Part 1. Token ring

The topics here teach you how to provide token-ring support for TCP/IP and SNA.

Existing installations:

Users who have existing token-ring line descriptions can change them to take advantage of the 100 megabit per second (Mbps) card. If you use the line description with TCP/IP, you must also assign it to a TCP/IP interface.

Token-ring support information:

To configure and manage token-ring support on your server, read this information:

- Print this topic.
- Understand token-ring support to successfully configure your system.
- Plan how to configure your connection after understanding how your system supports token ring.
- Configure token-ring support after planning your connection configuration.
- Manage token-ring support after you have configured it.
- Tune your system to increase performance after the configuration of token-ring support.
- Troubleshoot to locate problems and solutions.

Code disclaimer information

This document contains programming examples.

IBM grants you a nonexclusive copyright license to use all programming code examples from which you can generate similar function tailored to your own specific needs.

All sample code is provided by IBM for illustrative purposes only. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs.

All programs contained herein are provided to you "AS IS" without any warranties of any kind. The implied warranties of non-infringement, merchantability and fitness for a particular purpose are expressly disclaimed.

Chapter 1. Print this topic

To view or download the PDF version, select Token ring (about 564 KB or 48 pages).

To save a PDF on your workstation for viewing or printing:

1. Open the PDF in your browser (click the link above).
2. In the menu of your browser, click **File**.
3. Click **Save As...**
4. Navigate to the directory in which you would like to save the PDF.
5. Click **Save**.

If you need Adobe Acrobat Reader to view or print these PDFs, you can download a copy from the Adobe

Web site (www.adobe.com/prodindex/acrobat/readstep.html) 

Chapter 2. Token-ring support

To properly provide token-ring support, you must understand the information that follows. Then you plan how to configure the system. To understand token-ring support, read this information:

- What token-ring functions are supported by your system?
- What determines a successful connection?
- What connects SNA to token ring?
- What determines your maximum frame size?

Supported token-ring functions

Your server supports a range of token-ring technologies that support speeds of 4 Mbps, 16 Mbps, and 100 Mbps. These technologies support the IEEE 802.5 standard. The 100 Mbps token-ring input/output adapter (IOA) supports the High-Speed Token-Ring IEEE 802.5 standard that specifies 100 Mbps operation.

The 100 Mbps token ring IOA:

Your system can use the PCI 100/16/4 MB Token-Ring Adapter to support faster networking. The IOA supports many protocols including TCP/IP and SNA. It is compatible with earlier devices, but does not support token-pipes or multilink. The adapter is also known as the 2744 IOA. The IOA introduces these new functions:

- **Automatic ring-speed sensing** (automatic sense) enables your system and the switch to find the highest common ring speed to use between them. The destination does not need to match this speed, because the switch manages the differences in speed.
- **Duplex mode negotiation** enables your system and the switch to agree on the duplex mode to use (half or full duplex). The available duplexing modes are dependent on the ring speed that you use. At 4 Mbps or 16 Mbps you can use either half-duplex or full-duplex mode. At 100 Mbps you must use full-duplex mode (the speed for each channel (transmitting or receiving) is 100 Mbps).

Early token release:

Only 16 Mbps rings that use half-duplex mode can use the early token release function. This function reduces the time the next device on the same ring waits for a free token. Early token release enables the transmitting device to release the free token right after sending a frame. Thus, the next device receives the free token sooner and can thereby transmit a frame. This function is beneficial only in rings where the time to transmit a frame is shorter than the travel time of the frame. That is, the time for the frame to travel completely around the ring.

Connection establishment between LAN devices

If you use SNA with a LAN protocol, read this information to successfully connect to a device. The correct relationship between a line description and a controller description helps to ensure connection establishment. A controller description determines which line descriptions your system uses. Therefore, you must ensure that the controller description refers to the correct line description.

Also, a line description governs the number of active controllers that can access it. By making the number too small, you may prevent the controller description from accessing the line description. Therefore, you should ensure a large enough value to allow the controller description access to the line description.

Besides the correct relationship between the line and controller descriptions, the descriptions must also contain the correct information to ensure connection establishment. This information discusses some of the connection information that you are responsible for:

- Decide how a device should identify itself.
- Decide whether a device will initiate the connection request or not.

How LAN devices identify themselves

During the connection process, your system sends information to the remote device, which the device uses to ensure connection to the correct system. The remote device also sends information to your system, which your system also uses to ensure the connection to the correct device. Your system compares the exchanged information against the information that is contained in the line and controller descriptions. If a match occurs and other connection values are correct, the connection process continues. Likewise, the remote device performs a similar process.

Your system and the remote device use two verifications during the connection process to ensure connection to the correct device. One verification (required), matches the line description information and controller description information with the connection information that the remote device sent. If a match occurs, your system continues with the connection process.

This list shows the information that the remote device sends:

- The address associated with the input/output adapter (IOA) on the remote device. This address is either the preset address or the locally administered address.
- The source service access point (SSAP) on the remote device.
- The destination service access point (DSAP).

The other verification matches the exchange identifier values. For advanced program-to-program communications (APPC), this verification is optional. SNA hosts that use parallel connections require this verification.

SNA Exchange identifiers (XIDs)

To establish a connection, your system and the remote device exchange information that includes the exchange identifiers (XIDs). SNA hosts that use parallel connections require the XIDs. You define the XIDs in the controller description. Typically, during the connection process your system conducts an initial poll with NULL XIDs to determine whether the remote device is active or not. If the remote device does not respond to the poll within the specified time period, your system can send another XID to the device. If the remote device responds to the poll, your system and the remote device exchange XIDs and establish the link.

The controller description for SNA hosts names the XID value as the local exchange identifier. The APPC controller description names the XID value as the exchange identifier.

Which LAN device initiates the connection

In an SNA environment you can determine who initiates the connection request and who waits for an incoming connection request. To have your system initiate the connection, configure the controller description to dial the destination. If no connection is established, your controller description switches to answer mode (where it waits for a device to dial into your system).

To have your system wait for incoming calls, configure the controller description to answer the incoming calls. You use dial mode to make connection requests and answer mode to have the system wait for incoming connection requests. You specify one of these modes through the Initial connection (INLCNN) field of the controller description.

Dial mode (SNA)

You use dial mode (that is used by SNA controller descriptions) to send a connection request to a remote device. Dial mode starts when varying on the controller description. During the dialing process, the system polls the remote device to determine if the device is ready to transmit. If the remote device is ready, the connection process continues. Successful connection is still possible even if the local and remote devices dial each other simultaneously.

These controller description fields control the frequency and duration of the polling:

- LAN connection retry (LANCNRRTY) determines the number of times your system polls the remote device.
- LAN connection timer (LANCNTMR) determines the length of time between each poll.

If the remote device answers the poll within the time that these parameters specify, your system proceeds with establishing the connection. If not, your system sends an inquiry message (CPA58E0 or CPA57EF) to the system operator message queue. This message indicates that a connection attempt failed and that the controller description is now in answer mode.

Answer mode (SNA)

If you specify answer mode, the input/output adapter (IOA) cannot send connection requests, but can respond to incoming connection-requests. Systems with controller descriptions that are configured with dial mode send the connection requests. The controller description must be varied on before the system can respond to a connection request.

SNA connections to LAN protocols

You or the system can connect SNA to a LAN protocol by using one or more service access points (SAPs). Multiple SAPs allow you to have multiple connections between SNA and a LAN protocol, thus permitting multiple communication paths between independent applications.

You or the system specifies the SAPs to use in the line and controller descriptions. For SNA, the system can automatically create one SAP value (the default value). There may be cases where you want to change this value or have additional SAPs:

- The remote system does not use the default source service access point (SSAP).
- You want parallel station-to-station connections between adapters. This may be desirable if you link two applications that require different controller descriptions.
- You want station-to-station connections to the same adapters. You may want to do this to configure multiple SAPs to test an application on a single system.

If you plan to change the SAP defaults, see your SAPs for guidelines and other information.

SSAP and DSAP:

Local SAPs are known as source service access points (SSAPs). The remote SAPs are known as destination service access points (DSAPs). Your system sends data from a SSAP to a DSAP.

Your SNA service access points

If you decide to change the default SNA service access points (SAPs) or add more SAPs, you must define them in the line and controller descriptions. On the system, you define the source SAPs, or in other words the source service access points (SSAPs). You can specify up to 24 SSAPs per line description when you define the SAPs. The SSAPs that your controller description uses must come from the line description that is associated with the controller description.

Your controller description specifies the destination service access points (DSAPs) to which your line description can connect.

You should remember this point when specifying your SSAPs and DSAPs: your DSAP is the SSAP of the remote device, and the DSAP of the remote device is your SSAP. For example, this table shows how to define the SSAPs and DSAPs when your SSAP is 04 and the remote SSAP is 08:

Table 1. Local and remote SSAPs and DSAPs

Local device	Remote device
SSAP = 04	SSAP = 08
DSAP = 08	DSAP = 04

For SNA, you must use certain SSAP values. You can find the help for selecting these values by pressing F1 (Help) while your cursor is on the SSAP list field of the line description.

Maximum frame size of token ring

This page contains a few guidelines and tips for specifying the maximum frame size. First some background information to help you understand the reasons for the guidelines and tips.

Larger frames require less processing overhead than the same data that is divided up among many smaller frames. Therefore, the use of larger frame sizes can improve the performance of your system. However, the frame size that you select can be reduced if other entities within the communications path cannot support the frame size.

Maximum frame size fields:

You can use these fields to specify the maximum frame size (the parentheses show location of the field):

- Maximum frame size (line description) affects all devices that use the line description.
- Source service access point (SSAP) maximum frame size (line description) affects only devices that use the SSAP and line description.
- Maximum frame size (controller description) affects all line descriptions that are associated with the controller description.

If you specify a maximum frame size in two or more of these fields, the system selects the smallest size. To ease the frame size configuration of your line and controller descriptions, use these guidelines:

- Use the largest possible frame size that the network connection supports.
- Specify the maximum frame size only in the Maximum frame size field of the line description. The system then uses this value for all other maximum frame size fields.
- Specify a size smaller than the maximum frame size of the IOA if you receive a frame rejection error.

Reduction of selected maximum frame size:

Other entities within the communications path can reduce your maximum frame size if they cannot support it. Some of these entities are:

- Remote IOAs or other devices: Some support only smaller maximum frame sizes.
- Line or controller description: These descriptions on the remote system sometimes specify a smaller maximum frame size.
- Devices: Some do not support maximum frame size negotiations.

Solution:

If negotiation does not produce a common frame size, a frame reject (FRMR) condition occurs, and your system sends message CPA58E2 to message queue QSYSOPR. If you cannot change the frame size of the other entities, use an acceptable maximum frame size value in your line or controller description.

Chapter 3. Plan for token-ring support

To make the configuration of token-ring support easier, you need to make some decisions now about how to configure your connections. You can make decisions about these items:

- When do you need to use a smaller maximum frame size?
- What kind of LAN IOA address should you use?

Maximum LAN frame size

The larger your frame size, the more data your system can pack into it. Hence, your data throughput can increase. Usually, you set the maximum frame size to the largest size that is supported by your input/output adapter (IOA). However, a device will drop the frame if it cannot support your frame size. If you cannot configure the device to support your frame size, change your maximum frame size to a size that the device can support.

You can change one or more of these maximum frame size fields (the parentheses contain the location of the field):

- SSAP maximum frame size (line description)
- Maximum frame size (line descriptions for token ring and gigabit Ethernet networks)
- Maximum frame size (controller description)

The maximum frame size used by your system during the connection process will be the smallest of these fields.

LAN IOA addresses

In an SNA environment, you can determine the address for each input/output adapter (IOA). You can use one of two addresses:

- The manufacturer-assigned address that is otherwise known as the burned-in address, preset address, or universally-administered address.
- The locally administered address.

You define the locally administered address, and the system associates it with the adapter. Using a locally administered address minimizes the reconfiguration work when you replace the adapter.

For example, if you use the burned-in address of the adapter, you must configure this address into every device that communicates with the adapter. When you replace the adapter, you must go back to each device and reconfigure them with the burned-in address of the new adapter. You cannot assign the burned-in address of the replaced adapter to the new adapter.

You can avoid the reconfiguration work by associating a locally administered address with the adapter and using this address in all devices that communicate with the adapter. When you replace the adapter, associate the locally administered address with the new adapter. Since the devices already have the locally administered address, you do not need to reconfigure them.

Note: No two adapters can have the same address in the same network.

Chapter 4. Configure token-ring support

After understanding and planning your token-ring support, you are ready to configure token ring on the system. To configure token-ring support for TCP/IP or SNA, read this information:

1. Configuring TCP/IP over token ring.
2. Configuring SNA over token ring.
3. Examples: Configuring SNA over token ring.

Configure TCP/IP over token ring

You can use iSeries Navigator to configure token-ring support for TCP/IP. To do this, do these steps:

1. If you have not done so already, install iSeries Navigator.
2. iSeries Navigator can use an existing line description. To use an existing line description, change it. Then return here to continue these steps.
3. In iSeries Navigator, expand the server that will provide token-ring support for TCP/IP.
4. Use the LAN Configuration Wizard to configure a new TCP/IP interface to use token ring with TCP/IP. As you create a new token-ring line for the 100 Mbps card while creating the interface, remember these items about the duplex modes:
 - At 4 Mbps or 16 Mbps you can use half-duplex or full-duplex modes.
 - At 100 Mbps you can only use full duplex.
5. If you did not start the TCP/IP interface, you can do so now by enabling it to accept connections.

Configure SNA over token ring

To provide token-ring support for SNA, do these steps:

1. Create the token-ring line description. Ensure the correct configuration of these fields when you create the line description:
 - If the system uses this line description to communicate with an SNA host through a parallel connection, define a value other than *LIND in the Exchange identifiers field.
 - APPN and APPC connections use fields Link speed through Autodelete controller. You can use the defaults or press F1 (Help) for more information about each field.
 - If you want the system to create the APPC controller description when a call comes in, specify *YES in the Autocreate controller field. If you specified *YES, skip to step 3.
2. Create the controller description.
3. If your controller description does one of these, you must create a device description:
 - Specifies *NONE in the Autocreate device field.
 - Specifies *NO in the APPN-capable field (this applies only to APPC controller descriptions)
4. Enable the descriptions to accept connections.

If you need help with configuring the token-ring support for your SNA environment, see Examples: Configuring SNA over token ring.

Create the token-ring line description

To configure a token-ring line description, see the information on this page. The information assumes that you are not using token-ring card with Netfinity.

- **TCP/IP:** To use TCP/IP over token ring, see Configuring TCP/IP over token ring.
- **SNA:** To configure a token-ring line description through the server console, use the Create Line Description (Token Ring) (CRTLINTRN) command and follow the steps in this page.

Note: This page explains some of the fields that require additional information. You can also find other help information by pressing F1 (Help) when your cursor is on the field in question.

1. Select an input/output adapter (IOA) to use with your line description. If you are not familiar with the capabilities of the IOA, see Token-ring IOAs.

You are now at the Create Line Description (Token Ring) (CRTLINTRN) display. Notice that the system copied the name of the IOA to the Resource name field.

Do not press Enter while at this display unless instructed to do so; otherwise, you may exit the display. To move from field to field, move your cursor or press the Tab key.

2. Type a name for your line description into the Line description field.
3. Press Enter twice, and then F10 (Additional fields).
4. Indicate the appropriate number of active controller descriptions that can use the line description in the Maximum controller field. See Connection establishment between LAN devices for more information about accessing a line description through a controller description.
5. In the Line speed field, indicate the speed of the IOA.

Note: You enable automatic ring-speed sensing (automatic sense) when specifying *AUTO or 100M. Automatic sense starts initially at 100 megabit per seconds (Mbps). To use automatic sense successfully, you must enable it only on your system or on the switch to which your system connects. That is, do not enable both devices; otherwise, the correct speed may not be selected.

6. Select the duplex mode to use with your IOA.

Note: Duplex mode negotiation occurs when you specify *AUTO or *FULL. Duplex mode negotiation initially starts at full-duplex mode. The switch must support duplex negotiation before you can successfully use this function. If you are not familiar with the capabilities of the IOA, see Token-ring IOAs.

7. Specify the largest possible frame size in the Maximum frame size field.
8. Assign an address to the IOA by using the Local adapter address field.

To determine whether to use the burned-in address of the adapter or a locally administered address, read LAN IOA addresses. To use the burned-in address, accept the default value of *ADPT.

To specify a locally administered address, find a valid address and enter it into the field. To find a valid address, move your cursor to the field and press F1 (Help) for more information.

9. List all the source service access points (SSAP) that your controller should use in the Source service access point field. Accept the default value of *SYSGEN or specify your SSAPs. If you define the SSAP values, move the cursor to the field and press F1 (Help) to help determine what values to use.

For more information about whether you or the system should define the service access points (SAPs), see SNA connections to LAN protocols.

10. Leave the SSAP maximum frame field blank unless you need to enter a value.
11. If you use this line description with half duplex mode and with a 16 Mbps ring, you can take advantage of early token release. To do this, specify *YES in the Early token release field.
12. Press Enter to create the line description.
13. If an error occurs, the system may present to you some options to correct the error. Select the option that you desire. You can also move your cursor to the error message and press F1 (Help) to see the cause of the error and the possible fixes.
14. Press F3 (Exit).

Token-ring IOAs

This table shows the duplex modes and maximum frame sizes that are supported by the input/output adapters (IOAs):

Table 2. Duplex modes and maximum frame sizes supported by the token-ring IOAs.

IOA	Duplex modes supported		Maximum frame sizes		
	100 Mbps	16/4 Mbps	100 Mbps	16 Mbps	4 Mbps
2619, 2626	N/A	Half	N/A	16393	4060
6149, 2724	N/A	Full or half	N/A	16393	4060
2744	Full	Full or half	16393	16393	4060
N/A - Not applicable					

Selecting a LAN IOA

Before creating your line description, you must select the input/output adapter (IOA) to use with it. Use the Work with Hardware Resources (WRKHDWRSC) command to identify the name of your IOA and select the IOA. To do this, do these steps (even if you know the name of the IOA):

1. Type **WRKHDWRSC *CMN** and press Enter.
A list appears that shows the attached iSeries communications resources, and their type numbers, operational statuses, and descriptive text.
2. Locate an IOA by looking in the descriptive text column for a phrase that describes a port for your LAN type. For example, if you use Ethernet, look for "Ethernet Port." If you use token-ring, look for "Token-ring port."
3. Once you find an IOA, move your cursor to its Opt field.
4. Type 5 (Work with configuration descriptions) and press Enter.
5. Type 1 (Create) and press Enter.

Create the SNA controller description

The controller description indicates the remote devices to which the system connects. To create a controller description to use with your LAN adapter, do these steps:

1. See Creating an APPC controller description to find out which create controller command to use. Then return here to configure the description.
2. Type the name of the command to use and press F4 (Prompt).
3. Type the name of the controller description into the Controller description field.
4. Specify *LAN in the Link type field.
5. Press Enter three times.
6. The system displays more fields that may require this information (for more help, press F1 (Help) while your cursor is on the field):
 - **Switched line list** specifies one or more line descriptions that should use your controller description. For more information about the relationship between the line and controller descriptions, see connection establishment.
 - **Remote control point** names the local control point of the remote iSeries system. Use the Display Network Attributes (DSPNETA) command on the remote system to view its local control point name.
 - **Exchange identifier** contains the exchange identifier for your system. APPC requires the ID. This ID has two parts. To determine the value for the first part, press F1 (Help) when your cursor is on this field. You can get the value for the second part from the line description on the remote system that is used to connect to your system. To understand the purpose of exchange identifiers, read How LAN devices identify themselves.
 - **Local exchange identifier** identifies your iSeries to the host system. This field exists only in the host controller description. Parallel connections between your system and an SNA host require an exchange identifier.
 - **Initial connection** determines whether the controller description initiates connection requests (*DIAL), or waits for incoming connection requests (*ANS).
If you specify *DIAL and want to adjust the polling duration or frequency, change the LAN connection retry (LANCNRRTY) or LAN connection timer (LANCNTMR) field.
 - **LAN remote adapter address** contains the address of the remote input/output adapter (IOA). To find this address, see viewing the address of your adapter. If you are using the preset address of the adapter, read LAN IOA addresses to minimize your reconfiguration work.
 - **LAN DSAP** contains the source service access point (SSAP) value from the controller description that is on the remote device. For more information about service access points (SAPs), see SNA connections to LAN protocols.
 - **LAN SSAP** contains a value from the SSAP list of the line description that is associated with this controller description.
7. (Optional) For detailed information about all the parameters and their dependencies, see the chapter about communications controller descriptions in OS/400 Communications Configuration .

8. Press Enter three times to create the description.

Create the SNA device description

The device description describes the communications device that is used by the remote device. There are no LAN-specific parameters in the device description. To create the SNA device description, do these steps:

1. To create the device description, find the create command to use in Creating APPC device descriptions (this information also has other commands for APPN devices, SNPT devices, and so forth). Then return here to configure the description.
2. Type the name of the command to use and press F4 (Prompt).
3. Type the name of device description into the Device description field.
4. Complete these fields as described:
 - **Remote location** is the name from the Local location field of the device description that is on the remote device. If the Local location field contains *NETATR, use the Display Network Attributes (DSPNETA) command at the remote device. Use this command to view the name that is specified by the Default local location field.
 - **Remote network identifier** is the network identifier of the remote iSeries system. To find this value, use the Display Network Attributes (DSPNETA) command at the remote system to locate the Local network ID field. APPC device descriptions use the Remote network identifier field.
5. (Optional) For detailed information about all the parameters and their dependencies, see the chapter about communications device descriptions in OS/400 Communications Configuration .
6. Press Enter twice to create the description.

Examples: Configure SNA over token ring

The examples here describe the dependencies of a parameter or the required parameter values for various SNA network environments.

- I This disclaimer information pertains to code examples.

This command creates the TOKENRING1 line description that all the examples use:

```
CRTLINTRN LIND(TOKENRING1) RSRNAME(TRN_IOA) LINESPEED(16M)
          MAXFRAME(16393) ADPTADR(400003190001) EXCHID(05600000)
          SSAP((04 *MAXFRAME *CALC) (08))
```

This figure shows the network used by the examples:

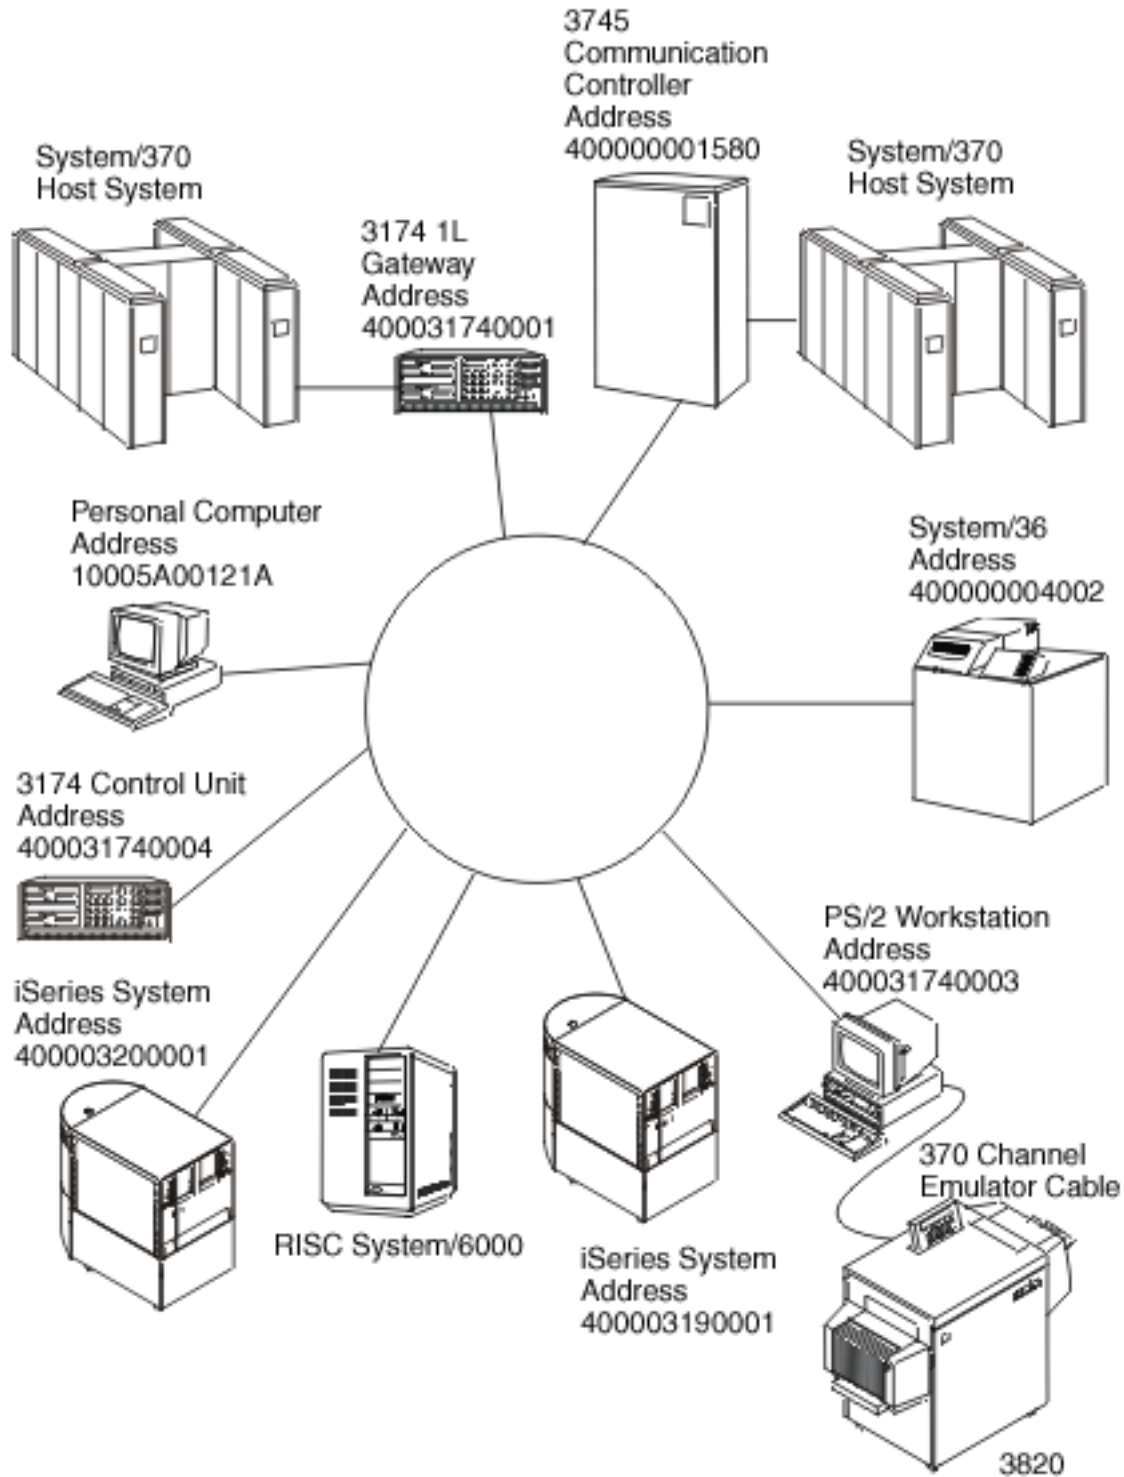

Figure 1. Example token-ring network

These are the SNA examples:

- Connecting a server to another server.
- Connecting the server to itself.
- Connecting an server to a System/36.
- Connecting an server to a 3745 host.

- Connecting an server to a 3174 Model 1L gateway.
- Connecting an server to a 3174 subsystem control unit.
- Creating parallel connections to a host.

For APPN, see APPN configuration examples.

Example: Connect a server to another server

This example shows how to create an APPC over token-ring connection from your server to another server. The name of the local server is LOCAL, and the name of the remote system is REMOTE.

Note: Since all the examples use the same token-ring line description, this example discusses only the controller and device descriptions.

Focus on these points in this example:

- The service access points (SAPs) in the controller descriptions. For more information about SAPs, read SNA connections to LAN protocols.
- The adapter address used by a controller description must match the address that is used in the line description on the remote device. This table shows the adapter addresses that are used by the line and controller descriptions on both systems.

Table 3. Local and remote adapter addresses

	LOCAL	REMOTE
Adapter address in line description	400003190001	400003200001
Adapter address referred to by the controller description	400003200001	400003190001

- The way a system identifies the other system to which it connects. Both sides must use the same method. These are the methods:
 - Only use the Remote exchange identifier parameter.
 - Use the Remote network identifier and the Remote control point name parameters.

In this example, each system uses the Remote network identifier and Remote control point name (RMTCPNAME) parameters to indicate the system to which it connects.

Note that within a system the remote network identifier must be the same in the controller and device description. Because the example uses the default value of *NETATR for the Remote network identifier parameter, this parameter is not shown.

Get the value for the Remote control point name parameter from the other system. To do this, use the Display Network Attributes (DSPNETA) command on the other system and locate the Local control point name field.

TOKENRING2:

| This disclaimer information pertains to code examples.

The example uses this line description on the remote system:

```
CRTLINTRN LIND(TOKENRING2) RSRNAME(TRN_IOA) LINESPEED(16M)
MAXFRAME(16393) ADPTADR(400003200001) EXCHID(05600000)
SSAP((04 *MAXFRAME *CALC) (08 *MAXFRAME *CALC))
TEXT('Line description for 400003200001')
```

Controller descriptions:

These examples show the controller descriptions that are used on the local and remote systems.

```
CRTCTLAPPC CTLD(LOCAL_CD) LINKTYPE(*LAN) SWTLINLST(TOKENRING1)
  RMTCPNAME(REMOTECP) ADPTADR(400003200001) DSAP(04)
  SSAP(08) TEXT('Controller description on LOCAL')
```

```
CRTCTLAPPC CTLD(REMOTE_CD) LINKTYPE(*LAN) SWTLINLST(TOKENRING2)
  RMTCPNAME(LOCALCP) ADPTADR(400003190001) DSAP(08)
  SSAP(04) TEXT('Controller description on REMOTE')
```

Device descriptions:

In the device descriptions, the Remote network identifier (RMTNETID) parameter should match the local network-identifier of the remote system. You must use the Display Network Attributes (DSPNETA) command on the remote system to view the local network-identifier.

```
CRTDEVAPPC DEVD(LOCAL_DD) RMTLOCNAME(REMOTE) LCLLOCNAME(LOCAL)
  CTL(LOCAL_CD) MODE(BLANK)
  TEXT('APPC device description describing system REMOTE')
```

```
CRTDEVAPPC DEVD(REMOTE_DD) RMTLOCNAME(LOCAL) LCLLOCNAME(REMOTE)
  CTL(REMOTE_CD) MODE(BLANK)
  TEXT('APPC device description describing system LOCAL')
```

Example: Connect the server to itself

This example connects your system to itself. That is, the tokens travel around the local token ring network before returning to your system. You can do this to test an application within your system before testing it in the network. Since all the examples use the same token-ring line description, this example discusses only the controller and device descriptions.

Two sets of controller and device descriptions connect your system to itself. The first set dials (initiates) a connection request, and the second set answers (accepts) the connection request.

In this example, focus on these points:

- Use a different source service access point (SSAP) for each controller.
- Use the same adapter address in both controller descriptions.
- Use dial mode in one controller description and answer mode in the other.

| This disclaimer information pertains to code examples.

Dial command set:

```
CRTCTLAPPC CTLD(DIAL_CD) LINKTYPE(*LAN) APPN(*NO) INLCNN(*DIAL)
  SWTLINLST(TOKENRING1) ADPTADR(400003190001)
  DSAP(08) SSAP(04)
  TEXT('Link from SAP 04 to 08')
```

```
CRTDEVAPPC DEVD(DIAL_DD) RMTLOCNAME(ANS) LCLLOCNAME(DIAL)
  CTL(DIAL_CD) MODE(BLANK) APPN(*NO)
```

Answer command set:

```
CRTCTLAPPC CTLD(ANS_CD) LINKTYPE(*LAN) APPN(*NO) INLCNN(*ANS)
  SWTLINLST(TOKENRING1) ADPTADR(400003190001)
  DSAP(04) SSAP(08)
  TEXT('Link from SAP 08 to 04')
```

```
CRTDEVAPPC DEVD(ANS_DD) RMTLOCNAME(DIAL) LCLLOCNAME(ANS)
  CTL(ANS_CD) MODE(BLANK) APPN(*NO)
```

Example: Connect a server to a System/36

| This disclaimer information pertains to code examples.

This example uses APPC to connect your server to a System/36 system. Since all the examples use the same token-ring line description, this example discusses only the controller and device descriptions. On the remote system, the System/36 administrator must configure an APPC-subsystem member and a token-ring-line member to connect to your system.

The controller and device descriptions must disable APPN and not use remote IDs by using the APPN and RMTNETID parameters like this:

```
CRTCTLAPPC CTLD(CTL_36) LINKTYPE(*LAN) APPN(*NO)
           SWTLINLST(TOKENRING1) RMTNETID(*NONE) EXCHID(03E00000)
           ADPTADR(400000004002)
           TEXT('APPC controller description describing System/36')

CRTDEVAPPC DEVD(DEV_36) RMTLOCNAME(SYSTEM36) RMTNETID(*NONE)
           MODE(BLANK) APPN(*NO)
```

Example: Connect a server to a 3745 host

This example connects your system to a 3745 host. You will also find more information about configuring the host at the end of this example. Focus on these points for this example:

- The controller description destination service access point (DSAP) must specify 04 to connect to the host. The example does not show this parameter because 04 is the default.
- The host can refer to only service access points (SAPs) 04 through 94; therefore, your service source access point (SSAP) must be within this range. The example does not show this parameter because it uses the default value of 04.

| This disclaimer information pertains to code examples.

Controller description:

```
CRTCTLHOST CTLD(TRLANHOST) LINKTYPE(*LAN) SWTLINLST(TOKENRING1)
           RMTCPNAME(LANAPPN) LCLEXCHID(*LIND)
           ADPTADR(4000000001580) NODETYPE(*LENNODE)
           TEXT('Controller description describing the 3745 host')
```

Device descriptions:

These are the device descriptions:

```
CRTDEVHOST DEVD(TRLANEML) LOCADR(01) RMTLOCNAME(HOST)
           CTL(TRLANHOST) APPTYPE(*EML)
           TEXT('3270 emulation over TOKENRING1')

CRTDEVHOST DEVD(TRLANPRT) LOCADR(0C) RMTLOCNAME(HOST)
           CTL(TRLANHOST) APPTYPE(*EML) EMLDEV(3287)
           TEXT('3270 printer emulation over TOKENRING1')

CRTDEVDSP DEVD(TRLANDHCF) DEVCLS(*RMT) TYPE(3277) MODEL(*DHCF)
           LOCADR(02) CTL(TRLANHOST) TEXT('DHCf over TOKENRING1')
```

Host configuration:

On the host, you must generate a physical and a logical configuration before the system can connect to it.

Example: Create a host physical-configuration

| This disclaimer information pertains to code examples.

The network control program generation (NCP GEN) produces the physical configuration that is necessary to connect the 3745 Communication Controller to your server. The system administrator creates the NCP GEN for the GROUP and LINE macroinstructions.

You must ensure that the location address (LOCADD) parameter matches the Remote adapter address (ADPTADR) field of the controller description. This example shows the LOCADD parameter in bold:

```
R1G006P GROUP ECLTYPE=PHYSICAL
R1080P LINE ADDRESS=(080,FULL),LOCADD=(400000001580),PORTADD=01,
        ISTATUS=INACTIVE
R1080PA PU ADDR=01,ISTATUS=INACTIVE
R1080PA1 LU LOCADDR=0,
        LUDR=NO
R1G006L GROUP ECLTYPE=LOGICAL,
        PHYPORT=80
R108000 LINE
R108000A PU MAXLU=32
R108001 LINE
R108001A PU MAXLU=32
R108002 LINE
R108002A PU MAXLU=32
R108003 LINE
R108003A PU MAXLU=32
R108004 LINE
R108004A PU MAXLU=32
R108005 LINE
R108005A PU MAXLU=32
R108006 LINE
R108006A PU MAXLU=32
R108007 LINE
R108007A PU MAXLU=32
```

Note: This example is valid only on Network Control Program (NCP) Version 4.2 and Virtual Telecommunications Access Method (VTAM) Version 3.1.1. Different NCP or VTAM levels may require different parameters.

Example: Create a host logical-configuration

The network control program generation (NCP GEN) produces the logical configuration to connect the 3745 Communication Controller to your server. This example configuration is valid only on Network Control Program (NCP) Version 4.2 and Virtual Telecommunications Access Method (VTAM) Version 3.1.1. Different NCP or VTAM levels may require different parameters.

In this example, focus on these points:

- Identifier block (IDBLK) and identifier number (IDNUM)
- Dial number (DIALNO)

The concatenation of the IDBLK and IDNUM values must match the Local exchange identifier (LCLEXCHID) value of your controller description. In this example, since the controller description specifies *LIND in field LCLEXCHID, the value comes from the Exchange identifier (EXCHID) field of the line description.

The DIALNO parameter specifies the source service access point (SSAP) and the adapter address of your server. This is the format of DIALNO:

```
aabb4000cccccccc
```

This is the explanation of the format:

- **aa** is the value of the PORTADD parameter that is specified in the physical configuration.
- **bb** is the SSAP value from your controller description.
- **4000cccccccc** is the address of your adapter that is specified in the line description. In this example, the address is 400003190001 (see the ADPTADR parameter of line description TOKENRING1).

I This disclaimer information pertains to code examples.

This logical configuration example shows the IDBLK, IDNUM, and DIALNO parameters in bold:

SW3270C	VBUILD	TYPE=SWNET, MAXNO=8, MAXGRP=5	REQUIRED PARAMETER	X *

Example: Connect a server to a 3174 Model 1L gateway

I This disclaimer information pertains to code examples.

In this example a 3174 Control Unit functions as a gateway to connect two systems that support different network architectures. You will also find an example to connect the gateway to your system at the end of this example. Since all the examples use the same token-ring line description, this example discusses only the controller and device descriptions. This example does not show the source service access point (SSAP) and destination service access point (DSAP) parameters because they use the default values.

Controller description:

```

CRTCTHST CTLD(TRLANHOST2) LINKTYPE(*LAN) SWTLINLST(TOKENRING1)
RMTCPNAME(*ANY) ADPTADR(400031740001)
TEXT('Controller description describing the 3174 Gateway')

```

Device description:

Although this device description example is not specific to token-ring networks, you can use it to configure an emulation display:

```

CRTDEVHST DEVD(TRLANEML2) LOCADR(01) RMTLOCNAME(HOST2)
CTL(TRLANHOST2) APPTYPE(*EML)
TEXT('3270 emulation for Host2')

```

3174 configuration example:

To connect the gateway to your system, see Creating the NCP GEN for a 3174 gateway.

Example: Create the NCP GEN for a 3174 gateway

The system administrator creates the network control program generation (NCP GEN) to connect your server to the 3174. You must ensure that the address specified by the control-unit address (CUADDR) parameter is correct. The last two characters of this parameter must match the Control Unit Address value. This value is specified in the Ring Address Assignment display and the Ring Transmission Definition display of the 3174.

Note: This example is valid on Network Control Program (NCP) Version 4.2 and Virtual Telecommunications Access Method (VTAM) Version 3.1.1. Different NCP or VTAM levels may require different parameters.

I This disclaimer information pertains to code examples.

This is the NCP GEN (the CUADDR parameter is in bold):

```
R13B1    VBUILD TYPE=LOCAL
R13B0A   PU    CUADDR=3B1,
                                     X
                                     X
          DISCNT=(NO,F),             X
          ISTATUS=ACTIVE,           X
          PUTYPE=2,                  X
          SPAN=(SYSPGMR),           X
          SSCPFM=USSSCS,            X
          VPACING=7
R13B102  LU    DLOGMOD=P6ES2,        X
          ENCR=NONE,                X
          ISTATUS=ACTIVE,           X
          LOCADDR=2,                X
          LOGAPPL=SAMON,            X
          MODETAB=LOGMOD38,         X
          SPAN=(SYSPGMR),           X
          SSCPFM=USSSCS,            X
          VPACING=7
```

Example: Connect a server to a 3174 subsystem control unit

This example connects your system to a 3174 (Model 3R or 53R) subsystem control unit. Since all the examples use the same token-ring line description, this example discusses only the controller and device descriptions. You will find suggestions for configuring the 3174 at the end of this example.

I This disclaimer information pertains to code examples.

Controller description:

```
CRTCTLRWS CTLD(TR_3174) TYPE(3174) MODEL(0) LINKTYPE(*LAN)
          SWTLINLST(TOKENRING1) ADPTADR(400031740004)
          TEXT('Controller description describing the 3174')
```

Device description:

This device description does not have any 3174 specific fields, so use whatever device descriptions you need:

```
CRTDEVDSP DEVD(3279_DSP) DEVCLS(*RMT) TYPE(3279) MODEL(0)
          CTL(TR_3174)
          TEXT('Device description describing the 3279 display')
```

3174 configuration suggestions:

You should ensure that the token-ring display on the 3174 contains the correct adapter addresses. The address fields must match the local adapter address field of the line description and the remote adapter address field of the controller description. You should also ensure, that the maximum frame sizes match those that are specified by the Maximum frame size field of the line description.

Example: Create parallel connections to a host

This example connects your system to a host system through a 3745 Communications Controller by using parallel connections. Each connection has a separate instance of the logical link control and a separate bandwidth. Thus, communications can still occur even if one link becomes nonfunctional.

Since all the examples use the same token-ring line description, this example discusses only the controller and device descriptions. You can find the configuration for the 3745 controller in Example: Configuring the physical and logical parallel connections on the host system.

I This disclaimer information pertains to code examples.

Controller descriptions:

In this example, focus on these points:

- The controller descriptions use the same line description.
- The controller descriptions use different local exchange IDs. You must use exchange IDs to establish parallel connections.
- The controller descriptions use different source service access points (SSAPs).
- The 3745 Communications Controller requires that you specify 04 for the destination service access point (DSAP).

```
CRTCTLHOST CTLD(CTL_1A) LINKTYPE(*LAN) APPN(*NO)
           SWTLINLST(TOKENRING1) LCLEXCHID(056A001A)
           ADPTADR(400000001592) DSAP(04) SSAP(04)
           TEXT('Controller for the first link')
```

```
CRTCTLHOST CTLD(CTL_2A) LINKTYPE(*LAN) APPN(*NO)
           SWTLINLST(TOKENRING1) LCLEXCHID(056A002A)
           ADPTADR(400000001592) DSAP(04) SSAP(08)
           TEXT('Controller for second link')
```

Device descriptions for CTL_1A:

These commands create the device descriptions that are used with the CTL_1A controller description:

```
CRTDEV DSP DEVD(DSPA001A02) DEVCLS(*RMT) TYPE(3279) MODEL(0)
           LOCADR(02) CTL(CTL_1A) APPTYPE(*NRF)
           TEXT('NRF device, LOCADDR 02')
```

```
CRTDEV DSP DEVD(DSPA001A03) DEVCLS(*RMT) TYPE(3279) MODEL(0)
           LOCADR(03) CTL(CTL_1A) APPTYPE(*NRF)
           TEXT('NRF device, LOCADDR 03')
```

```
CRTDEV HOST DEVD(EMLA001A04) LOCADR(04) RMTLOCNAME(SWXIDA04)
           CTL(CTL_1A) APPTYPE(*EML)
           TEXT('Emulation display, LOCADDR 04')
```

```
CRTDEV PRT DEVD(PRTA001A05) DEVCLS(*RMT) TYPE(3287) MODEL(0)
           LOCADR(05) CTL(SWTRNCTL1A) APPTYPE(*NRF)
           LOGON('LOGON APPLID(NRF2A07) LOGMODE(SCSTRYR)')
           TEXT('NRF printer, LOCADDR 05')
```

Device descriptions for CTL_2A:

These commands create the device descriptions that are used with the CTL_2A controller description:

```
CRTDEV DSP DEVD(DSPA002A02) DEVCLS(*RMT) TYPE(3279) MODEL(0)
           LOCADR(02) CTL(CTL_2A) APPTYPE(*NRF)
           TEXT('NRF device, LOCADDR 02')
```

```
CRTDEV HOST DEVD(EMLA002A04) LOCADR(04) RMTLOCNAME(SWXIDB04)
           CTL(CTL_2A) APPTYPE(*EML)
           TEXT('Emulation display, LOCADDR 04')
```

```
CRTDEV PRT DEVD(PRTA002A05) DEVCLS(*RMT) TYPE(3287) MODEL(0)
           LOCADR(05) CTL(CTL_2A) APPTYPE(*NRF)
           LOGON('LOGON APPLID(NRF2A07) LOGMODE(SCSTRYR)')
           TEXT('NRF printer, LOCADDR 05')
```

Example: Configure the physical and logical parallel connections on the host system

This example shows the network control program generation (NCP GEN) that is created by a system administrator to connect the 3745 Communication Controller to the server. This example is valid on Network Control Program (NCP) Version 5.4 and Virtual Telecommunications Access Method (VTAM) Version 3.3. Different NCP or VTAM levels may require different parameters.

This example shows one configuration for each connection and discusses two parameters: Identifier block (IDBLK) and identifier number (IDNUM). The concatenation of IDBLK and IDNUM must match the Local exchange identifier (LCLEXCHID) field of your controller description. The first configuration uses exchange ID 056A001A from controller description CTL_1A. The second uses 056A002A from CTL_2A.

I This disclaimer information pertains to code examples.

Configuration for the first connection:

In this example, see the IDBLK and IDNUM parameters in bold:

```
*
SWXID   VBUILD TYPE=SWNET,      THIS IS A SWITCHED MAJOR NODE      X

```

Chapter 5. Manage token-ring support

After setting up token-ring support, you may need to manage this support. These are some of the tasks that you can do:

- Change your existing line description to use it with the 100 megabit per second (Mbps) card.
- Assign your line description to a TCP/IP interface.
- Enable your configuration objects to accept connections after configuring the token-ring support.
- View the burned-in address or locally administered address of your adapter.
- See a list of commands that affect your configuration objects.

Change the line descriptions to use token ring

To use an existing token-ring line description with iSeries Navigator, you must first change the values for these fields:

- Resource name
- Address field
- Duplex
- Line speed
- SSAP list (for TCP/IP only)
- Link speed (Optional, used for APPN only)

To change the fields, do these steps:

1. Vary off the line description.
2. Change the field values.

Vary off the line description:

To vary off the line description, use the Work with Line Descriptions (WRKLIND) command like this:

1. Type **WRKLIND** and press Enter.
2. Locate your line description and place your cursor in its Opt field.
3. Type 8 (Work with status) and press Enter.
4. Type 2 (Vary off) and press Enter.
5. If your line description does not vary off, place your cursor on the error message and press F1 (Help) to view more information about the error. See Getting started with system troubleshooting for more troubleshooting help.
6. If an error did not occur, press F3 (Exit) to exit the command, and continue with the next step (Change the field values).

Change the field values:

Now you must change the values in the fields by using the Change Line Description (Token Ring) (CRTLINTRN) command. To do this, do these steps:

1. Record the name of the token-ring card by doing these steps:
 - a. Type **WRKHDWRSC *CMN** and press Enter.
 - b. Search the Type column to locate the desired token-ring card.
 - c. Record the name of the card that is found under the Resource column.
 - d. Press F3 (Exit).
2. Type **WRKLIND** and press Enter.
3. Locate the line description to change.
4. Type 2 (Change) and press Enter.
5. Type the name of the selected token-ring card into the Resource name field.
6. In the Line speed field, indicate the speed of the input/output adapter (IOA).

Note: You can enable automatic ring-speed sensing (automatic sense) when specifying *AUTO or 100M. Automatic sense starts initially at 100 Mbps. To use automatic sense successfully, you

must ensure that your system or the switch that the system connects to is enabled for ring-speed sensing. That is, you should enable ring-speed sensing only on one device; otherwise, an incorrect speed may be selected.

7. Select the duplex mode to use with your IOA.

Note: Duplex mode negotiation occurs when you specify *AUTO or *FULL. The negotiation starts initially at full-duplex mode. The switch must support this type of negotiation before you can successfully use this function. If you are not familiar with the capabilities of the IOA, see token-ring IOAs.

8. If you are using this line description with TCP/IP, ensure that source service access point (SSAP) X'AA' and its associated information are in the SSAP list field.
9. If needed, specify a maximum frame size. If you are not familiar with the capabilities of the IOA, see token-ring IOAs.
10. Press Enter to save your changes, and then press F3 (Exit).
11. Continue with the next step. If you are using this line description with SNA, enable the description to accept connections. If you are using this line description with TCP/IP, assign it to an interface.

Assign the token-ring line description to a TCP/IP interface

After changing the existing line description that will be used with the 100 Mbps adapter, you assign the line description to a TCP/IP interface. You do not need to do this if you are using the line description with SNA.

Assigning the line description to a TCP/IP interface:

You can assign the line description to a new or an existing TCP/IP interface through iSeries Navigator. To assign it to a new interface, you must follow the procedure in Configuring TCP/IP over token ring to create the interface. During this creation process, you must choose your description from a list of line descriptions.

Note: If other entities know the burned-in address of your old adapter, you must replace that address with the address of the 100 Mbps adapter. This is required if you want them to communicate with the adapter. You can use a locally administered address to avoid these kinds of changes in the future (see LAN IOA address for more information).

To associate your line description with an existing interface, do these steps:

1. If you have not done so already, install iSeries Navigator.
2. If this is the first time you are using iSeries Navigator to access your server, use the wizard to configure TCP/IP on the system.
3. In the navigation bar, expand the server that contains the changed line description.
4. Select **Network**—>**Protocol**.
5. Right-click **TCP/IP** and select **Interface**.
6. Double-click the interface that you will assign the line description to.
7. Click the **Resource** tab and select your line description from the **Line name** option.
8. Click **OK**, and then click **OK** again.

Enable objects to accept connections

After configuring LAN support, you are ready to enable your configuration objects to accept connections. For SNA, you enable or vary on the line and controller descriptions. For TCP/IP, you can enable or start the interface.

Vary on configuration objects:

To accept connections, you must vary on the configuration objects by using the Work with Configuration Status (WRKCFGSTS) command:

1. Type **WRKCFGSTS *L/I/N** and press Enter.

2. Locate your line description.
3. Move your cursor to the Opt field of the line description, type 1 (Vary on), and press Enter.
4. If the line description does not vary on successfully, press F3 (Exit). Then you should read Display message queues to understand how to view the error messages and to find possible solutions.
5. Press F3 (Exit).

If the line description varied on successfully, you should do the same for the controller description if you created one. Vary on the description by using the same instructions for varying on the line description. Instead of specifying *LIN for the WRKCFGSTS command, you must specify *CTL.

Start the TCP/IP interface:

To enable the interface, use iSeries Navigator to do these steps:

1. In iSeries Navigator, Expand the server that contains the TCP/IP interface to start.
2. Select **Network**—>**Protocol**.
3. Right-click **TCP/IP** and select **Interface**.
4. You can start the interface now, or every time TCP/IP starts.
 - a. **To start the interface now:**
 - 1) Select an inactive interface.
 - 2) Click **Start**.
 - 3) Click **OK** to close the dialog box.
 - b. **To start the interface every time TCP/IP starts:**
 - 1) Double-click the interface.
 - 2) Select **Start interface when TCP/IP is started**.
 - 3) Click **OK**.

View the address of your LAN IOA

When configuring a controller description, you must specify the address of the remote input/output adapter (IOA). On the remote system, do these steps to view the locally administered address or the preset address:

Viewing the locally administered address:

To view the locally administered address, do these steps:

1. Type **DSPLIND** *description_name* (where *description_name* is the name of the description to be displayed) and press Enter.
2. Locate the Local adapter address field to view the address of the adapter.
3. Press F3 (Exit).

Viewing the preset address:

To view the preset address of the remote IOA, do these steps:

1. Locate a line description that uses the IOA. This description must specify *ADPT in the Adapter address field. If you cannot find such a line description, create it, and then return here to continue the steps.
2. Use the Work with Configuration Status (WRKCFGSTS) command to vary on the line description:
 - a. Type **WRKCFGSTS *LIN** and press Enter.
 - b. Locate your line description and look for a status of varied on or active.
 - c. If it is varied on or active, press F3 (Exit) and skip to step 3 on page 28.
 - d. Place your cursor on the Opt field of the line description, type 1 (Vary on), and press Enter.
 - e. If your line description does not vary on, place your cursor on the error message and press F1 (Help) to view more information about the error. If you need help to understand the error message or to resolve it, see Getting started with system troubleshooting.
 - f. Press F3 (Exit).

3. Type **DSPLIND** *description_name* (where *description_name* is the name of your line description), and press Enter.
 4. Locate the Local adapter address field to view the preset address of the adapter.
 5. Press F3 (Exit).
-

Configuration object commands

You can view and use other commands that affect your line, controller, or device descriptions by using the GO command. To do this, do these steps:

- To view line description commands, type **GO CMDLIND** and press Enter.
- To view controller description commands, type **GO CMDCTLD** and press Enter.
- To view device description commands, type **GO CMDDEVD** and press Enter.

The list below shows other related commands that you can use with your descriptions. To use one of these commands, type the name of the command (that is shown in parentheses) and press F4 (Prompt):

- Retrieve Configuration Status (RTVCFGSTS)
- Vary Configuration (VRYCFG)
- Save Configuration (SAVCFG)
- Restore Configuration (RSTCFG)
- Work with Configuration Status (WRKCFGSTS)

Chapter 6. Tune token-ring performance

You can improve the performance of your connections by adjusting the default values that are contained in your controller description. To do this, see [Tuning your LAN performance](#).

Other performance tips:

See this information for other tips that may improve the performance of the connection:

- Early token release can decrease transmission delays for 16 Mbps token rings that use half duplex. The token-ring line description contains this parameter.
- You can find other tips in the chapter about communication performance in [iSeries Performance Capabilities Reference](#).

 The Web site has PDF files that contain the reference. To use the reference, you must download the file by clicking on a link and viewing it on your system. You should read the disclaimer under the special notice section before using any of the information.

Tune your LAN performance

If you change the default values of the LAN parameters, the performance of the connection or system may improve. The controller description contains these parameters. For information about these parameters, see [SNA over ATM timing information](#). This asynchronous transfer mode (ATM) information also applies to LANs. However, you should not use the procedures there to change the parameters.

To change the LAN parameters, do these steps:

1. To view a list of commands that can change your controller description, type **GO CMDCHG** and press Enter.
2. From the displayed list of commands, choose a command to change your controller description.
3. Type the command and press Enter.
4. Change the LAN parameters that you have chosen.
5. Press Enter to save your changes.

Other performance tips:

You can also find other performance tips here:

- Read the chapter about communications performance in [iSeries Performance Capabilities Reference](#)

 download the file by clicking on a link. You should read the disclaimer under the special notice section before using any of the information.

- Read other tips for using SNA over your LAN protocol in [Improving LAN performance](#).

Chapter 7. Troubleshooting token ring

The server has tools to help you locate and resolve errors. This information shows the tools that you can use and other troubleshooting help:

- Find your troubleshooting tools in Troubleshooting LANs.
- If your system or the remote system cannot successfully connect, read *Why some LAN connections fail* for possible causes and solutions.
- If the PCs cannot connect to your system, see *Why PCs do not connect to your system*.
- If you are tracing LAN communications, you may need to know the format of the token-ring frame to correctly understand the information it contains. If so, see *Understanding the token-ring address format*.

Connection problems when using the 2744 card:

If you have problems making a connection with the 2744 card, the automatic ring-speed sensing setting may be incorrectly configured. If this is the case, you should verify that only the line description or the switch to which your system connects is enabled for automatic sensing. That is, only one device must be enabled for automatic sensing. The other device should manually indicate the speed it can use.

Troubleshooting LANs

Your server has tools to help you quickly find the problem and possible solutions. For an overview of the tools of your system and instructions on how to use the tools, see *Getting started with system troubleshooting*.

Also, you have these tools to help you:

- Test the communications path.
- Trace the network data to locate a problem.

Note: Although the information in the list pertains to the asynchronous transfer mode (ATM) network, it also applies to LANs.

IBM also provides a Web site that may contain solutions for you, see *Global iSeries Technical Support*

Why some LAN connections fail

Sometimes an incorrectly configured controller description can cause a connection failure. The cases here involve the incorrect configuration of the adapter address, source service access point (SSAP), or destination service access point (DSAP) parameters.

For more information about how these parameters influence a successful connection, see *How LAN devices identify themselves*. For other causes of a connection failure, see *Which device initiates the connection*.

The remote system does not connect:

If your controller description uses dial mode, it is not unusual for the system to receive message CPA58E0 (Controller not replying) or CPA57EF (Contact not successful). Remote systems or controller descriptions that do not vary on can cause one of these messages to appear.

Your system does not connect:

If your controller description uses answer mode, you may receive the message CPI591A (Controller is online, varied off, or not recognized by the local system). There are some things that can cause this message to appear:

- The connection requested by the remote system does not exist on the local system. The local system searches for this connection (that is indicated by combining the local adapter address, the DSAP, and the SSAP) in all varied-on controller descriptions.
- The controller description does not refer to the line description that could answer the call.

Solution:

To correct any of the above problems, do one or more of these steps:

- On either side of the connection, verify that the controller description has the correct combination of adapter address, SSAP, and DSAP.
- Enter the line description that can accept the call into the Switched line list field of the controller description. See Understanding connection establishment for information about the relationship between line descriptions and controller descriptions.
- Vary on the correct controller description (use the Work with Configuration Status (WRKCFGSTS) command to vary on the controller).
- Verify that the local and remote adapters are wired into the network correctly.

Why PCs do not connect to your system

If the PCs cannot connect to your server, view the error log for messages about line descriptions and about system reference code AF06 if all these conditions occurred:

- The remote device is polling your system.
- The system operator message queue does not contain a message about the system being polled.
- The connection is not established.

You can verify that the above condition occurred by looking in the error log. Use the Start System Service Tools (STRSST) command to look in your error log. To view this log, see Displaying the Product Activity Log.

The above condition can occur if the remote device uses a destination service access point (DSAP) that your line description does not refer to. The condition can also occur if the line description that contains to the correct DSAP, is not in the Switched line list field of the correct controller description. Even if the AF06 system reference code is absent, the error may have occurred. You can resolve this problem by verifying that the adapter address, SSAP, and DSAP values at both ends of the connection are correct.

Understand the token-ring address format

While troubleshooting, you may need to view the information of the destination-address and source-address frames. These are the formats of the frames:

Destination address format:

This figure shows the destination address format:

Figure 2. Destination address format

Some of the bits indicate the characteristics of the destination address:

- **I/G bit (bit 0 of byte 0)** indicates the type (individual or group) of the destination address. These are the possible values for this bit:
 - 0: The destination address is an individual address (an address that is associated with a device on the network).
 - 1: The destination address is a group address (a multiple destination address that is associated with one or more devices on the network).
- **U/L bit (bit 1 of byte 0)** indicates who defined the address. These are the possible values for this bit:
 - 0: The manufacture defined the address (it is a universally administered address or in other words a burned-in address).
 - 1: The administrator defined the address (it is a locally administered address).
- **Functional address indicator (FAI) bit (bit 0 of byte 2)** indicates the address type of the locally administered address. These are the possible values for this bit:
 - 0: The address is a functional address.
 - 1: The address is a group address.

Source address format:

A source address is always an individual address (that is, an address that is associated with a device on the network). This figure shows the format of the address:

Figure 3. Source address format

Some of the bits indicate the type of address that the source address contains:

- **Bit 0 of byte 0** indicates whether or not the frame contains a routing information field. These are the possible values for this bit:
 - 0: The routing information field is present.
 - 1: The routing information field is not present.
- **Bit 1 of byte 0** indicates the type of the address. These are the possible values for this bit:
 - 0: The address is a universally administered address. Because this bit is 0, the burned-in address cannot be greater than X'7FFFFFFFFFFFF'.
 - 1: The address is a locally administered address. Because this bit is 1, the group address must be greater than X'800000000000'.
