count/s)

The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.

CRC Error Rate (count/s)

The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.

Encoding Disparity Error Rate (count/s)

The average number of disparity errors per second that are received.

Discarded Class 3 Frame Rate (count/s)

The average number of class 3 frames per second that are discarded.

Primitive Sequence Protocol Error Rate (count/s)

The average number of primitive sequence protocol errors per second that are detected.

This error occurs when there is a link failure for a port.

Invalid Transmission Word Rate (count/s)

The average number of bit errors per second that are detected.

Link Reset Transmitted Rate (count/s)

The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR1) state.

Link Reset Received Rate (count/s)

The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR2) state.

Short Frame Rate (count/s)

The average number of frames that are received per second that are shorter than 28 octets. This number excludes start-of-frame bytes and end-of-frame bytes.

The 28 octet limit is calculated based on the assumption that a frame has 24 header bytes, and 4 CRC bytes.

Long Frame Rate (count/s)

The average number of frames that are received per second that are longer than 2140 octets. This number excludes start-of-frame bytes and end-of-frame bytes.

The 2140 octet limit is calculated based on the assumption that a frame has 24 header bytes, 4 CRC bytes, and 2112 data bytes.

F-BSY Frame Rate (count/s)

The average number of F-BSY frames per second that are generated.

An F-BSY frame is issued by the fabric to indicate that a frame cannot be delivered because the fabric or destination N_port is busy.

F-RJT Frame Rate (count/s)

The average number of F-RJT frames per second that are generated.

An F-RJT frame is issued by the fabric to indicate that delivery of a frame was denied.

Zero Buffer Credit Rate

The average number of Zero Buffer Credit conditions per second that occurred. A Zero Buffer Credit condition occurs when a port is unable to send frames because of a lack of buffer credit since the last node reset. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

This property is available only for Brocade switches.

Class 3 Send Timeout Frame Rate

The average number of class 3 frames per second that were discarded before transmission because of a timeout condition. The timeout condition occurs while the switch or port waits for buffer credit from the receiving port at the other end of the fibre. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

This property is available only for Brocade switches.

Class 3 Receive Timeout Frame Rate

The average number of class 3 frames per second that were discarded after reception because of a timeout condition. The timeout condition occurs while a transmitting port waits for buffer credit from a port at the other end of the fibre. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

This property is available only for Brocade switches.

RDY Priority Override Rate

The average number of times per second during which the sending of R_RDY or VC_RDY signals was a higher priority than the sending of frames. This condition occurs because of diminishing credit reserves in the transmitter at the other end of the fibre. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

This property is available only for Brocade switches.

Port State Change Rate

The average number of times per second that the state of a port changes to offline, online, or faulty. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

This property is available only for Brocade switches.

Port Congestion Index

The estimated degree to which frame transmission was delayed due to a lack of buffer credits. This value is generally 0 - 100. The value 0 means there was no congestion. The value can exceed 100 if the buffer credit exhaustion persisted for an extended amount of time. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

Zero Buffer-to-Buffer Credit Percentage

The amount of time, as a percentage, that the port was not able to send frames between ports because of insufficient buffer-to-buffer credit. The amount of time value is measured from the last time that metadata was collected. In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports.

Credit Recovery Link Reset Rate

The estimated average number of link resets per second that a switch or port completed to recover buffer credits. This estimate attempts to disregard link resets that were caused by link initialization. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

Data for switch ports in performance reports

You can include properties and other information about switch ports in performance reports.

Information about switch ports

You can create performance reports that include the following information:

Switch Logical Name

The logical name of a switch or switch port.

Switch Port WWPN

The worldwide port name of the port on the switch.

Component properties

You can create performance reports that include the following information:

Switch Port Number

The port number on the resource.

Switch Port Type

The type of port on the storage system, storage virtualizer, or switch. For example, the port type can be N_Port, F_Port, or another type of port.

Switch Port Speed (GiB/s)

The speed of a port, which is measured in GiB per second.

Switch Blade Slot Number

The number of the slot on the switch to which the blade is attached. This property applies to ports on blades.

Status information

You can create performance reports that include the following information:

Switch Port Status

The condition of the resource, for example normal, warning, or error.

Switch Port Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Switch Port Enabled State

Shows whether a port is enabled, disabled, or is enabled but offline.

Switch Port Operational Status

The current operational state of the switch port. For example, this value can be **Error** or **OK**.

- [Performance metrics for switch ports](#)

You can include performance data for switch ports, including port error data, in performance reports.

Performance metrics for switch ports

You can include performance data for switch ports, including port error data, in performance reports.

Switch port data

You can create performance reports that include the following information:

Port Send Frame Rate (frames/s)

The average number of frames per second that are sent by the port.

Port Receive Frame Rate (frames/s)

The average number of frames per second that are received by the port.

Total Port Frame Rate (frames/s)

The average number of frames per second that are transferred. This value includes frames that are sent and received by the port.

Port Send Data Rate (MiB/s)

The average rate at which data is sent from the port. The rate is measured in MiB per second. A send operation is a read operation that is processed, or a write operation that is initiated by the port.

Port Receive Data Rate (MiB/s)

The average rate at which data is received by the port. The rate is measured in MiB per second. A receive operation is a write operation that is processed, or a read operation that is initiated by the port.

Total Port Data Rate (MiB/s)

The average rate at which data is transferred through the port. The rate is measured in MiB per second and includes both send and receive operations.

Port Peak Send Data Rate (MiB/s)

The fastest rate at which data is sent through this switch port.

Port Peak Receive Data Rate (MiB/s)

The fastest rate at which data is received through this switch port.

Port Send Frame Size (KiB/op)

The average size of a frame, in KiB, that is sent through the port.

Port Receive Frame Size (KiB/op)

The average size of a frame, in KiB, that is received by the port.

Overall Port Frame Size (KiB/op)

The average frame transfer size. This value is measured in KiB and includes frames that are sent and frames that are received by the port.

Port Send Bandwidth Percentage

The percentage of the port bandwidth that is used for send operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Port Receive Bandwidth Percentage

The percentage of the port bandwidth that is used for receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Overall Port Bandwidth Percentage

The percentage of the port bandwidth that is used for send and receive operations. This value is an indicator of port bandwidth usage that is based on the speed of the port.

Data for errors on switch ports

You can create performance reports that include the following information:

Error Frame Rate (count/s)

The average number of error frames per second that are received. An error frame is a frame that violates the Fibre Channel Protocol.

Discarded Frame Rate (count/s)

The average number of frames per second that are discarded because host buffers are unavailable for the port.

Link Failure Rate (count/s)

The average number of miscellaneous fibre channel link errors per second for ports. Link errors might occur when an unexpected Not Operational (NOS) is received or a link state machine failure was detected.

Loss of Sync Rate (count/s)

The average number of times per second that the port lost synchronization with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However in some cases this can also occur due to mismatching port speeds between the partner ports, when auto-negotiation of link speed is disabled. Synchronization is assumed lost after a timeout interval expires.

Loss of Signal Rate (count/s)

The average number of times per second at which the port lost communication with its partner port. These types of errors usually indicate physical link problems, caused by faulty SFP modules or cables, or caused by faulty connections at the switch or patch panel. However, in some cases, this error can also occur when the maximum link distance between ports is exceeded, for the type of connecting cable and light source.

CRC Error Rate (count/s)

The average number of frames per second that are received in which a cyclic redundancy check (CRC) error is detected. A CRC error is detected when the CRC in the transmitted frame does not match the CRC computed by the receiver. For Brocade switches, this metric includes only the CRC Errors with a good end-of-frame (EOF) indicator.

Encoding Disparity Error Rate (count/s)

The average number of disparity errors per second that are received.

Discarded Class 3 Frame Rate (count/s)

The average number of class 3 frames per second that are discarded.

Primitive Sequence Protocol Error Rate (count/s)

The average number of primitive sequence protocol errors per second that are detected. This error occurs when there is a link failure for a port.

Invalid Transmission Word Rate (count/s)

The average number of bit errors per second that are detected.

Link Reset Transmitted Rate (count/s)

The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR1) state.

Link Reset Received Rate (count/s)

The average number of times per second that the port changes from an active (AC) state to a Link Recovery (LR2) state.

Short Frame Rate (count/s)

The average number of frames that are received per second that are shorter than 28 octets. This number excludes start-of-frame bytes and end-of-frame bytes. The 28 octet limit is calculated based on the assumption that a frame has 24 header bytes, and 4 CRC bytes.

Long Frame Rate (count/s)

The average number of frames that are received per second that are longer than 2140 octets. This number excludes start-of-frame bytes and end-of-frame bytes. The 2140 octet limit is calculated based on the assumption that a frame has 24 header bytes, 4 CRC bytes, and 2112 data bytes.

F-BSY Frame Rate (count/s)

The average number of F-BSY frames per second that are generated.

An F-BSY frame is issued by the fabric to indicate that a frame cannot be delivered because the fabric or destination N_port is busy.

F-RJT Frame Rate (count/s)

The average number of F-RJT frames per second that are generated.

An F-RJT frame is issued by the fabric to indicate that delivery of a frame was denied.

Zero Buffer Credit Rate

The average number of Zero Buffer Credit conditions per second that occurred. A Zero Buffer Credit condition occurs when a port is unable to send frames because of a lack of buffer credit since the last node reset. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

This property is available only for Brocade switches.

Class 3 Send Timeout Frame Rate

The average number of class 3 frames per second that were discarded before transmission because of a timeout condition. The timeout condition occurs while the switch or port waits for buffer credit from the receiving port at the other end of the fibre. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

This property is available only for Brocade switches.

Class 3 Receive Timeout Frame Rate

The average number of class 3 frames per second that were discarded after reception because of a timeout condition. The timeout condition occurs while a transmitting port waits for buffer credit from a port at the other end of the fibre. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

This property is available only for Brocade switches.

RDY Priority Override Rate

The average number of times per second during which the sending of R_RDY or VC_RDY signals was a higher priority than the sending of frames. This condition occurs because of diminishing credit reserves in the transmitter at the other end of the fibre. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

This property is available only for Brocade switches.

Port State Change Rate

The average number of times per second that the state of a port changes to offline, online, or faulty. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

This property is available only for Brocade switches.

Port Congestion Index

The estimated degree to which frame transmission was delayed due to a lack of buffer credits. This value is generally 0 - 100. The value 0 means there was no congestion. The value can exceed 100 if the buffer credit exhaustion persisted for an extended amount of time. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

Zero Buffer-to-Buffer Credit Percentage

The amount of time, as a percentage, that the port was not able to send frames between ports because of insufficient buffer-to-buffer credit. The amount of time value is measured from the last time that metadata was collected. In Fibre Channel technology, buffer-to-buffer credit is used to control the flow of frames between ports.

Credit Recovery Link Reset Rate

The estimated average number of link resets per second that a switch or port completed to recover buffer credits. This estimate attempts to disregard link resets that were caused by link initialization. When you troubleshoot a SAN, use this metric to help identify port conditions that might slow the performance of the resources to which those ports are connected.

Custom reports about capacity and relationships

You can use Cognos® Analytics to create custom reports about capacity and relationships. Capacity and relationship reports can contain detailed information about the properties of monitored resources, and the available space and capacity of those resources.

Capacity and relationship reports can contain information about the following resources and their components:

- Fabrics
- Switches
- Servers
- Hypervisors
- Network-attached storage servers
- Storage virtualizers
- Storage systems
- Storage resource groups
- Groups

In the IBM Spectrum® Control GUI, storage resource groups are available as general groups.

- [Creating custom capacity and relationship reports](#)
You can create custom reports that show capacity and relationship information for resources in the Cognos Analytics reporting tool. Capacity and relationship reports can contain detailed information about the properties of monitored resources, and the available space and capacity of those resources. You access custom capacity and relationship reports from IBM Spectrum Control, and you create the reports in the Cognos Analytics reporting tool.
- [Adding filters to reports](#)
You can use filters with capacity and relationship reports. Filters allow you to show only certain data that complies with your criteria. You add filters to your capacity and relationship reports when you create the reports.
- [Data and properties in capacity and relationship reports](#)
You can include capacity data, properties, relationship information, and other information about resources in your storage environment in capacity and relationship reports.

Creating custom capacity and relationship reports

You can create custom reports that show capacity and relationship information for resources in the Cognos® Analytics reporting tool. Capacity and relationship reports can contain detailed information about the properties of monitored resources, and the available space and capacity of those resources. You access custom capacity and relationship reports from IBM Spectrum® Control, and you create the reports in the Cognos Analytics reporting tool.

Before you begin

Before you can create a custom report about capacity and relationships, ensure that data was collected from the resources. The following table shows where the data must be collected from for each resource:

Resource	Prerequisite
Fabric	Data must be collected from the fabric by a CIM agent or SNMP agent.
Switch	Data must be collected from the switch by a CIM agent or SNMP agent.
Server	Data must be collected from the server by the Storage Resource agent, or by an agentless server.
Hypervisor	Data must be collected from the VMware ESX server.
NAS	Data must be collected from any NetApp or IBM® Scale Out Network Attached Storage resources that are in your storage environment.
Storage virtualizer	Data must be collected from the any of the following storage virtualizers that are in your storage environment: <ul style="list-style-type: none">• IBM FlashSystem® family• Storwize® V7000• Storwize V7000 Unified• SAN Volume Controller• Hitachi Universal Storage Platform V
Storage system	Data must be collected from the storage system, or any of the following systems that are configured as back-end storage: <ul style="list-style-type: none">• IBM FlashSystem family• Storwize V7000• Storwize V7000 Unified• SAN Volume Controller• Hitachi Universal Storage Platform V

Restriction: If you create a custom report that includes properties from both Servers to Storage Systems and Fabrics and Switches, the relationships between resources are not displayed correctly.

Tip: Before you run a report, you can preview the report with no data.

Procedure

1. Go to the URL for your Cognos Analytics server. The format of the URL is similar to this URL: `http://myhostname:9300/bi`
2. Depending on the type of report that you want to see, complete one of the following steps:
 - To create a basic report with limited formatting about the capacity and relationships of resources, complete the following steps:
 - Click New  in the Welcome portal.
 - Click Other, then click Query Studio.
 - Click IBM Spectrum Control Packages, then click the Capacity and Relationships package.
 - To create a report about the capacity and relationships of resources and apply advanced formatting features to the report, complete the following steps:
 - In the Welcome portal, click Team Content .
 - Click IBM Spectrum Control Packages.
 - Right-click Capacity and Relationships, then click Create report.
 - Click a template for the report.
3. Expand IBM Spectrum Control in the list of data sources.
4. Expand Servers to Storage Systems or Fabrics and Switches in the list.
5. Explore the folders in the list to locate the resources, properties, and statistics that you want to include in the report.
6. Depending on your browser, do one of the following steps to add properties and statistics to the report:
 - In Internet Explorer, drag the items that you want to see information about to the work area.
 - In Firefox, select the items that you want to see information about, and then click Insert.
7. Click Save.

Adding filters to reports

You can use filters with capacity and relationship reports. Filters allow you to show only certain data that complies with your criteria. You add filters to your capacity and relationship reports when you create the reports.

About this task

Filters for resources are in the same list as the resources, in the appropriate resource folder. For example, to view the filters for servers, select Server Resources > Server Resource Filters > Server Filters.

Filters are available for all resources, except network-attached storage resources.

Procedure

1. To apply a filter to the data in the work area, locate the filter that you want to include in the folders in the list.
2. Depending on your browser, do one of the following steps to add a filter to the report:
 - In Internet Explorer, drag the filter that you want to use to the work area.
 - In Firefox, select the filter that you want to use, and then click Insert.The filter is applied to the report. If you did not add properties and statistics to the report, the filter is applied when you add the properties and statistics.
3. Optional: To delete the filter, right-click the filter in the work area, and then select Delete.

Related information

-  [Create a Simple Filter](#)

Filters for servers in capacity and relationship reports

You can filter capacity and relationship reports to include only the servers, server file systems, and server logical volumes that meet specific criteria.

Filters for servers

You can create capacity and relationship reports that include the following filters:

Servers Connected to Virtualizers or Storage Systems

Shows servers that are connected to storage virtualizers or storage systems. You can use this filter to identify servers that are connected directly to storage virtualizers, or connected directly or indirectly to storage systems. This filter excludes local disks from the report.

Servers Directly Connected to Storage Systems

Shows servers that are directly connected to a back-end storage system. You can use this filter to identify servers or server disks that are connected to a storage system, but are not connected through a storage virtualizer.

For example, you might want to migrate data from one storage system to another. In this case, you can use this filter to identify file systems or server disks that are not virtualized. These file systems or server disks might be affected if a storage system is removed.

Servers Directly Connected to Virtualizers

Shows servers that are directly connected to a storage virtualizer. You can use this filter to identify servers that are connected to a storage virtualizer, but are not connected directly to a back-end storage system.

For example, you can use this filter to identify only server disks that are on a SAN Volume Controller.

Filters for server file systems

You can create capacity and relationship reports that include the following filters:

Rows with File System Mount Points

Shows the file systems that have a mount point on the server.

Rows without File System Mount Points

Shows resources that do not have a mount point on the server. You can use this filter to identify disks that do not have file systems, that is, disks that are not in use. For example, to identify unused space include the Server Name property and the Server Disk Path property in a report, and then include the Rows without File System Mount Points filter.

Filters for server logical volumes

You can create capacity and relationship reports that include the following filters:

Rows with Logical Volume Path

Shows the logical volumes that have a path to the server.

Rows without Logical Volume Path

Shows resources that do not have a logical volume path to the server. You can use this filter to identify volumes that do not have paths, that is, volumes that are not in use.

For example, to identify unused space include the Server Name property and the Server Disk Path property in a report, and then include the Rows without Logical Volume Path filter.

Filters for hypervisors in capacity and relationship reports

You can filter capacity and relationship reports to include only the hypervisors, hypervisor file systems, and hypervisor logical volumes that meet specific criteria.

Filters for hypervisors

You can create capacity and relationship reports that include the following filters:

Hypervisor with Probed Servers

Shows hypervisors that are connected to servers. You can use this filter to include only hypervisors and their associated servers from which data was collected. For example, you might collect data only from your critical production servers on a hypervisor, but not your test servers. In this case, you can use this filter to exclude information for the test servers from the report.

Hypervisors Connected to Virtualizers or Storage Systems

Shows hypervisors that are connected to storage virtualizers or storage systems. You can use this filter to identify hypervisors that are connected directly to storage virtualizers, or connected directly or indirectly to storage systems. This filter excludes local disks from the report.

Hypervisors Directly Connected to Storage Systems

Shows hypervisors that are directly connected to a back-end storage system. You can use this filter to identify hypervisors or hypervisor disks that are connected to a storage system, but are not connected through a storage virtualizer.

For example, you might want to migrate data from one storage system to another. In this case, you can use this filter to identify file systems or hypervisor disks that are not virtualized. These file systems or hypervisor disks might be affected if a storage system is removed.

Hypervisors Directly Connected to Virtualizers

Shows hypervisors that are directly connected to a storage virtualizer. You can use this filter to identify hypervisors that are connected to a storage virtualizer, but are not connected directly to a back-end storage system.

For example, you can use this filter to identify only hypervisor disks that are on a SAN Volume Controller.

Filters for hypervisor file systems

You can create capacity and relationship reports that include the following filters:

Hypervisors with File System Mount Points

Shows the file systems that have a mount point on the hypervisor.

Hypervisors without File System Mount Points

Shows resources that do not have a mount point on the hypervisor. You can use this filter to identify disks that do not have file systems, that is, disks that are not in use.

For example, to identify unused space include the Hypervisor Name property and the Hypervisor Disk Path property in a report, and then include the Hypervisors without File System Mount Points filter.

Filters for hypervisor logical volumes

You can create capacity and relationship reports that include the following filters:

Hypervisors with Logical Volume Path

Shows the logical volumes that have a path to the hypervisor.

Hypervisors without Logical Volume Path

Shows resources that do not have a logical volume path to the hypervisor. You can use this filter to identify volumes that do not have paths, that is, volumes that are not in use.

For example, to identify unused space include the Hypervisor Name property and the Hypervisor Disk Path property in a report, and then include the Hypervisors without Logical Volume Path filter.

Filters for storage virtualizers in capacity and relationship reports

You can filter capacity and relationship reports to include only the storage virtualizers and storage virtualizer volumes that meet specific criteria.

Storage virtualizer filters

You can create capacity and relationship reports that include the following filters:

Virtualizers Not Connected to Servers

Shows storage virtualizers that are not connected to servers.

Filters for storage virtualizer volumes

You can create capacity and relationship reports that include the following filters:

Rows with Virtualizer Volumes

Shows storage virtualizer disks that are connected to the storage virtualizer that have an associated volume.

Rows without Virtualizer Volumes

Shows storage virtualizer disks that are connected to the storage virtualizer that do not have an associated volume.

Virtualizer Primary Volume Information

Shows primary volumes that are connected to the storage virtualizer. You can use this filter if you want to get a total of the used space on primary volumes in your storage environment.

Virtualizer Volume Copy Information

Shows copy volumes that are connected to the storage virtualizer. You can use this filter if you want to get a total of the used space on volume copies in your storage environment.

Filters for storage systems in capacity and relationship reports

You can filter capacity and relationship reports to include only the storage systems or storage volumes that meet specific criteria.

Filters for storage systems

You can create capacity and relationship reports that include the following filters:

Storage Systems Directly Connected to Servers

Shows back-end storage systems that are directly connected to a server. You can use this filter to identify storage systems that are connected to a server, but are not connected through a storage virtualizer.

For example, you might want to migrate data from one storage system to another. In this case, you can use this filter to identify file systems or server disks that are not virtualized. These file systems or server disks might be affected if a storage system is removed.

Storage Systems Connected to Servers through Virtualizers

Shows storage systems that are indirectly connected to a server through a storage virtualizer. You can use this filter to identify storage systems that are connected to a storage virtualizer, but are not connected directly to a server.

For example, you can use this filter to identify only server disks that are on a SAN Volume Controller.

Storage Systems not Connected to Servers

Shows storage systems that are not connected to a server either directly, or indirectly through a storage virtualizer.

Rows with Storage Volumes

Shows storage resources that have an associated storage volume.

Rows without Storage Volumes

Shows storage resources that do not have an associated storage volume.

Filters for storage resource groups in capacity and relationship reports

You can filter capacity and relationship reports to include only the storage resource groups that meet specific criteria.

Filters for storage resource groups

You can create capacity and relationship reports that include the following filters:

Storage Resource Group for Volumes

Shows only the volumes that are in a storage resource group.

Storage Resource Group for Pools

Shows only the pools that are in a storage resource group.

Storage Resource Group for Storage Systems

Shows only the storage systems that are in a storage resource group.

Storage Resource Group for Servers

Shows only the servers that are in a storage resource group.

Storage Resource Group for File Systems

Shows only the file systems that are in a storage resource group.

Data and properties in capacity and relationship reports

You can include capacity data, properties, relationship information, and other information about resources in your storage environment in capacity and relationship reports.

You can include general information, capacity data, path information, and other information about server disks on hypervisors in capacity and relationship reports.
- [Data for hypervisor controllers in capacity and relationship reports](#)
You can include general information about hypervisor controllers in capacity and relationship reports.
- [Data for multipath drivers on hypervisors in capacity and relationship reports](#)
You can include name and version information about multipath drivers on hypervisors in capacity and relationship reports.
- [Data for virtual machines managed by hypervisors in capacity and relationship reports](#)
You can include general information, and file and disk information for virtual machines in capacity and relationship reports.
- [Data for network-attached storage systems in capacity and relationship reports](#)
You can include general information, capacity data, properties, and other information about network-attached storage (NAS) systems in capacity and relationship reports.
- [Data for file systems on network-attached storage systems in capacity and relationship reports](#)
You can include general information, capacity data, and other information about file systems on network-attached storage (NAS) systems in capacity and relationship reports.
- [Data for network-attached storage exports in capacity and relationship reports](#)
You can include general information and status information about network-attached storage (NAS) exports in capacity and relationship reports.
- [Data for logical volumes on network-attached storage systems in capacity and relationship reports](#)
You can include general information, capacity data, and other information about logical volumes on network-attached storage (NAS) systems in capacity and relationship reports.
- [Data for network-attached storage disks in capacity and relationship reports](#)
You can include general information, capacity data, properties, and other information about network-attached storage (NAS) disks in capacity and relationship reports.
- [Data for pools on Storwize V7000 Unified systems in capacity and relationship reports](#)
You can include general information and capacity data about pools on Storwize® V7000 Unified systems in capacity and relationship reports.
- [Data for Storwize V7000 Unified filesets in capacity and relationship reports](#)
You can include general information, capacity data, and other information about Storwize V7000 Unified filesets in capacity and relationship reports.
- [Data for storage virtualizers in capacity and relationship reports](#)
You can include general information, capacity data, properties, and other information about storage virtualizers in capacity and relationship reports.
- [Data for storage virtualizer pools in capacity and relationship reports](#)
You can include general information, capacity data, properties, and other information about storage virtualizer pools in capacity and relationship reports.
- [Data for storage virtualizer volumes in capacity and relationship reports](#)
You can include general information, capacity data, properties, information about copies of volumes, and other information about storage virtualizer volumes in capacity and relationship reports.
- [Data for managed disks on storage virtualizers in capacity and relationship reports](#)
You can include general information, capacity data, properties, and other information about managed disks on storage virtualizers in capacity and relationship reports.
- [Data for local disks on storage virtualizers in capacity and relationship reports](#)
You can include general information, capacity data, properties, and other information about local disks on storage virtualizers in capacity and relationship reports.
- [Data for storage virtualizer groups in capacity and relationship reports](#)
You can include the name of storage virtualizer groups and properties for storage virtualizer groups in capacity and relationship reports.
- [Data for storage systems in capacity and relationship reports](#)
You can include general information, capacity data, properties of components, and other information about storage systems in capacity and relationship reports.
- [Data for storage system pools in capacity and relationship reports](#)
You can include general information, capacity data, properties of components, and other information about storage system pools in capacity and relationship reports.
- [Data for storage system volumes in capacity and relationship reports](#)
You can include general information, capacity data, properties, information about copies of volumes, and other information about storage system volumes in capacity and relationship reports.
- [Data for storage system disks in capacity and relationship reports](#)
You can include properties, and other data about storage system disks in capacity and relationship reports.
- [Data for storage system groups in capacity and relationship reports](#)
You can include general information about, and properties of, storage system groups in capacity and relationship reports.
- [Data for managed disks on storage systems in capacity and relationship reports](#)
You can include general information, capacity data, properties, and other information about managed disks on storage systems in capacity and relationship reports.
- [Data for storage resource groups in capacity and relationship reports](#)
You can include general information about storage resource groups in capacity and relationship reports. In the IBM Spectrum® Control GUI, storage resource groups are available as general groups.
- [Data for groups in capacity and relationship reports](#)
You can include general information about groups in capacity and relationship reports. A group is a set of logically related volumes, file systems, and shares. For example, a group that represents a business critical application might include the volumes, file systems, and shares that provide storage to the application.
- [Data for switches in capacity and relationship reports](#)
You can include properties and other information about switches in capacity and relationship reports.
- [Data for switch ports in capacity and relationship reports](#)
You can include properties and other information about switch ports in capacity and relationship reports.
- [Data for fabrics in capacity and relationship reports](#)
You can include properties and other information about fabrics in capacity and relationship reports.

Data for clusters in capacity and relationship reports

You can include general information about clusters in capacity and relationship reports.

Information about clusters

You can create capacity and relationship reports that include the following information:

Cluster Name

The name that was assigned to the cluster when it was created.

Cluster Type

The type of the cluster. The cluster can be a Microsoft Cluster Server or a High-Availability Cluster Multiprocessing (HACMP) server.

Cluster IP Address

The IP address of the resource.

Cluster Domain Name

The domain name of the cluster.

Data for servers in capacity and relationship reports

You can include general information, capacity data, properties of components, and other information about servers in capacity and relationship reports.

Information about servers

You can create capacity and relationship reports that include the following information:

Server Name

The fully qualified domain name of the server. For example, the name of a server might be `server.example.com`.

Server Domain Name

The domain name of the server.

If a IBM Spectrum® Control server uses one DNS server, and another server, which has a Storage Resource agent installed, uses a different DNS server, the IBM Spectrum Control server might be displayed in some IBM Spectrum Control pages with different fully qualified host names. This is because the IBM Spectrum Control server is identified by two different DNS servers.

Server Short Name

The host name from the fully qualified domain name of the server. For example, if the fully qualified domain name of the server is `mycomputer.example.com`, the host name is `mycomputer`.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Server Swap Space (GiB)

The amount of disk space on a resource that is available to store some of the contents of the RAM when the RAM is full.

Server Total Disk Capacity (GiB)

The amount of storage space that is on a server.

Server Total Disk Available Space (GiB)

The amount of unused storage space on all disks on a server.

Server Total File System Available Space (GiB)

The amount of unused storage space that is available on the file systems on a server.

Component properties

You can create capacity and relationship reports that include the following information:

Server Cluster Current Hosting Node

The name of the server that is hosting the cluster resource group.

Server Cluster Resource Type

Shows whether the cluster is a node or a cluster resource group.

Server IP Address

The IP address of the resource.

Server Is Virtual Machine

Shows whether a resource is a virtual machine. If this value is **Yes**, the resource is a virtual machine.

Server OS Type

The operating system that is running on the server.

Server OS Version

The version number of the operating system that is running on the resource.

Server Processor Architecture

The architecture of the processor on the server or hypervisor. For example, the architecture of a processor might be Intel 64 bit (IA64) or Intel 32 bit (IA32).

Server Processor Count

The number of processors on the server or hypervisor.

Server Processor Speed (MHz)

The speed of the processor on the server or hypervisor.

Server Processor Type

Shows information about the processor, such as the family and model of the processor.

Server RAM (GiB)

The amount of RAM on the server or hypervisor.

Server Time Zone

The time zone in which a resource is located.

Server Location

The physical location of a server. The location is defined when a server is added to IBM Spectrum Control. You can add or edit the location of the server in the Properties pane of the server.

Server Custom Tag 1, 2, and 3

User-defined text that is associated with a server. You can add or edit the custom tags for a server in the Properties pane of the server.

Vendor, model, and device information

You can create capacity and relationship reports that include the following information:

Server Model

The model name or model number of the resource.

Server Serial Number

The serial number of the resource.

Server Vendor

The vendor who supplied the resource.

Status information

You can create capacity and relationship reports that include the following information:

Server Status

The status of a server, such as **Normal**, **Warning**, **Error**, **Unreachable**, **Unknown**, or **Agentless**. Use the status to determine the condition of the server, and if any actions must be taken. If this value is **Agentless**, the server is an unmanaged server.

Server Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Server Last Data Collection

The date and time when storage statistics were last collected from the resource.

Server Last Start Time

The last time that the resource was started.

Data for file systems on servers in capacity and relationship reports

You can include general information, capacity data, and status information about file systems on servers in capacity and relationship reports.

Information about file systems on servers

You can create capacity and relationship reports that include the following information:

File System Mount Point

The name or mount point of the file system for the resource. For example, on Microsoft Windows systems, the value in this property might be c:\ or d:\. On operating systems such as AIX®, Linux®, Solaris, or HP-UX, the mount point might be /opt or /export/home.

File System Export Name

The name of the exported file system.

File System Type

The type of file system that the resource uses.

Capacity and usage data

Tip:

In the IBM Spectrum® Control interface, the capacity values of file systems are displayed in one column, Total File System Capacity (GiB).

You can create capacity and relationship reports that include the following information:

File System Capacity (GiB)

The amount of storage space on the file system of the resource.

File System Directory Count

The number of directories in the file systems that are on a server.

File System File Count

The number of files in the file system.

File System Available Space (GiB)

The amount of unused storage space in the file system of the resource.

File System Available Inodes

The number of unused inodes in file systems on the operating system.

File System Used Inodes

The number of used inodes in file systems on the operating system.

Tip: For Microsoft Windows systems, this property is blank.

File System Maximum Files

The maximum number of files that the file system on the resource can contain.

File System Physical Size (GiB)

The amount of physical storage space on the file systems on a resource. The physical size is the size of all the clusters that the file system uses.

File System Used Space (GiB)

The amount of used storage space in the file system of the resource.

Component properties

You can create capacity and relationship reports that include the following information:

File System Is Remote Mount

Shows whether the file system is remotely mounted on another server. If this value is **Yes**, the file system is remotely mounted.

Status information

You can create capacity and relationship reports that include the following information:

File System Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

File System Last Scan

The date and time when file statistics were last collected from the resource.

Data for logical volumes on servers in capacity and relationship reports

You can include general information, capacity data, and status information about logical volumes on servers in capacity and relationship reports.

Information about logical volumes on servers

You can create capacity and relationship reports that include the following information:

Logical Volume Path

The path to a logical volume on a resource, for example `/dev/hd1`.

Logical Volume Is Swap Space

Shows whether a logical volume is used to store some of the contents of the RAM when the RAM is full. If this value is **Yes**, the logical volume is used to store some of the contents of the RAM.

Logical Volume Mirror Count

The number of mirrors that keep a synchronous copy of the resource.

Logical Volume Type

The type of server logical volume. For example, the logical volume type can be concatenation or stripe set.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Logical Volume Allocation on Server Disk (GiB)

The amount of disk storage space that is allocated to the logical volume.

Logical Volume Capacity (GiB)

The amount of storage space that is on a logical volume.

Logical Volume Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Status information

You can create capacity and relationship reports that include the following information:

Logical Volume Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Data for volume groups on servers in capacity and relationship reports

You can include general information and capacity data about volume groups on servers in capacity and relationship reports.

Information about volume groups on servers

You can create capacity and relationship reports that include the following information:

Volume Group Name

The name that was assigned to the volume group when it was added to the system.

Volume Group Type

The type of the volume manager that manages the volume group. The volume manager can be a logical volume manager (LVM) or a Veritas volume manager.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Volume Group Capacity (GiB)

The amount of storage space that is on a volume group.

Volume Group Available Space (GiB)

The amount of unused storage space on a server volume group.

Volume Group Number of Logical Volumes

The number of logical volumes on a resource.
Volume Group Number of Server Disks
The number of server disks in a volume group.

Data for server disks in capacity and relationship reports

You can include general information, capacity data, properties of components, and other information about server disks in capacity and relationship reports.

Information about server disks

You can create capacity and relationship reports that include the following information:

Server Disk Name
The path that the operating system uses for the server disk, for example /dev/hdisk0.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Server Disk Capacity (GiB)
The amount of storage space that is on a server disk.
Server Disk Available Space (GiB)
The amount of unused storage space that is on a server disk.

Component properties

You can create capacity and relationship reports that include the following information:

Server Disk Is Removable
Shows whether the disk can be removed from the server. If this value is **Yes**, the disk can be removed from the server.
Server Disk Multipathing Policy
The multipathing policy that is in effect for a disk. For example, the policy can be **Round Robin**, **Load Balancing**, **Failover Only**, or other policies.

Status information

You can create capacity and relationship reports that include the following information:

Server Disk Status
The condition of the resource, for example normal, warning, or error.
Server Disk Is Detected
Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Vendor, model, and device information

You can create capacity and relationship reports that include the following information:

Server Disk Firmware Version
The version number of the firmware that is running on the disk.
Server Disk Model
The model name or model number of the resource.
Server Disk Serial Number
The serial number of the resource.
Server Disk Vendor
The vendor who supplied the resource.

Path information

You can create capacity and relationship reports that include the following information:

Server Disk Path Name
The name of a path to a server disk. Typically the multipath driver defines this name.
Server Disk Path Mode
The online status of the path to the server disk.
Server Disk Path State
The state of the disk path shows whether the path is functioning correctly.
Server Disk Path Status
The aggregate status of the paths to the server disk.
Server Disk Preferred Path
The preferred path status of the path to the server disk, that is, whether the path is the preferred path for the disk. The multipath driver might use non-preferred paths if a failover occurs. The disk might have no preferred path, depending on the multipathing policy that is in effect for the disk.
Server Disk LUN
The logical unit within a small computer system interface target on a disk.
Server Disk SCSI Target
The bus address for the small computer system interface of the target on a disk.

Server Disk Target WWPN
The worldwide port name of the storage port that the volume is mapped to.

Data for server groups in capacity and relationship reports

You can include general information and properties of server groups in capacity and relationship reports.

Information about server groups

Server groups are deprecated in IBM Spectrum® Control 5.2.10 and later. Use storage resource groups instead. In the IBM Spectrum Control GUI, storage resource groups are available as general groups.

You can create capacity and relationship reports that include the following information:

Server Group Name
The name that was assigned to the server group when it was added to the system.

Component properties

You can create capacity and relationship reports that include the following information:

Server Group Creator
The user name of the user who created the group.
Server Group Last Modified
The date and time that the resource was last modified.
Server Group Last Modified by User
The user name of the user who last modified the resource.

Data for server controllers in capacity and relationship reports

You can include general information about server controllers in capacity and relationship reports.

Information about server controllers

You can create capacity and relationship reports that include the following information:

Server Controller Name
The name of the disk controller on a server.
Server Controller Status
The status of a disk controller. Statuses include Normal, Warning, Error, and Unknown. Use the status to determine the condition of a controller, and if any actions must be taken. For example, if a controller has an Error status, take immediate action to correct the problem.
Server Controller Description
A short description of a disk controller that was provided by the manufacturer.
Server Controller Type
The type of disk controller, such as IDE, SCSI, Floppy, and RAID. Host Bus Adapters (HBAs) have a controller type of Fibre Channel Arbitrated Loop (FCAL).
Server Controller Driver Version
The version identifier of the device driver on the disk controller. This value is only available for HBAs.
Server Controller Firmware
The firmware version of the microcode on a disk controller. This value is only available for HBAs.
Server Controller ROM Version
The version of the read-only memory (ROM) on a controller. This value is only available for HBAs.
Server Controller Hardware Version
The hardware version identifier for a disk controller. This value is only available for HBAs.
Server Controller WWN
The worldwide name of a disk controller. This value is only available for HBAs.
Server Controller Serial Number
The serial number of the server controller.
Server Controller Bus Address
The SCSI bus address that is associated with a disk controller. This property is available only for SCSI disk controllers.
Server Controller Bus Number
The SCSI bus number that is associated with a disk controller. This property is available only for SCSI disk controllers.

Data for multipath drivers on servers in capacity and relationship reports

You can include name and version information about multipath drivers on servers in capacity and relationship reports.

Information about multipath drivers on servers

You can create capacity and relationship reports that include the following information:

Server Multipath Driver Name
The name of a multipath driver on a server.

Server Multipath Driver Version
The version number of a multipath driver on a server.

Data for file system groups on servers in capacity and relationship reports

You can include general information about file system groups on servers, and properties of file system groups in capacity and relationship reports.

Information about file system groups on servers

File system groups are deprecated in IBM Spectrum® Control 5.2.10 and later. Use storage resource groups instead. In the IBM Spectrum Control GUI, storage resource groups are available as general groups.

You can create capacity and relationship reports that include the following information:

File System Group Name
The name that was assigned to the file system group when it was added to the system.

Component properties

You can create capacity and relationship reports that include the following information:

File System Group Creator
The user name of the user who created the group.

File System Group Last Modified
The date and time that the resource was last modified.

File System Group Last Modified by User
The user name of the user who last modified the resource.

Data for hypervisors in capacity and relationship reports

You can include general information, capacity data, properties, and other information about hypervisors in capacity and relationship reports.

Information about hypervisors

You can create capacity and relationship reports that include the following information:

Hypervisor Name
The fully qualified domain name of the hypervisor. For example, the name of a hypervisor might be **hypervisor.example.com**.

Hypervisor Short Name
The host name from the fully qualified domain name of the hypervisor. For example, if the fully qualified domain name of the hypervisor is **mycomputer.example.com**, the host name is **mycomputer**.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Hypervisor Kernel Memory (GiB)
The amount of memory on a hypervisor that is used for kernel memory. Kernel memory is used to perform internal operating system processes.

Hypervisor Service Console Memory (GiB)
The amount of memory on a hypervisor that is used for the VMware ESX Service Console. Service Console is the operating system that is used to interact with ESX and the virtual machines that run on the hypervisor.

Hypervisor Swap Space (GiB)
The amount of disk space on a resource that is available to store some of the contents of the RAM when the RAM is full.

Hypervisor Total Disk Capacity (GiB)
The amount of storage space on disks on a hypervisor.

Hypervisor Total Disk Available Space (GiB)
The amount of unused storage space on disks on the hypervisor.

Hypervisor Total File System Available Space (GiB)
The amount of unused storage space that is available on the file systems on a hypervisor.

Component properties

You can create capacity and relationship reports that include the following information:

Hypervisor IP Address
The IP address of the resource.

Hypervisor OS Type
The software that runs the hypervisor, that is, VMware ESX.

Hypervisor OS Version
The version number of the operating system that is running on the resource.

Hypervisor Processor Architecture

The architecture of the processor on the server or hypervisor. For example, the architecture of a processor might be Intel 64 bit (IA64) or Intel 32 bit (IA32).

Hypervisor Processor Count
The number of processors on the server or hypervisor.

Hypervisor Processor Speed (MHz)
The speed of the processor on the server or hypervisor.

Hypervisor Processor Type
Shows information about the processor, such as the family and model of the processor.

Hypervisor RAM (GiB)
The amount of RAM on the server or hypervisor.

Hypervisor Software API Version
The version number of the software API that runs on the hypervisor.

Hypervisor Software Full Name
The name, version number, and build number of the software that runs the hypervisor.

Hypervisor Time Zone
The time zone in which a resource is located.

Hypervisor Location
The physical location of a hypervisor. The location is defined when a hypervisor is added to IBM Spectrum® Control. You can add or edit the location of the hypervisor in the Properties pane of the hypervisor.

Hypervisor Custom Tag 1, 2, and 3
User-defined text that is associated with a hypervisor. You can add or edit the custom tags for a hypervisor in the Properties pane of the hypervisor.

Vendor, model, and device information

You can create capacity and relationship reports that include the following information:

Hypervisor Model
The model name or model number of the resource.

Hypervisor Serial Number
The serial number of the resource.

Hypervisor Vendor
The vendor who supplied the resource.

Status information

You can create capacity and relationship reports that include the following information:

Hypervisor Status
The condition of the resource, for example normal, warning, or error.

Hypervisor Is Detected
Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Hypervisor Last Data Collection
The date and time when storage statistics were last collected from the resource.

Hypervisor Last Start Time
The last time that the resource was started.

Data for clusters on hypervisors in capacity and relationship reports

You can include general information about clusters on hypervisors in capacity and relationship reports.

Information about clusters on hypervisors

You can create capacity and relationship reports that include the following information:

Hypervisor Cluster Name
The name of a cluster that is monitored in your storage environment. A cluster is a group of hypervisors that collaborate for the purposes of workload balancing and failover.

Hypervisor Cluster Type
The type of a cluster that is monitored in your storage environment. For example, the type might be VMware Cluster.

Data for file systems on hypervisors in capacity and relationship reports

You can include general information, capacity data, and other information about file systems on hypervisors in capacity and relationship reports.

Information about file systems on hypervisors

You can create capacity and relationship reports that include the following information:

Hypervisor File System Mount Point
The name or mount point of the file system for the resource. For example, on Microsoft Windows systems, the value in this property might be c:\ or d:\. On operating systems such as AIX®, Linux®, Solaris, or HP-UX, the mount point might be /opt or /export/home.

Hypervisor File System Export Name
The name of the exported file system.

Hypervisor File System Type

The type of file system that the hypervisor uses.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Hypervisor File System Capacity (GiB)

The amount of storage space on the file system of the resource.

Hypervisor File System Directory Count

The number of directories in the file systems that are on a server.

Hypervisor File System File Count

The number of files in the file system.

Hypervisor File System Available Space (GiB)

The amount of unused storage space in the file system of the resource.

Hypervisor File System Available Inodes

The number of unused inodes in file systems on the operating system.

Hypervisor File System Used Inodes

The number of used inodes in file systems on the operating system.

Tip: For Microsoft Windows systems, this property is blank.

Hypervisor File System Maximum Files

The maximum number of files that the file system on the resource can contain.

Hypervisor File System Physical Size (GiB)

The amount of physical storage space on the file systems on a resource. The physical size is the size of all the clusters that the file system uses.

Hypervisor File System Used Space (GiB)

The amount of used storage space in the file system of the resource.

Status information

You can create capacity and relationship reports that include the following information:

Hypervisor File System Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Hypervisor File System Last Scan

The date and time when file statistics were last collected from the resource.

Data for data stores on hypervisors in capacity and relationship reports

You can include general information, capacity data, and other information about data stores on hypervisors in capacity and relationship reports.

Information about data stores on hypervisors

You can create capacity and relationship reports that include the following information:

Hypervisor Data Store

The path to the VMware ESX data store on the hypervisor, for example datastore_svc3c.

Hypervisor Data Store Cluster Name

The name of the cluster, if the data store is a member of a data store cluster. If the data store is not a member of a data store cluster, no information is displayed.

Hypervisor Data Store Type

The type of file system that the hypervisor data store uses. For example, the type can be NFS or VMFS.

Hypervisor NAS Name

The name of the network-attached storage that the data store is obtained from.

Hypervisor NAS Path Name

The path name on the network-attached storage of the data store.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Hypervisor Data Store Capacity (GiB)

The amount of storage space that is on the hypervisor data store.

Hypervisor Data Store Available Space (GiB)

The amount of unused storage space on a hypervisor data store.

Hypervisor Data Store Allocation on Hypervisor Disk (GiB)

The amount of storage space that is allocated to the hypervisor data store on hypervisor server disks.

Hypervisor Data Store VM File System Version

The version number of the virtual machine file system on the hypervisor data store.

Status information

You can create capacity and relationship reports that include the following information:

Hypervisor Data Store Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Data for server disks on hypervisors in capacity and relationship reports

You can include general information, capacity data, path information, and other information about server disks on hypervisors in capacity and relationship reports.

Information about server disks

You can create capacity and relationship reports that include the following information:

Hypervisor Disk Name

The path that the operating system uses for the server disk.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Hypervisor Disk Capacity (GiB)

The amount of storage space that is on the hypervisor disk.

Hypervisor Disk Available Space (GiB)

The amount of unused storage space on a hypervisor server disk.

Component properties

You can create capacity and relationship reports that include the following information:

Hypervisor Disk Multipathing Policy

The multipathing policy that is in effect for a disk. For example, the policy can be **Round Robin, Load Balancing, Failover Only**, or other policies.

Status information

You can create capacity and relationship reports that include the following information:

Hypervisor Disk Status

The condition of the resource, for example normal, warning, or error.

Hypervisor Disk Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Vendor, model, and device information

You can create capacity and relationship reports that include the following information:

Hypervisor Disk Firmware Version

The version number of the firmware that is running on the disk.

Hypervisor Disk Model

The model name or model number of the resource.

Hypervisor Disk Serial Number

The serial number of the resource.

Hypervisor Disk Vendor

The vendor who supplied the resource.

Path information

You can create capacity and relationship reports that include the following information:

Hypervisor Disk Path Name

The name of a path to a server disk. Typically the multipath driver defines this name.

Hypervisor Disk Path State

The state of the disk path shows whether the path is functioning correctly.

Hypervisor Disk Path Status

The aggregate status of the paths to the server disk.

Hypervisor Disk Preferred Path

The preferred path status of the path to the server disk, that is, whether the path is the preferred path for the disk. The multipath driver might use non-preferred paths if a failover occurs. The disk might have no preferred path, depending on the multipathing policy that is in effect for the disk.

Hypervisor Disk LUN

The logical unit within a small computer system interface target on a disk.

Hypervisor Disk SCSI Target

The bus address for the small computer system interface of the target on a disk.

Hypervisor Disk Target WWPN

The worldwide port name of the storage port that the volume is mapped to.

Data for hypervisor controllers in capacity and relationship reports

You can include general information about hypervisor controllers in capacity and relationship reports.

Information about hypervisor controllers

You can create capacity and relationship reports that include the following information:

Hypervisor Controller Name

The name of the disk controller on a hypervisor.

Hypervisor Controller Description

A short description of a disk controller that was provided by the manufacturer.

Hypervisor Controller Type

The type of disk controller, such as IDE, SCSI, Floppy, and RAID. Host Bus Adapters (HBAs) have a controller type of Fibre Channel Arbitrated Loop (FCAL).

Hypervisor Controller WWN

The worldwide name of a disk controller. This value is only available for HBAs.

Hypervisor Controller Bus Address

The SCSI bus address that is associated with a disk controller. This property is available only for SCSI disk controllers.

Data for multipath drivers on hypervisors in capacity and relationship reports

You can include name and version information about multipath drivers on hypervisors in capacity and relationship reports.

Information about multipath drivers on hypervisors

You can create capacity and relationship reports that include the following information:

Hypervisor Multipath Driver Name

The name of a multipath driver on a hypervisor.

Hypervisor Multipath Driver Version

The version number of a multipath driver on a hypervisor.

Data for virtual machines managed by hypervisors in capacity and relationship reports

You can include general information, and file and disk information for virtual machines in capacity and relationship reports.

Information about virtual machines

You can create capacity and relationship reports that include the following information:

Virtual Machine Name

The name that was assigned to the virtual machine when it was added to the system.

Virtual Machine Configuration File

The path to the virtual machine configuration file for a hypervisor virtual machine, for example [datastore1] example/example.vmx.

Virtual Machine Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Virtual Machine Number of CPU

The number of processors on the virtual machine.

Virtual Machine Status

The condition of the resource, for example normal, warning, or error.

Virtual Machine Total Memory (GiB)

The amount of memory on a hypervisor virtual machine.

Virtual machine file information

You can create capacity and relationship reports that include the following information:

Virtual Machine File Path

The path to the virtual machine configuration file, or to the virtual machine disk file for the virtual machine. The virtual machine configuration file is a .vmx file, and the virtual machine disk file is a .vmdk file.

Virtual Machine File Logical Size (GiB)

The logical size of a virtual machine disk file for a hypervisor virtual machine.

Virtual Machine File Type

The type of the file for the virtual machine. For example, the file can be a virtual machine configuration file, a virtual machine disk file, an ISO image file, or other types of virtual machine file.

Virtual machine disk information

You can create capacity and relationship reports that include the following information:

Virtual Machine Disk Name

The name that was assigned to the virtual machine disk when it was added to the system.

Virtual Machine Disk SCSI Target

The bus address for the small computer system interface of the target on a disk.

Virtual Machine Disk Type

The type of virtual machine disk, for example, collection mirroring or logical disk mirroring.

Data for network-attached storage systems in capacity and relationship reports

You can include general information, capacity data, properties, and other information about network-attached storage (NAS) systems in capacity and relationship reports.

Information about NAS systems

You can create capacity and relationship reports that include the following information:

NAS Name

The fully qualified domain name of the NAS device. For example, the name of a NAS device might be **nas.example.com**.

NAS Domain Name

The domain name of the cluster, server, or NAS server.

NAS Short Name

The host name from the fully qualified domain name of the NAS device. For example, if the fully qualified domain name of the NAS device is **mycomputer.example.com**, the host name is **mycomputer**.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

NAS Total Disk Capacity (GiB)

The amount of storage space on all disks on a NAS resource.

NAS Total Disk Available Space (GiB)

The amount of unused storage space on all disks on a NAS resource.

NAS Total File System Available Space (GiB)

The amount of unused storage space on the file systems on a NAS resource.

Component properties

You can create capacity and relationship reports that include the following information:

NAS OS Type

The operating system that is running on the server.

NAS OS Version

The version number of the operating system that is running on the resource.

NAS Location

The physical location of a NAS system that is probed as a file server. You can add or edit the location of the NAS system on the File Storage tab in the Storage Systems pane.

NAS Custom Tag 1, 2, and 3

User-defined text that is associated with a NAS system that is probed as a file server. You can add or edit the custom tags for a NAS system on the File Storage tab in the Storage Systems pane.

Vendor, model, and device information

You can create capacity and relationship reports that include the following information:

NAS Model

The model name or model number of the resource.

NAS Vendor

The vendor who supplied the resource.

NAS Serial Number

The serial number of the resource.

Status information

You can create capacity and relationship reports that include the following information:

NAS Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

NAS Last Data Collection

The date and time when storage statistics were last collected from the resource.

NAS Last Start Time

The last time that the resource was started.

NAS system components information

You can create capacity and relationship reports that include the following information:

NAS System Name

The name that was assigned to the NAS system when it was added to the system.

NAS System IP Address

The IP address of the resource.

NAS System Location

The physical location of a NAS system that is probed as a storage system. The location is defined when a NAS system is added to IBM Spectrum® Control. You can add or edit the location of the NAS system on the File Storage tab in the Storage Systems pane.

NAS System Custom Tag 1, 2, and 3

User-defined text that is associated with a NAS system that is probed as a storage system. You can add or edit the custom tags for a NAS system on the File Storage tab in the Storage Systems pane.

Data for file systems on network-attached storage systems in capacity and relationship reports

You can include general information, capacity data, and other information about file systems on network-attached storage (NAS) systems in capacity and relationship reports.

Information about file systems on NAS systems

You can create capacity and relationship reports that include the following information:

NAS File System Mount Point

The name or mount point of the file system for the resource. For example, on Microsoft Windows systems, the value in this property might be c:\ or d:\. On operating systems such as AIX®, Linux®, Solaris, or HP-UX, the mount point might be /opt or /export/home.

NAS File System Export Name

The name of the exported file system.

NAS File System Type

The type of file system that the resource uses.

Capacity and usage data

Tip:

In the IBM Spectrum® Control interface, the capacity values of file systems are displayed in one column, Total File System Capacity (GiB).

You can create capacity and relationship reports that include the following information:

NAS File System Capacity (GiB)

The amount of storage space on the file system of the resource.

NAS File System Directory Count

The number of directories in the file systems that are on a server.

NAS File System File Count

The number of files in the file system.

NAS File System Available Space (GiB)

The amount of unused storage space in the file system of the resource.

NAS File System Available Inodes

The number of unused inodes on the file system on a NAS server.

NAS File System Used Inodes

The number of used inodes on the file system on a NAS server.

NAS File System Maximum Files

The maximum number of files that the file system on the resource can contain.

NAS File System Physical Size (GiB)

The amount of physical storage space on the file systems on a resource. The physical size is the size of all the clusters that the file system uses.

NAS File System Used Space (GiB)

The amount of used storage space in the file system of the resource.

Component properties

You can create capacity and relationship reports that include the following information:

NAS File System Custom Tag 1, 2, and 3

User-defined text that is associated with a NAS file system. You can add or edit the custom tags for a NAS file system in the Properties pane of the resource.

Status information

You can create capacity and relationship reports that include the following information:

NAS File System Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

NAS File System Last Scan

The date and time when file statistics were last collected from the resource.

Data for network-attached storage exports in capacity and relationship reports

You can include general information and status information about network-attached storage (NAS) exports in capacity and relationship reports.

Information about network-attached storage exports

You can create capacity and relationship reports that include the following information:

NAS Export Name

The name of the network-attached storage export. Use this name to mount the network-attached storage export on a server.

NAS Export Path

The path to a logical volume on a resource, for example /dev/hd1.

NAS Export State

Shows whether the network-attached storage export is active.

Status information

You can create capacity and relationship reports that include the following information:

NAS Export Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Data for logical volumes on network-attached storage systems in capacity and relationship reports

You can include general information, capacity data, and other information about logical volumes on network-attached storage (NAS) systems in capacity and relationship reports.

Information about logical volumes on NAS systems

You can create capacity and relationship reports that include the following information:

NAS Logical Volume Name

The name that was assigned to the NAS logical volume when it was added to the system.

NAS Logical Volume Type

The type of NAS logical volume. The logical volume type can be a NetApp traditional volume or a NetApp flexible volume.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

NAS Logical Volume Capacity (GiB)

The amount of storage space on the NAS logical volume.

NAS Logical Volume Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Status information

You can create capacity and relationship reports that include the following information:

NAS Logical Volume Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

NAS Logical Volume Last Scan

The date and time when file statistics were last collected from the resource.

Data for network-attached storage disks in capacity and relationship reports

You can include general information, capacity data, properties, and other information about network-attached storage (NAS) disks in capacity and relationship reports.

Information about NAS disks

You can create capacity and relationship reports that include the following information:

NAS Disk Name

The name that was assigned to the NAS disk when it was added to the system.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

NAS Disk Total Capacity (GiB)

The amount of storage space that is on the NAS disk.

NAS Disk Available Space (GiB)

The amount of unused storage space on a NAS disk.

Status information

You can create capacity and relationship reports that include the following information:

NAS Disk Status

The condition of the resource, for example normal, warning, or error.

NAS Disk Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Storwize® V7000 Unified information

You can create capacity and relationship reports that include the following information:

NSD Available Fragments

The number of fragments of disk space that are unused on the Network Shared Disk (NSD).

NSD Failover Group

The failover group that the NSD belongs to. A failover group is a group of resources that are grouped together to ensure that some of those resources are available if one or more of the resources fail.

NSD Type

The type of the NSD. For example, the type can be:

- Data and metadata
- Metadata only
- Data only

NSD Last Data Collection

The date and time when storage statistics were last collected from the resource.

NSD Custom Tag 1, 2, and 3

User-defined text that is associated with a Network Shared Disk (NSD). You can add or edit the custom tags for an NSD in the Properties pane of the resource.

NetApp information

You can create capacity and relationship reports that include the following information:

NAS Disk Flag

Shows whether the NAS disk is a spare device. If this value is **Spare device**, the NAS disk is a spare device.

NAS Disk Is Encrypted

Shows whether the resource is encrypted. If this value is **Yes**, the resource is encrypted.

NAS Disk Is Removable

Shows whether the disk can be removed from the server. If this value is **Yes**, the disk can be removed from the server.

NAS Disk Is Solid State

Shows whether the disk is a solid-state drive.

NetApp paths information

You can create capacity and relationship reports that include the following information:

NAS Disk LUN

The logical unit within a small computer system interface target on a disk.

NAS Disk SCSI Target

The bus address for the small computer system interface of the target on a disk.

NAS Disk Target WWPN

The worldwide port name of the storage port that the volume is mapped to.

NetApp vendor, model, and device information

You can create capacity and relationship reports that include the following information:

NAS Disk Firmware Version

The version number of the firmware that is running on the disk.

NAS Disk Model

The model name or model number of the resource.

NAS Disk Serial Number

The serial number of the resource.

NAS Disk Vendor

The vendor who supplied the resource.

Data for pools on Storwize V7000 Unified systems in capacity and relationship reports

You can include general information and capacity data about pools on Storwize® V7000 Unified systems in capacity and relationship reports.

Information about pools on network-attached storage systems

You can create capacity and relationship reports that include the following information:

NAS Pool Name

The name that was assigned to the NAS pool when it was added to the system.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

NAS Pool Capacity (GiB)

The amount of storage space that is in a NAS pool.

NAS Pool Available Space (GiB)

The amount of unused storage space in a NAS pool.

NAS Pool Number of Logical Volumes

The number of logical volumes on a resource.

Data for Storwize V7000 Unified filesets in capacity and relationship reports

You can include general information, capacity data, and other information about Storwize® V7000 Unified filesets in capacity and relationship reports.

Information about network-attached storage filesets

You can create capacity and relationship reports that include the following information:

NAS Fileset Name

The name that was assigned to the network-attached storage (NAS) fileset when it was added to the system.

NAS Fileset Comment

A comment that is associated with the NAS fileset.

NAS Fileset Path

The path to a logical volume on a resource, for example /dev/hd1.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

NAS Fileset Used Space (GiB)

The amount of used storage space in the fileset of the NAS resource.

NAS Fileset Used Inodes

The number of used inodes in file systems on operating systems such as AIX®, Linux®, Solaris, or HP-UX.

Status information

You can create capacity and relationship reports that include the following information:

NAS Fileset Status

Shows whether the network-attached storage fileset is linked or unlinked.

NAS Fileset Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Data for storage virtualizers in capacity and relationship reports

You can include general information, capacity data, properties, and other information about storage virtualizers in capacity and relationship reports.

Information about storage virtualizers

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Name

A user-defined name of the storage virtualizer. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage virtualizer was added for monitoring.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Total Pool Capacity (GiB)

The total amount of storage space in pools on the storage virtualizer.

Storage Virtualizer Pool Used Space (GiB)

The amount of allocated space that is used by the volumes in a pool, which includes thin-provisioned and standard volumes.

For resources that are running IBM Spectrum Virtualize, note the following information about the Storage Virtualizer Pool Used Space:

- You can pre-allocate thin-provisioned volume space when the volumes are created. In this case, the Storage Virtualizer Pool Used Space might be different than the Storage Virtualizer Pool Allocated Space for pools that contain thin-provisioned volumes.

- For pools with compressed volumes, the Storage Virtualizer Pool Used Space reflects the size of compressed data that is written to disk. As the data changes, the Storage Virtualizer Pool Used Space might at times be less than the Storage Virtualizer Pool Allocated Space.
- For pools with volumes that are not thin provisioned or compressed, the values for Storage Virtualizer Pool Used Space and Storage Virtualizer Pool Allocated Space are equal.

This value is accurate as of the most recent time that IBM Spectrum Control collected data about a pool. Because data collection is run on a set schedule and the used space on volumes can change rapidly, the value in this column might not be 100% accurate for the current state of volumes.

Storage Virtualizer Pool Available Space (GiB)

The amount of space in a pool that is not reserved for volumes.

Storage Virtualizer Total Volume Capacity (GiB)

The amount of virtual volume space on all volumes on the storage virtualizer.

Storage Virtualizer Volume Allocated Space (GiB)

The amount of space that is reserved for a volume.

The space that is allocated for a thin-provisioned volume is less than its virtual capacity, which is shown in Storage Virtualizer Capacity.

This value is equal to Storage Virtualizer Volume Used Space for the following resources:

- Resources that are not running IBM Spectrum Virtualize
- Resources that are running IBM Spectrum Virtualize and are not thin-provisioned

Storage Virtualizer Volume Assigned Space (GiB)

The amount of virtual volume space that is assigned to the server or storage virtualizer.

Storage Virtualizer MDisk Available Space (GiB)

The amount of space on managed disks that is available in a pool, or is available to be added to a pool.

Storage Virtualizer MDisk Capacity (GiB)

The amount of storage space on the managed disk.

Storage Virtualizer Disk Capacity (GiB)

The amount of local disk storage on the storage virtualizer. The local disks are the internal disk drives.

Storage Virtualizer Number of MDisk

The number of managed disks on a resource.

Storage Virtualizer Number of Volumes

The number of volumes on a resource.

Storage Virtualizer Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Storage Virtualizer Tier Available Space (GiB)

The amount of unused tier storage of a particular type. The type is identified in the Storage Virtualizer Tier Type property.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Tier Capacity (GiB)

The amount of tier storage of a particular type. The type is identified in the Storage Virtualizer Tier Type property.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Physical Allocation Percentage

The percentage of physical space in storage virtualizer pools that is reserved for volumes. This value is always less than or equal to 100% because you cannot reserve more physical space than is available in the pools.

IBM Spectrum Control uses the following formula to determine the allocation percentage:

$$(\text{allocated space} \div \text{pool capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a total storage virtualizer pool size of 200 GiB. Therefore, the space that is reserved for volumes is 50 GiB.

Storage Virtualizer Virtual Allocation Percentage

The percentage of physical space in storage virtualizer pools that is committed to the total virtual capacity of the volumes in the pool. In thin-provisioned environments, this percentage exceeds 100% if a pool is overcommitted (over-provisioned).

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{total volume capacity} \div \text{pool capacity}) \times 100$$

For example, the allocation percentage is 200% for a total pool size of 15 GiB. Therefore, the virtual capacity that is committed to the volumes in the pools is 30 GiB.

This configuration means that twice as much space is committed than is physically contained in the pools. If the allocation percentage is 100% for the same pools, then the virtual capacity that is committed to the pools is 15 GiB. This configuration means that all the physical capacity of the pools is already allocated to volumes.

An allocation percentage that is higher than 100% is considered aggressive. The pools have insufficient physical capacity to satisfy the maximum allocation for all the thin-provisioned volumes in the pools. In such cases, use the Storage Virtualizer Shortfall Percentage property to estimate how critical the shortage of space is for storage virtualizer pools.

This value is only available for pools with thin-provisioned volumes.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Shortfall Percentage

The percentage of the remaining unallocated volume space in storage virtualizer pools that is not available to be allocated. The higher the percentage, the more critical the shortfall of pool space.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{unallocatable space} \div (\text{volume space} - \text{used volume space})) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in pools reaches a critically high level. For example, the physical space in pools might be less than the committed virtual space. In this case, the pools do not have enough space to fulfill the commitment to virtual space.

This Storage Virtualizer Shortfall Percentage represents the percentage of the committed virtual space that is not available in pools. As more space is used over time by volumes while the pool capacity remains the same, this percentage increases.

For example, the physical capacity of pools is 70 GiB, but 150 GiB of virtual space is committed to thin-provisioned volumes. If the volumes are using 50 GiB, then there is still 100 GiB committed to those volumes (150 GiB - 50 GiB). There is only 20 GiB of available pool space (70 GiB - 50 GiB). Because only 20 GiB of pool space is available, 80 GiB of the committed space cannot be allocated (100 GiB - 20 GiB). In this case, the percentage of committed space that is unavailable is 80% (80 GiB ÷ 100 GiB × 100).

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

This property is available only for storage virtualizer pools with thin-provisioned volumes.

Component properties

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Access Information

The URL from which you can access the storage system or storage virtualizer.

Storage Virtualizer Alias

Shows an alternative name for a storage virtualizer.

Storage Virtualizer Code Level

The microcode or firmware level of the storage virtualizer.

Storage Virtualizer Time Zone

The time zone in which a resource is located.

Storage Virtualizer Location

The physical location of a storage virtualizer. The location is defined when a storage virtualizer is added to IBM Spectrum Control. You can add or edit the location of the storage virtualizer in the Properties pane for the storage system.

Storage Virtualizer Custom Tag 1, 2, and 3

User-defined text that is associated with a storage virtualizer. You can add or edit the custom tags for a storage virtualizer on the Properties page of the storage system.

Storage Virtualizer User Provided Name

The name that was specified for the storage virtualizer in the storage environment.

Storage Virtualizer Tier Type

The type of tier that is used on the storage virtualizer. For example, the tier type can be hard disk drive (HDD) or solid-state drive (SSD). The tier is configured to be controlled by the Easy Tier® function.

This value is available only for resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Is Compression Active

Shows whether the compression feature is enabled on the storage virtualizer. If this value is **Yes**, the compression feature is enabled.

Storage Virtualizer Configuration

Shows that a storage virtualizer is configured to virtualize back-end storage. This value is always Storage Virtualizer.

Status information

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Status

The condition of the resource, for example normal, warning, or error.

Storage Virtualizer Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Storage Virtualizer Last Data Collection

The date and time when storage statistics were last collected from the resource.

Storage Virtualizer Last Data Collection Status

The condition of the last data collection. The status can show if the collection was a success, a failure, or if data was collected from the resource.

Vendor, model, and device information

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Type

The type of storage virtualizer. For example, the storage virtualizer can be an IBM Storwize V7000 system, an IBM SAN Volume Controller system, or another type of storage virtualizer.

Storage Virtualizer Vendor

The vendor who supplied the resource.

Storage Virtualizer Model

The model name or model number of the storage virtualizer.

Storage Virtualizer Machine Type

The machine type of a storage virtualizer. For example, the storage virtualizer can be Storwize V7000 - 2076, SAN Volume Controller - 2145, or another type of storage virtualizer.

Storage Virtualizer IP Address

The IP address of the resource.

Storage Virtualizer Serial Number

The serial number of the resource.

Data for storage virtualizer pools in capacity and relationship reports

You can include general information, capacity data, properties, and other information about storage virtualizer pools in capacity and relationship reports.

Information about storage virtualizer pools

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Pool Name

The name that was assigned to the pool when it was added to the system.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Pool Capacity (GiB)

The total amount of storage space in a pool.

Storage Virtualizer Pool Available Space (GiB)

The amount of unused storage space in a storage virtualizer pool.

Storage Virtualizer Pool Total Volume Capacity (GiB)

The total storage space on all the volumes in a pool, which includes thin-provisioned and standard volumes. For thin-provisioned volumes, this value includes virtual space.

Storage Virtualizer Pool Allocated Space (GiB)

The amount of space that is reserved for all the volumes in a pool, which includes both thin-provisioned and standard volumes.

The space that is allocated for thin-provisioned volumes is less than their virtual capacity. The Storage Virtualizer Pool Total Volume Capacity (GiB) property shows the virtual capacity of the volumes. If a pool does not contain thin-provisioned volumes, this value is the same as the value of the Storage Virtualizer Pool Total Volume Capacity (GiB) property.

This value is equal to Storage Virtualizer Used Space (GiB) for volumes that are not thin provisioned.

Storage Virtualizer Pool Used Volume Space (GiB)

The amount of allocated space that is used by the volumes in a pool, which includes thin-provisioned and standard volumes.

For resources that are running IBM Spectrum Virtualize, you can preallocate thin-provisioned volume space when volumes are created. For these resources, the Storage Virtualizer Pool Used Space might be different than the Storage Virtualizer Pool Allocated Space for pools that contain thin-provisioned volumes. In other cases, the values for Storage Virtualizer Pool Used Space and Storage Virtualizer Pool Allocated Space are equal.

This value is accurate as of the most recent time that IBM Spectrum® Control collected data about a volume. The value in this property might not be 100% accurate for the current state of volumes. This inaccuracy might occur because data collection is run on a set schedule and the used space on volumes can change rapidly.

Storage Virtualizer Pool Extent Size (MiB)

The size of the extents that were specified when a pool was created. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Pool Assigned Volume Space (GiB)

The amount of space in the pool that is on volumes that are assigned to a server or storage virtualizer.

Storage Virtualizer Pool Unassigned Volume Space (GiB)

The amount of volume space in the pool that is not assigned to a server or storage virtualizer.

Storage Virtualizer Pool Tier Capacity (GiB)

The amount of pool tier storage of a particular type. The type can be hard disk drive (HDD) or solid-state drive (SSD) and is identified in the Storage Virtualizer Pool Tier Type property. The tier is configured to be controlled by the Easy Tier® function.

This value is available only for resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Pool Tier Available Space (GiB)

The amount of pool tier storage of a particular type that is unused. The type can be hard disk drive (HDD) or solid-state drive (SSD) and is identified in the Storage Virtualizer Pool Tier Type property. The tier is configured to be controlled by the Easy Tier function.

This value is available only for resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Pool Tier Number of MDisks

The number of managed disks that is on a storage virtualizer pool. The tier is configured to be controlled by the Easy Tier function.

This value is available only for resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Pool Number of Storage Volumes

The number of volumes in the storage virtualizer pool.

Storage Virtualizer Pool Number of MDisks

The number of managed disks on a resource.

Storage Virtualizer Pool Maximum I/O Capability

The projected maximum number of I/O operations per second for a pool. This value is calculated based on the value in the Storage Virtualizer Pool Back-End Storage Disks property, and on the values in following properties:

- Storage Virtualizer Pool Back-End Storage System Type
- Storage Virtualizer Pool Back-End Storage RAID Level
- Storage Virtualizer Pool Back-End Storage Disk Type

This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Pool Back-End Storage Disks

The number of physical disks that contribute to the volumes on the back-end storage system. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Pool Physical Allocation Percentage

The percentage of physical space in a pool that is reserved for volumes. This value is always less than or equal to 100% because you cannot reserve more physical space than is available in a pool.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{allocated space} \div \text{pool capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a total pool size of 200 GiB. Therefore, the space that is reserved for volumes is 50 GiB.

Storage Virtualizer Pool Virtual Allocation Percentage

The percentage of physical space in a pool that is committed to the total virtual capacity of the volumes in the pool. In thin-provisioned environments, this percentage exceeds 100% if a pool is overcommitted (over-provisioned).

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{total volume capacity} \div \text{pool capacity}) \times 100$$

For example, for a total pool size of 15 GiB, the allocation percentage might be 200%. In this case, the virtual capacity that is committed to the volumes in the pool is 30 GiB. This configuration means that twice as much space is committed than is physically contained in the pool. If the allocation percentage is 100% for the same pool, then the virtual capacity that is committed to the pool is 15 GiB. This configuration means that all the physical capacity of the pool is already allocated to volumes.

An allocation percentage that is higher than 100% is considered aggressive. The pool has insufficient physical capacity to satisfy the maximum allocation for all the thin-provisioned volumes in the pool. In such cases, use the Storage Virtualizer Pool Shortfall Percentage property to estimate how critical the shortage of space is for storage system pools.

This value is only available for pools with thin-provisioned volumes.

Storage Virtualizer Pool Shortfall Percentage

The percentage of the remaining unallocated volume space in a pool that is not available to be allocated. The higher the percentage, the more critical the shortfall of pool space.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{unallocatable space} \div (\text{total volume capacity} - \text{allocated space})) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in a pool reaches a critically high level. For example, the physical space in a pool might be less than the committed virtual space. In this case, the pool does not have enough space to fulfill the commitment to virtual space.

This value represents the percentage of the committed virtual space that is not available in a pool. As more space is used over time by volumes while the pool capacity remains the same, this percentage increases.

For example, the physical capacity of a pool is 70 GiB, but 150 GiB of virtual space is committed to thin-provisioned volumes. If the volumes are using 50 GiB, then there is still 100 GiB committed to those volumes (150 GiB - 50 GiB). There is only 20 GiB of available pool space (70 GiB - 50 GiB). Because only 20 GiB of pool space is available, 80 GiB of the committed space cannot be allocated (100 GiB - 20 GiB). In this case, the percentage of committed space that cannot be allocated is 80% (80 GiB ÷ 100 GiB × 100).

This value is only available for pools with thin-provisioned volumes.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Pool Unallocated Volume Space (GiB)

The amount of the Total Volume Capacity in the pool that is not allocated.

IBM Spectrum Control uses the following formula to determine this percentage:

$$\text{total volume capacity} - \text{allocated space}$$

The space that is allocated for thin-provisioned volumes is typically less than their virtual capacity. Therefore, the unallocated space represents the difference between the virtual capacity and the allocated space for all the volumes in the pool.

Storage Virtualizer Pool Unused Volume Space (GiB)

The amount of space that is allocated to the volumes in a pool and is not yet used.

IBM Spectrum Control uses the following formula to determine this value:

$$\text{allocated space} - \text{used pool space}$$

Storage Virtualizer Pool Unallocatable Volume Space (GiB)

The amount of space by which the Total Volume Capacity exceeds the physical capacity of a pool.

In thin-provisioned environments, it is possible to over commit (over provision) storage in a pool. If you create volumes with more virtual capacity than can be physically allocated in the pool, you can over commit storage in the pool.

This value represents the amount of volume space that cannot be allocated based on the current capacity of the pool.

Storage Virtualizer Pool Used Space Percentage

The percentage of allocated space that is used by the volumes in a pool, which includes thin-provisioned and standard volumes.

Storage Virtualizer Pool Compressed Virtual Capacity (GiB)

The total virtual capacity of all the volumes that are compressed in a storage virtualizer pool.

Storage Virtualizer Pool Compressed Capacity (GiB)

The amount of storage space that is used by compressed volumes in a storage virtualizer pool. For example, if 100 GiB of uncompressed data is compressed, and the size of the compressed data is 20 GiB, the value is 20.

Storage Virtualizer Pool Uncompressed Capacity (GiB)

The amount of storage space that is used if the compressed volume space is uncompressed. For example, if 100 GiB of uncompressed data is compressed, and the size of the compressed data is 20 GiB, the value is 100.

Component properties

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Pool Is Encryptable

Shows whether the storage virtualizer pool can be encrypted. If this value is **Yes**, the storage virtualizer pool can be encrypted.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Pool Is Encrypted

Shows whether the storage virtualizer pool is encrypted. If this value is **Yes**, the storage virtualizer pool is encrypted.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Pool Is Solid State

Shows whether there are solid-state drives in the pool. This property can contain the following values:

Mixed

The pool contains both hard disk drives and solid-state drives.

Non solid state

The pool contains no solid-state drives.

Solid state

The pool contains a least one solid-state drive.

Storage Virtualizer Pool Is Thin Provisioned

Shows whether a pool, volume, or volume copy is thin-provisioned. If this value is **Yes**, the resource is thin-provisioned.

Storage Virtualizer Pool RAID Level

The RAID level of the resource, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the resource.

Storage Virtualizer Pool Warning Level

The percentage of used capacity of the resource at which a warning is generated. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Pool Tier

The tier level of pools on storage virtualizers. For example, the tier can be 1, 2, 3, or another tier number.

Storage Virtualizer Pool Tier Type

The type of tier that is used on the storage virtualizer pool. For example, the tier type can be hard disk drive (HDD) or solid-state drive (SSD). The tier is configured to be controlled by the Easy Tier function.

This value is available only for resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Pool Is Easy Tier

Shows whether the IBM® System Storage® Easy Tier feature is enabled. The IBM System Storage Easy Tier feature can be set to **auto**, **on**, or **off**.

The IBM System Storage Easy Tier feature automatically helps optimize solid-state storage deployments in multitier systems.

Storage Virtualizer Pool Back-End Storage System Type

The type of storage system that is providing storage space to a pool. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Pool Back-End Storage RAID Level

The RAID level of the volumes on the back-end storage system that are providing storage space to a pool. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Pool Back-End Storage Disk Type

The class and speed of the physical disks that contribute to the volumes on the back-end storage system. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Pool Custom Tag 1, 2, and 3

User-defined text that is associated with a storage virtualizer pool. You can add or edit the custom tags for a storage virtualizer pool on the Properties notebook of the pool.

Storage Virtualizer Pool Is Compression Active

Shows whether the compression feature is enabled on the storage virtualizer pool. If this value is **Yes**, the compression feature is enabled.

Status information

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Pool Status

The condition of the resource, for example normal, warning, or error.

Storage Virtualizer Pool Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Storage Virtualizer Pool Easy Tier Status

Shows whether the Easy Tier function is active or inactive. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Data for storage virtualizer volumes in capacity and relationship reports

You can include general information, capacity data, properties, information about copies of volumes, and other information about storage virtualizer volumes in capacity and relationship reports.

Information about storage virtualizer volumes

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Volume Name

The name that was assigned to the storage virtualizer volume when it was added to the system.

Storage Virtualizer Volume Assigned Host Connection

The host connection to which the storage virtualizer volume is assigned. The host connection is a definition in the storage virtualizer that contains the WWPN for the server. The storage virtualizer uses the WWPN to assign volumes to servers.

Storage Virtualizer Volume Host Connection OS Type

The operating system type of the server or hypervisor that the virtualizer volume is assigned to.

Storage Virtualizer Volume Preferred Node Name

The number of the storage virtualizer node that is used for I/O operations for the storage virtualizer volume.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Volume Capacity (GiB)

The total amount of storage space that is committed to a volume.

For thin-provisioned volumes, this value represents the virtual capacity of the volume.

Storage Virtualizer Volume Allocated Space (GiB)

The amount of space that is reserved for a volume.

The space that is allocated for a thin-provisioned volume is less than its virtual capacity, which is shown in Storage Virtualizer Capacity.

This value is equal to Storage Virtualizer Volume Used Space for the following resources:

- Resources that are not running IBM Spectrum Virtualize
- Resources that are running IBM Spectrum Virtualize and are not thin-provisioned

Storage Virtualizer Volume Used Space (GiB)

The amount of allocated space that is used by a volume.

For resources that are running IBM Spectrum Virtualize, you can preallocate thin-provisioned volume space when the volumes are created. In these cases, the Storage Virtualizer Volume Used Space (GiB) might be different than the Storage Virtualizer Volume Allocated Space (GiB). For volumes that are not thin provisioned, the values for Storage Virtualizer Volume Used Space (GiB) and Storage Virtualizer Volume Allocated Space (GiB) are equal.

This value is accurate as of the most recent time that IBM Spectrum® Control collected data about a volume. The value in this property might not be 100% accurate for the current state of volumes. This inaccuracy might occur because data collection is run on a set schedule and the used space on volumes can change rapidly.

Storage Virtualizer Volume Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Storage Virtualizer Volume Used Allocated Space Percentage

The percentage of reserved space for a volume that is being used. This value is always less than or equal to 100% because a volume cannot use more space than is allocated.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{volume used space} \div \text{volume allocated space}) \times 100$$

This property is available only for volumes on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Volume Unallocated Space (GiB)

The amount of space in a pool that is not reserved for a volume.

IBM Spectrum Control uses the following formula to determine the value:

capacity - allocated space

Storage Virtualizer Volume Physical Allocation Percentage

The percentage of physical space that is reserved for a volume. This value is always less than or equal to 100% because you cannot reserve more physical space than is available.

IBM Spectrum Control uses the following formula to determine this percentage:

(allocated space ÷ capacity) × 100

For example, the physical allocation percentage is 25% for a volume size of 200 GiB. Therefore the space that is reserved for volumes is 50 GiB.

Storage Virtualizer Volume Unused Space (GiB)

The amount of space that is allocated to a volume and is not yet used.

IBM Spectrum Control uses the following formula to determine this value:

allocated space - used space

This property is available only for pools on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Volume Shortfall Percentage

The percentage of the remaining unallocated volume space in a pool that is not available to be allocated to a volume. The higher the percentage, the more critical the shortfall of space.

IBM Spectrum Control uses the following formula to determine this percentage:

(unallocatable volume space ÷ unallocated volume space) × 100

You can use this percentage to determine when the amount of overcommitted space in a pool reaches a critically high level for the volume. For example, the physical space in a pool might be less than the committed virtual space. In this case, the pool does not have enough space to fulfill the commitment to virtual space for a volume.

This value represents the percentage of the committed virtual space that is not available in a pool. As more space is used over time by a volume while the pool capacity remains the same, this percentage increases.

For example, the remaining physical capacity of a pool is 70 GiB, however, 150 GiB of virtual space is committed to a thin-provisioned volume. If the volume is using 50 GiB, then there is still 100 GiB committed to that volume (150 GiB - 50 GiB). There is a shortfall of 30 GiB (70 GiB remaining pool space - 100 GiB remaining commitment of volume space to the volume). The volume is overcommitted by 30 GiB based on the available space in the pool. The shortfall is 30% when you use the following calculation:

(100 GiB unallocated volume space - 70 GiB remaining pool space) ÷ 100 GiB unallocated volume space × 100

This value is only available for pools with thin-provisioned volumes.

Storage Virtualizer Volume Unallocatable Space (GiB)

The unallocatable storage space in GiB of a thin-provisioned volume. Unallocatable space cannot be supplied by the pool to which the volume belongs.

Storage Virtualizer Volume Uncompressed Capacity (GiB)

The amount of storage space that is used if the compressed volume space is uncompressed. For example, if 100 GiB of uncompressed data is compressed, and the size of the compressed data is 20 GiB, the value is 100.

Storage Virtualizer Volume Tier Capacity (GiB)

The amount of tier storage of a particular type on a virtualizer volume. The type is identified in the Storage Virtualizer Volume Tier Type property. The tier is configured to be controlled by the Easy Tier® function.

Storage Virtualizer Volume Tier Available Space (GiB)

The amount of tier storage of a particular type that is unused on a virtualizer volume. The type is identified in the Storage Virtualizer Volume Tier Type property. The tier is configured to be controlled by the Easy Tier function.

Component properties

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Volume Type

The type of storage virtualizer volume. For example, the storage virtualizer volume can be striped, sequential, or another type of storage virtualizer volume. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Volume WWN

The worldwide name of the volume.

Storage Virtualizer Volume Fast Write State

Shows whether the cache for a volume on a disk that is managed by a storage virtualizer is empty, contains data, or is corrupted.

Storage Virtualizer Volume Grain Size (KiB)

The grain size with which a thin-provisioned volume was created. This value is typically 32, 64, 128, or 256 KiB. Larger grain sizes maximize performance, whereas smaller grain sizes maximize space efficiency. Grain sizes also limit the maximum virtual space of a volume.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Volume Is Assigned

Shows whether the volume is assigned to a server. If this value is **Yes**, the volume is assigned to a server.

Storage Virtualizer Volume Is Auto Expand Enabled

Shows whether a volume or volume copy can allocate new extents from a pool automatically. Volumes or volume copies might allocate new extents to expand the real capacity of the storage virtualizer volume or volume copy. If this value is **Yes**, the volume or volume copy can allocate new extents from a pool automatically.

Storage Virtualizer Volume Is Encryptable

Shows whether the resource can be encrypted. If this value is **Yes**, the resource can be encrypted.

Storage Virtualizer Volume Is Encrypted

Shows whether the resource is encrypted. If this value is **Yes**, the resource is encrypted.

Storage Virtualizer Volume Is Formatted

Shows whether a storage virtualizer volume is formatted. If this value is **Yes**, the storage virtualizer volume is formatted.

Storage Virtualizer Volume Is Thin Provisioned

Shows whether a pool, volume, or volume copy is thin-provisioned. If this value is **Yes**, the resource is thin-provisioned.

Storage Virtualizer Volume Metro Mirror Name

The name of the Metro Mirror that keeps the synchronous copy of the storage virtualizer volume.

Storage Virtualizer Volume Mirror Count

- The number of mirrors that keep a synchronous copy of the resource.
- Storage Virtualizer Volume Throttle
 - The maximum number of commands that the storage virtualizer volume can queue.
- Storage Virtualizer Volume Warning Level
 - The percentage of used capacity of the resource at which a warning is generated.
- Storage Virtualizer Volume FlashCopy® Relationship
 - Shows whether a volume on a storage virtualizer is in a FlashCopy relationship. This property can contain the following values:
 - Source Relationship
 - The volume is the source of the relationship.
 - Target Relationship
 - The volume is the target of the relationship.
 - Both Source and Target Relationship
 - The volume is both the source and target of the relationship.
 - Not in a FlashCopy Relationship
 - The volume is not in a FlashCopy relationship.
- Storage Virtualizer Volume Remote Copy Relationship
 - Shows whether a volume on a storage virtualizer is in a remote copy relationship. This property can contain the following values:
 - Not in a Copy Relationship
 - The volume is not in a remote copy relationship.
 - Source Relationship
 - The volume is the source of the relationship.
 - Target Relationship
 - The volume is the target of the relationship.
 - Both Source and Target Relationship
 - The volume is both the source and target of the relationship.
- Storage Virtualizer Volume RAID Level
 - The RAID level of a storage virtualizer volume, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the resource.
- Storage Virtualizer Volume Is Compressed
 - Shows whether the storage virtualizer volume is compressed. If this value is **Yes**, the volume is compressed.
- Storage Virtualizer Volume Is Easy Tier
 - Shows how the Easy Tier function is enabled on a virtualizer volume. For example, if the value of this column is auto, the Easy Tier function is enabled in automatic mode.
- Storage Virtualizer Volume Tier Type
 - The type of tier that is used on the virtualizer volume. The tier is configured to be controlled by the Easy Tier function.

Status information

You can create capacity and relationship reports that include the following information:

- Storage Virtualizer Volume Status
 - The condition of the resource, for example normal, warning, or error.
- Storage Virtualizer Volume Is Detected
 - Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.
- Storage Virtualizer Volume Native Status
 - Shows the level of access of nodes in the system to the storage virtualizer managed disk or volume. The level of access can be online, offline, degraded, or excluded.
- Storage Virtualizer Volume Easy Tier Status
 - Shows whether the Easy Tier function is active or inactive on the virtualizer volume.

Volume copy information

You can create capacity and relationship reports that include the following information:

- Storage Virtualizer Volume Copy ID
 - The identifier of a volume copy. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.
- Storage Virtualizer Volume Copy Grain Size (KiB)
 - The grain size with which a thin-provisioned volume was created. This value is typically 32, 64, 128, or 256 KiB. Larger grain sizes maximize performance, whereas smaller grain sizes maximize space efficiency. Grain sizes also limit the maximum virtual space of a volume.
- Storage Virtualizer Volume Copy Is Auto Expand Enabled
 - Shows whether a volume or volume copy can allocate new extents from a pool automatically. Volumes or volume copies might allocate new extents to expand the real capacity of the storage virtualizer volume or volume copy. If this value is **Yes**, the volume or volume copy can allocate new extents from a pool automatically.
- Storage Virtualizer Volume Copy Is Detected
 - Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.
- Storage Virtualizer Volume Copy Is Primary
 - Shows whether the volume copy is the primary volume copy. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.
- Storage Virtualizer Volume Copy Is Thin Provisioned
 - Shows whether a pool, volume, or volume copy is thin-provisioned. If this value is **Yes**, the resource is thin-provisioned.
- Storage Virtualizer Volume Copy Total Number of Extents
 - The number of extents that are used by the storage virtualizer volume copy.
- Storage Virtualizer Volume Copy Type
 - The type of copy of the storage virtualizer volume. For example, the copy of the storage virtualizer volume can be sequential, a mirror copy, or another type of copy.
- Storage Virtualizer Volume Copy Warning Level
 - The percentage of used capacity of the resource at which a warning is generated.
- Storage Virtualizer Volume Copy Used Allocated Space Percentage

The percentage of reserved space for a volume copy that is being used. This value is always less than or equal to 100% because a volume copy cannot use more space than is allocated.

IBM Spectrum Control uses the following formula to determine this value:

$$(\text{used space} \div \text{allocated space}) \times 100$$

This property is available only for pools on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Volume Copy Used Space (GiB)

The amount of allocated space that is used by a volume copy.

Storage Virtualizer Volume Copy Allocated Space (GiB)

The amount of space that is reserved for a volume copy.

The space that is allocated for a thin-provisioned volume copy is less than its virtual capacity, which is shown in Storage Virtualizer Capacity (GiB).

This value is equal to Storage Virtualizer Volume Copy Used Space (GiB) for volume copies that are not thin provisioned.

Storage Virtualizer Volume Copy Unallocated Space (GiB)

The amount of space in a pool that is not reserved for a volume copy.

IBM Spectrum Control uses the following formula to determine this value:

$$\text{capacity} - \text{allocated space}$$

Storage Virtualizer Volume Copy Physical Allocation Percentage

The percentage of physical space that is reserved for a volume copy. This value is always less than or equal to 100% because you cannot reserve more physical space than is available.

IBM Spectrum Control uses the following formula to determine this value:

$$(\text{allocated space} \div \text{capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a total pool size of 200 GiB. Therefore, the space that is reserved for volume copies is 50 GiB.

Storage Virtualizer Volume Copy Unused Space (GiB)

The amount of space that is allocated to a volume copy and is not yet used.

IBM Spectrum Control uses the following formula to determine this value:

$$\text{allocated space} - \text{used space}$$

This property is available only for pools on resources that are running IBM Spectrum Virtualize.

Storage Virtualizer Volume Copy Shortfall Percentage

The percentage of the remaining unallocated volume copy space in a pool that is not available to be allocated to a volume copy.

The higher the percentage, the more critical the shortfall of space.

IBM Spectrum Control uses the following formula to determine this value:

$$(\text{unallocatable space} \div (\text{capacity} - \text{real capacity})) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in a pool reaches a critically high level for the volume. For example, the physical space in a pool might be less than the committed virtual space. In this case, the pool does not have enough space to fulfill the commitment to virtual space for a volume.

This value represents the percentage of the committed virtual space that is not available in a pool. As more space is used over time by a volume while the pool capacity remains the same, this percentage increases.

For example, the remaining physical capacity of a pool is 70 GiB, however, 150 GiB of virtual space is committed to a thin-provisioned volume. If the volume is using 50 GiB, then there is still 100 GiB committed to that volume (150 GiB - 50 GiB). There is a shortfall of 30 GiB (70 GiB remaining pool space - 100 GiB remaining commitment of volume space to the volume). The volume is overcommitted by 30 GiB based on the available space in the pool. The shortfall is 30% when you use the following calculation:

$$(\text{100 GiB unallocatable volume copy space} - \text{70 GiB remaining pool space}) \div \text{100 GiB unallocated volume space} \times 100$$

Available only for thin-provisioned volume copies.

Storage Virtualizer Volume Copy Unallocatable Space (GiB)

The unallocatable storage space in GiB of a thin-provisioned volume copy. Unallocatable space cannot be supplied by the pool to which the volume copy belongs.

Storage Virtualizer Volume Copy Is Compressed

Shows whether the volume copy is compressed. If this value is **Yes**, the volume copy is compressed.

Storage Virtualizer Volume Copy Uncompressed Capacity (GiB)

The amount of storage space that is used if the compressed space on the volume copy is uncompressed. For example, if 100 GiB of data is compressed, the value is 100.

Data for managed disks on storage virtualizers in capacity and relationship reports

You can include general information, capacity data, properties, and other information about managed disks on storage virtualizers in capacity and relationship reports.

Information about managed disks on storage virtualizers

You can create capacity and relationship reports that include the following information:

Storage Virtualizer MDisk Name

The name that was assigned to the managed disk on a storage virtualizer when it was added to the system.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Storage Virtualizer MDisk Capacity (GiB)

The amount of storage space on the managed disk.

Storage Virtualizer MDisk Available Space (GiB)

The amount of space on managed disks that is available in a pool, or is available to be added to a pool.

Storage Virtualizer MDisk Strip Size (KB)

The RAID strip size on a managed disk on a storage virtualizer. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Component properties

You can create capacity and relationship reports that include the following information:

Storage Virtualizer MDisk RAID Level

The RAID level of the managed disk, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the managed disk.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer MDisk Spare Goal

The number of spare drives that are required to maintain redundancy. Use spare drives to protect against drive failures in the array on a managed disk on a storage virtualizer.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer MDisk Type

The type of managed disk on a storage virtualizer. For example, the storage virtualizer can be a local or virtual managed disk.

Storage Virtualizer MDisk Mode

The access mode of a managed disk on a storage virtualizer. The access mode describes how extents are provided for virtual disks. Extents can be provided to virtual disks in the following ways:

Array

Extents are provided from local disks.

Managed

Extents are provided from a back-end storage volume.

Unmanaged

The managed disk is not used in the system.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer MDisk Is Balanced

Shows whether LUNs are balanced across storage controllers on the managed disk. If this value is **Yes**, the LUNs are balanced.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer MDisk Fast Write State

Shows whether the cache for a volume on a disk that is managed by a storage virtualizer is empty, contains data, or is corrupted. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer MDisk Write Verify

Shows whether all write operations on a managed disk on a storage virtualizer are verified by an immediate follow-up read operation. The follow-up read operation verifies that the write operation was successful. If this value is **Yes**, all write operations are verified by a follow-up read operation.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Status information

You can create capacity and relationship reports that include the following information:

Storage Virtualizer MDisk Status

The condition of the resource, for example normal, warning, or error.

Storage Virtualizer MDisk Native Status

Shows the level of access of nodes in the system to a managed disk or volume on a storage virtualizer. The level of access can be online, offline, degraded, or excluded.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Data for local disks on storage virtualizers in capacity and relationship reports

You can include general information, capacity data, properties, and other information about local disks on storage virtualizers in capacity and relationship reports.

Information about local disks on storage virtualizers

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Local Disk Name

The name that was assigned to the local disk on the storage virtualizer when it was added to the system.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Local Disk Capacity (GiB)

The amount of storage space on the local disk.

Component properties

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Local Disk Is Encryptable

Shows whether the local disk can be encrypted. If this value is **Yes**, the local disk can be encrypted.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Local Disk Is Encrypted

Shows whether the local disk is encrypted. If this value is **Yes**, the local disk is encrypted.

This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Local Disk Storage Class

The storage technology of the local disk on a storage virtualizer. For example, the storage class can be a serial-attached SCSI (SAS) or solid-state drive (SSD). This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Local Disk Is Solid State

Shows whether the disk is a solid-state drive. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Local Disk Speed (RPM)

The speed of the local disk on a storage virtualizer. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Local Disk Tag

A number that identifies the array to which a local disk belongs.

Status information

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Local Disk Status

The condition of the resource, for example normal, warning, or error.

Vendor, model, and device information

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Local Disk Firmware Version

The version number of the firmware that is running on the local disk. This value is not shown for Hitachi Universal Storage Platform V storage systems that are configured to virtualize back-end storage.

Storage Virtualizer Local Disk Model

The model name or model number of the resource.

Storage Virtualizer Local Disk Serial Number

The serial number of the resource.

Storage Virtualizer Local Disk Vendor

The vendor who supplied the resource.

Data for storage virtualizer groups in capacity and relationship reports

You can include the name of storage virtualizer groups and properties for storage virtualizer groups in capacity and relationship reports.

Information about storage virtualizer groups

Storage virtualizer groups are deprecated in IBM Spectrum® Control 5.2.10 and later. Use storage resource groups instead. In the IBM Spectrum Control GUI, storage resource groups are available as general groups.

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Group Name

A user-defined name of the storage virtualizer group.

Component properties

You can create capacity and relationship reports that include the following information:

Storage Virtualizer Group Creator

The user name of the user who created the storage virtualizer group.

Storage Virtualizer Group Last Modified

The date and time that the storage virtualizer group was last modified.

Storage Virtualizer Group Last Modified by User

The user name of the user who last modified the storage virtualizer group.

Data for storage systems in capacity and relationship reports

You can include general information, capacity data, properties of components, and other information about storage systems in capacity and relationship reports.

Information about storage systems

You can create capacity and relationship reports that include the following information:

Storage System Name

A user-defined name of the storage system. If a name was not defined, IBM Spectrum® Control shows the name that was defined when the storage system was added for monitoring.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Storage System Pool Capacity (GiB)

The amount of storage space in pools that are on the storage system. For an XIV® or IBM Spectrum Accelerate, this value represents the physical capacity of the pool, not the virtual capacity. For other storage systems, this value might also include overhead space if the pool is unformatted.

Storage System Used Pool Space (GiB)

The amount of space that is in use in all pools on a storage system.

Storage System Pool Available Space (GiB)

The amount of unused space that is not reserved for volumes in pools that are on the storage system.

Storage System Volume Capacity (GiB)

The amount of space on all volumes on the storage system.

Storage System Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Storage System Assigned Volume Space (GiB)

The amount of space on the storage system that is on volumes that are assigned to a server or storage virtualizer.

Storage System Unallocated Disk Space (GiB)

The amount of disk space that can be added to a pool.

Storage System Number of Disks

The number of disks on the storage system.

Storage System Number of Volumes

The number of volumes on a resource.

Storage System Cache (GiB)

The size of the cache on the storage system. This value is not shown for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System Real Available Pool Space (GiB)

The amount of unused space in pools that have an associated soft size on an XIV or IBM Spectrum Accelerate. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage System Real Configured Pool Space (GiB)

The amount of storage space that is in pools that have an associated soft size on an XIV or IBM Spectrum Accelerate. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage System Volume Capacity for z/OS (GiB)

The amount of space on all volumes on the storage system that the z/OS® operating system can use.

Storage System Volume Capacity Assigned to MDisks (GiB)

The amount of space that is on volumes that are assigned to a storage virtualizer to use as managed disks.

Storage System Disk Capacity (GiB)

The amount of storage space on physical disks in a storage system, excluding spare disks. This value is not shown for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System Total Disk Capacity (GiB)

The amount of space on physical disks on a storage system, including spare disks.

Storage System Physical Allocation Percentage

The percentage of physical space in storage system pools that is reserved for volumes. This value is always less than or equal to 100% because you cannot reserve more physical space than is available in the pools.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{allocated pool space} \div \text{pool capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a 200 GiB storage pool. Therefore, the space that is reserved for volumes is 50 GiB.

Storage System Virtual Allocation Percentage

The percentage of physical space in storage system pools that is committed to the total virtual capacity of the volumes in the pool. In thin-provisioned environments, this percentage exceeds 100% if a pool is overcommitted (over-provisioned).

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{total volume capacity} \div \text{pool capacity}) \times 100$$

For example, for a total pool size of 15 GiB, the allocation percentage might be 200%. Therefore, the virtual capacity that is committed to the volumes in the pools is 30 GiB. This configuration means that twice as much space is committed than is physically contained in the pools. If the allocation percentage is 100% for the same pools, then the virtual capacity that is committed to the pools is 15 GiB. This configuration means that all the physical capacity of the pools is already allocated to volumes.

An allocation percentage that is higher than 100% is considered aggressive. The pools have insufficient physical capacity to satisfy the maximum allocation for all the thin-provisioned volumes in the pools. In such cases, use the Storage System Shortfall Percentage property to estimate how critical the shortage of space is for storage system pools.

Storage System Shortfall Percentage

The percentage of the remaining unallocated volume space in storage system pools that is not available to be allocated. The higher the percentage, the more critical the shortfall of pool space.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{unallocatable space} \div (\text{volume space} - \text{used volume space})) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in pools reaches a critically high level. For example, the physical space in pools might be less than the committed virtual space. In this case, the pools do not have enough space to fulfill the commitment to virtual space for a volume.

This value represents the percentage of the committed virtual space that is not available in pools. As more space is used over time by volumes while the pool capacity remains the same, this percentage increases.

For example, the physical capacity of pools is 70 GiB, but 150 GiB of virtual space is committed to thin-provisioned volumes. If the volumes are using 50 GiB, then there is still 100 GiB committed to those volumes (150 GiB - 50 GiB). There is only 20 GiB of available pool space (70 GiB - 50 GiB). Because only 20 GiB of pool space is available, 80 GiB of the committed space cannot be allocated (100 GiB - 20 GiB). In this case, the percentage of committed space that is unavailable is 80% (80 GiB ÷ 100 GiB × 100).

This value is only available for pools with thin-provisioned volumes.

Storage System MDisk Available Space (GiB)

The amount of storage space that is available on a managed disk. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System Tier Available Space (GiB)

The amount of unused space in a tier. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System Tier Capacity (GiB)

The total amount of storage space in a tier. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Component properties

You can create capacity and relationship reports that include the following information:

Storage System Access Information

The URL from which you can access the storage system or storage virtualizer.

Storage System Code Level

The Shared Ethernet Adapter level of a DS8000® storage system. For other storage systems, this value is the firmware version.

Storage System Location

The physical location of a storage system. The location is defined when a storage system is added to IBM Spectrum Control. You can add or edit the location of the storage system in the Properties pane of the storage system.

Storage System Custom Tag 1, 2, and 3

User-defined text that is associated with a storage system. You can add or edit the custom tags for a storage system in the Properties pane of the storage system.

Storage System User Provided Name

The name that was specified for the storage system in the storage environment.

Storage System Tier Type

The type of tier that is used on a storage system. For example, the tier type can be hard disk drive (HDD) or solid-state drive (SSD).

This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System Configuration

Shows whether a storage system is configured as back-end storage or configured to virtualize back-end storage. If this value is **Storage System**, the storage system is configured as back-end storage. If this value is **Storage Virtualizer**, the storage system is configured to virtualize back-end storage.

Storage System Is Compression Active

Shows whether the compression feature is enabled on the storage system. If this value is **Yes**, the compression feature is enabled.

Status information

You can create capacity and relationship reports that include the following information:

Storage System Status

The condition of the resource, for example normal, warning, or error.

Storage System Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Storage System Last Data Collection

The date and time when storage statistics were last collected from the resource.

Storage System Last Data Collection Status

The condition of the last data collection. The status can show if the collection was a success, a failure, or if data was collected from the resource.

Vendor, model, and device information

You can create capacity and relationship reports that include the following information:

Storage System Type

The type of storage system. For example, the storage system can be an IBM System Storage DS8800 system, an IBM System Storage DS8700 system, an IBM System Storage XIV system, or another type of storage system.

Storage System Vendor

The vendor who supplied the resource.

Storage System Model

The model name or model number of the storage system.

Storage System Machine Type

The machine type of a storage system. For example, the storage system can be DS8800, DS8700, XIV - 2812, or another type of storage system.

Storage System IP Address

The IP address of the resource.

Storage System Serial Number

The serial number of the resource.

Data for storage system pools in capacity and relationship reports

You can include general information, capacity data, properties of components, and other information about storage system pools in capacity and relationship reports.

Information about storage systems pools

You can create capacity and relationship reports that include the following information:

Storage Pool Name

The name that was assigned to the pool when it was added to the system.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Storage Pool Capacity (GiB)

The total amount of storage space in a pool.

Storage Pool Available Space (GiB)

The amount of unused space that is not reserved for volumes in pools that are on the storage system.

IBM Spectrum® Control uses the following formula to determine this value:

$$\text{pool capacity} - \text{used space}$$

For XIV® systems and IBM Spectrum Accelerate, this value represents the unallocated physical space in the pool, not the unallocated virtual space. For some storage systems, this value usually includes only the usable capacity, but might also include overhead space if the pool is unformatted.

Storage Pool Assigned Volume Space (GiB)

The amount of space in the pool that is on volumes that are assigned to a server or storage virtualizer.

Storage Pool Unassigned Volume Space (GiB)

The amount of volume space in the pool that is not assigned to a server or storage virtualizer.

Storage Pool Total Volume Capacity (GiB)

The total storage space on all the volumes in a pool, which includes thin-provisioned and standard volumes. For thin-provisioned volumes, this value includes virtual space.

Storage Pool Real Configured Space (GiB)

The amount of storage space that is in an XIV or IBM Spectrum Accelerate pool that has an associated soft size. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage Pool Used Volume Space (GiB)

The amount of allocated space that is used by the volumes in a pool, which includes thin-provisioned and standard volumes.

For resources that are running IBM Spectrum Virtualize, you can preallocate thin-provisioned volume space when volumes are created. For these resources, the Storage Pool Used Space might be different than the Storage Pool Allocated Space for pools that contain thin-provisioned volumes. In other cases, the values for Storage Pool Used Space and Storage Pool Allocated Space are equal.

This value is accurate as of the most recent time that IBM Spectrum Control collected data about a volume. The value in this property might not be 100% accurate for the current state of volumes. This inaccuracy might occur because data collection is run on a set schedule and the used space on volumes can change rapidly.

Storage Pool Real Available Space (GiB)

The amount of unused space that is in an XIV or IBM Spectrum Accelerate pool that has an associated soft size. The soft size of a pool is the virtual size of a thin-provisioned pool.

Storage Pool Repository Capacity (GiB)

The amount of space on all extents in the repository of a pool. This space can be used to allocate track space-efficient volumes. This attribute applies only to DS8000® storage systems.

Storage Pool Used Repository Space (GiB)

The amount of space on all extents in the repository of a pool that are allocated. This space can be used to allocate track space-efficient volumes. This attribute applies only to the DS8000 storage systems.

Storage Pool Physical Allocation Percentage

The percentage of physical space in a pool that is reserved for volumes. This value is always less than or equal to 100% because you cannot reserve more physical space than is available in a pool.

IBM Spectrum Control uses the following formula to determine the allocation percentage:

$$(\text{allocated space} \div \text{pool capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a total pool size of 200 GiB. Therefore, the space that is reserved for volumes is 50 GiB.

Storage Pool Virtual Allocation Percentage

The percentage of physical space in a pool that is committed to the total virtual capacity of the volumes in the pool. In thin-provisioned environments, this percentage exceeds 100% if a pool is overcommitted (over-provisioned).

IBM Spectrum Control uses the following formula to determine the allocation percentage:

$$(\text{total volume capacity} \div \text{pool capacity}) \times 100$$

For example, the allocation percentage is 200% for a total pool size of 15 GiB. Therefore, the virtual capacity that is committed to the volumes in the pool is 30 GiB. This configuration means that twice as much space is committed than is physically contained in the pool. If the allocation percentage is 100% for the same pool, then the virtual capacity that is committed to the pool is 15 GiB. This configuration means that all the physical capacity of the pool is already allocated to volumes. An allocation percentage that is higher than 100% is considered aggressive. The pool has insufficient physical capacity to satisfy the maximum allocation for all the thin-provisioned volumes in the pool. In such cases, you can use the value for Storage Pool Shortfall Percentage to estimate how critical the shortage of space is for a pool.

This value is only available for pools with thin-provisioned volumes.

Storage Pool Shortfall Percentage

The percentage of the remaining unallocated volume space in a pool that is not available to be allocated.

The higher the percentage, the more critical the shortfall of pool space.

IBM Spectrum Control uses the following formula to determine this percentage:

$$(\text{unallocatable space} \div (\text{virtual capacity} - \text{allocated space})) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in a pool reaches a critically high level. For example, the physical space in a pool might be less than the committed virtual space. In this case, the pool does not have enough space to fulfill the commitment to virtual space.

This value represents the percentage of the committed virtual space that is not available in a pool. As more space is used over time by volumes while the pool capacity remains the same, this percentage increases.

For example, the physical capacity of a pool is 70 GiB, however, 150 GiB of virtual space is committed to thin-provisioned volumes. If the volumes are using 50 GiB, then there is still 100 GiB committed to those volumes (150 GiB - 50 GiB). There is only 20 GiB of available pool space (70 GiB - 50 GiB). Because only 20 GiB of pool space is available, 80 GiB of the committed space cannot be allocated (100 GiB - 20 GiB). In this case, the percentage of committed space that cannot be allocated is 80% (80 GiB ÷ 100 GiB × 100).

This value is only available for pools with thin-provisioned volumes.

Storage Pool Allocated Space (GiB)

The amount of space that is reserved for all the volumes in a pool, which includes both thin-provisioned and standard volumes. The space that is allocated for thin-provisioned volumes is less than their virtual capacity, which is shown in the Storage Pool Total Volume Capacity (GiB) property. If a pool does not contain thin-

provisioned volumes, this value is the same as the value in the Storage Pool Total Volume Capacity (GiB) property. This value is equal to the value in the Storage Pool Used Volume Space (GiB) property for the following resources:

- Resources other than those that are running IBM Spectrum Virtualize and are configured as back-end storage
- Resources that are running IBM Spectrum Virtualize, are configured as back-end storage, and are not thin-provisioned

Storage Pool Extent Size (MiB)

The size of the extent that was specified when a pool was created. Smaller extent sizes limit the maximum size of the volumes that can be created in a pool. Smaller extent sizes minimize the amount of potentially wasted space per volume.

This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Pool Tier Capacity (GiB)

The information that this property shows depends on whether the report includes the Storage Pool Tier Type property:

- Report includes Storage Pool Tier Type: Shows the amount of space on solid-state drives and hard disk drives in a pool. The report shows the storage space on solid-state drives and on hard disk drives on different rows.
- Report does not include Storage Pool Tier Type: Shows the total storage space on all of the solid-state drives and hard disk drives in a pool.

The tier is configured to be controlled by the Easy Tier® function.

This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Pool Tier Available Space (GiB)

The information that this property shows depends on whether the report includes the Storage Pool Tier Type property:

- Report includes Storage Pool Tier Type: Shows the amount of unused space on solid-state drives and hard disk drives in a pool. The report shows the unused space on solid-state drives and on hard disk drives on different rows.
- Report does not include Storage Pool Tier Type: Shows the total unused space on all of the solid-state drives and hard disk drives in a pool.

The tier is configured to be controlled by the Easy Tier function.

This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Pool Tier Number of MDisks

The information that this property shows depends on whether the report includes the Storage Pool Tier Type property:

- Report includes Storage Pool Tier Type: Shows the number of managed disks on the tier that are solid-state drives or hard disk drives. The report shows the number of managed disks that are solid-state drives and the number that are hard disk drives on different rows.
- Report does not include Storage Pool Tier Type: Shows the total number of managed disks on all of the solid-state drives and hard disk drives in a tier.

This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Pool Unallocated Volume Space (GiB)

The amount of the Total Volume Capacity in the pool that is not allocated.

IBM Spectrum Control uses the following formula to determine this value:

total volume capacity - allocated space

The space that is allocated for thin-provisioned volumes is typically less than their virtual capacity. Therefore, the unallocated space represents the difference between the virtual capacity and the allocated space for all the volumes in the pool.

Storage Pool Unallocatable Volume Space (GiB)

The amount of space by which the Total Volume Capacity exceeds the physical capacity of a pool.

In thin-provisioned environments, it is possible to over commit (over provision) storage in a pool. If you create volumes with more virtual capacity than can be physically allocated in the pool, you can over commit storage in the pool.

This value represents the amount of volume space that cannot be allocated based on the current capacity of the pool.

Storage Pool Number of MDisks

The number of managed disks in a storage pool.

Storage Pool Compressed Virtual Capacity (GiB)

The total virtual capacity of all the volumes that are compressed in a pool.

Storage Pool Compressed Capacity (GiB)

The amount of storage space that is used by compressed volumes in a pool. For example, if 100 GiB of uncompressed data is compressed, and the size of the compressed data is 20 GiB, the value is 20.

Storage Pool Uncompressed Capacity (GiB)

The amount of storage space that is used if the compressed volume space is uncompressed. For example, if 100 GiB of uncompressed data is compressed, and the size of the compressed data is 20 GiB, the value is 100.

Storage Pool Maximum I/O Capability

The projected maximum number of I/O operations per second for a pool. This value is calculated based on the value in the Storage Pool Back-End Storage Disks property, and on the values in following properties:

- Storage Pool Back-End Storage System Type
- Storage Pool Back-End Storage RAID Level
- Storage Pool Back-End Storage Disk Type

This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Pool Back-End Storage Disks

The number of physical disks that contribute to the volumes on the back-end storage system. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Component properties

You can create capacity and relationship reports that include the following information:

Storage Pool RAID Level

The RAID level of the resource, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the resource.

Storage Pool Is Solid State

Shows whether there are solid-state drives in the pool. This property can contain the following values:

Mixed

- The pool contains both hard disk drives and solid-state drives.
- Non solid state
 - The pool contains no solid-state drives.
- Solid state
 - The pool contains a least one solid-state drive.

Storage Pool Is Encrypted

Shows whether the resource is encrypted. If this value is **Yes**, the resource is encrypted.

Storage Pool Format

Shows the format of the volume or pool. The format can be a Count Key Data (CKD) format, or a fixed block format.

Storage Pool Is Thin Provisioned

Shows whether a pool, volume, or volume copy is thin-provisioned. If this value is **Yes**, the resource is thin-provisioned.

Storage Pool Logical Subsystem

The logical subsystem (LSS) to which a volume or pool belongs.

Storage Pool Rank Group

The rank group to which a pool is assigned, that is, 0 or 1. This property applies only to the DS8000 storage systems.

Storage Pool Lock Behavior

Shows whether the pool is locked for write operations, or is disabled for both read and write operations when storage space is limited. This property applies only to XIV systems and IBM Spectrum Accelerate.

Storage Pool Tier

The tier level of pools on storage systems. For example, the tier can be 1, 2, 3, or another tier number.

Storage Pool Custom Tag 1, 2, and 3

User-defined text that is associated with a storage pool. You can add or edit the custom tags for a storage pool on the Properties notebook of the pool.

Storage Pool Is Compression Active

Shows whether the compression feature is enabled on the storage pool. If this value is **Yes**, the compression feature is enabled.

Storage Pool Back-End Storage System Type

The type of storage system that provides storage space to a pool. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Pool Back-End Storage Disk Type

The class and speed of the physical disks that contribute to the volumes on the back-end storage system. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Storage Pool Back-End Storage RAID Level

The RAID level of the volumes on the back-end storage system that provide storage space to a pool. This property applies only to pools on resources that are running IBM Spectrum Virtualize.

Status information

You can create capacity and relationship reports that include the following information:

Storage Pool Status

The condition of the resource, for example normal, warning, or error.

Storage Pool Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Storage Pool Tier Type

The type of tier that is used on the storage pool. For example, the tier type can be hard disk drive (HDD) or solid-state drive (SSD). The tier is configured to be controlled by the Easy Tier function.

This value is available only for resources that are running IBM Spectrum Virtualize.

Data for storage system volumes in capacity and relationship reports

You can include general information, capacity data, properties, information about copies of volumes, and other information about storage system volumes in capacity and relationship reports.

Information about storage system volumes

You can create capacity and relationship reports that include the following information:

Storage Volume Name

The name that was assigned to the storage volume when it was added to the system.

Storage Volume Assigned Host Connection

The host connection to which the storage volume is assigned. The host connection is a definition in the storage system that contains the WWPN for the server. The storage system uses the WWPN to assign volumes to servers.

Storage Volume Host Connection OS Type

The operating system type of the server or hypervisor that the volume is assigned to.

Storage System Volume Group ID

The unique identifier for a collection of volumes on DS8000® storage systems. The storage system generates this identifier.

Storage System Volume Group Name

The user-defined name for a collection of volumes on DS8000 storage systems.

Storage System Volume Preferred Node Name

The name of the node that is used for I/O operations for the storage system volume.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Storage Volume Capacity (GiB)

The total amount of storage space that is committed to a volume.

For thin-provisioned volumes, this value represents the virtual capacity of the volume.

For XIV® systems and IBM Spectrum Accelerate, this value represents the physical (hard) capacity of the volume, not the virtual (soft) capacity. For other storage systems, this value might also include overhead space if the pool is unformatted.

Storage Volume Overhead (GiB)

The amount of space that is used for system management. The amount of space also includes space that is reserved for redundancy.

Storage Volume Allocated Space (GiB)

The amount of space that is reserved for a volume. The space that is allocated for a thin-provisioned volume is less than its virtual capacity, which is shown in the Storage Volume Capacity (GiB) property. This value is equal to the value in the Storage Volume Used Space (GiB) property for the following resources:

- Resources other than those that are running IBM Spectrum Virtualize and are configured as back-end storage
- Resources that are running IBM Spectrum Virtualize, are configured as back-end storage, and are not thin-provisioned

Storage Volume Used Space (GiB)

The amount of allocated space that is used by a volume.

For resources that are running IBM Spectrum Virtualize, you can preallocate thin-provisioned volume space when the volumes are created. In these cases, the Storage Volume Used Space (GiB) might be different than the Storage Volume Allocated Space (GiB). For volumes that are not thin provisioned, the values for Storage Volume Used Space (GiB) and Storage Volume Allocated Space (GiB) are equal.

This value is accurate as of the most recent time that IBM Spectrum® Control collected data about a volume. The value in this property might not be 100% accurate for the current state of volumes. This inaccuracy might occur because data collection is run on a set schedule and the used space on volumes can change rapidly.

Storage Volume Used Allocated Space Percentage

The percentage of reserved space for a volume that is being used. This value is always less than or equal to 100% because a volume cannot use more space than is allocated.

IBM Spectrum Control uses the following formula to determine this value:

$$(\text{volume used space} \div \text{volume allocated space}) \times 100$$

This property is available only for volumes on resources that are running IBM Spectrum Virtualize.

Storage Volume Unallocated Space (GiB)

The amount of space in a pool that is not reserved for a volume.

IBM Spectrum Control uses the following formula to determine this value:

$$\text{capacity} - \text{allocated space}$$

Available only for thin provisioned volumes.

Storage Volume Physical Allocation Percentage

The percentage of physical space that is reserved for a volume. This value is always less than or equal to 100% because you cannot reserve more physical space than is available.

IBM Spectrum Control uses the following formula to determine this value:

$$(\text{allocated space} \div \text{capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a volume size of 200 GiB. Therefore, the space that is reserved for volumes is 50 GiB.

Storage Volume Unused Space (GiB)

The amount of space that is allocated to a volume and is not yet used.

IBM Spectrum Control uses the following formula to determine this value:

$$\text{allocated space} - \text{used space}$$

This property is available only for pools on resources that are running IBM Spectrum Virtualize.

Storage Volume Shortfall Percentage

The percentage of the remaining unallocated volume space in a pool that is not available to be allocated to a volume.

The higher the percentage, the more critical the shortfall of space.

IBM Spectrum Control uses the following formula to determine this value:

$$(\text{unallocatable volume space} \div \text{volume unallocated space}) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in pools reaches a critically high level. For example, the physical space in pools might be less than the committed virtual space. In this case, the pools do not have enough space to fulfill the commitment to virtual space for a volume.

This Storage Volume Shortfall Percentage represents the percentage of the committed virtual space that is not available in a pool. As more space is used over time by a volume while the pool capacity remains the same, this percentage increases.

For example, the remaining physical capacity of a pool is 70 GiB, however, 150 GiB of virtual space is committed to a thin-provisioned volume. If the volume is using 50 GiB, then there is still 100 GiB committed to that volume (150 GiB - 50 GiB). There is a shortfall of 30 GiB (70 GiB remaining pool space - 100 GiB remaining commitment of volume space to the volume). The volume is overcommitted by 30 GiB based on the available space in the pool. The shortfall is 30% when you use the following calculation:

$$\frac{100 \text{ GiB unallocated volume space} - 70 \text{ GiB remaining pool space}}{100 \text{ GiB unallocated volume space}} \times 100$$

Storage Volume Unallocatable Space (GiB)

The unallocatable storage space in GiB of a thin-provisioned volume. Unallocatable space cannot be supplied by the pool to which the volume belongs.

Storage Volume Uncompressed Capacity (GiB)

The amount of storage space that is used if the compressed volume space is uncompressed. For example, if 100 GiB of uncompressed data is compressed, and the size of the compressed data is 20 GiB, the value is 100.

Storage Volume Tier Capacity (GiB)

The amount of volume tier storage of a particular type. The type is identified in the Storage Volume Tier Type property. The tier is configured to be controlled by the Easy Tier® function.

Storage Volume Tier Available Space (GiB)

The amount of volume tier storage of a particular type that is unused. The type is identified in the Storage Volume Tier Type property. The tier is configured to be controlled by the Easy Tier function.

Component properties

You can create capacity and relationship reports that include the following information:

Storage Volume Type

The type of storage volume. For example, the storage volume can be striped or sequential. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume WWN

The worldwide name of the volume.

Storage Volume Fast Write State

Shows whether the cache for a volume on a disk that is managed by a storage virtualizer is empty, contains data, or is corrupted.

Storage Volume Grain Size (KiB)

The grain size with which a thin-provisioned volume was created. This value is typically 32, 64, 128, or 256 KiB. Larger grain sizes maximize performance, whereas smaller grain sizes maximize space efficiency. Grain sizes also limit the maximum virtual space of a volume.

This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Is Assigned

Shows whether the volume is assigned to a server. If this value is **Yes**, the volume is assigned to a server.

Storage Volume Is Auto Expand Enabled

Shows whether a volume or volume copy can allocate new extents from a pool automatically. Volumes or volume copies might allocate new extents to expand the real capacity of the storage virtualizer volume or volume copy. If this value is **Yes**, the volume or volume copy can allocate new extents from a pool automatically.

Storage Volume Is Encryptable

Shows whether the resource can be encrypted. If this value is **Yes**, the resource can be encrypted.

Storage Volume Is Encrypted

Shows whether the resource is encrypted. If this value is **Yes**, the resource is encrypted.

Storage Volume Is Formatted

Shows whether a storage volume is formatted. If this value is **Yes**, the volume is formatted. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage Volume Is Thin Provisioned

Shows whether a pool, volume, or volume copy is thin-provisioned. If this value is **Yes**, the resource is thin-provisioned.

Storage Volume Metro Mirror Name

The name of the Metro Mirror that keeps the synchronous copy of the storage virtualizer volume.

Storage Volume Mirror Count

The number of mirrors that keep a synchronous copy of the resource.

Storage Volume Throttle

The maximum number of commands that the storage volume can queue.

Storage Volume Warning Level

The percentage of used capacity of the resource at which a warning is generated.

Storage Volume FlashCopy® Relationship

Shows whether a volume on a storage system is in a FlashCopy relationship. This property can contain the following values:

Source Relationship

The volume is the source of the relationship.

Target Relationship

The volume is the target of the relationship.

Both Source and Target Relationship

The volume is both the source and target of the relationship.

Not in a FlashCopy Relationship

The volume is not in a FlashCopy relationship.

Storage Volume Remote Copy Relationship

Shows whether a volume on a storage system is in a remote copy relationship. This property can contain the following values:

Not in a Copy Relationship

The volume is not in a remote copy relationship.

Source Relationship

The volume is the source of the relationship.

Target Relationship

The volume is the target of the relationship.

Both Source and Target Relationship

The volume is both the source and target of the relationship.

Storage Volume RAID Level

The RAID level of a storage volume, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the resource.

Storage Volume Is Compressed

Shows whether the volume is compressed. If this value is **Yes**, the volume is compressed.

Storage Volume Is Volume Control Manager Database

Shows whether a volume is used as the Volume Control Manager Database. If this value is **Yes**, the volume is used as the Volume Control Manager Database.

Storage Volume Format

Shows the format of the volume or pool. The format can be a Count Key Data (CKD) format, or a fixed block format.

Storage Volume Serial Number

The serial number or volume ID of the volume.

Storage Volume Number

The number of the volume that is assigned by the system.

Storage Volume Logical Subsystem

The logical subsystem (LSS) to which a volume or pool belongs.

Storage Volume Is Easy Tier

Shows how the Easy Tier function is enabled on a volume. For example, if the value of this column is auto, the Easy Tier function is enabled in automatic mode.

Storage Volume Tier Type

The type of tier that is used on the volume. The tier is configured to be controlled by the Easy Tier function.

Status information

You can create capacity and relationship reports that include the following information:

Storage Volume Status

The condition of the resource, for example normal, warning, or error.

Storage Volume Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Storage Volume Is Easy Tier

Shows how the Easy Tier function is enabled on a volume. For example, if the value of this column is auto, the Easy Tier function is enabled in automatic mode.

Volume copy information

You can create capacity and relationship reports that include the following information:

Storage Volume Copy ID

The identifier of a volume copy.

Storage Volume Copy Grain Size (KiB)

The grain size with which a thin-provisioned volume was created. This value is typically 32, 64, 128, or 256 KiB. Larger grain sizes maximize performance, whereas smaller grain sizes maximize space efficiency. Grain sizes also limit the maximum virtual space of a volume.

Storage Volume Copy Is Auto Expand Enabled

Shows whether a volume or volume copy can allocate new extents from a pool automatically. Volumes or volume copies might allocate new extents to expand the real capacity of the storage virtualizer volume or volume copy. If this value is **Yes**, the volume or volume copy can allocate new extents from a pool automatically.

Storage Volume Copy Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Storage Volume Copy Is Primary

Shows whether the volume copy is the primary volume copy.

Storage Volume Copy Is Thin Provisioned

Shows whether a pool, volume, or volume copy is thin-provisioned. If this value is **Yes**, the resource is thin-provisioned.

Storage Volume Copy Total Number of Extents

The number of extents that are used by the storage volume copy.

Storage Volume Copy Type

The type of copy of the storage volume. For example, the copy of the storage volume can be sequential, a mirror copy, or another type of copy.

Storage Volume Copy Warning Level

The percentage of used capacity of the resource at which a warning is generated.

Storage Volume Copy Used Allocated Space Percentage

The percentage of reserved space for a volume copy that is being used. This value is always less than or equal to 100% because a volume copy cannot use more space than is allocated.

IBM Spectrum Control uses the following formula to determine this value:

$$(\text{used space} \div \text{allocated space}) \times 100$$

This property is available only for pools on resources that are running IBM Spectrum Virtualize.

Storage Volume Copy Used Space (GiB)

The amount of allocated space that is used by a volume copy.

Storage Volume Copy Allocated Space (GiB)

The amount of space that is reserved for a volume copy.

The space that is allocated for a thin-provisioned volume copy is less than its virtual capacity, which is shown in the Storage Virtualizer Capacity (GiB) property.

For volume copies that are not thin provisioned, this value is equal to the value of the Storage Volume Copy Used Space (GiB) property.

Storage Volume Copy Unallocated Space (GiB)

The amount of space in a pool that is not reserved for a volume copy.

IBM Spectrum Control uses the following formula to determine this value:

$$\text{capacity} - \text{allocated space}$$

Storage Volume Copy Physical Allocation Percentage

The percentage of physical space that is reserved for a volume copy. This value is always less than or equal to 100% because you cannot reserve more physical space than is available.

IBM Spectrum Control uses the following formula to determine this value:

$$(\text{allocated space} \div \text{capacity}) \times 100$$

For example, the physical allocation percentage is 25% for a total pool size of 200 GiB. Therefore, the space that is reserved for volume copies is 50 GiB.

Storage Volume Copy Unused Space (GiB)

The amount of space that is allocated to a volume copy and that is not yet used.

IBM Spectrum Control uses the following formula to determine this value:

$$\text{allocated space} - \text{used space}$$

This property is available only for pools on resources that are running IBM Spectrum Virtualize.

Storage Volume Copy Shortfall Percentage

The percentage of the remaining unallocated volume copy space in a pool that is not available to be allocated to a volume copy.

This value represents the percentage of the committed virtual space that is not available in a pool. As more space is used over time by a volume while the pool capacity remains the same, this percentage increases.

The higher the percentage value is, the more critical the shortfall of space is.

IBM Spectrum Control uses the following formula to determine this value:

$$(\text{unallocatable space} \div (\text{capacity} - \text{real capacity})) \times 100$$

You can use this percentage to determine when the amount of overcommitted space in a pool reaches a critically high level for the volume. For example, the physical space in a pool might be less than the committed virtual space. In this case, the pool does not have enough space to fulfill the commitment to virtual space for a volume.

For example, the remaining physical capacity of a pool is 70 GiB, however, 150 GiB of virtual space is committed to a thin-provisioned volume. If the volume uses 50 GiB, 100 GiB is, nevertheless, committed to that volume (150 GiB minus 50 GiB). There is a shortfall of 30 GiB when you use the following calculation:

$$(100 \text{ GiB remaining commitment of volume space to the volume} - 70 \text{ GiB remaining pool space})$$

The volume is overcommitted by 30 GiB based on the available space in the pool. The shortfall is 30% when you use the following calculation:

```
(100 GiB unallocatable volume copy space - 70 GiB
remaining pool space) ÷ 100 GiB unallocated volume space × 100
```

This property is available only for volume copies that are thin provisioned.

Storage Volume Copy Unallocatable Space (GiB)

The unallocatable storage space in GiB of a thin-provisioned volume copy. Unallocatable space cannot be supplied by the pool to which the volume copy belongs.

Storage Volume Copy Is Compressed

Shows whether the volume copy is compressed. If this value is **Yes**, the volume copy is compressed.

Storage Volume Copy Uncompressed Capacity (GiB)

The amount of storage space that is used if the compressed space on the volume copy is uncompressed. For example, if 100 GiB of data is compressed, the value is 100.

Data for storage system disks in capacity and relationship reports

You can include properties, and other data about storage system disks in capacity and relationship reports.

Information about storage system disks

You can create capacity and relationship reports that include the following information:

Storage Disk Name

The name that was assigned to the storage disk when it was added to the system.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Storage Disk Capacity (GiB)

The amount of storage space that is on a physical disk on the storage system.

Component properties

You can create capacity and relationship reports that include the following information:

Storage Disk Flags

Shows whether a device is a spare device. This property applies only to DS8000® storage systems.

Storage Disk Is Encryptable

Shows whether the resource can be encrypted. If this value is **Yes**, the resource can be encrypted.

Storage Disk Is Encrypted

Shows whether the resource is encrypted. If this value is **Yes**, the resource is encrypted.

Storage Disk Is Solid State

Shows whether the disk is a solid-state drive.

Storage Disk Speed (RPM)

The speed of the disk.

Storage Disk Tag

A number that identifies the array to which a disk belongs. This property applies only to DS8000 storage systems.

Storage Disk Class

The storage technology of the disk. This property applies only to DS8000 storage systems. This property can contain the following values:

FC

The disk is a Fibre Channel disk.

Nearline ATA

The disk is a nearline Advanced Technology Attachment disk.

Nearline SAS

The disk is a nearline serial-attached SCSI disk.

SAS

The disk is a serial-attached SCSI disk.

SATA

The disk is a Serial Advanced Technology Attachment disk.

SSD

The disk is a solid-state drive.

Unsupported

The disk is on a system that is not a DS8000 series system.

Status information

You can create capacity and relationship reports that include the following information:

Storage Disk Status

The condition of the resource, for example normal, warning, or error.

Storage Disk Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Vendor, model, and device information

You can create capacity and relationship reports that include the following information:

Storage Disk Firmware Version

The version number of the firmware that is running on the disk.

Storage Disk Model

The model name or model number of the resource.

Storage Disk Serial Number

The serial number of the resource.

Storage Disk Vendor

The vendor who supplied the resource.

Data for storage system groups in capacity and relationship reports

You can include general information about, and properties of, storage system groups in capacity and relationship reports.

Information about storage system groups

Storage system groups are deprecated in IBM Spectrum® Control 5.2.10 and later. Use storage resource groups instead. In the IBM Spectrum Control GUI, storage resource groups are available as general groups.

You can create capacity and relationship reports that include the following information:

Storage System Group Name

The name that was assigned to the storage system group when it was added to the system.

Component properties

You can create capacity and relationship reports that include the following information:

Storage System Group Creator

The user name of the user who created the group.

Storage System Group Last Modified

The date and time that the resource was last modified.

Storage System Group Last Modified by User

The user name of the user who last modified the resource.

Data for managed disks on storage systems in capacity and relationship reports

You can include general information, capacity data, properties, and other information about managed disks on storage systems in capacity and relationship reports.

Information about managed disks on storage systems

You can create capacity and relationship reports that include the following information:

Storage System MDisk Name

The name that was assigned to the managed disk on a storage system when it was added to the system.

Capacity and usage data

You can create capacity and relationship reports that include the following information:

Storage System MDisk Capacity (GiB)

The amount of storage space on the managed disk.

Storage System MDisk Available Space (GiB)

The amount of storage space that is available on a managed disk. This value is only available for resources that are running IBM Spectrum Virtualize and are configured as back-end storage.

Storage System MDisk Strip Size (KB)

The RAID strip size on a managed disk on a storage system.

Component properties

You can create capacity and relationship reports that include the following information:

Storage MDisk RAID Level

The RAID level of the managed disk, such as RAID 5 or RAID 10. The RAID level affects the performance and fault tolerance of the volumes that are allocated from the managed disk.

Storage MDisk Spare Goal

The number of spare drives that are required to maintain redundancy. Use spare drives to protect the system against drive failures in the array on a managed disk on a storage virtualizer.

Storage System MDisk Type

The type of managed disk on a storage system. For example, the disk on a storage system can be a local managed disk.

Storage System MDisk Mode

The access mode of a managed disk on a storage virtualizer. The access mode describes how extents are provided for virtual disks. Extents can be provided to virtual disks in the following ways:

Array

Extents are provided from local disks.

Managed

Extents are provided from a back-end storage volume.

Unmanaged

The managed disk is not used in the system.

Storage System MDisk Is Balanced

Shows whether LUNs are balanced across storage controllers on the managed disk. If this value is **Yes**, the LUNs are balanced.

Storage System MDisk Fast Write State

Shows whether the cache for a volume on a disk that is managed by a storage system is empty, contains data, or is corrupted.

Storage System MDisk Write Verify

Shows whether all write operations on a managed disk on a storage system are verified by an immediate follow-up read operation. The follow-up read operation verifies that the write operation was successful. If this value is **Yes**, all write operations are verified by a follow-up read operation.

Status information

You can create capacity and relationship reports that include the following information:

Storage System MDisk Status

The condition of the resource, for example normal, warning, or error.

Storage MDisk Native Status

Shows the level of access of nodes in the system to a managed disk or volume on a storage system. The level of access can be online, offline, degraded, or excluded.

Data for storage resource groups in capacity and relationship reports

You can include general information about storage resource groups in capacity and relationship reports. In the IBM Spectrum® Control GUI, storage resource groups are available as general groups.

Information about storage resource groups

You can create capacity and relationship reports that include the following information:

Storage Resource Group Name

The name that was assigned to the storage resource group when it was created.

Storage Resource Group Description

A user-defined description of the storage resource group. The description is created by the user when the storage resource group is created from the IBM Spectrum Control CLI.

Storage Resource Group Last Modified by User

The user name of the user who last modified the resource.

Storage Resource Group Custom Tag 1, 2, and 3

User-defined text that is associated with a storage resource group.

Data for groups in capacity and relationship reports

You can include general information about groups in capacity and relationship reports. A group is a set of logically related volumes, file systems, and shares. For example, a group that represents a business critical application might include the volumes, file systems, and shares that provide storage to the application.

Information about groups

You can create capacity and relationship reports that include the following information:

Group Name

The name that was assigned to the group by the user when the group was created.

Group Description

A user-defined description of the group. The description is created by the user when the group is created from the IBM Spectrum® Control CLI.

Group Last Modified by User

The user name of the user who last modified the resource.

Group Custom Tag 1, 2, and 3

User-defined text that is associated with a group.

Group Type

User-defined text that specifies the type of group. For example, the group type might be Application, Department, Project, General, or a similar type.

Group Subtype

User-defined text that is associated with a group. For example, if the Group Type property is Application, the Group Subtype property might specify the type of application. If the Group Type property is DB2® Group, the Group Subtype property might be Logs, Tablespace, or another group that is related to DB2.

Data for switches in capacity and relationship reports

You can include properties and other information about switches in capacity and relationship reports.

Information about switches

You can create capacity and relationship reports that include the following information:

Switch Name

The logical name of the switch where a Fibre Channel port is located, or the name that was defined when the switch was added for monitoring. If neither name is available, IBM Spectrum® Control uses the WWN of the switch.

Component properties

You can create capacity and relationship reports that include the following information:

Switch WWN

The World Wide Name (WWN) of the switch. A WWN is the unique 64-bit identifier for the switch.

Parent Switch Name

The name of the parent switch of a logical switch. If a user-defined name is not set for the parent switch, the WWN is shown. If the switch is not a logical switch, no value is displayed.

Parent Switch WWN

The worldwide name of the parent switch.

Switch Management Telnet Address

The Telnet address that you access to manage the switch.

Switch Management SNMP Address

The Simple Network Management Protocol (SNMP) address that you access to manage the switch.

Switch Management URL Address

The URL that you access to manage the switch.

Switch Domain

The domain ID of a switch. The ID is an 8-bit identifier with a range of 0-255. This column is blank for physical switches that are parents of virtual switches.

Switch Firmware Version

The firmware version of the microcode on a switch.

Switch Location

The physical location of the switch. The location is defined when a switch is added to IBM Spectrum Control. You can add or edit the location of the switch on the General tab of the properties notebook.

Switch Custom Tag 1, 2, and 3

User-defined text that is associated with the switch. You can add or edit the custom tags for the switch on the General tab of the properties notebook.

Switch Data Source Count

The number of data sources that are managing a switch. A switch can be managed by multiple data sources, and a single data source can manage multiple switches. Data sources might include CIM agents, SNMP agents, or Storage Resource agents. IBM Spectrum Control communicates with a data source to collect information about a switch.

Only the data sources that were added to IBM Spectrum Control are included in this number. For example, a switch is managed by two CIM agents and one Storage Resource agent. If one of the CIM agents was not added to IBM Spectrum Control, then the value for this property is 2.

Switch Is Virtual

Shows whether a switch is a logical switch. If this value is **Yes**, the switch is a logical switch.

Switch Ports

The total number of ports on the switch that are not online, and ports that are online and connected to other ports.

Switch Connected Ports

The number of ports that are connected to a storage resource, where the storage resource can be a storage system, server, or hypervisor. This value is only available when a switch is viewed as a related resource of a storage system, server, or hypervisor.

Status information

You can create capacity and relationship reports that include the following information:

Switch Status

The condition of the resource, for example normal, warning, or error.

Switch Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Switch Last Data Collection

The date and time when storage statistics were last collected from the resource.

Switch Last Data Collection Status

The condition of the last data collection. The status can show if the collection was a success, a failure, or if data was collected from the resource.

Vendor, model, and device information

You can create capacity and relationship reports that include the following information:

Switch IP Address

The IP address of the resource.

Switch Serial Number

The serial number of the resource.

Switch Vendor

The vendor who supplied the resource.

Switch Model

The model name or model number of the resource.

Data for switch ports in capacity and relationship reports

You can include properties and other information about switch ports in capacity and relationship reports.

Information about switch ports

You can create capacity and relationship reports that include the following information:

Switch Name

The logical name of the switch where a Fibre Channel port is located, or the name that was defined when the switch was added for monitoring. If neither name is available, IBM Spectrum® Control uses the WWN of the switch.

Component properties

You can create capacity and relationship reports that include the following information:

Switch Port Number

The port number on the resource.

Switch Port WWPN

The worldwide port name of the port on the switch.

Switch Port Type

The type of port on the storage system, storage virtualizer, or switch. For example, the port type can be N_Port, F_Port, or another type of port.

Switch Port Speed (GiB/s)

The speed of a port, which is measured in GiB per second.

Switch Blade Slot Number

The number of the slot on the switch to which the blade is attached. This property applies to ports on blades.

Switch Port Domain, Port

The domain ID of a switch, followed by the port index of a switch. In switches that have blades, the port index can differ from the port number.

Status information

You can create capacity and relationship reports that include the following information:

Switch Port Status

The condition of the resource, for example normal, warning, or error.

Switch Port Is Detected

Shows whether the resource was detected the last time that data was collected. If this value is **Yes**, the resource was detected.

Switch Port Enabled State

Shows whether a port is enabled, disabled, or is enabled but offline.

Switch Port Operational Status

The current operational state of the switch port. For example, this value can be **Error** or **OK**.

Data for fabrics in capacity and relationship reports

You can include properties and other information about fabrics in capacity and relationship reports.

Information about fabrics

You can create capacity and relationship reports that include the following information:

Fabric Name

The user-defined name for the fabric, or the name that was assigned to the fabric by the vendor.

Fabric WWN

The worldwide name of the fabric.

Component properties

You can create capacity and relationship reports that include the following information:

Fabric Type

The vendor of the switches in a fabric, such as IBM®, Brocade, or Cisco. If there are different switch vendors in the same fabric, the fabric type is displayed as **Mixed**. If this information is unknown, the property does not contain a value.

Principal Switch of Fabric

The name of the principal switch in the fabric at the time of the last data collection. The fabric can change its principal switch dynamically when conditions require it.

Important: Cisco physical switches are part of a SAN and not a fabric, therefore this property does not contain a value for those switches.

Fabric Switches

The number of physical and virtual switches in the fabric.

Fabric Switch Ports

The number of ports that are on all the switches in the fabric.

Fabric Connected Switch Ports

The number of switch ports that are online and connected to other ports in a fabric. The value is not shown when a fabric is viewed as a related resource of a storage system, server, or hypervisor.

Parent Fabric Name

The user-defined name for the parent fabric, or the name that was assigned to the parent fabric by the vendor.

Fabric Active Zone Set

The name of the zone set that is active. A zone set is a collection of zones within a single fabric. Only one zone set can be active for a fabric.

Fabric Location

The physical location of the fabric. The location is defined when a fabric is added to IBM Spectrum® Control. You can add or edit the location of the fabric on the General tab of the properties notebook.

Fabric Data Source Count

The number of data sources that are managing a fabric. A fabric can be managed by multiple data sources, and a single data source can manage multiple fabrics. Data sources can include SMI agents for Brocade switches or SNMP agents for Cisco switches. IBM Spectrum Control communicates with a data source to collect information about a fabric.

Only the data sources that were added to IBM Spectrum Control are included in this number. For example, a fabric is managed by two SMI agents on separate switches, but only one of the switches was added to IBM Spectrum Control. The value for the Fabric Data Source Count property is 1, because IBM Spectrum Control is configured to communicate with just the SMI agent of the switch that was added.

Fabric Is Virtual

Shows whether a fabric is a virtual fabric. If this value is **Yes**, the fabric is a virtual fabric.

Fabric Custom Tag 1, 2, and 3

User-defined text that is associated with a fabric. You can add or edit the custom tags for the fabric on the General tab of the properties notebook.

Status information

You can create capacity and relationship reports that include the following information:

Fabric Status

The condition of the resource, for example normal, warning, or error.

Fabric Last Data Collection

The date and time when storage statistics were last collected from the resource.

Fabric Last Data Collection Status

The condition of the last data collection. The status can show if the collection was a success, a failure, or if data was collected from the resource.

Troubleshooting Cognos Analytics reports

Find answers to questions about resolving issues with reports in the optional Cognos® Analytics reporting tool.

Problem

You can set output format options for reports either when you schedule a report or run a report. If you choose PDF format for your report and the report contains many columns, all of the columns might not fit on one page. For example, if a report contains 20 columns, then the row for a specific resource might be shown on more than one page: 10 columns on the first page and 10 columns on the second page.

Solution

To fit the maximum number of columns on one page, set the PDF options in one of the following ways:

When you schedule a report

1. Navigate to a report in the Cognos Analytics reporting tool.
2. Right-click the report, then click Properties.
3. Click the Schedule tab for the report.
4. Click the New icon.
5. Click Select in the PDF options area.
6. From the Orientation list, select Landscape.
7. From the Paper size list, select 11 × 17.

When you run a report

1. Navigate to a report in the Cognos Analytics reporting tool.
2. Right-click the report, then click Edit report.
3. Click the Run options icon , then click Show run options.
4. From the Paper size list, select 11 × 17.
5. From the Paper orientation list, select Landscape.

Problem

When you create a custom report, you cannot find online help that describes the columns that you can include in your reports.

Solution

To view the online help, follow these steps:

1. Go to the URL for your Cognos Analytics server. The URL is similar to this URL: `http://myhostname:9300/bi`
2. Click Team Content in the Welcome portal.
3. Click IBM Spectrum Control Predefined Reports.
4. Click any predefined report.
5. Click the Help link at the upper right of the page.
6. Go to the custom reports help content.

To view information about custom reports, see [Custom reports about performance](#) and [Custom reports about capacity and relationships](#).

Problem

If the IBM Spectrum® Control database (TPCDB) is not accessible, you are prompted to reenter your user ID and password although you previously entered the correct user ID and password.

Solution

Check that the server that hosts TPCDB is available. Check that the firewall settings on the server are not preventing you from accessing TPCDB.

Problem

If the password to access the IBM Spectrum Control database (TPCDB) is changed, you must also change the password in the Cognos Analytics reporting tool.

Solution

In the Cognos Analytics reporting tool, complete the following steps:

1. Go to the URL for your Cognos Analytics server. The URL is similar to this URL: **http://myhostname:9300/bi**
2. Click Manage in the Welcome portal, then click Administration console.
3. Click the Configuration tab.
4. Click the TPCDB data source
5. Click the TPCDB connection. The breadcrumb text is **Directory > Cognos > TPCDB > TPCDB**.
6. In the Actions column, click the Set properties icon , and then click the Signon tab.
7. Click Edit the signon.
8. Make your changes, and then click OK.

Problem

When you use particular combinations of properties from the Storage Volume section in the Performance package in a custom report, a **No data available** message might be displayed. This occurs when you use the following combinations of properties in a custom report:

- Server Name, Hypervisor Name, and any other property from the Storage Volume section
- Server Name, Hypervisor Name, Hypervisor Cluster Name, and any other property from the Storage Volume section
- Server Name, Hypervisor Cluster Name, and any other property from the Storage Volume section

Solution

Do not use these combinations of properties in custom reports.

Problem

When you add a filter to a property in Query Studio, not all of the resources are listed in the Filter (Pick values from a list) area. For example, when you add a filter to the Storage Volume Name property, not all of the volumes are listed.

This problem occurs because the maximum number of items in a list in Query Studio is 5000. If there are more than 5000 items in the list, only the first 5000 values are displayed, in alphabetical order.

Solution

Click Search for values in the Filter (Pick values from a list) area. Type a keyword, and then click Search to search for volumes on a resource. For example, type a% to find volume names that begin with 'a' or 'A'.

Problem

When you run a report, it takes a long time for the report output to display. It might take a long time to run a report for some combinations of the interval and reporting period. For example, the report might take a long time if you select the Sample interval or Hourly interval with one of the following periods:

- Last 30 days
- Last 90 days
- All

Solution

When you run a report, use shorter reporting periods with the Sample interval or Hourly interval.

Problem

When you run a report, the output that is displayed contains no data. If you select the Daily interval and a recent reporting period, then no data might be available. For example, if you select Last 24 hours or Today, the data for those reporting periods is unlikely to be collected yet.

Solution

When you run a report with a Daily interval, use a reporting period other than Last 24 hours or Today.

Problem

If you create a custom performance report in Query Studio, in particular circumstances, the report takes a long time to complete. This problem might occur in the following circumstances:

- The report is for more than 10,000 volumes.
- The interval for the report is Hourly, and the data for the report was collected for more than 15 days.
- The interval for the report is Sample, and the data for the report was collected for more than 7 days.

Solution

When this problem occurs, complete the following steps for the report in Query Studio:

1. Click Run Report in the menu pane.
2. Click Advanced Options.
3. Clear each of the following check boxes:
 - Automatically generate footer summaries for measures
 - Automatically summarize detail values, suppressing duplicates
 - Enable drill up and drill down in the report output
 - Enable drill through from a package in the report output
4. Click OK.

Problem

If you used the IBM Spectrum Control Capacity and Relationships package in 5.2, 5.2.1, 5.2.2, 5.2.3, or 5.2.4 to create custom reports, you might need to re-create those reports.

Solution

If your custom reports use any of the following properties, you must re-create the reports in the Capacity and Relationships package:

- NAS File Set Name
- NAS File Set Comment
- NAS File Set Path
- NAS File Set Used Space (GiB)
- NAS File Set Used Inodes

- NAS File Set Is Detected
- NAS File Set Status

To view information about how to create custom reports in the Capacity and Relationships package, see [Creating custom capacity and relationship reports](#).

Showing the package version number and build ID

Access information about the packages for custom reports and predefined reports, such as the version number and the build ID.

About this task

You can identify the version number and build ID for each of the following packages:

- Capacity and Relationships
- Performance

Procedure

1. Go to the URL for your Cognos® Analytics server. The format of the URL is similar to this URL: `http://myhostname:9300/bi`
2. Click Team Content in the Welcome portal.
3. Click IBM Spectrum Control Packages.
4. Depending on the package whose version number and build ID you want to see, complete one of the following steps:
 - To identify the version number and build ID of the Capacity and Relationships package, right-click Capacity and Relationships, then click Create report.
 - To identify the version number and build ID of the Performance package, right-click Performance, then click Create report.
5. In the navigation tree, position the cursor over the item under the name of the package.

Results

The version number and the build ID for the package is shown.

Reference

View reference information that is related to IBM Spectrum® Control. Topics include information about alerts, fabrics, commands, configuration and log files, performance metrics, protocols, standards, and accessibility features.

- [Return codes used by Storage Resource agent](#)
This topic lists the return codes used by the Storage Resource agent.
- [Agent types for monitoring fabrics and switches](#)
Depending on the type of switch you want to manage, you can use a CIM agent or SNMP agent as the data source for the switch.
- [Supported storage systems providing full disk encryption and solid-state drives](#)
IBM Spectrum Control supports full disk encryption and solid-state drives in the IBM® System Storage® DS8000® systems described in this topic.
- [Performance counters](#)
Use the metrics based on performance counters to measure and view the performance of storage systems and switches.
- [Command-line interface](#)
The following sections describe the IBM Spectrum Control command-line interface (CLI).
- [agent.sh command](#)
The `agent.sh` command lets you start, stop, and restart the Storage Resource agent. You can also display the status and version of the Storage Resource agent.
- [dataCollector command](#)
The `dataCollector` command is used to start and stop the data collector service.
- [Configuration files](#)
Use the parameters in IBM Spectrum Control configuration files to help resolve problems.
- [Log files](#)
When you have a problem, you can check several product log files.
- [Script parameters](#)
Script parameters provide specific information on the alert that triggered the script to be run.
- [Opening IBM Spectrum Control on Windows operating systems](#)
You can open IBM Spectrum Control CLIs and GUIs and administer IBM Spectrum Control on Windows operating systems.
- [Windows services used by IBM Spectrum Control](#)
To start, stop, or restart a component or related program in IBM Spectrum Control, use the Windows Services panel.
- [Frequently Asked Questions](#)
View answers to common questions about IBM Spectrum Control.
- [Protocols and standards](#)
This section provides an overview of the protocols and standards that are used within IBM Spectrum Control.
- [IBM Spectrum Control technical community](#)
Connect, learn, and share with storage professionals: product support technical experts who provide their perspectives and expertise.
- [Accessibility features for IBM Spectrum Control](#)
Accessibility features help users who have a disability, such as restricted mobility or limited vision, to use information technology products successfully.

Return codes used by Storage Resource agent

This topic lists the return codes used by the Storage Resource agent.

The following table lists the return codes used by the Storage Resource agent during installation, uninstallation, and upgrade.

Table 1. Storage resource agent return codes

Return code	Explanation
1	There is a problem uninstalling the Fabric agent. For more information about what caused the uninstallation to fail, check the uninstallation logs for the Fabric agent.
2	Command not valid.
3	Option provided is not valid.
5	Argument is not valid.
6	Missing value for argument (e.g. -installLoc <Value>, where <Value> is missing).
7	Missing localized string in message file.
8	Probe is running.
9	Failed to open file for write.
10	Failed to close file.
11	Logfile not specified.
19	Failed in tracing.
21	Cannot spawn a probe because it is busy.
30	This is an internal error in initializing tracing. Save the error message and error log and contact your service representative for assistance in resolving the error.
32	Invalid socket.
33	Start service failed.
34	Registry entry not found.
35	Deployment of the agent failed, error creating startup scripts.
36	File does not exist.
40	Missing upgrade files.
41	Failed to extract files in upgrade process.
42	Failed to stop probe in upgrade process.
43	Failed to stop Agent.
44	Failed to start Agent.
45	Agent Registration to server failed.
46	File extraction needs more space.
47	Failed to open archive file.
48	Agent did not start after upgrade.
49	Installation directory not valid at upgrade time.
50	Probe is running.
51	Data file not found.
52	Exit code not in the output file.
53	Failed to send job status.
54	Failed to copy certificate files.
55	Failed to create directory.
56	Failed to remove directory.
57	Exec command failed.
58	Conversion of wide character failed.
59	Installation directory not valid.
60	Server name not defined.
61	Error in removing entries from configuration file.
62	Failed to stop probe at uninstall time.
63	Failed to remove registry entry at uninstall time.
64	Failed to remove service entry at uninstall time.
65	Failed to stop service at uninstall time.
66	Specified server name is not valid.
67	There is an error installing the Storage Resource agent as part of the migration process. For more information about what caused the installation to fail, check the installation logs for the Storage Resource agent.
71	Failed to spawn process.
73	Failed to spawn probe process.
101	Failed to create lock at installation time.
102	Failed to stop probe at re-installation time.
103	Failed to stop agent at re-installation time.
104	Failed to create registry at installation time.
105	Failed to extract files at installation time.
106	Failed to create entries in configuration file at installation time.
107	Failed to stop service at re-installation time.
108	Service already exists.
109	Failed to create service.
110	Failed to start service.
111	Probe failed at installation time.
112	Creation of daemon failed.
113	Installation of GUID failed.

Return code	Explanation
114	Commttype parameter is not valid.
115	Specified port is in use.
116	Installation/Upgrade does not have enough space.
117	Installation in progress.
118	Cannot get server name from Server.
119	Installation location is not empty.
120	Missing parameter Server Name.
121	Missing parameter Server Port.
123	Missing parameter Server IP.
124	Missing parameter Agent Port.
125	Missing parameter Installation location.
126	A value has not been specified for parameter userID. A value for this parameter is required when using RXA-based communication to deploy a Storage Resource agent as a non-daemon service. IBM Spectrum® Control uses this user ID when connecting to the computer on which the agent will be installed.
127	Deployment from Windows to Linux® failed.
130	Failed to send probe results.
131	Failed to initialize Agent.
133	Missing port number for Service.
134	Get data file stat failed.
135	Get data file read failed.
137	Failed to send data to server.
138	Failed to receive data from server.
139	Full path not specified for copy file.
140	Create file failed in copy file function.
141	Write file failed in copy file function.
142	Open file failed in copy file function.
143	Read file failed in copy file function.
145	UCS conversion failed.
146	Server connection failed.
148	Failed to create zip file.
149	Failed to unzip file.
160	Failed to send scan results.
161	Failed to send TSM status results.
164	Failed to validate user.
165	Job file was not found.
166	Job was not stopped.
168	Not enough free space available while copying file from server.
169	Multipath driver not found.
170	Multipath device not found.
171	Multipath policy is not supported.
172	Only Round Robin policy is supported for Multipath DM driver.
175	The command failed to run.
176	The command ran, but failed to complete successfully.

Agent types for monitoring fabrics and switches

Depending on the type of switch you want to manage, you can use a CIM agent or SNMP agent as the data source for the switch.

Table 1. Agent types for switch and fabric functions

Function	Brocade	Cisco
Monitor performance	REST API or SMI agent	SNMP agent
Collect information about switches and switch ports	REST API or SMI agent	SNMP agent
Collect information about topology connectivity	REST API or SMI agent	SNMP agent
Collect information about zoning information and zone control	REST API or SMI agent	SNMP agent
Generate alerts	REST API or SMI agent	SNMP agent

Check the [IBM Spectrum Control interoperability matrix for switches](#) for information about the switches and directors that are supported by IBM Spectrum® Control, and limitations that you need to know about when you use these devices.

Supported storage systems providing full disk encryption and solid-state drives

IBM Spectrum® Control supports full disk encryption and solid-state drives in the IBM® System Storage® DS8000® systems described in this topic.

IBM Spectrum Control supports full disk encryption and solid-state drives in DS8000 4.2 and later.

Performance counters

Use the metrics based on performance counters to measure and view the performance of storage systems and switches.

Overview

Performance counters are available for the following resources:

- [Volume counters](#)
- [Disk counters](#)
- [Storage system and switch port counters](#)

Volume counters

Volume performance counters are divided into the following categories:

- [Volume I/O counters](#)
- [Volume cache hit counters](#)
- [Volume data counters](#)
- [Volume service time counters](#)
- [Volume cache counters](#)
- [Volume miscellaneous counters](#)
- [Volume special computed values](#)

Table 1. Volume I/O counters

Counter	Counter type	Resource or component type	Description
Read I/O Count (normal)	001	DS8000®: volume, array, controller, storage system	Number of input/output (I/O) operations for nonsequential read requests, for a particular component over a particular time interval.
Read I/O Count (sequential)	002	DS8000: volume, array, controller, storage system	Number of I/O operations for sequential read requests, for a particular component over a particular time interval.
Read I/O Count (overall)	003	IBM Spectrum Virtualize: volume, node, I/O group, pool, storage system SMI-S BSP: volume, controller, storage system XIV®: volume, module, storage system	Number of I/O operations for all read requests, for a particular component over a particular time interval.
Write I/O Count (normal)	004	DS8000: volume, array, controller, storage system	Number of I/O operations for nonsequential write requests, for a particular component over a particular time interval.
Write I/O Count (sequential)	005	DS8000: volume, array, controller, storage system	Number of I/O operations for sequential write requests, for a particular component over a particular time interval.
Write I/O Count (overall)	006	IBM Spectrum Virtualize: volume, node, I/O group, pool, storage system SMI-S BSP: volume, controller, storage system XIV: volume, module, storage system	Number of I/O operations for all write requests, for a particular component over a particular time interval.
Total I/O Count (overall)	009	SMI-S BSP: volume, controller, storage system	Total number of I/O operations for all read and write requests, both sequential and nonsequential, for a particular component over a particular time interval.
Read Track Count	062	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of cache track read operations, for a particular component over a particular time interval.
Write Track Count	063	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of cache track write operations, for a particular component over a particular time interval.
Fast Write Mode Track Count	065	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of tracks writes that were processed in fast-write write mode, for a particular component over a particular time interval. Included as part of the "Write Track Count".
Write Through Mode Track Count	066	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of tracks writes that were processed in write-through write mode, for a particular component over a particular time interval. Included as part of the "Write Track Count".
Flush Through Mode Track Count	067	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of tracks writes that were processed in flush-through write mode, for a particular component over a particular time interval. Included as part of the "Write Track Count".
Cache Overflow Mode Track Count	068	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of tracks writes that were processed in cache overflow write mode, for a particular component over a particular time interval. Included as part of the "Write Track Count".
Global Mirror Write Count	090	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of write operations issued to the secondary site for Global Mirror, for a particular component over a particular time interval.

Counter	Counter type	Resource or component type	Description
Global Mirror Overlapping Write Count	091	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of serialized overlapping write operations encountered at the primary site for Global Mirror, for a particular component over a particular time interval.
HPF Read I/O Count	093	DS8000: volume, array, controller, storage system	Number of read I/O operations (both normal and sequential) that were issued using the High Performance FICON® (HPF) feature of the storage system, for a particular component over a particular time interval.
HPF Write I/O Count	094	DS8000: volume, array, controller, storage system	Number of write I/O operations (both normal and sequential) that were issued using the High Performance FICON (HPF) feature of the storage system, for a particular component over a particular time interval.
Non-Preferred Node I/O Count	096	IBM Spectrum Virtualize: I/O group, volume	Number of I/O operations (both read and write) that were performed using the non-preferred nodes of the volumes. This value is a subset of the total I/O operations for the component, and is normally expected to be 0.
Maintenance Operations Count	098	BSP: volume, controller, storage system	Cumulative count of all disk maintenance operations (SCSI commands such as: Verify, skip-mask, XOR read, XOR write-read, and so on). This value is required to understand the load on the component that might interfere with normal read and write operations.
Read Hit I/O Percentage for Small Transfers	104	XIV: volume, module, storage system	Percentage of I/O read operations over a specified interval that resulted in cache hits. Applies to data transfers that are ≤ 8 KB.
Read Hit I/O Percentage for Medium Transfers	105	XIV: volume, module, storage system	Percentage of I/O read operations over a specified interval that resulted in cache hits. Applies to data transfers that are > 8 KB and ≤ 64 KB.
Read Hit I/O Percentage for Large Transfers	106	XIV: volume, module, storage system	Percentage of I/O read operations over a specified interval that resulted in cache hits. Applies to data transfers that are > 64 KB and ≤ 512 KB.
Read Hit I/O Percentage for Huge Transfers	107	XIV: volume, module, storage system	Percentage of I/O read operations over a specified interval that resulted in cache hits. Applies to data transfers that are > 512 KB.
Read Miss I/O Percentage for Small Transfers	108	XIV: volume, module, storage system	Percentage of I/O read operations over a specified interval that resulted in cache misses. Applies to data transfers that are ≤ 8 KB.
Read Miss I/O Percentage for Medium Transfers	109	XIV: volume, module, storage system	Percentage of I/O read operations over a specified interval that resulted in cache misses. Applies to data transfers that are > 8 KB and ≤ 64 KB.
Read Miss I/O Percentage for Large Transfers	110	XIV: volume, module, storage system	Percentage of I/O read operations over a specified interval that resulted in cache misses. Applies to data transfers that are > 64 KB and ≤ 512 KB.
Read Miss I/O Percentage for Huge Transfers	111	XIV: volume, module, storage system	Percentage of I/O read operations over a specified interval that resulted in cache misses. Applies to data transfers that are > 512 KB.
Write Hit I/O Percentage for Small Transfers	112	XIV: volume, module, storage system	Percentage of I/O write operations over a specified interval that resulted in cache hits. Applies to data transfers that are ≤ 8 KB.
Write Hit I/O Percentage for Medium Transfers	113	XIV: volume, module, storage system	Percentage of I/O write operations over a specified interval that resulted in cache hits. Applies to data transfers that are > 8 KB and ≤ 64 KB.
Write Hit I/O Percentage for Large Transfers	114	XIV: volume, module, storage system	Percentage of I/O write operations over a specified interval that resulted in cache hits. Applies to data transfers that are > 64 KB and ≤ 512 KB.
Write Hit I/O Percentage for Huge Transfers	115	XIV: volume, module, storage system	Percentage of I/O write operations over a specified interval that resulted in cache hits. Applies to data transfers that are > 512 KB.
Write Miss I/O Percentage for Small Transfers	116	XIV: volume, module, storage system	Percentage of I/O write operations over a specified interval that resulted in cache misses. Applies to data transfers that are ≤ 8 KB.
Write Miss I/O Percentage for Medium Transfers	117	XIV: volume, module, storage system	Percentage of I/O write operations over a specified interval that resulted in cache misses. Applies to data transfers that are > 8 KB and ≤ 64 KB.
Write Miss I/O Percentage for Large Transfers	118	XIV: volume, module, storage system	Percentage of I/O write operations over a specified interval that resulted in cache misses. Applies to data transfers that are > 64 KB and ≤ 512 KB.
Write Miss I/O Percentage for Huge Transfers	119	XIV: volume, module, storage system	Percentage of I/O write operations over a specified interval that resulted in cache misses. Applies to data transfers that are > 512 KB.
Read SSD Hit Percentage for Small Transfer Sizes	153	XIV: volume, pool, module, host connection, storage system	Percentage of read operations over a specified time interval that accessed SSD cache memory. Applies to data transfers that are ≤ 8 KB.
Read SSD Hit Percentage for Medium Transfer Sizes	154	XIV: volume, pool, module, host connection, storage system	Percentage of read operations over a specified time interval that accessed SSD cache memory. Applies to data transfers that are > 8 KB and ≤ 64 KB.

Counter	Counter type	Resource or component type	Description
Read SSD Hit Percentage for Large Transfer Sizes	155	XIV: volume, pool, module, host connection, storage system	Percentage of read operations over a specified time interval that accessed SSD cache memory. Applies to data transfers that are > 64 KB and ≤ 512 KB.
Read SSD Hit Percentage for Huge Transfer Sizes	156	XIV: volume, pool, module, host connection, storage system	Percentage of read operations over a specified time interval that accessed SSD cache memory. Applies to data transfers that are > 512 KB.
Unaligned Write I/O Count	180	IBM Spectrum Virtualize ² : node, I/O group, host connection, storage system	The number of write operations that are not aligned on a boundary between 4 KB physical blocks. Unaligned write operations can cause a significant decrease in efficiency of write operations to some types of back-end disks. You can ignore this counter for iSeries servers.
Compressed Volumes I/O Count	182	IBM Spectrum Virtualize: node, I/O group, storage system	The total number of all read and write operations for compressed volumes.
Cache Read I/O Count - Volume Cache	610	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of read I/Os measured at the volume cache, which includes host reads as well as reads needed for remote replication.
Cache Read I/O Count - Volume Copy Cache	609	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of read I/Os measured at the volume copy cache, which includes host reads as well as reads needed for replication and other internal processing.
Cache Write I/O Count - Volume Cache	612	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of write I/Os measured at the volume cache, which includes host writes as well as writes needed for remote replication.
Cache Write I/O Count - Volume Copy Cache	611	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of write I/Os measured at the volume copy cache, which includes host writes as well as writes needed for replication and other internal processing.
Cache Prestage I/O Count - Volume Copy Cache	613	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of prefetch disk-to-cache transfer operations that are processed in the volume copy cache.
Cache Stage I/O Count - Volume Cache	615	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of disk-to-cache transfer operations that are processed in the volume cache.
Cache Stage I/O Count - Volume Copy Cache	614	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of disk-to-cache transfer operations that are not prefetch operations and are processed in the volume copy cache.
Cache Destage I/O Count - Volume Cache	617	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache-to-disk transfer operations that are processed in the volume cache.
Cache Destage I/O Count - Volume Copy Cache	616	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache-to-disk transfer operations that are processed in the volume copy cache.
In-flight I/O Count	658	IBM Spectrum Virtualize ¹ : managed disk	The actual number of concurrent operations that are issued from the cache to the managed disk. The number of in-flight operations cannot exceed the target, but also varies over time, depending on the type of I/O operations and on the performance of the managed disk.
Target I/O Count	657	IBM Spectrum Virtualize ¹ : managed disk	The maximum number of concurrent operations that can be issued from the cache to the managed disk. This target changes over time, depending on changes in cache utilization and on changes in the performance of the managed disk.
Notes:			
1. This counter is only available for resources that are running IBM Spectrum Virtualize 7.3 or later.			
2. This counter is only available for resources that are running IBM Spectrum Virtualize 7.4 or later.			

Table 2. Volume cache hit counters

Counter	Counter type	Resource or component type	Description
Read Cache Hits (normal)	010	DS8000: volume, array, controller, storage system	Number of cache hits for nonsequential read requests, for a particular component over a particular time interval.
Read Cache Hits (sequential)	011	DS8000: volume, array, controller, storage system	Number of cache hits for sequential read requests, for a particular component over a particular time interval.
Read Cache Hits (overall)	012	SMI-S BSP: volume, controller, storage system XIV: volume, module, storage system	Number of cache hits for all read requests, for a particular component over a particular time interval.
Write Cache Hits (normal)	013	DS8000: volume, array, controller, storage system	Number of cache hits for nonsequential write requests, for a particular component over a particular time interval.

Counter	Counter type	Resource or component type	Description
Write Cache Hits (sequential)	014	DS8000: volume, array, controller, storage system	Number of cache hits for sequential write requests, for a particular component over a particular time interval.
Write Cache Hits (overall)	015	SMI-S BSP: volume, controller, storage system XIV: volume, module, storage system	Number of cache hits for all write requests, for a particular component over a particular time interval.
Read Tracks Cache Hits	069	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of read track cache hits that were entirely serviced from prestaged or non-prestaged tracks for a particular component over a particular time interval.
Read Track Cache Hits Sector Count	070	IBM Spectrum Virtualize: node	Number of sectors read for cache hits that were entirely serviced from prestaged or non-prestaged tracks for a particular component over a particular time interval.
Read Sector Cache Hits - Volume Cache	69	IBM Spectrum Virtualize: volume, pool, node, I/O group, host connection, storage system	The number of cache sectors or tracks that achieved read cache hits in the volume cache. For resources that are running a version of IBM Spectrum Virtualize that is earlier than 7.3, the unit of the counter is tracks.
Read Sector Cache Hits - Volume Copy Cache	607	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache sectors that achieved read cache hits in the volume copy cache.
Prestage Cache Hits	80	IBM Spectrum Virtualize: volume, pool, node, I/O group, host connection, storage system	The number of prefetched cache sectors or tracks that achieved read cache hits in the volume copy cache. For resources that are running a version of IBM Spectrum Virtualize that is earlier than 7.3, the unit of the counter is tracks.
Destage Cache Hits - Volume Cache	81	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of destaged cache sectors or tracks that achieved write cache hits in the volume cache. That is, the number of writes that modified only data that was already marked "dirty" in the cache. For resources that are running a version of IBM Spectrum Virtualize that is earlier than 7.3, the unit of the counter is tracks.
Destage Cache Hits - Volume Copy Cache	608	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of destaged cache sectors that achieved write cache hits in the volume copy cache. That is, the number of writes that modified only data that was already marked "dirty" in the cache.
Note:			
1. This counter is only available for resources that are running IBM Spectrum Virtualize 7.3 or later.			

Table 3. Volume data counters

Counter	Counter type	Resource or component type	Description
Read KB Count	019	IBM Spectrum Virtualize: volume, node, I/O group, pool, storage system SMI-S BSP: volume, controller, storage system XIV: volume, module, storage system	Number of KB (2 ¹⁰ bytes) of data transferred for read operations, for a particular component over a particular time interval.
Write KB Count	020	IBM Spectrum Virtualize: volume, node, I/O group, pool, storage system SMI-S BSP: volume, controller, storage system XIV: volume, module, storage system	Number of KB (2 ¹⁰ bytes) of data transferred for write operations, for a particular component over a particular time interval.
Total KB Count	021	SMI-S BSP: volume, controller, storage system	Total number of KB (2 ¹⁰ bytes) of data transferred for read and write operations, for a particular component over a particular time interval.
Read Data Count	022	DS8000: volume, array, controller, storage system	Number of 128 KB chunks (128*2 ¹⁰ bytes) of data transferred for read operations, for a particular component over a particular time interval.
Write Data Count	023	DS8000: volume, array, controller, storage system	Number of 128 KB chunks (128*2 ¹⁰ bytes) of data transferred for write operations, for a particular component over a particular time interval.
Read Sector Count	071	IBM Spectrum Virtualize: node	Number of cache sectors read, for a particular component over a particular time interval.
Write Sector Count	072	IBM Spectrum Virtualize: node	Number of cache sectors written, for a particular component over a particular time interval.
Fast Write Mode Sector Count	074	IBM Spectrum Virtualize: node	Number of written cache sectors processed in fast-write write mode, for a particular component over a particular time interval. Included as part of the "Write Sector Count".
Write Through Mode Sector Count	075	IBM Spectrum Virtualize: node	Number of written cache sectors processed in write-through write mode, for a particular component over a particular time interval. Included as part of the "Write Sector Count".
Flush Through Mode Sector Count	076	IBM Spectrum Virtualize: node	Number of written cache sectors processed in flush-through write mode, for a particular component over a particular time interval. Included as part of the "Write Sector Count".
Cache Overflow Mode Sector Count	077	IBM Spectrum Virtualize: node	Number of written cache sectors processed in cache overflow write mode, for a particular component over a particular time interval. Included as part of the "Write Sector Count".
Non-Preferred Node KB Count	097	IBM Spectrum Virtualize: I/O group, volume	Number of KB (both read and write) that were transferred using the non-preferred nodes of the volumes. This value is a subset of the total KB transferred for the component, and is normally expected to be 0.

Counter	Counter type	Resource or component type	Description
Read Hit KB Percentage for Small Transfers	120	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of read operations that resulted in cache hits. Applies to data transfers ≤ 8 KB.
Read Hit KB Percentage for Medium Transfers	121	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of read operations that resulted in cache hits. Applies to data transfers > 8 KB and ≤ 64 KB.
Read Hit KB Percentage for Large Transfers	122	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of read operations that resulted in cache hits. Applies to data transfers > 64 KB and ≤ 512 KB.
Read Hit KB Percentage for Huge Transfers	123	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of read operations that resulted in cache hits. Applies to data transfers > 512 KB.
Read Miss KB Percentage for Small Transfers	124	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of read operations that resulted in cache misses. Applies to data transfers ≤ 8 KB.
Read Miss KB Percentage for Medium Transfers	125	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of read operations that resulted in cache misses. Applies to data transfers > 8 KB and ≤ 64 KB.
Read Miss KB Percentage for Large Transfers	126	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of read operations that resulted in cache misses. Applies to data transfers > 64 KB and ≤ 512 KB.
Read Miss KB Percentage for Huge Transfers	127	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of read operations that resulted in cache misses. Applies to data transfers > 512 KB.
Write Hit KB Percentage for Small Transfers	128	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of write operations that resulted in cache hits. Applies to data transfers ≤ 8 KB.
Write Hit KB Percentage for Medium Transfers	129	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of write operations that resulted in cache hits. Applies to data transfers > 8 KB and ≤ 64 KB.
Write Hit KB Percentage for Large Transfers	130	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of write operations that resulted in cache hits. Applies to data transfers > 64 KB and ≤ 512 KB.
Write Hit KB Percentage for Huge Transfers	131	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of write operations that resulted in cache hits. Applies to data transfers > 512 KB.
Write Miss KB Percentage for Small Transfers	132	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of write operations that resulted in cache misses. Applies to data transfers ≤ 8 KB.
Write Miss KB Percentage for Medium Transfers	133	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of write operations that resulted in cache misses. Applies to data transfers > 8 KB and ≤ 64 KB.
Write Miss KB Percentage for Large Transfers	134	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of write operations that resulted in cache misses. Applies to data transfers > 64 KB and ≤ 512 KB.
Write Miss KB Percentage for Huge Transfers	135	XIV: volume, module, storage system	Percentage of KB of data that is transferred over a specified interval because of write operations that resulted in cache misses. Applies to data transfers > 512 KB.
Read SSD Data Hit Percentage for Small Transfer Sizes	157	XIV: volume, pool, module, host connection, storage system	Percentage of data transfers over a specified time interval that accessed SSD cache memory. Applies to data transfers ≤ 8 KB.
Read SSD Data Hit Percentage for Medium Transfer Sizes	158	XIV: volume, pool, module, host connection, storage system	Percentage of data transfers over a specified time interval that accessed SSD cache memory. Applies to data transfers > 8 KB and ≤ 64 KB.
Read SSD Data Hit Percentage for Large Transfer Sizes	159	XIV: volume, pool, module, host connection, storage system	Percentage of data transfers over a specified time interval that accessed SSD cache memory. Applies to data transfers > 64 KB and ≤ 512 KB.
Read SSD Data Hit Percentage for Huge Transfer Sizes	160	XIV: volume, pool, module, host connection, storage system	Percentage of data transfers over a specified time interval that accessed SSD cache memory. Applies to data transfers > 512 KB.
Compressed Volumes KB Count	183	IBM Spectrum Virtualize: node, I/O group, storage system	The total number of KiB that were read from or written to compressed volumes.

Table 4. Volume service time counters

Counter	Counter type	Resource or component type	Description
Read Service Time	025	IBM Spectrum Virtualize: volume, node, I/O group, pool, storage system XIV: volume, module, storage system	Number of milliseconds that it took to service all read operations, for a particular component over a particular time interval.
Write Service Time	026	IBM Spectrum Virtualize: volume, node, I/O group, pool, storage system XIV: volume, module, storage system	Number of milliseconds that it took to service all write operations, for a particular component over a particular time interval.
Read Service Periods	028	DS8000: volume, array, controller, storage system SMI-S BSP: volume, controller, storage system	Number of time periods that it took to service all read operations, for a particular component over a particular time interval. The exact time interval length is device-dependent, but is typically 16 milliseconds for DS devices.
Write Service Periods	029	DS8000: volume, array, controller, storage system SMI-S BSP: volume, controller, storage system	Number of time periods that it took to service all write operations, for a particular component over a particular time interval. The exact time interval length is device-dependent, but is typically 16 milliseconds for DS devices.

Counter	Counter type	Resource or component type	Description
Overall Service Periods	030	SMI-S BSP: volume, controller, storage system	Total number of time periods that it took to service all I/O operations (read and write), for a particular component over a particular time interval. The exact time interval length is device-dependent, but is typically 16 milliseconds for DS devices.
Peak Read Response Time	088	IBM Spectrum Virtualize: volume, node, I/O group, storage system	The peak (worst) response time for disk reads for a particular component over a particular time interval. Value in microseconds.
Peak Write Response Time	089	IBM Spectrum Virtualize: volume, node, I/O group, storage system	The peak (worst) response time for disk writes for a particular component over a particular time interval. Value in microseconds.
Global Mirror Service Time	092	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of additional milliseconds it took to service all secondary write operations for Global Mirror, beyond the time required to service the primary writes, for a particular component over a particular time interval.
Overall Host Attributed Service Time	095	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Cumulative transfer latency, in microseconds, coalesced for both reads and writes excluding any status-only transfers. This value is the time taken for hosts to respond to transfer-ready notifications from the nodes (for read) and the time taken for hosts to send the write data after receiving transfer-ready notification from the nodes (for write). This value is provided as an aid to diagnose slow hosts and poorly performing fabrics.
Read Cache Hit Service Periods	099	BSP: volume, controller, storage system	Number of time periods that it took to service all read cache hit operations, for a particular component over a particular time interval. The exact time interval length is device-dependent.
Write Cache Hit Service Periods	100	BSP: volume, controller, storage system	Number of time periods that it took to service all write cache hit operations, for a particular component over a particular time interval. The exact time interval length is device-dependent.
Idle Periods	102	BSP: volume, storage system	The number of time periods during which the component was idle. The exact time interval length is device-dependent.
Maintenance Service Periods	103	BSP: volume, controller, storage system	Number of time periods it took to service all disk maintenance operations, for a particular component over a particular time interval. The exact time interval length is device-dependent.
Read Hit Time Percentage for Small Transfers	136	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on read operations that resulted in cache hits. Applies to data transfers ≤ 8 KB.
Read Hit Time Percentage for Medium Transfers	137	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on read operations that resulted in cache hits. Applies to data transfers > 8 KB and ≤ 64 KB.
Read Hit Time Percentage for Large Transfers	138	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on read operations that resulted in cache hits. Applies to data transfers > 64 KB and ≤ 512 KB.
Read Hit Time Percentage for Huge Transfers	139	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on read operations that resulted in cache hits. Applies to data transfers > 512 KB.
Read Miss Time Percentage for Small Transfers	140	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on read operations that resulted in cache misses. Applies to data transfers ≤ 8 KB.
Read Miss Time Percentage for Medium Transfers	141	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on read operations that resulted in cache misses. Applies to data transfers > 8 KB and ≤ 64 KB.
Read Miss Time Percentage for Large Transfers	142	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on read operations that resulted in cache misses. Applies to data transfers > 64 KB and ≤ 512 KB.
Read Miss Time Percentage for Huge Transfers	143	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on read operations that resulted in cache misses. Applies to data transfers > 512 KB.
Write Hit Time Percentage for Small Transfers	144	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on write operations that resulted in cache hits. Applies to data transfers ≤ 8 KB.
Write Hit Time Percentage for Medium Transfers	145	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on write operations that resulted in cache hits. Applies to data transfers > 8 KB and ≤ 64 KB.
Write Hit Time Percentage for Large Transfers	146	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on write operations that resulted in cache hits. Applies to data transfers > 64 KB and ≤ 512 KB.
Write Hit Time Percentage for Huge Transfers	147	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on write operations that resulted in cache hits. Applies to data transfers > 512 KB.
Write Miss Time Percentage for Small Transfers	148	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on write operations that resulted in cache misses. Applies to data transfers ≤ 8 KB.

Counter	Counter type	Resource or component type	Description
Write Miss Time Percentage for Medium Transfers	149	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on write operations that resulted in cache misses. Applies to data transfers > 8 KB and ≤ 64 KB.
Write Miss Time Percentage for Large Transfers	150	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on write operations that resulted in cache misses. Applies to data transfers > 64 KB and ≤ 512 KB.
Write Miss Time Percentage for Huge Transfers	151	XIV: volume, module, storage system	Percentage of service time, over a specified interval, that was spent on write operations that resulted in cache misses. Applies to data transfers > 512 KB.
Read SSD Response Time for Small Transfer Sizes	161	XIV: volume, pool, module, host connection, storage system	Average number of milliseconds that was required to service each hit operation of SSD read memory over a specified time interval. Applies to transfer operations ≤ 8 KB.
Read SSD Response Time for Medium Transfer Sizes	162	XIV: volume, pool, module, host connection, storage system	Average number of milliseconds that was required to service each hit operation of SSD read memory over a specified time interval. Applies to transfer operations > 8 KB and ≤ 64 KB.
Read SSD Response Time for Large Transfer Sizes	163	XIV: volume, pool, module, host connection, storage system	Average number of milliseconds that was required to service each hit operation of SSD read memory over a specified time interval. Applies to transfer operations > 64 KB and ≤ 512 KB.
Read SSD Response Time for Huge Transfer Sizes	164	XIV: volume, pool, module, host connection, storage system	Average number of milliseconds that was required to service each hit operation of SSD read memory over a specified time interval. Applies to transfer operations > 512 KB.
Compressed Volumes Service Time	184	IBM Spectrum Virtualize: node, I/O group, storage system	The total number of milliseconds that it took to service all read and write operations for compressed volumes.
Cache Prestage Service Time - Volume Cache	618	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of milliseconds that it took to service all prestage I/Os measured at the volume copy cache.
Cache Stage Service Time - Volume Cache	620	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of milliseconds that it took to complete all stage operations in the volume cache. That is, the time that it took to do read operations from the disk to the volume cache.
Cache Stage Service Time - Volume Copy Cache	619	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of milliseconds that it took to complete all stage operations in the volume copy cache. That is, the time that it took to do read operations from the disk to the volume copy cache.
Cache Destage Service Time - Volume Cache	622	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of milliseconds that it took to complete all destage operations in the volume cache. That is, the time that it took to do write operations from the volume cache to the disk.
Cache Destage Service Time - Volume Copy Cache	621	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of milliseconds that it took to complete all destage operations in the volume copy cache. That is, the time that it took to do write operations from the volume copy cache to the disk.
Cache Data Transfer Service Time	179	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of milliseconds that is taken to transfer a track from the cache to the host, including any queuing time that occurs because of throttling. This is similar to the Host Attributed Service Time but includes any queuing delay incurred at the host layer.
Exclusive Track Lock Latency - Volume Cache	638	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The average number of microseconds that it took to acquire an exclusive track lock at the volume cache.
Exclusive Track Lock Latency - Volume Copy Cache	637	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The average number of microseconds that it took to acquire an exclusive track lock at the volume copy cache.

Counter	Counter type	Resource or component type	Description
Shared Track Lock Latency - Volume Cache	640	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The average number of microseconds that it took to acquire a shared track lock at the volume cache.
Shared Track Lock Latency - Volume Copy Cache	639	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The average number of microseconds that it took to acquire a shared track lock at the volume copy cache.
Cache Queue Time IOCB - Volume Cache	642	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume cache spent queuing for I/O control blocks.
Cache Queue Time IOCB - Volume Copy Cache	641	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume copy cache spent queuing for I/O control blocks.
Cache Queue Time CTCB - Volume Cache	644	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume cache spent queuing for cache track control blocks.
Cache Queue Time CTCB - Volume Copy Cache	643	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume copy cache spent queuing for cache track control blocks.
Cache Queue Time PNRC - Volume Cache	646	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume cache spent queuing for remote credits on a preferred node.
Cache Queue Time PNRC - Volume Copy Cache	645	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume copy cache spent queuing for remote credits on a preferred node.
Cache Queue Time NNRC - Volume Cache	648	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume cache spent queuing for remote credits on a non-preferred node.
Cache Queue Time NNRC - Volume Copy Cache	647	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume copy cache spent queuing for remote credits on a non-preferred node.
Cache Queue Time ARC - Volume Cache	650	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume cache spent queuing for remote credits for administrative tasks.
Cache Queue Time ARC - Volume Copy Cache	649	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume copy cache spent queuing for remote credits for administrative tasks.
Cache Queue Time CDCB - Volume Cache	652	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume cache spent queuing for control blocks in the cache directory.
Cache Queue Time CDCB - Volume Copy Cache	651	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume copy cache spent queuing for control blocks in the cache directory.
Cache Queue Time CBR - Volume Cache	654	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume cache spent queuing for buffer resources.
Cache Queue Time CBR - Volume Copy Cache	653	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume copy cache spent queuing for buffer resources.
Cache Queue Time CHR - Volume Cache	656	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume cache spent queuing for hardening rights.
Cache Queue Time CHR - Volume Copy Cache	655	IBM Spectrum Virtualize ¹ : node	The average number of microseconds that the volume copy cache spent queuing for hardening rights.
Note:			
1. This counter is only available for resources that are running IBM Spectrum Virtualize 7.3 or later.			

Table 5. Volume cache counters

Counter	Counter type	Resource or component type	Description
---------	--------------	----------------------------	-------------

Counter	Counter type	Resource or component type	Description
Disk to Cache Transfer Count (normal)	031	DS8000: volume, array, controller, storage system	Number of tracks transferred from disk to cache, for nonsequential I/O requests, for a particular component over a particular time interval.
Disk to Cache Transfer Count (sequential)	032	DS8000: volume, array, controller, storage system	Number of tracks transferred from disk to cache, for sequential I/O requests, for a particular component over a particular time interval.
Cache to Disk Transfer Count	033	DS8000: volume, array, controller, storage system	Number of tracks transferred from cache to disk, for both sequential and nonsequential I/O requests, for a particular component over a particular time interval.
Prestage Track Count	078	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of prestage reads (tracks of read-ahead data) initiated for a particular component over a particular time interval.
Destage Track Count	079	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of destage writes (tracks of dirty write data) initiated for a particular component over a particular time interval.
Prestage Tracks Cache Hits	080	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Number of read track cache hits that were serviced from prestaged tracks for a particular component over a particular time interval. Included as part of the "Read Track Cache Hits".
Destage Tracks Cache Hits	081	IBM Spectrum Virtualize: volume, node, I/O group, storage system	The number of write track cache hits for a particular component over a particular time interval. That is, the track writes that modified only data that was already marked "dirty" in the cache.
Prestage Sector Count	082	IBM Spectrum Virtualize: node	Number of prestage sectors (sectors of read-ahead data) initiated for a particular component over a particular time interval.
Destage Sector Count	083	IBM Spectrum Virtualize: node	Number of destage writes (sectors of dirty write data) initiated for a particular component over a particular time interval.
Prestage Tracks Cache Hits Sector Count	084	IBM Spectrum Virtualize: node	Number of sectors read for cache hits that were serviced from prestaged tracks for a particular component over a particular time interval. Included as part of the "Read Track Cache Hits Sector Count".
Destage Tracks Cache Hits Sector Count	085	IBM Spectrum Virtualize: node	The number of sectors written for cache hits for a particular component over a particular time interval. That is, the writes that modified only data that was already marked "dirty" in the cache.
Read Sector Count - Volume Cache	62	IBM Spectrum Virtualize: volume, pool, node, I/O group, host connection, storage system	The number of cache sectors or tracks read by the volume cache. For resources that are running a version of IBM Spectrum Virtualize that is earlier than 7.3, the unit of the counter is tracks.
Read Sector Count - Volume Copy Cache	601	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache sectors read by the volume copy cache.
Write Sector Count - Volume Cache	63	IBM Spectrum Virtualize: volume, pool, node, I/O group, host connection, storage system	The number of cache sectors or tracks written by the volume cache. For resources that are running a version of IBM Spectrum Virtualize that is earlier than 7.3, the unit of the counter is tracks.
Write Sector Count - Volume Copy Cache	602	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache sectors written by the volume copy cache.
Fast Write Mode Count - Volume Cache	65	IBM Spectrum Virtualize: volume, pool, node, I/O group, host connection, storage system	The number of cache sectors or tracks written in fast-write mode in the volume cache. For resources that are running a version of IBM Spectrum Virtualize that is earlier than 7.3, the unit of the counter is tracks.
Fast Write Mode Count - Volume Copy Cache	603	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache sectors written in fast-write mode in the volume copy cache.
Flush-through Mode Count - Volume Cache	67	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache sectors or tracks written in flush-through write mode in the volume cache. For resources that are running a version of IBM Spectrum Virtualize that is earlier than 7.3, the unit of the counter is tracks.
Flush-through Mode Count - Volume Copy Cache	604	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache sectors written in flush-through write mode in the volume copy cache.
Write-through Mode Count - Volume Cache	66	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache sectors or tracks written in write-through write mode in the volume cache. For resources that are running a version of IBM Spectrum Virtualize that is earlier than 7.3, the unit of the counter is tracks.
Write-through Mode Count - Volume Copy Cache	605	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache sectors written in write-through write mode in the volume copy cache.
Cache Overflow Mode Track Count	068	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache track that were processed in Cache-Overflow write mode.
Prestage Count	78	IBM Spectrum Virtualize: volume, pool, node, I/O group, host connection, storage system	The number of cache sectors or tracks prestaged into the volume copy cache. For resources that are running a version of IBM Spectrum Virtualize that is earlier than 7.3, the unit of the counter is tracks.
Destage Count - Volume Cache	79	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache sectors or tracks destaged from the volume cache. For resources that are running a version of IBM Spectrum Virtualize that is earlier than 7.3, the unit of the counter is tracks.
Destage Count - Volume Copy Cache	606	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of cache sectors destaged from the volume copy cache.
Cache Data Transfer Count	178	IBM Spectrum Virtualize ¹ : volume, pool, node, I/O group, host connection, storage system	The number of tracks transferred from the volume cache to the host I/O layer. In combination with the Cache Data Transfer Service Time counter determines the Data Transfer Response Time.

Counter	Counter type	Resource or component type	Description
Note:			
1. This counter is only available for resource that are running IBM Spectrum Virtualize 7.3 or later.			

Table 6. Volume miscellaneous counters

Counter	Counter type	Resource or component type	Description
NVS Allocation Count	034	DS8000: volume	Number of NVS space allocations for a particular component over a particular time interval.
DFW I/O Count (normal)	035	DS8000: volume, array, controller, storage system	Number of nonsequential "DASD Fast Write" requests for a particular component over a particular time interval. This value typically applies only for count-key data (CKD).
DFW I/O Count (sequential)	036	DS8000: volume, array, controller, storage system	Number of sequential "DASD Fast Write" requests for a particular component over a particular time interval. This value typically applies only for CKD.
DFW Delayed I/O Count	037	DS8000: volume, array, controller, storage system	Number of I/O requests that were delayed due to nonvolatile storage (NVS) space constraints, for a particular component over a particular time interval.
Cache Delayed I/O Count	038	DS8000: volume	Number of I/O requests that were delayed due to cache space constraints, for a particular component over a particular time interval.
Record Mode Read I/O Count	039	DS8000: volume, array, controller, storage system	Number of record-mode read I/O operations for a particular component over a particular time interval.
Record Mode Read Cache Hits	040	DS8000: volume, array, controller, storage system	Number of cache hits for record-mode read I/O operations for a particular component over a particular time interval.
Quick Write Promote Count	041	DS8000: volume, array, controller, storage system	Number of quick write promote operations for a particular component over a particular time interval. This value typically applies only for CKD.
CFW Read I/O Count	042	DS8000: volume	Number of "Cache Fast Write" read I/O requests for a particular component over a particular time interval. This value typically applies only for CKD.
CFW Write I/O Count	043	DS8000: volume	Number of "Cache Fast Write" write I/O requests for a particular component over a particular time interval. This value typically applies only for CKD.
CFW Read Hits	044	DS8000: volume	Number of cache hits for "Cache Fast Write" read I/O requests for a particular component over a particular time interval. This value typically applies only for CKD.
CFW Write Hits	045	DS8000: volume	Number of cache hits for "Cache Fast Write" write I/O requests for a particular component over a particular time interval. This value typically applies only for CKD.
XRC Read Count	046	DS8000: volume	Number of track reads from the Concurrent Copy or XRC Sidefile for a particular component over a particular time interval. This value typically applies only for CKD.
XRC Contaminating Write Count	047	DS8000: volume	Number of contaminating writes for Concurrent Copy or XRC operations for a particular component over a particular time interval. This value typically applies only for CKD.
PPRC Transfer Count	048	DS8000: volume, array, controller, storage system	Number of tracks or portions of tracks that were transferred to the secondary device of a Peer-to-Peer Remote Copy (PPRC) pair, for a particular component over a particular time interval. This counter shows the activity for the source of the PPRC relationship, but shows no activity for the target.
ITA I/O Count	049	DS8000: volume	Number of irregular track access I/O requests, for a particular component over a particular time interval. This value typically applies only for CKD.
ITA Hits	050	DS8000: volume	Number of cache hits for irregular track access I/O requests, for a particular component over a particular time interval. This value typically applies only for CKD.
Rank Read I/O Count	051	DS8000: volume	Number of read I/O operations issued to the physical arrays associated with a particular component over a particular time interval.
Rank Write I/O Count	052	DS8000: volume	Number of write I/O operations issued to the physical arrays associated with a particular component over a particular time interval.
Rank Read Data Chunk Count	053	DS8000: volume	Number of 128 KB chunks (128*2 ¹⁰ bytes) of data transferred for read I/O operations issued to the physical arrays associated with a particular component over a particular time interval.
Rank Write Data Chunk Count	054	DS8000: volume	Number of 128 KB chunks (128*2 ¹⁰ bytes) of data transferred for write I/O operations issued to the physical arrays associated with a particular component over a particular time interval.
Rank Read Service Periods	055	DS8000: volume	Number of 16 millisecond time periods that it took to service all read operations issued to the physical arrays associated with a particular component over a particular time interval.
Rank Write Service Periods	056	DS8000: volume	Number of 16 millisecond time periods that it took to service all write operations issued to the physical arrays associated with a particular component over a particular time interval.
ICL Read I/O Count	057	DS8000: volume	Number of Inhibit Cache Loading I/O requests, for a particular component over a particular time interval. This value typically applies only for CKD.
BC Write I/O Count	058	DS8000: volume	Number of Bypass Cache I/O requests, for a particular component over a particular time interval. This value typically applies only for CKD.
Rank Transfer Time	059	DS8000: volume	Number of milliseconds of lower-interface I/O activity, for a particular component over a particular time interval. This value typically applies only for CKD.
Read Cache KB Count	086	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Amount of read cache, in KB, that was in use for a particular component, at the start of the particular time interval.

Counter	Counter type	Resource or component type	Description
Write Cache KB Count	087	IBM Spectrum Virtualize: volume, node, I/O group, storage system	Amount of write cache, in KB, that was in use for a particular component, at the start of the particular time interval.

Table 7. Volume special computed values

Counter	Counter type	Resource or component type	Description
Cache Holding Time	060	DS8000: controller, storage system	Average cache holding time, in seconds, for I/O data in this subsystem controller (cluster). Shorter time periods indicate adverse performance.
Utilization Percentage	061	DS8000: volume, array, controller, storage system IBM Spectrum Virtualize: volume, node, I/O group, storage system XIV: volume	Approximate utilization percentage for a particular component over a particular time interval. The value is multiplied by 100 to gain 2 extra digits of precision; for example, 3860 would indicate that the component is running at approximately 38.6% of capacity. The value might exceed 100% to indicate stress beyond the capacity of the component.
Compression CPU Utilization	175	IBM Spectrum Virtualize: node, I/O group, storage system	The approximate percentage of time that the processors used for data compression I/O tasks are busy.
System CPU Core Utilization	176 (Core 1 to 8) 185 (Core 9 to 16) 186 (Core 17 to 24) 187 (Core 25 to 32)	IBM Spectrum Virtualize: node, I/O group, storage system	The approximate percentage of time that each set of eight processor cores was busy with system I/O tasks. The value is encoded such that each byte contains the percentage of one of the cores; the low-order byte is for core 1.
Compression CPU Core Utilization	177 (Core 1 to 8) 188 (Core 9 to 16) 189 (Core 17 to 24) 190 (Core 25 to 32)	IBM Spectrum Virtualize: node, I/O group, storage system	The approximate percentage of time that each set of eight processor cores was busy with data compression tasks. The value is encoded such that each byte contains the percentage of one of the cores; the low-order byte is for core 1.

Disk counters

Performance counters for back-end storage systems are divided into the following categories:

- [Back-end storage system I/O counters](#)
- [Back-end storage system data counters](#)
- [Back-end storage system service time counters](#)
- [Other back-end counters for storage systems](#)

Table 8. Back-end storage system I/O counters

Counter	Counter type	Resource or component type	Description
Backend Read I/O Count	201	DS8000: rank, array, controller, storage system IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system	Number of I/O operations for read requests, for a particular component over a particular time interval.
Backend Write I/O Count	202	DS8000: rank, array, controller, storage system IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system	Number of I/O operations for write requests, for a particular component over a particular time interval.

Table 9. Back-end storage systems data counters

Counter	Counter type	Resource or component type	Description
Backend Read KB Count	204	IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system IBM FlashSystem® 900: flash module, storage system	Number of KB (2 ¹⁰ bytes) of data that were transferred for read operations, for a particular component over a particular time interval.
Backend Write KB Count	205	IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system IBM FlashSystem 900: flash module, storage system	Number of KB (2 ¹⁰ bytes) of data that were transferred for write operations, for a particular component over a particular time interval.
Backend Read Data Count	207	DS8000: rank, array, controller, storage system	Number of 128 KB chunks (128*2 ¹⁰ bytes) of data that were transferred for read operations, for a particular component over a particular time interval.
Backend Write Data Count	208	DS8000: rank, array, controller, storage system	Number of 128 KB chunks (128*2 ¹⁰ bytes) of data that were transferred for write operations, for a particular component over a particular time interval.

Table 10. Back-end service time counters

Counter	Counter type	Resource or component type	Description
---------	--------------	----------------------------	-------------

Counter	Counter type	Resource or component type	Description
Backend Read Service Time	210	IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system	Number of milliseconds that it took to service all read operations, for a particular component over a particular time interval. For IBM Spectrum Virtualize, this value is the <i>external</i> response time of the managed disk.
Backend Write Service Time	211	IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system	Number of milliseconds that it took to service all write operations, for a particular component over a particular time interval. For IBM Spectrum Virtualize, this value is the <i>external</i> response time of the managed disk.
Backend Read Service Periods	213	DS8000: rank, array, controller, storage system	Number of 16 millisecond time periods that it took to service all read operations, for a particular component over a particular time interval.
Backend Write Service Periods	214	DS8000: rank, array, controller, storage system	Number of 16 millisecond time periods that it took to service all write operations, for a particular component over a particular time interval.
Backend Read Queued Service Time	216	IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system	Number of milliseconds that it took to service all read operations, for a particular component over a particular time interval. Includes the time that pending I/O operations spent on the queue waiting to be issued to the backend disk device.
Backend Write Queued Service Time	217	IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system	Number of milliseconds that it took to service all write operations, for a particular component over a particular time interval. Includes the time that pending I/O operations spent on the queue waiting to be issued to the backend disk device.
Peak Backend Read Response Time	219	IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system	The peak (worst) response time for disk reads for a particular component over a particular time interval, in microseconds. For IBM Spectrum Virtualize, this value is the peak <i>external</i> response time of the managed disks.
Peak Backend Write Response Time	220	IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system	The peak (worst) response time for disk writes for a particular component over a particular time interval, in microseconds. For IBM Spectrum Virtualize, this is the peak <i>external</i> response time of the managed disks.
Peak Backend Read Queued Response Time	222	IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system	The peak (worst) response time for disk reads for a particular component over a particular time interval, in microseconds. Includes the time that pending I/O operations spent on the queue waiting to be issued to the backend disk device.
Peak Backend Write Queued Response Time	223	IBM Spectrum Virtualize: managed disk, pool, node, I/O group, storage system	The peak (worst) response time for disk reads for a particular component over a particular time interval, in microseconds. Includes the time that pending I/O operations spent on the queue waiting to be issued to the backend disk device.

Table 11. Other back-end counters for storage systems

Counter	Counter type	Resource or component type	Description
Flash Health Percentage	238	Flash module, storage system	The overall flash module health. The health percentage is calculated based on the number of unusable blocks on the flash module.

Storage system and switch port counters

Performance counters for ports and fabrics are divided into the following categories:

- [Storage system and switch port I/O or frame counters](#)
- [Storage system and switch port data counters](#)
- [Storage system port service time counters](#)
- [Storage system and switch port utilization percentages](#)
- [Storage system and switch port error counts](#)

Table 12. Storage system and switch port I/O or frame counters

Counter	Counter type	Resource or component type	Description
Port Send I/O Count	401	DS8000: port, storage system IBM FlashSystem 900: port XIV: port	Number of read I/O operations processed (or write I/O operations initiated) by a particular component over a particular time interval. For ports, available only for hourly/daily data.
Port Receive I/O Count	402	DS8000: port, storage system IBM FlashSystem 900: port XIV: port	Number of write I/O operations processed (or read operations initiated) by a particular component over a particular time interval. For ports, available only for hourly/daily data.
Total Port I/O Count	403	SMI-S BSP: port	Total number of read and write I/O operations processed by a particular component over a particular time interval.
Port Send Frame Count	404	Switch port Outer-switch connection ¹ Switch	Number of frames sent by a particular component over a particular time interval.
Port Receive Frame Count	405	Switch port Inter-switch connection ¹ Switch	Number of frames received by a particular component over a particular time interval.

Counter	Counter type	Resource or component type	Description
Total Port Frame Count	406	Switch port Inter-switch connection ¹ Switch	Number of frames sent and received by a particular component over a particular time interval.
Port FB Send I/O Count	407	DS8000: port	Number of read I/O operations processed (or write operations initiated) for FB requests, for a particular port over a particular time interval.
Port FB Receive I/O Count	408	DS8000: port	Number of write I/O operations processed (or read operations initiated) for FB requests, for a particular port over a particular time interval.
Port CKD Send I/O Count	410	DS8000: port	Number of read I/O operations processed (or write operations initiated) for CKD requests, for a particular port over a particular time interval.
Port CKD Receive I/O Count	411	DS8000: port	Number of write I/O operations processed (or read operations initiated) for CKD requests, for a particular port over a particular time interval.
Port PPRC Send I/O Count	413	DS8000: port, storage system	Number of write operations initiated by the PPRC primary, for a particular port over a particular time interval.
Port PPRC Receive I/O Count	414	DS8000: port, storage system	Number of write operations processed by the PPRC secondary, for a particular port over a particular time interval.
Port to Host Send I/O Count	442	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of exchanges (I/Os) initiated to host computers from a particular port over a particular time interval.
Port to Host Receive I/O Count	443	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of exchanges (I/Os) received from host computers by a particular port over a particular time interval.
Port to Disk Send I/O Count	445	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of exchanges (I/Os) initiated to storage systems from a particular port over a particular time interval.
Port to Disk Receive I/O Count	446	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of exchanges (I/Os) received from storage systems by a particular port over a particular time interval.
Port to Local Send I/O Count	448	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of exchanges (I/Os) initiated to other IBM Spectrum Virtualize nodes on the local IBM Spectrum Virtualize cluster from a particular port over a particular time interval.
Port to Local Receive I/O Count	449	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of exchanges (I/Os) received from other IBM Spectrum Virtualize nodes on the local cluster by a particular port over a particular time interval.
Port to Remote Send I/O Count	451	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of exchanges (I/Os) initiated to a remote IBM Spectrum Virtualize cluster from a particular port over a particular time interval.
Port to Remote Receive I/O Count	452	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of exchanges (I/Os) received from a remote cluster by a particular port over a particular time interval.
Port to Local Send Message Count	478	IBM Spectrum Virtualize: node, I/O group, storage system	Number of messages sent to nodes on the local IBM Spectrum Virtualize cluster, by the ports associated with a particular component, over a particular time interval. This count might be larger or smaller than the Port to Local Send I/O Count, because multiple small messages might be batched into a single I/O, or a single large message split between multiple I/Os.
Port to Local Receive Message Count	479	IBM Spectrum Virtualize: node, I/O group, storage system	Number of messages received from nodes on the local IBM Spectrum Virtualize cluster, by the ports associated with a particular component, over a particular time interval. This count might be larger or smaller than the Port to Local Receive I/O Count, because multiple small messages might be batched into a single I/O, or a single large message split between multiple I/Os.
Port to Remote Send Message Count	481	IBM Spectrum Virtualize: node, I/O group, storage system	Number of messages sent to nodes on the remote IBM Spectrum Virtualize cluster, by the ports associated with a particular component, over a particular time interval. This count might be larger or smaller than the Port to Remote Send I/O Count, because multiple small messages might be batched into a single I/O, or a single large message split between multiple I/Os.
Port to Remote Receive Message Count	482	IBM Spectrum Virtualize: node, I/O group, storage system	Number of messages received from nodes on the remote IBM Spectrum Virtualize cluster, by the ports associated with a particular component, over a particular time interval. This count might be larger or smaller than the Port to Remote Receive I/O Count, because multiple small messages might be batched into a single I/O, or a single large message split between multiple I/Os.
<p>Note:</p> <p>1. Performance data for inter-switch connections contains performance data for the following resources:</p> <ul style="list-style-type: none"> Switch ports on ISLs and NPV links. Switch trunks for ISL trunks, ICL trunks, F_port channels, and port channels. <p>The performance data for both resources is displayed together in the IBM Spectrum® Control GUI. However, to obtain this data from the CLI, you must run separate queries.</p>			

Table 13. Storage system and switch port data counters

Counter	Counter type	Resource or component type	Description
Port Send KB Count	416	DS8000: storage system IBM FlashSystem 900: port Switch port Inter-switch connection ¹ Switch XIV: port	Number of KB (2^{10} bytes) of data that were sent from a particular component over a particular time interval. This value is read KB if the port is the target of a read operation, or write KB if the port is the initiator of a write operation (for example, a PPRC primary).
Port Receive KB Count	417	DS8000: storage system IBM FlashSystem 900: port Switch port Inter-switch connection ¹ Switch XIV: port	Number of KB (2^{10} bytes) of data that were received by a particular component over a particular time interval. This value is write KB if the port is the target of a write operation, or read KB if the port is the initiator of a read operation.
Total Port KB Count	418	Switch port Inter-switch connection ¹ Switch SMI-S BSP: port	Total number of KB (2^{10} bytes) of data that were transferred, by a particular port over a particular time interval.
Port Peak Send Data Rate ²	419	Switch port Inter-switch connection ¹ Switch	Peak number of megabytes (2^{20} bytes) per second that were sent by a particular port over a time interval.
Port Peak Receive Data Rate	420	Switch port Inter-switch connection ¹ Switch	Peak number of megabytes (2^{20} bytes) per second that were received by a particular port over a time interval.
Port FB Send Data Count	421	DS8000: port	Number of 128 KB chunks (128×2^{10} bytes) of data that were sent for FB requests, from a particular component over a particular time interval. This value is read KB if the port is the target of a read operation, or write KB if the port is the initiator of a write operation (for example, a PPRC primary).
Port FB Receive Data Count	422	DS8000: port	Number of 128 KB chunks (128×2^{10} bytes) of data that were received for FB requests, by a particular component over a particular time interval. This value is write KB if the port is the target of a write operation, or read KB if the port is the initiator of a read operation.
Port CKD Send Data Count	424	DS8000: port	Number of 128 KB chunks (128×2^{10} bytes) of data that were sent for CKD requests, from a particular component over a particular time interval. This value is read KB if the port is the target of a read operation, or write KB if the port is the initiator of a write operation (for example, a PPRC primary).
Port CKD Receive Data Count	425	DS8000: port	Number of 128 KB chunks (128×2^{10} bytes) of data that were received for CKD requests, by a particular component over a particular time interval. This value is write KB if the port is the target of a write operation, or read KB if the port is the initiator of a read operation.
Port PPRC Send Data Count	427	DS8000: port, storage system	Number of 128 KB chunks (128×2^{10} bytes) of data that were sent by a particular port over a particular time interval, as result of write operations initiated by a PPRC primary.
Port PPRC Receive Data Count	428	DS8000: port, storage system	Number of 128 KB chunks (128×2^{10} bytes) of data that were received by a particular port over a particular time interval, as result of write operations processed by a PPRC secondary.
Port to Host Send KB Count	454	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of KB of data sent to host computers from a particular port over a particular time interval.
Port to Host Receive KB Count	455	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of KB of data received from host computers by a particular port over a particular time interval.
Port to Disk Send KB Count	457	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of KB of data sent to storage systems from a particular port over a particular time interval.
Port to Disk Receive KB Count	458	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of KB of data received from storage systems by a particular port over a particular time interval.

Counter	Counter type	Resource or component type	Description
Port to Local Send KB Count	460	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of KB of data sent to other IBM Spectrum Virtualize nodes on the local IBM Spectrum Virtualize cluster from a particular port over a particular time interval.
Port to Local Receive KB Count	461	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of KB of data received from other IBM Spectrum Virtualize nodes on the local cluster by a particular port over a particular time interval.
Port to Remote Send KB Count	463	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of KB of data sent to a remote IBM Spectrum Virtualize cluster from a particular port over a particular time interval.
Port to Remote Receive KB Count	464	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of KB of data received from a remote IBM Spectrum Virtualize cluster by a particular port over a particular time interval.
<p>Note:</p> <ol style="list-style-type: none"> Performance data for inter-switch connections contains performance data for the following resources: <ul style="list-style-type: none"> Switch ports on ISLs and NPV links. Switch trunks for ISL trunks, ICL trunks, F_port channels, and port channels. <p>The performance data for both resources is displayed together in the IBM Spectrum Control GUI. However, to obtain this data from the CLI, you must run separate queries.</p> This counter is available only for ports on Brocade switches. 			

Table 14. Storage system port service time counters

Counter	Counter type	Resource or component type	Description
Port Send Service Time	430	DS8000: storage system IBM FlashSystem 900: port XIV: port	Number of milliseconds it took to service all send operations, for a particular component over a particular time interval. This value is read times, if the port is the target of a read operation, or write times if the port is the initiator of a write operation (for example, a PPRC primary).
Port Receive Service Time	431	DS8000: storage system IBM FlashSystem 900: port XIV: port	Number of milliseconds it took to service all receive operations, for a particular port over a particular time interval. This value is write times, if the port is the target of a write operation, or read times if the port is the initiator of a read operation.
Port FB Send Service Periods	433	DS8000: port	Number of 16 millisecond periods it took to service all send operations for FB requests, for a particular component over a particular time interval. This value is read times, if the port is the target of a read operation, or write times if the port is the initiator of a write operation (for example, a PPRC primary).
Port FB Receive Service Periods	434	DS8000: port	Number of 16 millisecond periods it took to service all receive operations for FB requests, for a particular component over a particular time interval. This value is write times, if the port is the target of a write operation, or read times if the port is the initiator of a read operation.
Port CKD Send Service Periods	436	DS8000: port	Number of 16 millisecond periods it took to service all send operations for CKD requests, for a particular component over a particular time interval. This value is read times, if the port is the target of a read operation, or write times if the port is the initiator of a write operation (for example, a PPRC primary).
Port CKD Receive Service Periods	437	DS8000: port	Number of 16 millisecond periods it took to service all receive operations for CKD requests, for a particular component over a particular time interval. This value is write times, if the port is the target of a write operation, or read times if the port is the initiator of a read operation.
Port PPRC Send Service Periods	439	DS8000: port, storage system	Number of 16 millisecond periods it took to service write requests by a PPRC primary, for a particular port over a particular time interval.
Port PPRC Receive Service Periods	440	DS8000: port, storage system	Number of 16 millisecond periods it took to service write requests by a PPRC secondary, for a particular port over a particular time interval.
Port to Local Send Service Time	466	IBM Spectrum Virtualize: node, I/O group, storage system	Number of milliseconds it took to service all send operations to other nodes on the local IBM Spectrum Virtualize cluster, for a particular component over a particular time interval. For IBM Spectrum Virtualize, this value is the <i>external</i> service time of the transfers.
Port to Local Receive Service Time	467	IBM Spectrum Virtualize: node, I/O group, storage system	Number of milliseconds it took to service all receive operations from other nodes on the local IBM Spectrum Virtualize cluster, for a particular component over a particular time interval. For IBM Spectrum Virtualize, this value is the <i>external</i> service time of the transfers.
Port to Local Send Queued Service Time	469	IBM Spectrum Virtualize: node, I/O group, storage system	Number of milliseconds it took to service all send operations to other nodes on the local IBM Spectrum Virtualize cluster, including the time that pending operations spent on the queue, for a particular component over a particular time interval. For IBM Spectrum Virtualize, this value is the <i>queued</i> service time of the transfers.
Port to Local Receive Queued Service Time	470	IBM Spectrum Virtualize: node, I/O group, storage system	Number of milliseconds it took to service all receive operations from other nodes on the local IBM Spectrum Virtualize cluster, including the time that pending operations spent on the queue, for a particular component over a particular time interval. For IBM Spectrum Virtualize, this value is the <i>queued</i> service time of the transfers.

Counter	Counter type	Resource or component type	Description
Port to Remote Send Service Time	472	IBM Spectrum Virtualize: node, I/O group, storage system	Number of milliseconds it took to service all send operations to nodes on the remote IBM Spectrum Virtualize cluster, for a particular component over a particular time interval. For IBM Spectrum Virtualize, this value is the <i>external</i> service time of the transfers.
Port to Remote Receive Service Time	473	IBM Spectrum Virtualize: node, I/O group, storage system	Number of milliseconds it took to service all receive operations from nodes on the remote IBM Spectrum Virtualize cluster, for a particular component over a particular time interval. For IBM Spectrum Virtualize, this value is the <i>queued</i> service time of the transfers.
Port to Remote Send Queued Service Time	475	IBM Spectrum Virtualize: node, I/O group, storage system	Number of milliseconds it took to service all send operations to nodes on the remote IBM Spectrum Virtualize cluster, including the time that pending operations spent on the queue, for a particular component over a particular time interval. For IBM Spectrum Virtualize, this value is the <i>queued</i> service time of the transfers.
Port to Remote Receive Queued Service Time	476	IBM Spectrum Virtualize: node, I/O group, storage system	Number of milliseconds it took to service all receive operations from nodes on the remote IBM Spectrum Virtualize cluster, including the time that pending operations spent on the queue, for a particular component over a particular time interval. For IBM Spectrum Virtualize, this value is the <i>queued</i> service time of the transfers.

Table 15. Storage system and switch port utilization percentages

Counter	Counter type	Resource or component type	Description
Port Send Utilization Percentage	484	DS8000: port	Approximate percentage of time that the associated port was busy with sending data. The value is multiplied by 100 to give 2 extra digits of precision, for example, 3860 would indicate that the port is busy 38.6% of the time. The port is busy sending data when servicing read I/Os from hosts, and when initiating write I/Os from a PPRC primary.
Port Receive Utilization Percentage	485	DS8000: port	Approximate percentage of time that the associated port was busy with receiving data. The value is multiplied by 100 to give 2 extra digits of precision, for example, 3860 would indicate that the port is busy 38.6% of the time. The port is busy receiving data when servicing non-PPRC write I/Os from hosts, and when servicing write I/Os at a PPRC secondary.
Port Send Bandwidth Percentage	487	DS8000: port IBM FlashSystem 900: port IBM Spectrum Virtualize: port Switch port Inter-switch connection ¹	Approximate percentage of bandwidth utilization for send operations by this port, based on the current negotiated speed of the port. The value is multiplied by 100 to give 2 extra digits of precision, for example, 3860 would indicate that 38.6% of the port bandwidth was being used. The port is busy sending data when servicing read I/Os from hosts, and when initiating write I/Os from a PPRC primary.
Port Receive Bandwidth Percentage	488	DS8000: port IBM FlashSystem 900: port IBM Spectrum Virtualize: port Switch port Inter-switch connection ¹	Approximate percentage of bandwidth utilization for receive operations by this port, based on the current negotiated speed of the port. The value is multiplied by 100 to give 2 extra digits of precision, for example, 3860 would indicate that 38.6% of the port bandwidth was being used. The port is busy receiving data when servicing non-PPRC write I/Os from hosts, and when servicing write I/Os at a PPRC secondary.
Port Link Quality Percentage	490	Switch port Inter-switch connection ¹	The estimated link quality of the switch port. The percentage is based on whether the port is an expansion port (E_port) or a fabric port (F_port), and on the error statistics for the port.

Note:

1. Performance data for inter-switch connections contains performance data for the following resources:

- Switch ports on ISLs and NPV links.
- Switch trunks for ISL trunks, ICL trunks, F_port channels, and port channels.

The performance data for both resources is displayed together in the IBM Spectrum Control GUI. However, to obtain this data from the CLI, you must run separate queries.

Table 16. Storage system and switch port error counts

Counter	Counter type	Resource or component type	Description
Operational Status	501	Switch port Inter-switch connection ¹	The operational status of a port over a time interval.
LIP Count	502	Switch port Inter-switch connection ¹ Switch	Number of LIP events that occurred on the associated arbitrated loops, for a particular component over a particular time interval.

Counter	Counter type	Resource or component type	Description
NOS Count	503	Switch port Inter-switch connection ¹ Switch	Number of NOS events that occurred on the associated switched fabrics, for a particular component over a particular time interval.
Error Frame Count ²	504	DS8000: port, storage system	Number of frames received in error by a particular component over a particular time interval.
Discarded Frame Count	505	Switch port Inter-switch connection ¹ Switch	Number of frames that were lost due to a lack of available host buffers, for a particular component over a particular time interval.
Link Failure Count	506	DS8000: port, storage system IBM Spectrum Virtualize: port, node, I/O group, storage system	The number of link errors that were experienced by a particular component over a particular time interval.
Loss of Sync Count	507	DS8000: port, storage system IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of times that synchronization was lost after the last reset of the device, for a particular component over a particular time interval. Synchronization is assumed lost after a timeout interval identified by the Receiver-Transmitter-Timeout property. This count is part of the Link Error Status Block (LESB).
Loss of Signal Count	508	DS8000: port, storage system IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of times that the signal was lost after the last reset of the device, for a particular component over a particular time interval. This count is part of the Link Error Status Block (LESB).
CRC Error Count	509	DS8000: port, storage system IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of frames received in which the CRC in a frame does not match the CRC computed by the receiver. This count is part of the Link Error Status Block (LESB).
Primitive Sequence Protocol Error Count	510	DS8000: port, storage system IBM Spectrum Virtualize: port, node, I/O group, storage system	Count of primitive sequence protocol errors detected at this port. This count is part of the Link Error Status Block (LESB).
Invalid Transmission Word Count	511	DS8000: port, storage system IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of transmission words that had an 8b10b code violation in one or more of its characters; had a K28.5 in its second, third, or fourth character positions; or was an ordered set that had an incorrect Beginning Running Disparity. This count is part of the Link Error Status Block (LESB).
Short Frame Count ³	512	Switch port Inter-switch connection ¹ Switch	Number of frames received that were shorter than 28 octets. The value of 28 is calculated based on an assumption of 24 header bytes plus 4 CRC bytes. The count does not include SOF/EOF bytes which are not data.
Long Frame Count	513	Switch port Inter-switch connection ¹ Switch	Number of frames received that were longer than 2140 octets. The value of 2140 is calculated based on an assumption of 24 header bytes plus 4 CRC bytes plus 2112 bytes of payload.
Address Error Count	514	Switch port Inter-switch connection ¹ Switch	Count of frames received with unknown addressing. An example is an unknown SID.
Buffer Credit Not Provided Count	515	Switch port Inter-switch connection ¹ Switch	Count of occurrences when all input buffers of a port were full and outbound buffer-to-buffer credit transitioned to zero. There is no credit to provide to other side.
Buffer Credit Not Received Count	516	Switch port Inter-switch connection ¹ Switch	Count of transitions in/out of Bbcredit zero state. The other side is not providing any credit.

Counter	Counter type	Resource or component type	Description
Delimiter Error Count	517	Switch port Inter-switch connection ¹ Switch	Count of invalid frame delimiters received at this port. An example is a frame with a class 2 start and a class 3 at the end.
Encoding Disparity Error Count	518	Switch port Inter-switch connection ¹ Switch	Count of disparity errors received at this port.
Link Reset Transmitted Count	519	DS8000: port, storage system	Count of link resets. This value is the number of LRs transmitted.
Link Reset Received Count	520	DS8000: port, storage system	Count of link resets. This value is the number LRs received.
Discarded Class 3 Frame Count ²	521	Switch port Inter-switch connection ¹ Switch	Class3FramesDiscarded is the count of class 3 frames that were discarded upon reception.
Invalid Ordered Set Count	522	Switch port Inter-switch connection ¹ Switch	The total number of invalid ordered sets received.
F-BSY Frame Count ³	523	Switch port Inter-switch connection ¹ Switch	Number of F_BSY frames generated.
P-BSY Frame Count	524	Switch port Inter-switch connection ¹ Switch	Number of P_BSY frames generated.
F-RJT Frame Count ³	525	Switch port Inter-switch connection ¹ Switch	Number of F_BSY frames generated.
P-RJT Frame Count	526	Switch port Inter-switch connection ¹ Switch	Number of P_BSY frames generated.
Buffer Credit Zero Error Count	527	Switch port Inter-switch connection ¹ Switch	Number of times that frame transmission was blocked by a transmit credit of zero.
Zero Buffer Credit Timer	528	IBM Spectrum Virtualize: port, node, I/O group, storage system	Number of microseconds for which the port has been unable to send frames due to lack of buffer credit since the last node reset.
Out of Order Data Count	529	DS8000: port, storage system	Number of times that an out of order frame is detected.
Out of Order ACK Count	530	DS8000: port, storage system	Number of times that an out of order ACK frame is detected.
Duplicate Frame Count	531	DS8000: port, storage system	Number of times a frame was received that has been detected as previously processed.
Invalid Relative Offset Count	532	DS8000: port, storage system	Number of times that a frame was received with bad relative offset in the frame header.
Sequence Timeout Count	533	DS8000: port, storage system	Number of times the port has detected a timeout condition on receiving sequence initiative for a fibre channel exchange.
Class 3 Send Timeout Frame Count ²	534	Brocade switch port Brocade Inter-switch connection ¹ Brocade switch	Average count of class 3 frames per second that were discarded before transmission because of a timeout condition. The timeout condition occurs while the switch or port waits for buffer credit from the receiving port at the other end of the fibre. When you troubleshoot a SAN, use this count to view port conditions that might slow the performance of the resources to which those ports are connected.

Counter	Counter type	Resource or component type	Description
Class 3 Receive Timeout Frame Count ²	535	Brocade switch port Brocade Inter-switch connection ¹ Brocade switch	Average count of class 3 frames per second that were discarded after reception because of a timeout condition. The timeout condition occurs while the transmitting port waits for buffer credit from a port at the other end of the fibre. When you troubleshoot a SAN, use this count to view port conditions that might slow the performance of the resources to which those ports are connected.
RDY Priority Override Count ² ³	536	Brocade switch port Brocade Inter-switch connection ¹ Brocade switch	Average count of times per second during which the sending of R_RDY or VC_RDY signals was a higher priority than the sending of frames. This condition occurs because of diminishing credit reserves in the transmitter at the other end of the fibre. When you troubleshoot a SAN, use this count to view port conditions that might slow the performance of the resources to which those ports are connected.
Port State Change Rate	537	Brocade switch port Brocade Inter-switch connection ¹ Brocade switch	Average count of times per second that the state of a port changes to offline, online, or faulty. When you troubleshoot a SAN, use this count to view port conditions that might slow the performance of the resources to which those ports are connected.
Bad EOF CRC Error Count ²	538	Fabrics	The number of cyclic redundancy check (CRC) errors that were detected in frames with a bad end-of-frame (EOF) indicator. In Brocade fabrics, a bad EOF in a frame can indicate that the frame has a known, previously detected CRC error. A good EOF in a frame with a CRC error indicates that the CRC error was not previously detected.
Port Abort Count	539	DS8000: port	The number of times that the port on DS8000 received an abort error.
Extreme I/O Concurrency Count	540	DS8000: port	The number of times that the port on DS8000 had more than 1500 concurrent I/O operations or exchanges. The number of concurrent I/O operations for a port on DS8000 cannot exceed 2000.
I/O Busy Count	541	DS8000: port	The number of times that the port on DS8000 returned a SCSI Queue Full or a Busy status to the server. Ports can return these statuses if the number of concurrent I/O operations or exchanges exceeds an internal DS8000 threshold.
I/O Overrun Count	542	DS8000: port	The number of times that the port on DS8000 had to discard commands because the number of concurrent I/O operations or exchanges for the port exceeded 2000.
Zero Send Buffer Credit Time ²	543	DS8000: port	The number of one-second intervals during which the port on DS8000 had depleted its send buffer credits. That is, the approximate amount of time that the receiving port had no credit to provide to the port on DS8000.
Zero Receive Buffer Credit Time ²	544	DS8000: port	The number of one-second intervals during which the port on DS8000 had depleted its receive buffer credits. That is, the approximate amount of time that the port on DS8000 had no credit to provide to the sending port.
Port Transmit Delay Time	547	IBM Spectrum Virtualize: port	The duration of the delay on the port during send operations, in microseconds. The reason for the delay might be a lack of buffer credits.
Port Transmit Delay Count	548	IBM Spectrum Virtualize: port	The number of send operations by the port that were delayed. The reason for these delays might be a lack of buffer credits.
Port Transmit Delay Measured Count	549	IBM Spectrum Virtualize: port	The number of send operations by the port that were measured to allow the detection of any potential transmission delay due to lack of buffer credits.
<p>Note:</p> <ol style="list-style-type: none"> Performance data for inter-switch connections contains performance data for the following resources: <ul style="list-style-type: none"> Switch ports on ISLs and NPV links. Switch trunks for ISL trunks, ICL trunks, F_port channels, and port channels. The performance data for both resources is displayed together in the IBM Spectrum Control GUI. However, to obtain this data from the CLI, you must run separate queries. This counter is only available for ports on Brocade switches. You must use an SNMP agent to collect data for this counter. 			

Command-line interface

The following sections describe the IBM Spectrum® Control command-line interface (CLI).

The following topics are included.

- CLI requirements
- Command modes
- Syntax diagram conventions that are used in this guide
- Tptool commands
- Command aliases
- Parameter aliases

- [CLI requirements](#)

Verify the requirements for running the command-line interpreter and for using the command-line interface.

- [Command modes](#)
You can use the CLI to run one command or a series of commands, either interactively or from a script.
- [Conventions used in this guide](#)
Information is given about the conventions that are used in this publication.
- [tpctool command](#)
The **tpctool** command is the IBM Spectrum Control CLI program. The IBM Spectrum Control **tpctool** command can be used either on its own, using the associated options and arguments, or interactively by starting the **tpctool** command with no options or arguments to start an interactive session.
- [Command aliases](#)
This topic discusses command aliasing.
- [Parameter aliases](#)
This topic lists common parameters and their aliases.

CLI requirements

Verify the requirements for running the command-line interpreter and for using the command-line interface.

- Verify that the installer checks for and installs the correct version of Java™, and configures the CLI to use the installed Java.
- Verify that IBM Spectrum® Control is installed and running, and that storage devices are discovered.
- Verify that the CLI is connected to a IBM Spectrum Control Device server before you use all commands. The **encrypt** command is the only exception that does not require the connection.
- Verify that you have a valid user ID, password, and URL before you use all commands, except for the **encrypt** command.

Command modes

You can use the CLI to run one command or a series of commands, either interactively or from a script.

Single-shot mode

To run a single command, specify the CLI program and that command at the shell prompt, for example:

```
shell> tpctool lsdev -user me -pwd mypass -url myhost:myport -l -sys
```

Interactive mode

To run in interactive mode, enter the **tpctool** command with no command-line options. In the following example, the string "shell>" represents the shell prompt and "tpctool>" represents the prompt from the CLI while in interactive mode. At the CLI prompt, any valid CLI command can be entered.

```
shell> tpctool
tpctool> lsdev -user me -pwd mypass -url myhost:myport -l -sys
```

Script mode

To run a set of commands that you defined in a file, start the CLI program and specify a file that contains the commands, for example:

```
shell> tpctool -script ~/bin/containersetup
shell>
```

Conventions used in this guide

Information is given about the conventions that are used in this publication.

This publication uses several conventions for special terms and actions, and for operating system-dependent commands and paths. The following typeface conventions are used in this publication:

Bold

- Flags that display with text
- Graphical user interface (GUI) elements (except for titles of windows and dialogs)
- Names of keys

Italic

- Variables
- Values that you must provide
- New terms
- Words and phrases that are emphasized
- Titles of documents

monospace

- Commands and command options
- Flags that display on a separate line
- Code examples and output
- Message text
- Names of files and directories
- Text strings that you must type, when they display within text
- Names of Oracle Java™ methods and classes
- HTML and XML tags that display **like this**, in monospace type

For syntax notations, remember the following details.

- In AIX®, the prompt for the root user is #.
- In AIX and Linux®, the commands are case-sensitive, so you must type commands exactly as they are shown.
- **Syntax diagram conventions**
A syntax diagram uses symbols to represent the elements of a command and to specify the rules for using these elements.

Syntax diagram conventions

A syntax diagram uses symbols to represent the elements of a command and to specify the rules for using these elements.

Syntax diagrams use position to indicate required, optional, and default values for keywords, variables, and operands.

A keyword represents the name of a command, flag, parameter, or argument. Required keywords indicate the parameters or arguments that must be specified for the command.

To read syntax diagrams, follow the path of the line. Read the diagrams from left-to-right, top-to-bottom, following the main path line.

Main path line

The main path line begins on the left with double arrowheads (>>) and ends on the right with two arrowheads facing each other (<>). If a diagram is longer than one line, each line to be continued ends with a single arrowhead (>) and the next line begins with a single arrowhead. The -->< symbol indicates the end of the syntax diagram.

Required keywords

Required keywords appear on the main path line. Mutually exclusive required keywords are stacked vertically. In the following example, you must choose A, B, and C.

➤ A — B — C ➤

Optional keywords

Optional keywords indicate parameters or arguments that you might choose to specify for the command. Optional keywords appear below the main path line. Mutually exclusive optional keywords are stacked vertically. In the following example, you must choose A, B, or C.

When an optional item appears above the main line, the item above the line is the default value when no optional item is specified in the command. In the following example, the user has the same choices as above (A, B, C, or nothing at all), but if nothing is selected, the default value will be A.

Repeatable items

A stack of items followed by an arrow returning to the left means that you can select more than one item or, in some cases, repeat a single item. For example:

An arrow returning to the left means you can repeat the item.

If one or more characters appear in the arrow's line, those characters are required as a delimiter to separate repeated items.

If you can choose from two or more items, they are displayed vertically in a stack. A stack of items followed by an arrow returning to the left means that you can select more than one item or, in some cases, repeat a single item. In the following example, you can choose any combination of A, B, or C.

Variables

Italicized, lowercase elements denote variables. In the following example, you must specify a variable value when you enter the keyword command:

➤ keyword — *variable* ➤

tpctool command

The **tpctool** command is the IBM Spectrum Control CLI program. The IBM Spectrum Control **tpctool** command can be used either on its own, using the associated options and arguments, or interactively by starting the **tpctool** command with no options or arguments to start an interactive session.

Syntax

➡ **tpctool** — *command* — *connection-options* — *formatting-options* — *command-options* — *command-arguments* →

Parameters

command

Either one of the commands (generic, disk, fabric, or reporting) or a command alias.

connection-options

Options that are used to connect to IBM Spectrum® Control. These options are included.

- -user
- -pwd
- -url

These options are described with details in the **tpctool** arguments and options list.

formatting-options

Options that are used to format output for some of the commands.

command-options

Options that are associated with commands that define command behavior.

command-arguments

Generally, values used to define command options. They can be defined as lists of string values that are separated by commas or spaces.

The following arguments and options are valid for **tpctool**:

-user *user_name*

Specifies an IBM Spectrum Control user ID.

-pwd *password*

Specifies the password for the IBM Spectrum Control user ID.

-url *url*

Specifies the Device server. The format of the URL is *system:port_number*, where *system* represents either the host name or IP address, and *port_number* represents the IBM Spectrum Control Device server port.

-help | -h | -?

Lists help information for the command.

-ver

Displays the version of the installed IBM Spectrum Control.

Command aliasing

The IBM Spectrum Control CLI provides the capability for command aliasing by using the command configuration file. The default configuration file is `c:\program files\ibm\tpc\cli\libs\tpccli.conf`. With aliasing, you define a name for the alias followed by a value that is the name of a command and any options that are associated with command. The aliased command string is replaced by the defined value and the entire line is parsed again. Passwords that are used in aliased commands must first be encrypted by using the **encrypt** command.

For example, to shorten a frequently used command that you can define the following alias:

```
tpctool>lsperf = lsdev -user dsadmin -pwd dsadmpw1 -url 9.44.33.126:8990 -fabric -perf
```

After the alias is defined, you can run the **lsperf** command to run the aliased **lsdev** command.

You can provide a short form command that targets different Device servers, as follows:

```
tpctool>lsperf1 = lsdev -user dsadmin -pwd dsadmpw1 -url hostOne:9161 -perf
```

```
tpctool>lsperf2 = lsdev -user dsadmin -pwd dsadmpw1 -url hostTwo:9161 -perf
```

You can specify more options and arguments for an aliased command.

```
tpctool>lsperf2 -fabric -ctype port
```

Which expands to:

```
tpctool>lsdev -user dsadmin -pwd dsadmpw1 -url hostTwo:9161 -perf -fabric -ctype port
```

You can also nest aliases:

```
tpctool>lsperf = lsdev -user dsadmin -pwd dsadmpw1 -url hostTwo:9161 -perf -fabric
```

```
tpctool>lsperf1 = lsdev -user dsadmin -pwd dsadmpw1 -url hostOne:9161
```

```
tpctool>lsperf2 = lsdev -user dsadmin -pwd dsadmpw1 -url hostTwo:9161
```

To unset an alias, type the name of the command alias followed by the equals (=) sign.

```
lsperf =
```

When you use an alias with a key and value pair in the `tpccli.conf` file, you must specify four back slashes for each back slash.

For example, this value:

```
ABCDE1 = CLARiON\+ABC01234567890+0
```

Is specified as:

Examples

To start an interactive session for the IBM Spectrum Control CLI:

The following command starts an interactive session. After the session starts, you can use other CLI commands in the session:

```
tpctool
```

To start an interactive session with credentials:

The following command starts an interactive session and specifies the user ID, password, and destination:

```
tpctool -user adminpass
-pwd adminpw1
-url 9.43.124.255:8080
```

Setting up credentials for automatic log in

You can set up and save your credentials in a different CLI program configuration file other than the default file without entering the interactive mode to eliminate the requirement of specifying the credentials again for every **tpctool** command session.

Creating a new configuration file

You can set a new location and file name and create a new configuration file that contains your credentials for logging in to the **tpctool** command.

This is the default configuration file location for the Windows operating system:

```
C:\program files\ibm\tpc\cli\libs\tpccli.conf
```

For the Linux® operating system:

```
/opt/IBM/TPC/cli/libs/tpccli.conf
```

Perform these steps to create a new configuration file:

1. In a command prompt window, enter the following command, for a Windows operating system:

```
SET TPCCFG=C:\installation_dir\cli\config file
```

Where the `cli.properties` file is the default configuration file that already exists and `TPCCFG` is the new name of the configuration file.

For a Linux operating system:

```
export TPCCFG=../installation_dir/cli/config file
```

Where the `cli.properties` file is the default configuration file that already exists and `TPCCFG` is the new name of the configuration file.

2. Edit your new configuration file to include a destination, your user ID and password.

For example, a Windows operating system:

```
C:\installation_dir\cli>tpctool
tpctool> url=localhost:9550
tpctool> user=db2admin
tpctool> password=xxxxxxxxx
```

Where:

```
url=localhost:9550
```

The name or IP address of your local or remote server.

```
user=db2admin
```

The DB2® instance name that is used when installing IBM Spectrum Control.

```
password=xxxxxxxxx
```

The password that you use to log in to IBM Spectrum Control.

For example, a Linux operating system:

```
</installation_dir/cli/tpctool.sh
tpctool> url=localhost:9550
tpctool> user=db2inst1
tpctool> password=xxxxxxxxx
```

3. Exit the **tpctool** session:

```
tpctool> quit
```

When you exit the command line interface on a Linux operating system, and, then want to access the command again, you need to run the **export** command again.

For example:

```
export TPCCFG=../installation_dir/cli/config file
```

You can interactively create a new configuration file. Once you locate the IBM Spectrum Control installation directory, double-click the **tpctool.bat** file or enter **tpctool.bat|sh file** on a command prompt window to start the **tpctool** session in the interactive mode. Enter your credentials to alleviate the need to specify the credentials again, when you start each **tpctool** command.

For example, on a Windows system, the **tpctool.bat** file is located here:

```
c:\program files\ibm\tpc\cli directory file
```

On Linux operating systems, you must add the directory path as `/opt/IBM?TPC/c11` to the `tpctool.sh` file. The command input can be either lowercase, uppercase, or mixed case, unless specific command parameters require case sensitivity.

Return codes

The following table contains the codes that are returned by the **tpctool** command.

Table 1. Return codes for the **tpctool** command

Code	Description
0	The command completed successfully.
1	The command was unknown to tpctool and was not resolved as an alias.
2	A required option was not provided.
3	An option was unknown to tpctool or was not applicable to the command.
4	An option was missing a required parameter.
5	The format of a parameter for the option was not valid.
6	The format of an argument was not valid.
7	An extraneous argument or argument list was provided.
8	The tpctool client could not connect with the Device server.
9	The tpctool client could not log in to tIBM Spectrum Control using the specified credentials.
10	The specified credentials are not authorized to perform the requested action.
11	A required component is not installed and enabled.
12	The command might have started, but the connection with IBM Spectrum Control was lost. The command might not be completed successfully.
13	Some operations were partially completed before IBM Spectrum Control returned a failure.
14	The command failed.
15	An attempt was made to remove a group that has a child group associated with it. Remove the child group and try the operation again.

- [actzs](#)
Use the **actzs** command to activate changes to the zone set in the fabric. This command must be run within a transaction. You must have Administrator authority to use this command.
- [addza](#)
Use the **addza** command to add a zone alias to a zone. You must have Administrator authority to use this command.
- [addzaptops](#)
Use the **addzaptops** command to add ports to a zone alias. You must have Administrator authority to use this command.
- [addzone](#)
Use the **addzone** command to add a zone to a zone set. This command must be run as a transaction. For more information, see the **start** command. You must have Administrator authority to use this command.
- [addzoneports](#)
Use the **addzoneports** command to add switch ports to a zone. This command must be run as a transaction. You must have Administrator authority to use this command.
- [assignvol](#)
Use the **assignvol** command to assign host ports to volumes. You must have Administrator authority to use this command.
- [autosetarray](#)
Use the **autosetarray** command to extract and save information about storage pools.
- [catdscfg](#)
Use the **catdscfg** command to list the contents of the property files for the Device server and to check the status of the Device server. You must have Administrator authority to use this command.
- [chexport](#)
Use the **chexport** command to change the protocol configuration for an export.
- [chfs](#)
Use the **chfs** command to change the properties of a file system, and to add or remove disks to or from a file system.
- [chfset](#)
Use the **chfset** command to change the attributes of a fileset.
- [chkquota](#)
Use the **chkquota** command to check quota limits for users, user groups, and filesets on a file system and to write the information to the GPFS database.
- [chwcach](#)
Use the **chwcach** command to modify the attributes of a cache fileset on a wide area network (WAN) cluster.
- [chwcachesource](#)
Use the **chwcachesource** command to change the properties of a home system on a fileset. The home system is the source of the data in a wide area network (WAN) cache configuration. You can use WAN caching to distribute data transparently among data centers and multiple remote locations without disruption to applications. You must have Administrator authority to use this command.
- [ckzone](#)
Use the **ckzone** command to verify that a fabric contains a zone.
- [ckzs](#)
Use the **ckzs** command to verify that a fabric contains a zone set.
- [commit](#)
Use the **commit** command to commit a transaction. When you commit a transaction, all the commands issued after you started the transaction are enacted. You must have Administrator authority to use this command.
- [ctlwcache](#)
Use the **ctlwcache** command to run maintenance operations on a cache fileset on a wide area network (WAN) cluster. Data on a source cluster is cached to this fileset. You can resynchronize cache data to the source fileset, flush the cache to the source fileset, remove cached data, and expire or unexpire the data in a fileset. Use the **lswcache** command to view the attributes of the cache fileset. You must have Administrator authority to use this command.
- [deactzs](#)
Use the **deactzs** command to deactivate the active zone set. This command must be run as a transaction. You must have Administrator authority to use this command.
- [encrypt](#)
Use the **encrypt** command to generate an encrypted password for use in the configuration file. This command takes text from standard input and generates 7-bit ASCII-equivalent characters (uuencode).

- [**getdscfg**](#)
Use the **getdscfg** command to list the current value of a property from the property file for the Device server. You must have Administrator authority to use this command.
- [**getrpt**](#)
Use the **getrpt** command to list a performance report for a specified storage subsystem.
- [**linkset**](#)
Use the **linkset** command to create a junction to connect a name in a directory of a parent file set to the root directory of a child fileset. You must have Administrator authority to use this command.
- [**lsappgroup**](#)
Use the **lsappgroup** command to display a list of applications that are known to IBM Spectrum Control.
- [**lsappgroupmembers**](#)
Use the **lsappgroupmembers** command to list members of a specified application.
- [**lsarray**](#)
Use the **lsarray** command to display information about arrays and back-end storage systems. For SAN Volume Controller, XIV® systems, and Dell EMC VMAX and VNX storage systems, the command displays information about block pools.
- [**lsbackenddisktypes**](#)
Use the **lsbackenddisktypes** command to list the types of back-end disks and their average input/output.
- [**lsbackendraidtypes**](#)
Use the **lsbackendraidtypes** command to list the types of back-end RAID arrays that are available for managed disk groups.
- [**lsbackendtypes**](#)
Use the **lsbackendtypes** command to list the types of back-end storage systems.
- [**lscluster**](#)
Use the **lscluster** command to list all clusters or specified clusters that are on a Storwize® V7000 Unified storage system.
- [**lscomp**](#)
Use the **lscomp** command to list the components for which performance data is collected.
- [**lscounters**](#)
Use the **lscounters** command to list available performance counters.
- [**lsdeptgroup**](#)
Use the **lsdeptgroup** command to display a list of departments that are known to IBM Spectrum Control.
- [**lsdeptgroupmembers**](#)
Use the **lsdeptgroupmembers** command to list members of a specified department.
- [**lsdev**](#)
Use the **lsdev** command to list information about storage systems, fabrics, and switches. This information includes the globally unique identifier (GUID) or worldwide name (WWN) for the fabric, the user-defined name, the resource type, the status, and the time that the status was updated.
- [**lsdevp**](#)
Use the **lsdevp** command to list worldwide port names (WWPNs) for a subsystem.
- [**lsdisk**](#)
Use the **lsdisk** command to list all the physical disks on a specified storage subsystem.
- [**lsexport**](#)
Use the **lsexport** command to list all exports or specified exports that are associated with a cluster that is on a Storwize V7000 Unified storage system. You can also list exports by file system, Netapp, or server that is managed by a Storage Resource Agent (SRA).
- [**lsextent**](#)
Use the **lsextent** command to display a list of all the storage extents on a specified storage system. An example of a storage extent is a managed disk on a SAN Volume Controller. For Dell EMC VMAX storage systems, the command displays the Disk Group.
- [**lsfcpath**](#)
Use the **lsfcpath** command to list the paths for data transmission between a system with a fibre-channel host bus adapter (HBA) and a storage subsystem.
- [**lsfs**](#)
Use the **lsfs** command to list all file systems or specified file systems that are associated with a cluster on a Storwize V7000 Unified or IBM Spectrum Scale storage system. You can also list file systems by pool or Network Shared Disk (NSD).
- [**lsfset**](#)
Use the **lsfset** command to list all filesets or specified filesets that are associated with a file system on a Storwize V7000 Unified or IBM Spectrum Scale storage system.
- [**lshtype**](#)
Use the **lshtype** command to list host types. You must have Administrator authority to use this command.
- [**lsoptschedules**](#)
Use the **lsoptschedules** command to show a list of the schedules that you created to analyze storage tiering.
- [**lsmetrics**](#)
Use the **lsmetrics** command to list available performance metrics. You must have Fabric operator or Disk operator authority to use this command.
- [**lsnode**](#)
Use the **lsnode** command to list all nodes or specified nodes that are associated with a cluster that is on a Storwize V7000 Unified storage system.
- [**lsnsd**](#)
Use the **lsnsd** command to list all Network Shared Disks (NSDs) or specified NSDs that are on a Storwize V7000 Unified storage system. You can also list NSDs by file system, pool, or both.
- [**lspool**](#)
Use the **lspool** command to list all file system pools that are on a specified Storwize V7000 Unified storage system. You can also list the pools by file system.
- [**lsport**](#)
Use the **lsport** command to list the ports that are on a Fibre Channel host bus adapter (HBA).
- [**lsquota**](#)
Use the **lsquota** command to list all quotas or specified quotas that are on a Storwize V7000 Unified storage system. You can also list quotas by file system.
- [**lssrg**](#)
Use the **lssrg** command to display a list of storage resource groups that are known to IBM Spectrum Control.
- [**lssrgmembers**](#)
Use the **lssrgmembers** command to list members of a specified storage resource group.
- [**lssvr**](#)
Use the **lssvr** command to list all systems that are discovered by Fabric Manager. You must have Fabric Administrator authority to use this command.
- [**lssvrdisk**](#)
Use the **lssvrdisk** command to list all of the physical disks that are known to a specified server.
- [**lsswitch**](#)
Use the **lsswitch** command to display a list of all switches in a specified fabric.

- [**lstime**](#)
Use the **lstime** command to list the time ranges for which performance data is available.
- [**lstype**](#)
Use the **lstype** command to list the components that are recognized by IBM Spectrum Control. No authorization is required to run this command.
- [**lsvm**](#)
Use the **lsvm** command to list all virtual machines that are known to IBM Spectrum Control. You can also list only the virtual machines that were discovered through hypervisors.
- [**lsvmdisk**](#)
Use the **lsvmdisk** command to list all the VMWare virtual machine disks that are known to the given virtual machine or hypervisor.
- [**lsvol**](#)
Use the **lsvol** command to list all volumes on a system, list a specific volume or volumes, or list volumes on a specific array.
- [**lsvolgroup**](#)
Use the **lsvolgroup** command to display a list of volume groups that are known to IBM Spectrum Control.
- [**lszone**](#)
Use the **lszone** command to list the zones in a zone set.
- [**lszs**](#)
Use the **lszs** command to list information about zone sets. This information includes the zone set name and status.
- [**mkappgroup**](#)
Use the **mkappgroup** command to create an application with a specific name, type, description, and user-defined properties. You must have Administrator authority to use this command.
- [**mkdeptgroup**](#)
Use the **mkdeptgroup** command to create a department with a specific name, description, type, subtype, and user-defined properties. You must have Administrator authority to use this command.
- [**mkexport**](#)
Use the **mkexport** command to create an export to access data through a data transfer protocol.
- [**mkfs**](#)
Use the **mkfs** command to create a GPFS file system to manage files on a storage device.
- [**mkfset**](#)
Use the **mkfset** command to create a fileset that is associated with a file system on a Storwize V7000 File Module storage system. With filesets, you can use functions such as snapshots or quotas within a file system. You must have Administrator authority to use this command.
- [**mksrg**](#)
Use the **mksrg** command to create a storage resource group with a specific name, type, description, and user-defined properties. You must have Administrator authority to use this command.
- [**mkzone**](#)
Use the **mkzone** command to create a zone. This command must be run within a transaction. You must have Administrator authority to use this command.
- [**mkzs**](#)
Use the **mkzs** command to create a zone set. This command must be run as a transaction. You must have Administrator authority to use this command.
- [**modifyappgroup**](#)
Use the **modifyappgroup** command to modify an existing application. You can add and remove members of the application by specifying the member type and the key for the individual member. You can also use a -tagkey and -tagvalue member pair.
- [**modifyappgroupviafile**](#)
Use the **modifyappgroupviafile** command to modify an existing application by using an input file. You can add and remove members by specifying the member type and identifiers or by using a member type with a -tagkey and -tagvalue pair.
- [**modifydeptgroup**](#)
Use the **modifydeptgroup** command to modify an existing department. You can add and remove members of a department by specifying the member type. For example, a deptgroup type for a department or an appgroup type for an application and the -memberid parameter for the individual member. You can also use a -tagkey and -tagvalue member pair.
- [**modifydeptgroupviafile**](#)
Use the **modifydeptgroupviafile** command to modify an existing department by using an input file. You can add and remove members by specifying the member type (deptgroup, appgroup) and identifiers or by using a member type with a -tagkey and -tagvalue pair.
- [**modifysrg**](#)
Use the **modifysrg** command to modify an existing storage resource group. You can add and remove members by specifying the member type, such as switch or volume, and the key for the member you want to add or remove.
- [**mountfs**](#)
Use the **mountfs** command to mount a file system on all interface and management nodes or a specified subset. You must have Data Administrator authority to use this command.
- [**rmappgroup**](#)
Use the **rmappgroup** command to delete a specific application and its members. If you use the **rmappgroup** command without the -rmchildren parameter, the application is deleted, and the members are moved up a level in the hierarchy.
- [**rmbackenddisktype**](#)
Use the **rmbackenddisktype** command to remove a back-end type of disk.
- [**rmbackendraidtype**](#)
Use the **rmbackendraidtype** command to remove a back-end RAID array type from the set of RAID array types available for managed disk groups.
- [**rmbackendtype**](#)
Use the **rmbackendtype** command to remove a type of back-end storage system.
